EXECUTIVE SUMMARY

1. PROPOSED DEVELOPMENT

AREG AC Makena Propco LLC proposes the development of Mākena Mauka (the "**Project**"), a low-density master planned residential community within the Makena area of South Maui. The Project site encompasses about 1,043.71 acres, including the existing Mākena North Golf Course, the Mākena South Golf Course, and 18 currently vacant development "parcels" located around the golf courses. About 473 acres are planned for residential development.

The Project will provide 652 housing units, comprising 543 market-priced homes and 109 affordable homes. Approximately 135,000 sq. ft. of support buildings will be developed, including space for golf operations and maintenance, restaurants, staff offices, etc. The community will feature hiking trails; walking, bicycling, and golf cart paths for connectivity; beach access and parking for the public; and areas reserved for conservation/open space.

The Project is within an area that has largely been planned for such uses for decades.

2. LAND CLASSIFICATIONS

Much of the Project area has the necessary State and County land-use designations to support the proposed Project. However, changes in designations will be needed for the proposed rural-residential community in the most mauka portion of the Project area near the upper reaches of the 18-hole Mākena North Golf Course. Anticipated changes include: (1) a District Boundary Amendment (**DBA**) by the State Land Use Commission (**SLUC**) to change most of the lands used for the North Golf Course from the current Agricultural designation to Rural, (2) a Community Plan Amendment (**CPA**) (as may be required), and (3) a Change of Zoning (**CIZ**).

3. AGRICULTURAL CONDITIONS

About 510 acres (52%) of the Project site are within the State's Agricultural District (the **Project's Ag lands**). These lands are unsuitable for crop farming due to stony, low-quality soils and lack of water for irrigating crops. Soil ratings are low: NRCS ratings of VIs or VIIs (severe limitations or very severe limitations that make them unsuited to cultivation); ALISH rating of Not Classified, and an LSB rating of E which is lowest productivity rating. Depending on rainfall, about 267 acres are suitable for low-quality pastures for seasonally grazing a small number of cattle.

4. PAST, CURRENT AND SURROUNDING LAND USES

a. Past Agricultural Use

Before cattle were introduced to Maui and extending into the 1800s, the upland forest zone was much lower than it is today, and the Mākena region received more rainfall. This rainfall was sufficient to allow the seasonal cultivation of sweet potato (ʻuala) in small gardens within Mākena. About a month before the rainy season began, soil for planting was carried in lauhala baskets from the mountains to Mākena.

For most of the past century, and possibly longer, nearly all of the Project site was used for grazing cattle. In 1973, ʻUlupalakua Ranch (the **Ranch**) sold the property to The Seibu Group of Japan. Starting in the early 1980s, the area used for grazing cattle was reduced to allow development of Mākena Resort.

b. Current Uses of the Project's Ag Lands

At the northern end of the Project site, ʻUlupalakua Ranch is allowed to graze cattle on about 88 acres of the Project's Ag lands. The grazing is infrequent (a few weeks per year) by a small number of cattle.

Naulu Farm is a non-commercial 2-acre farm located adjacent to the clubhouse of the Mākena North Golf Course. Operations include an animal farm, a greenhouse dedicated to cultivating native species, a vegetable and fruit garden, an aquaponics system, and educational programs. Edibles are supplied to the restaurant. The greenhouse propagates native species for replanting areas within the Project site. The Farm does not generate revenues through sales; instead, its operations are subsidized by a portion of the homeowner's association fees.

About 36 acres of the Project's Ag lands are landscaped for the Mākena North Golf Course. The remaining Ag lands consists of dry forest dominated by kiawe trees, sourgrass, koa haole and wild basil.

c. Surrounding Land Uses

Lands mauka of the Project site include (1) the 750-acre U-1 Agricultural Subdivision, of which about 700 acres will remain available to ʻUlupalakua Ranch for grazing cattle and occasionally sheep; and (2) other lands used by the Ranch for grazing. To the north are the Wailea Gold Golf Course, Wailea Resort, and existing and planned resort-residential projects. Makai are resort facilities, homes, the historic Keawalaʻi Church, beach parks, and undeveloped land. To the south are the Mākena State Park (Big Beach or Oneloa), various single-family homes and, farther south, ʻĀhihi-Kīnaʻu Natural Preserve Area (La Perouse).

Consistent with the absence of high-quality soils in Mākena and nearby communities, the region lacks commercial farming activities and does not host a farming community.

While the region does support limited and intermittent cattle and sheep grazing, most ranching activities are concentrated mauka on lands of ʻUlupalakua Ranch.

5. IMPACTS ON AGRICULTURE

The Project's 510 acres of Ag land is about 0.21% of the 242,723 acres in the Agricultural District on Maui Island, and 0% of the 72,300 acres of high-quality farmland.

a. Impacts on Grazing Operations

On-Site Grazing

The Project will end ʻUlupalakua Ranch's use of 88 acres of the Project Ag land for grazing cattle. Grazing on this land occurs sporadically over a few weeks each year by a small number of cattle. The low grazing intensity is attributed to the low forage growth, which is consistent with the low-quality soils and low rainfall.

ʻUlupalakua Ranch grazes about 2,300 brood cows on over 18,000 acres of land on the southern slopes of Haleakalā. The higher-quality pastures are at higher elevations where rainfall exceeds 30 inches per year.

The reduction in pasture acreage and beef production attributable to the loss of 88 acres of low-quality pasture (less than 0.5% of the Ranch's grazing lands) will be negligible. No loss in Ranch employment will occur due to the Project.

Nearby Grazing

Cattle and sheep operations by ʻUlupalakua Ranch on lands mauka of the Project site will not be impacted by Project construction nor operations at full development. Numerous residential and resort projects throughout Hawaiʻi have demonstrated that low-intensity grazing is compatible with such projects, resulting in minimal or no impacts on grazing operations. Furthermore, low-intensity grazing operations are desirable near residential and resort projects because the grazing of grasses reduces the fire hazard to homes and buildings.

b. Impacts on Crop Farming

Currently, no commercial crops are grown within or near the Project site, and there are no known plans to establish commercial farms nearby. In addition, development of commercial farms in the vicinity is unlikely due to poor soils and water scarcity. Consequently, Project development and operations will not impact current or anticipated commercial crop farms.

Regarding the non-commercial Naulu Farm, plans are to expand the greenhouse operations to supply native species for replanting various areas within the Project and for maintaining preservation areas. Employment is projected to increase from the current five workers to 12 workers in a few years. In addition, educational programs will be increased.

c. Impacts on the Growth of Crop Farming

The Project will result in redistricting about 510 acres from the State Agricultural District to the Rural District. However, this redistricting will have no impact on the growth of commercial crop farming on Maui since the stony, low-quality soils and lack of irrigation water render this land unsuitable for cultivating commercial crops.

d. Mitigating Measures

No mitigation measures are warranted in view of the findings of: (1) negligible impacts on cattle-grazing operations, (2) no impacts on existing or anticipated commercial crop-farming operations, (3) a beneficial expansion of the non-commercial Naulu Farm, and (4) no impact on the growth of commercial crop farming.

6. OFFSETTING BENEFITS

The redistricting of about 510 acres of low-quality agricultural land from the Agricultural District to the Rural District will be offset by the following benefits of the Project:

— Benefits from construction activity

- Construction jobs and payroll associated with Project development.
- Indirect jobs and payroll generated by the purchase of goods and services by construction companies and families of construction workers.
- County tax revenues (excise tax surcharge, etc.) and State tax revenues (excise taxes, personal income taxes, corporate income taxes, etc.) paid by construction companies and workers, and by companies and families that are supported by construction activity.

— Benefits from operations at full development

- Expansion of Naulu Farm operations and its educational programs.
- New on-site affordable homes.
- Recreational improvements (renovated golf course, new clubhouse and new practice range; hiking trails; walking, bicycling, and golf cart paths; beach parking stalls; and an expansion of Mākena Landing).
- Direct jobs and payroll provided by operations and maintenance (**O&M**) of the homes, grounds, and expanded golf-course operations.
- Indirect jobs and payroll supported by the purchase of goods and services for O&M, by families of employees involved with O&M, and by families who will occupy the Project's new homes.
- County tax revenues (excise tax surcharge, property taxes, etc.) and State tax revenues (excise taxes, personal income taxes, corporate income taxes, etc.) paid by companies supply goods and services, and by families who will occupy the Project's new homes.

7. CONSISTENCY WITH STATE AND COUNTY POLICIES

a. Availability of Lands for Agriculture

State and County plans and policies call directly or implicitly for preserving the economic viability of plantation agriculture (sugarcane or pineapple) and promoting the growth of diversified agriculture (i.e., non-plantation agriculture). To accomplish this, an adequate supply of agriculturally suitable lands and water must be assured.

The Project's Ag lands have stony, low-quality soils and lack water for irrigating crops.

Regarding plantation agriculture, none of the Project site has a history of being used for sugarcane or pineapple cultivation.

Regarding diversified agriculture, none of the Project site has a known history of being used for growing diversified crops in the past 150+ years, and none of the land is suitable for commercial crops. However, the Project's Ag lands include about 267 acres of low-quality pastureland of which about 88 acres are used by ʻUlupalakua Ranch for grazing cattle over a few weeks each year. The loss of this land for grazing cattle will have a negligible impact on Ranch operations and, as a result, Hawaiʻi's cattle industry (see Subsection 5.a).

b. Conservation of Agricultural Lands

In addition to the above, State and County policies call for conserving and protecting prime agricultural lands, including protecting farmland from urban development.

As mentioned, the Project's Ag lands are characterized by stony, low-quality soils lacking access to irrigation water. None of this land is classified as prime agricultural land, none is suitable for commercial crop farming, and none is commercially farmed.

c. Redesignation from Agricultural to Urban/Rural

Discussions in the *Agriculture State Functional Plan* recognize that redesignation of lands from Agricultural to Urban and/or Rural should be allowed "… upon a demonstrated change in economic or social conditions, and where the requested redesignation will provide greater benefits to the general public than its retention in …agriculture;" that is, when an "overriding public interest exists."

The enormous contraction of plantation agriculture and the resulting increase in the supply of land that came available for diversified crop farming constitutes a major change in economic conditions. Moreover, the Project will provide community benefits (expansion of Naula Farm and its educational programs, homes, recreational improvements, jobs, payroll, tax revenues, etc.) that far exceed the benefits of leaving the land in agriculture (a mere fraction of a full-time job). Furthermore, the Project lands to be re-designated from Agricultural to Rural are within the Urban Growth Boundary (**UGB**) identified by Maui County.

d. Important Agricultural Lands (IAL)

None of the Project area is currently designated as Important Agricultural Lands (**IAL**), and future designation is highly improbable. Lands that are designated Urban and/or located within the County's UGB are not eligible for IAL designation. Furthermore, the Project's Ag lands do not meet the definition of IAL due to stony, low-quality soils and lack of water for irrigating crops. Specifically, these lands: (1) are incapable of producing sustained high agricultural yields, (2) contribute negligibly to the State's economic base, and (3) are not needed to promote the expansion of agricultural activities and income for the future.

e. County of Maui Land-Use Plans (MIP & KMCP)

Homes and other structures will be built within the County's UGB of the Maui Island Plan (**MIP**). The Project's Ag lands are located outside the UGB (about 133 acres) and will be preserved as open space. Therefore, the Project is consistent with the MIP.

Regarding the 1998 Kīhei-Mākena Community Plan (**KMCP**), about 44 acres at the north-east and southern areas of the Project site are designated Agriculture. These lands are outside the UGB and will remain as open space. Therefore, the Project is consistent with the Community Plan.

MĀKENA MAUKA:
IMPACTS ON AGRICULTURE

1. INTRODUCTION

AREG AC Makena Propco LLC (the **Applicant**), which does business as Mākena Golf & Beach Club Owners, proposes the development of Mākena Mauka (the "**Project**"), a low-density master planned residential community within the Mākena area of South Maui (**Mākena Resort**).

This report addresses the impacts of the Project on agriculture. The material below gives information about the Project, land designations, the agricultural conditions of the Project's agricultural lands, past and current agricultural uses, the impact of the Project on agriculture, benefits of the Project that would offset adverse agricultural impacts, and consistency of the Project with State and County agricultural policies. Figures are at the end of the report. The Appendix provides a summary of State and County goals, objectives, policies and guidelines related to agricultural lands.

2. PROJECT INFORMATION

a. Project Location and TMKs

The Project site is located in the Mākena region of south Maui, within the ahupuaʻa of Keauhou, Kalihi, Waipao, Pāpaʻanui, Kāʻeo, Maluaka, Mooiki, Mooloa, and Moomuku, in the moku of Honuaʻula, district of Makawao (see Figures 1 and 2).

Tax Map Keys (**TMKs**) for the Project include: (2)2-1-005:108; (2)2-1-006:036 and 057; (2)2-1-007:068, 092 and 093; (2)2-1-008:078, 079, 081, and 090; and (2)2-1-031:036(Por.).

b. Project Acreage

The Project site encompasses about 1,043.71 acres, including the existing Mākena North Golf Course and the Mākena South Golf Course. About 473 acres are planned for residential development.

c. Project Plans

Mākena Mauka is a low-density master-planned residential community (see Figure 3). The Project will provide 652 housing units, comprising 543 market-priced homes and 109 affordable homes. Additionally, it will incorporate the existing Mākena North Golf Course

and a renovated Mākena South Golf Course. Approximately 135,000 sq. ft. of support buildings will be developed, including space for golf operations and maintenance, restaurants, staff offices, etc. The community will feature hiking trails; walking, bicycling, and golf cart paths for connectivity; beach access and parking for the public; and areas reserved for conservation/open space.

The Project is within an area that has largely been planned for such uses for decades.

3. LAND-USE DESIGNATIONS AND REQUIRED APPROVALS

Much of the Project area has the necessary State and County land-use designations to support the proposed Project. However, changes in designations will be needed for the proposed rural-residential community in the most mauka portion of the Project area near the upper reaches of the 18-hole Mākena North Golf Course. Anticipated changes include: (1) a District Boundary Amendment (**DBA**) by the State Land Use Commission (**SLUC**) to change most of the lands used for the North Golf Course from the current Agricultural designation to Rural, (2) a Community Plan Amendment (**CPA**) (as may be required), and (3) a Change of Zoning (**CIZ**).

a. State Land-Use Districts

About 510 acres (52%) of the Project site are within the State's Agricultural District (the **Project's Ag lands**), including about 416 acres at the northern end of the site and 94 acres at the southern end (see Figure 4). The remaining lands (about 531 acres) are within the Urban District.

To support the proposed Project, the Applicant will petition the SLUC for a DBA to change the land designation from Agricultural to Rural. These Project's Ag lands include most of the Mākena North Golf Course. The Rural District designation will provide a gradual transition from the more makai Urban District lands and the Agricultural District lands mauka of the Project site. The Project lands to be re-designated from Agricultural to Rural are already within the Urban Growth Boundary (**UGB**) identified by Maui County.

The primary focus of the agricultural impact assessment contained in the report is on the Project's Ag lands.

b. Important Agricultural Lands (IAL)

None of the Project area is designated as Important Agricultural Lands (**IAL**). This is a supplemental State land-use classification administered by the SLUC (see Subsection 8.d. for further information on IAL).

c. Maui Island Plan (MIP)

Planned homes and other structures will be built within the County's UGB of the Maui Island Plan **(MIP)** (see Figures 3 and 5). The Project's Ag lands located outside the UGB (about 133 acres at the north-east and southern areas of the Project site) will remain as open space. Consequently, no amendments to the UGB will be necessary to accommodate the planned development.

d. Kīhei-Mākena Community Plan (KMCP)

The 1998 Kīhei-Mākena Community Plan (**KMCP**) designates much of the Project area for "Single-Family" or "Multi-Family" use (see Figure 6). However, about 44 acres at the north-east and southern areas of the Project site are designated Agriculture, and will remain as Open Space in the proposed Project plan.

The KMCP is currently undergoing an update by the County of Maui. It's possible that the revised Community Plan will incorporate land-use designations which align more closely with the Applicant's proposed Project. Consequently, the Applicant may not require a CPA to develop the project. If not, an application for a CPA may be submitted to the Maui Department of Planning for review and approval by the Maui County Council.

e. Maui County Zoning

Most of the development "parcels" around the North Golf Course were re-zoned for residential use in 2009 by the Maui County Council via Ordinance 3613 (see Figure 7). However, about 33 acres along the mauka border of the Project site are zoned Agriculture.

Areas within the Project currently designated as "Open Zone" will require rezoning to facilitate the proposed development. Following the DBA petition and, if necessary, the CPA application, an application for a Change in Zoning (**CIZ**) will be submitted to the Department of Planning for review and approval by the Maui County Council.

f. Special Management Area (SMA)

A portion of the project area lies within the Special Management Area (**SMA**) for the County of Maui (see Figure 3). A SMA Use Permit application(s) will be submitted to the Maui Department of Planning for those lands that are within the SMA, and which Project plans currently align with State and County land-use designations.

g. Shoreline Setback

A small portion of the planned planned Project—which includes golf-course, park and non-residential lands—is adjacent to the coastline. No new vertical development is proposed within this area.

4. AGRICULTURAL CONDITIONS

a. Soil Types and Characteristics

According to the Natural Resources Conservation Service (**NRCS**) of the U.S. Department of Agriculture, formerly known as the Soil Conservation Service, the Project Ag lands are comprised of (1) Keawakapu-Mākena soil association, Mākena series, and (2) Kamaole-Oanapuka soil association, Oanapuka series (see Figure 8). NRCS characterizes the soils of the Keawakapu-Mākena soil association as gently sloping to moderately steep and well drained. The underlying material is fine-textured to medium-textured subsoil and ranges in depth from shallow to deep and is comprised of fragmental ‘a‘a lava. The Mākena series consists of well-drained soils on uplands developed in volcanic ash. These soils are gently to moderate sloping and range in elevation from sea level to approximately 500 feet.

The Kamaole-Oanapuka association is also characterized as gently sloping to moderately steep and well-drained. These soils are extremely stony and are shallow to deep over fragmental lava. The Oanapuka series has surface and sub-layers of silt loam. The substratum is comprised of fragmental ‘a‘a lava.

Figure 9 shows the specific soil types underlying the Project area. These soil types and their corresponding acreages within the State Agricultural District are as follows:

— **MXC**: Makena loam, stony complex, 3 to 15 percent slopes (about 344 acres)

This complex consists of Makena loam and Stony land. Stony land occurs on low ridges and makes up 30 to 60 percent of the complex. Makena loam occurs in gently sloping areas between the low ridges of Stony land. Included are small areas of Keawakapu and Oanapuka soils. Also included are areas where out-crops of ‘a‘a lava cover as much as 15 percent of the surface.

In a representative profile the surface layer, about 4 inches thick, is very dark brown loam that has platy structure. The subsoil, about 19 inches thick, is very dark grayish-brown and. dark yellowish-brown silt loam that has prismatic structure. The substratum is dark yellowish-brown cobbly silt loam. The depth to ‘a‘a lava is more than 40 inches. Surface stoniness varies from nonstony to extremely stony near lava flows and drainage ways. The texture is loam or silt loam.

The soil is mildly alkaline in the surface layer and subsoil. On the Makena part of the complex, permeability is moderately rapid, runoff is slow to medium, and the erosion hazard is slight to moderate. The available water capacity is about 1.8 inches per foot of soil. On the Stony land part, permeability is very rapid and there is no erosion hazard.

This soil complex is used for pasture and wildlife habitat.

— **OAD**: Oanapuka very stony silt loam, 7 to 25 percent slopes (about 72 acres)

In a representative profile the surface layer, about 6 inches thick, is very dark brown and very dark grayish-brown silt loam that has granular and subangular blocky structure. The subsoil, about 9 inches thick, is very dark grayish-brown silt loam that has prismatic structure. The substratum is dark yellowish-brown silt loam, loam, and stone-size ʻaʻa lava. The depth of the soil ranges from 40 to more than 60 inches.

The soil is medium acid to slightly acid in the surface layer, neutral in the subsoil, and neutral to mildly alkaline in the substratum. Permeability is moderately rapid. Runoff is slow, and the erosion hazard is slight to moderate. The available water capacity is about 1.0 inch per foot of soil. In places roots penetrate to a depth of 4 feet or more.

This soil is used for pasture and wildlife habitat.

— **OED**: Oanapuka extremely stony silt loam, 7 to 25 percent slopes (about 8 acres)

This soil is similar to OAD, except that stones cover 3 to 15 percent of the surface area and includes small areas of rock outcrop.

This soil is used for pasture and wildlife habitat.

— **rVS**: Very stony land (rVS) (about 86 acres)

This land type consists of areas where 50 to 90 percent of the surface is covered with stones and boulders, and includes some very steep gulches. Slopes range from 7 to 30 percent. On Maui, this land type consists of young ʻaʻa lava that has a thin covering of volcanic ash which locally extends deep into cracks and depressions. The ash-covered areas support a stand of shrubs and grasses.

This land type is used for pasture and wildlife habitat. Pasture improvements are very difficult because of the many stones.

b. Soil Ratings

Three classification systems are commonly used to rate Hawaiʻi soils: (1) Land Capability and Pasture Groupings, (2) Agricultural Lands of Importance to the State of Hawaiʻi, and (3) Overall Productivity Rating.

Land Capability and Pasture Groupings (NRCS Rating)

NRCS's 1972 Land Capability Grouping rates soils according to eight levels, ranging from the highest classification level "I" to the lowest "VIII."

The soil ratings for the Project's Ag lands, along with the pasture group, are as follows:

Soil Type	Acres	Rating Irrigated	Rating Non-Irrigated	Pasture Group
MSC	344			
Makena	40 - 70%	nr	**VIs**	**1**
Stony	30 - 60%	nr	**VIIs**	nr
OAD	72	nr	**VIIs**	**2**
OED	8	nr	**VIIs**	**2**
rVS	86	nr	**VIIs**	nr

nr = not rated

Class VI rated soils have severe limitations that make them generally unsuited to cultivation and limit their use largely to pasture or range, woodland, or wildlife habitat. Class VII rated soils have very severe limitations that make them unsuited to cultivation and that restrict their use largely to pasture or range, woodland, or wildlife habitat. The sub-classification "s" indicates that the limitation is due to stoniness, unfavorable texture, shallowness, or low water-holding capacity.

Soils in Pasture Groups 1 and 2 yield the lowest forage of the 14 Pasture Groups. For Pasture Group 1, unimproved pasture produces 400 to 1,300 pounds of air-dry forage per acre per year. Three-fourths or more of the annual forage crop is produced during the rainy season. In summer, most of the annuals die and the perennials become dormant. Well-managed improved pasture produces 1,700 to 2,600 pounds of air-dry forage per acre per year. Improvements of pasture are difficult in stony areas. Seeding, fertilization, and weed and brush control are limited to hand and aerial methods. Improvements of pasture on eroded soils can be difficult because of winds and low rainfall.

For Pasture Group 2, unimproved pasture produces 700 to 1,700 pounds of air-dry forage per acre per year. Forage production in winter is about three times as much as that in summer. Well-managed improved pasture produces 1,400 to 2,600 pounds of air-dry forage per acre per year. Improvements of pasture are difficult on extremely stony and extremely rocky soils and on soils steeper than 40 percent. Seeding, fertilization, and weed and brush control are limited to hand and aerial methods. Improvements are difficult on eroded soils because of winds and low rainfall.

For comparison, the highest forage yields are produced on lands in Pasture Group 7: 3,000 to 6,000 pounds of air-dry forage per acre per year for unimproved pastures, and 7,000 to 16,000 pounds of air-dry forage per acre per year for will-managed improved pastures.

Agricultural Lands of Importance in the State of Hawai‘i (ALISH)

ALISH ratings were developed in 1977 by the NRCS, University of Hawai‘i (**UH**) College of Tropical Agriculture and Human Resources, and the State of Hawai‘i, Department of Agriculture. This system classifies land into three broad categories: (a) "**Prime**" agricultural land which is land that is best suited for the production of crops because of its ability to sustain high yields with relatively little input and with the least damage to the environment; (b) "**Unique**" agricultural land which is non-Prime agricultural land used for the production of specific high-value crops (e.g., taro); and (c) "**Other**" agricultural land which is non-Prime and non-Unique agricultural land that is important to the production of crops. Agricultural land that is not rated in any of these three categories is labeled "**Not Classified**" due to poor agricultural quality, and/or inability to produce high-value crops or important crops.

As shown in Figure 10, the entire Project site is comprised of soils that are "**Not Classified**."

Overall Productivity Rating (LSB Rating)

In 1967, the UH Land Study Bureau (**LSB**) developed the Overall Productivity Rating, which classifies soils according to five levels, with "**A**" representing the class of highest productivity and "**E**" the lowest.

As indicated in Figure 11, the Agricultural lands within the Project Area have soils with the lowest productivity rating of "**E**."

c. Elevations

The Agricultural land within the Project site ranges in elevation from about 25 feet in the south to nearly 790 feet in the north.

d. Slopes

The Agricultural land within the Project site averages about 5% in the north and about 7.2% in the south.

e. Climatic Conditions

Like other areas in Hawai‘i, Mākena has a mild semitropical climate that is due primarily to three factors: (1) Hawai‘i's mid-Pacific location near the Tropic of Cancer, (2) the surrounding warm ocean waters that vary little in temperature between the winter and summer seasons, and (3) the prevailing northeasterly tradewinds that bring air having temperatures which are close to those of the surrounding waters. In terms of local conditions, Mākena is located within one of the drier areas of Maui along the southwest coast. This area is generally sunny, warm, and dry throughout the entire year.

Solar Radiation

The site receives considerable sunshine, with average daily insolation of about 500 calories per square centimeter per day.

Rainfall

Rainfall at the Mākena North Golf Course averages about 16 inches annually. Most of this rainfall occurs during the winter rainy season (October through March).

Temperatures

At the Mākena North Golf Course, average monthly temperatures range from 63°F to 81°F in the winter (February), and 69°F to 88°F in the summer (August).

Winds

At the Mākena Beach State Park, prevailing surface winds are tradewinds that blow from the east at about 5 to 15 miles per hour (**mph**).

f. Irrigation Water

Because of the poor soils for growing crops on the Project's Ag lands, a water source for irrigating crops was never developed for these lands, nor was irrigation water transported from outside the region.

Recycled wastewater is available from the Mākena Wastewater Reclamation Plant. The plant's capacity is 0.75 million gallons per day (**mgd**) of recycled water, although the current supply from the plant is only 60,000 to 80,000 gallons per day (**gpd**). This plant was designed to supply recycled water to irrigate portions of the golf-course grounds and landscaped areas at Mākena. None of the recycled water is currently available to irrigate crops.

g. Road Access

Currently, the Agricultural lands within the Project site are reached primarily via gravel roads which connect to Makena Alanui Road and Makena Road.

h. Distance to Markets and Shipping Terminals

Trucking distance from Makena to Kahului is about 18 miles. Kahului serves as the island's primary commercial, industrial, distribution and transportation center. The town encompasses Kahului Harbor and Kahului Airport.

i. Summary of Agricultural Conditions

The 510 acres of the Project's Ag land are unsuitable for crop farming due to stony, low-quality soils and lack of water for irrigating crops. Depending on rainfall, about 267 acres are suitable for low-quality pastures for seasonally grazing a small number of cattle.

5. PAST, CURRENT AND SURROUNDING LAND USES

a. Past Agricultural Use5

Before cattle were introduced to Maui and extending into the 1800s, the upland forest zone was much lower than it is today, and the Mākena region received more rainfall. This rainfall was sufficient to allow the seasonal cultivation of sweet potato (ʻuala) in small gardens within Mākena. About a month before the rainy season began, soil for planting was carried in lauhala baskets from the mountains to Mākena. Most other fruits and vegetables for Hawaiians living in Mākena were imported from areas having better soils and abundant water.

For most of the past century, and possibly longer, nearly all of the Project site was used for grazing cattle. In 1973, ʻUlupalakua Ranch (the **Ranch**) sold the property to The Seibu Group of Japan. Starting in the early 1980s, the area used for grazing cattle was reduced to allow development of Mākena Resort.

b. Current Uses of the Project's Ag Lands

At the northern end of the Project site, ʻUlupalakua Ranch is allowed to graze cattle on about 88 acres of the Project's Ag lands. The grazing is infrequent (a few weeks per year) by a small number of cattle.

Naulu Farm is a small non-commercial farm located adjacent to the clubhouse of the Mākena North Golf Course. The Farm began in 2020, and encompass approximately 2 acres. A small volume of water is supplied to the Farm from a private well that supplies water to Mākena Resort. Operations include an animal farm (sheep, rabbits, pigs, chickens, and turtles), a greenhouse dedicated to cultivating native species, a vegetable and fruit garden, an aquaponics system, and educational programs. The garden yields about 3,400 pounds annually, including vegetables, papayas, kalo, squash, lettuce, ulu, limes, bananas, etc. Edibles are supplied to the restaurant. The greenhouse propagates over 30 native species and can produce approximately 25,000 native plants annually for replanting areas within the Project site. Five workers are currently employed at the Farm. The Farm does not generate revenues through sales; instead, its operations are subsidized by a portion of the homeowner's association fees.

About 36 acres of the Project's Ag lands are landscaped for the Mākena North Golf Course. Grasses are grown on soil that was transported to the site for the golf-course greens and fairways.

The remaining Ag lands consists of dry forest dominated by kiawe trees, sourgrass, koa haole and wild basil. A detailed list of native species is provided in the Flora & Fauna report by Rick Barboz.

c. Surrounding Land Uses

Figure 2 shows the current use of lands surrounding the Project's Ag lands. Mauka lands include (1) the 750-acre U-1 Agricultural Subdivision, of which about 700 acres will remain available to ʻUlupalakua Ranch for grazing cattle and occasionally sheep; and (2) other lands used by the Ranch for grazing. To the north are the Wailea Gold Golf Course, Wailea Resort, and existing and planned resort-residential projects. Makai are resort facilities, homes, the historic Keawalaʻi Church, beach parks, and undeveloped land. To the south are the Mākena State Park (Big Beach or Oneloa), various single-family homes and, farther south, ʻĀhihi-Kīnaʻu Natural Preserve Area (La Perouse).

Consistent with the absence of high-quality soils in Mākena and nearby communities, the region lacks commercial farming activities and does not host a farming community (see Figure 12). While the region does support limited and intermittent cattle and sheep grazing, most ranching activities are concentrated mauka on lands of ʻUlupalakua Ranch.

6. IMPACTS ON AGRICULTURE

The Project's 510 acres of Ag land is about 0.21% of the 242,723 acres in the Agricultural District on Maui Island, and 0% of the 72,300 acres of high-quality farmland (see Figure 12). The accounting of high-quality farmland encompasses land in the Agricultural District that possesses one or more high soil ratings: an NRCS rating of I or II; an ALISH rating of Prime or Unique, and/or an LSB rating of A or B. However, this accounting excludes land used for country estates and golf courses.

a. Impacts on Grazing Operations

<u>On-Site Grazing</u>

The Project will end ʻUlupalakua Ranch's use of 88 acres of the Project Ag land for grazing cattle. Grazing on this land occurs sporadically over a few weeks each year by a small number of cattle. The low grazing intensity is attributed to the low forage growth, which is consistent with the low-quality soils and low rainfall (see Subsection 4.i).

Established in 1845, ʻUlupalakua Ranch currently grazes about 2,300 brood cows on over 18,000 acres of land on the southern slopes of Haleakalā. The higher-quality pastures are at higher elevations where rainfall exceeds 30 inches per year.

The reduction in pasture acreage and beef production attributable to the loss of 88 acres of low-quality pasture will be negligible, representing less than 0.5% of the Ranch's total acreage. No loss in Ranch employment will occur due to the Project.

Nearby Grazing

Cattle and sheep operations by ʻUlupalakua Ranch on lands mauka of the Project site will not be impacted by Project construction nor operations at full development. Numerous residential and resort projects throughout Hawaiʻi have demonstrated that low-intensity grazing is compatible with such projects, resulting in minimal or no impacts on grazing operations. Examples of such projects include Mākena, Wailea, Kula, Makakilo on Oʻahu, Princeville on Kauaʻi, Waimea on the Big Island, and many others.

Furthermore, low-intensity grazing operations are desirable near residential and resort projects because the grazing of grasses reduces the fire hazard to homes and buildings.

b. Impacts on Crop Farming

Currently, no commercial crops are grown within or near the Project site, and there are no known plans to establish commercial farms nearby. In addition, development of commercial farms in the vicinity is unlikely due to poor soils and water scarcity. Consequently, Project development and operations will not impact current or anticipated commercial crop farms.

Regarding the non-commercial Naulu Farm, plans are to expand the greenhouse operations to supply native species for replanting various areas within the Project and for maintaining preservation areas. Employment is projected to increase from the current five workers to 12 workers in a few years. In addition, educational programs will be increased.

c. Impacts on the Growth of Crop Farming

The Project will result in redistricting about 510 acres from the State Agricultural District to the Rural District. However, this redistricting will have no impact on the growth of commercial crop farming on Maui since the stony, low-quality soils and lack of irrigation water render this land unsuitable for cultivating commercial crops (see Subsection 4.i).

d. Mitigating Measures

No mitigation measures are warranted in view of the findings of: (1) negligible impacts on cattle-grazing operations, (2) no impacts on existing or anticipated commercial crop-farming operations, (3) a beneficial expansion of the non-commercial Naulu Farm, and (4) no impact on the growth of commercial crop farming.

7. OFFSETTING BENEFITS

The redistricting of about 510 acres of low-quality agricultural land from the Agricultural District to the Rural District will be offset by the following benefits of the Project:

— Benefits from construction activity

- Construction jobs and payroll associated with Project development.
- Indirect jobs and payroll generated by the purchase of goods and services by construction companies and families of construction workers.
- County tax revenues (excise tax surcharge, etc.) and State tax revenues (excise taxes, personal income taxes, corporate income taxes, etc.) paid by construction companies and workers, and by companies and families that are supported by construction activity.

— Benefits from operations at full development

- Expansion of Naulu Farm operations and its educational programs.
- New on-site affordable homes.
- Recreational improvements (renovated golf course, new clubhouse and new practice range; hiking trails; walking, bicycling, and golf cart paths; beach parking stalls; and an expansion of Mākena Landing).
- Direct jobs and payroll provided by operations and maintenance (**O&M**) of the homes, grounds, and expanded golf-course operations.
- Indirect jobs and payroll supported by the purchase of goods and services for O&M, by families of employees involved with O&M, and by families who will occupy the Project's new homes.
- County tax revenues (excise tax surcharge, property taxes, etc.) and State tax revenues (excise taxes, personal income taxes, corporate income taxes, etc.) paid by companies supply goods and services, and by families who will occupy the Project's new homes.

8. CONSISTENCY WITH STATE AND COUNTY POLICIES

a. Availability of Lands for Agriculture

The *Hawai'i State Constitution*, the *Hawai'i State Plan*, the *State Agriculture Functional Plan*, the *County of Maui 2030 General Plan,* the County's *Maui Island Plan,* and the County's *Kihei-Makena Community Plan* call directly or implicitly for preserving the economic viability of plantation agriculture (sugarcane or pineapple) and promoting the growth of diversified agriculture (i.e., non-plantation agriculture). To accomplish this, an adequate supply of agriculturally suitable lands and water must be assured.

The Project's Ag lands have stony, low-quality soils and lack water for irrigating crops.

Regarding plantation agriculture, none of the Project site has a history of being used for sugarcane or pineapple cultivation.

Regarding diversified agriculture, none of the Project site has a known history of being used for growing diversified crops in the past 150+ years, and none of the land is suitable for commercial crops. However, the Project's Ag lands include about 267 acres of low-quality pastureland of which about 88 acres are used by ʻUlupalakua Ranch for grazing cattle over a few weeks each year. The loss of this land for grazing cattle will have a negligible impact on Ranch operations and, as a result, Hawaiʻi's cattle industry (see Subsection 6.a).

b. Conservation of Agricultural Lands

In addition to the above, State and County policies call for conserving and protecting prime agricultural lands, including protecting farmland from urban development.

As mentioned, the Project's Ag lands are characterized by stony, low-quality soils lacking access to irrigation water. None of this land is classified as prime agricultural land, none is suitable for commercial crop farming, and none is commercially farmed (see Section 4 and Subsection 5.b).

c. Redesignation from Agricultural to Urban/Rural

Discussions in the *Agriculture State Functional Plan* recognize that redesignation of lands from Agricultural to Urban and/or Rural should be allowed "… upon a demonstrated change in economic or social conditions, and where the requested redesignation will provide greater benefits to the general public than its retention in …agriculture;" that is, when an "overriding public interest exists."

The enormous contraction of plantation agriculture and the resulting increase in the supply of land that came available for diversified crop farming constitutes a major change in economic conditions (see Figure 13 for Statewide acreage in crop from 1960 to 2023[1]). Moreover, the Project will provide community benefits (expansion of Naula Farm and its educational programs, homes, recreational improvements, jobs, payroll, tax revenues, etc.) that far exceed the benefits of leaving the land in agriculture (a mere fraction of a full-time job)—see Subsection 6.a and Section 7. Furthermore, the Project lands to be re-designated from Agricultural to Rural are within the UGB identified by Maui County.

d. Important Agricultural Lands (IAL)

Chapter 205, Hawai'i Revised Statutes (**HRS**), declares "… that the people of Hawaii have a substantial interest in the health and sustainability of agriculture as an industry in the State. There is a compelling state interest in conserving the State's agricultural land resource base and assuring the long-term availability of agricultural lands for agricultural use to achieve the purposes of: (1) Conserving and protecting agricultural lands; (2) Promoting

1. In Figure 13, the recent increase in crop acreage reflects plantings by Mahi Pono on former sugarcane lands in Central Maui.

diversified agriculture; (3) Increasing agricultural self-sufficiency; and (4) Assuring the availability of agriculturally suitable lands …". "The objective for the identification of important agricultural lands is to identify and plan for the maintenance of a strategic agricultural land resource base that can support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities and increase agricultural self-sufficiency for current and future generations."

IALs are defined as lands that: "(1) Are capable of producing sustained high agricultural yields when treated and managed according to accepted farming methods and technology; (2) Contribute to the State's economic base and produce agricultural commodities for export or local consumption; or (3) Are needed to promote the expansion of agricultural activities and income for the future, even if currently not in production."

The IAL designation is a supplemental State land use classification that provides access to incentives that promote profitable farming of IALs. The designation does not change existing land classifications (i.e., State Land Use Districts, County community plan designations, County zoning, etc.), nor does it restrict allowable uses of IAL-designated agricultural land.

Landowners can petition the SLUC to designate as IAL all or portions of their agricultural land. In addition, each county is required to identify, map and recommend lands within its jurisdiction that have potential for IAL designation in keeping with the standards, criteria and procedures established by law. After the SLUC reviews a County's recommendations, the SLUC is responsible for designating IALs.

None of the Project area is currently designated as IAL, and future designation is highly improbable. Lands that are designated Urban and/or located within the County's UGB are not eligible for IAL designation. Furthermore, the Project's Ag lands do not meet the definition of IAL due to stony, low-quality soils and lack of water for irrigating crops. Specifically, these lands: (1) are incapable of producing sustained high agricultural yields, (2) contribute negligibly to the State's economic base, and (3) are not needed to promote the expansion of agricultural activities and income for the future.

e. County of Maui Land-Use Plans (MIP & KMCP)

As mentioned in Subsection 3.d, homes and other structures will be built within the County's UGB of the MIP (see Figures 3 and 5). The Project's Ag lands are located outside the UGB (about 133 acres) and will be preserved as open space. Therefore, the Project is consistent with the MIP.

Regarding the KMCP, about 44 acres at the north-east and southern areas of the Project site are designated Agriculture (see Subsection 3.e and Figure 6). These lands are outside the UGB and will remain as open space. Therefore, the Project is consistent with the Community Plan.

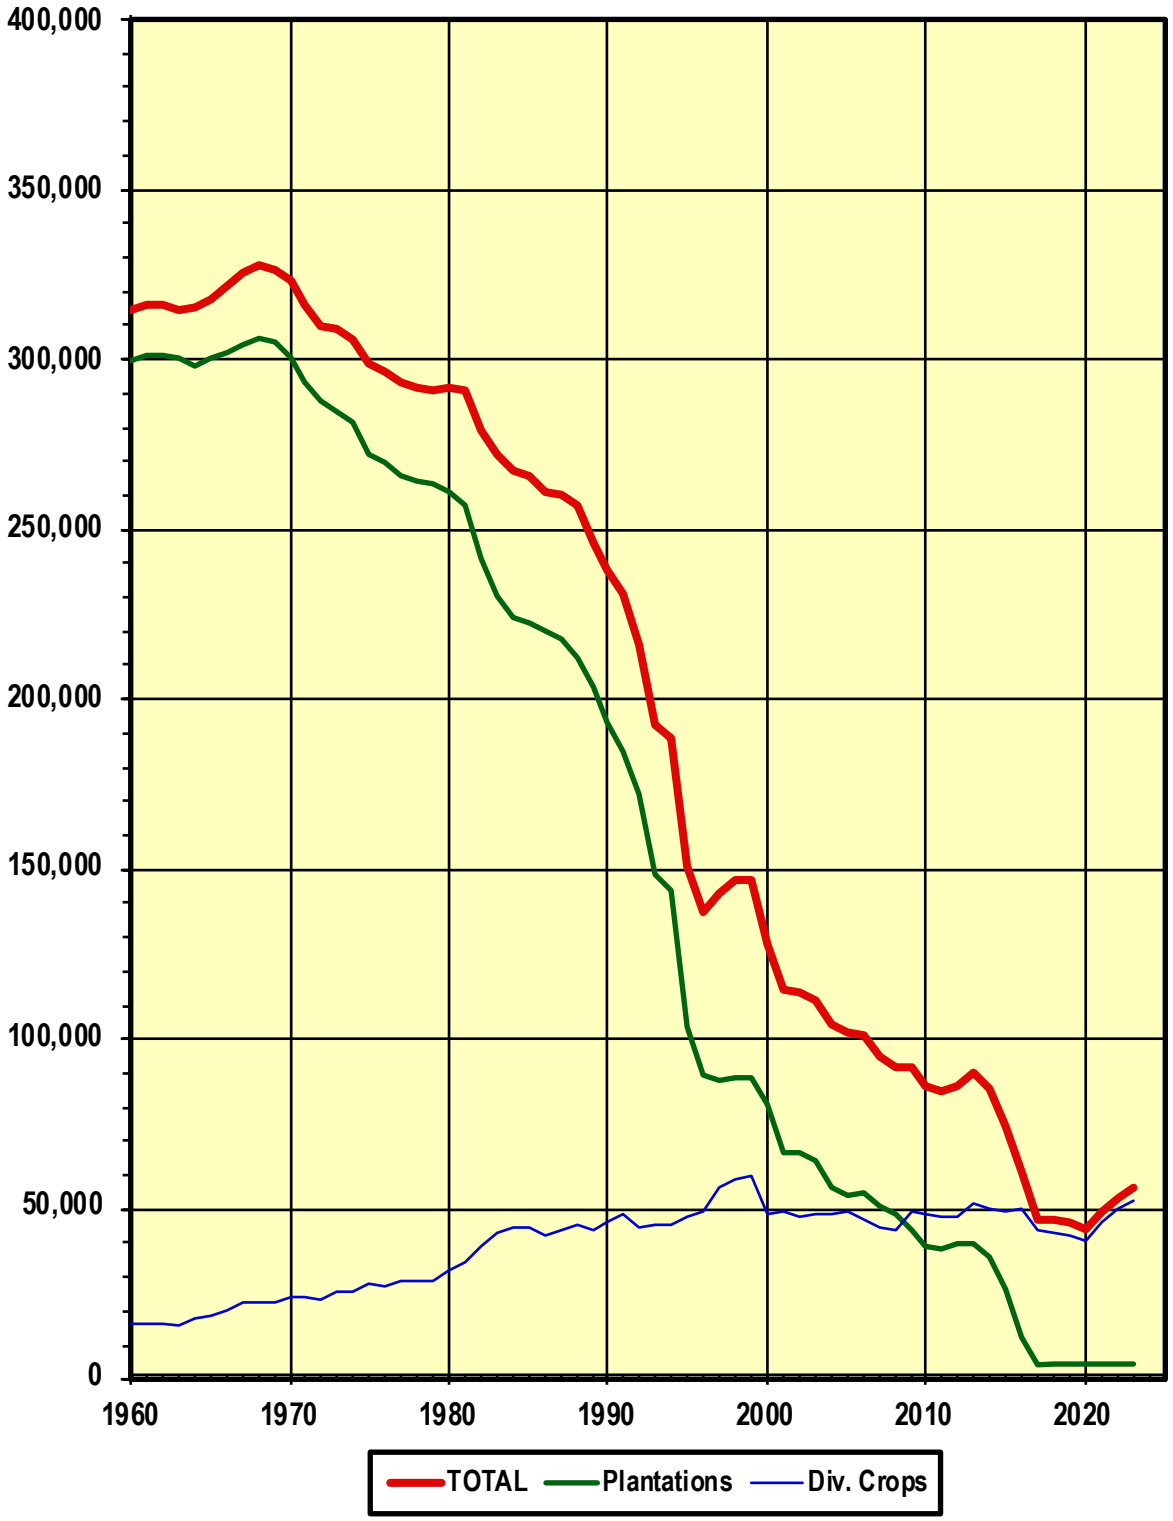

Figure 13. Acreage in Crop, Hawaii: 1960 to 2023

APPENDIX

STATE AND COUNTY GOALS, OBJECTIVES, POLICIES AND GUIDELINES RELATED TO AGRICULTURAL LANDS

1. HAWAI'I STATE CONSTITUTION (Article XI, Section 3):

> …to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands…

2. HAWAI'I STATE PLAN (Chapter 226, Hawaii Revised Statutes, as amended):

Section 226-7 Objectives and policies for the economy--agriculture.

(a) Planning for the State's economy with regard to agriculture shall be directed towards achievement of the following objectives:

(1) Viability in Hawaii's sugar and pineapple industries.

(2) Growth and development of diversified agriculture throughout the State.

(3) An agriculture industry that continues to constitute a dynamic and essential component of Hawaii's strategic, economic, and social well-being.

(b) To achieve the agricultural objectives, it shall be the policy of the State to:

(2) Encourage agriculture by making best use of natural resources.

(10) Assure the availability of agriculturally suitable lands with adequate water to accommodate present and future needs.

(16) Facilitate the transition of agricultural lands in economically nonfeasible agricultural production to economically viable agricultural uses.

Section 226-103 Economic priority guidelines.

(c) Priority guidelines to promote the continued viability of the sugar and pineapple industries:

(1) Provide adequate agricultural lands to support the economic viability of the sugar and pineapple industries.

(d) Priority guidelines to promote the growth and development of diversified agriculture and aquaculture:

(1) Identify, conserve, and protect agricultural and aquacultural lands of importance and initiate affirmative and comprehensive programs to promote

economically productive agricultural and aquacultural uses of such lands.

(10) Support the continuation of land currently in use for diversified agriculture.

Section 226-104 Population growth and land resources priority guidelines.

(b) Priority guidelines for regional growth distribution and land resource utilization:

(2) Make available marginal or non-essential agricultural lands for appropriate urban uses while maintaining agricultural lands of importance in the agricultural district.

3. AGRICULTURAL STATE FUNCTIONAL PLAN (1991)

(Functional plans are guidelines for implementing the State Plan. They are approved by the Governor, but not adopted by the State Legislature.)

Objective H: Achievement of Productive Agricultural Use of Lands Most Suitable and Needed for Agriculture.

Policy H(2): Conserve and protect important agricultural lands in accordance with the Hawaii State Constitution.

Action H(2)(a): Propose enactment of standards and criteria to identify, conserve, and protect important agricultural lands and lands in agricultural use.

Action H(2)(c): Administer land use district boundary amendments, permitted land uses, infrastructure standards, and other planning and regulatory functions on important agricultural lands and lands in agricultural use, so as to ensure the availability of agriculturally suitable lands and promote diversified agriculture.

4. COUNTY OF MAUI 2030 GENERAL PLAN, COUNTYWIDE POLICY PLAN (2010)

Countywide goals, objectives, policies and actions

F. Strengthen the Local Economy

Objective

2. Diversify and expand sustainable forms of agriculture and aquaculture.

Policies

b. Prioritize the use of agricultural land to feed the local population, and promote the use of agriculture lands for sustainable and diversified agricultural activities.

e. Support ordinances, programs, and policies that keep agricultural land and water available and affordable to farmers.

Implementing Actions

c. Create agricultural parks in areas distant from genetically modified crops.

J. Promote Sustainable Land Use and Growth Management

Objective

2. Improve planning for and management of agricultural lands and rural areas.

Policies

a. Protect prime, productive, and potentially productive agricultural lands to maintain the islands' agricultural and rural identities and economies.

c. Discourage developing or subdividing agriculturally designated lands when non-agricultural activities would be primary uses.

Implementing Actions

a. Inventory and protect prime, productive, and potentially productive agricultural lands from competing non-agricultural land uses.

5. MAUI ISLAND PLAN, GENERAL PLAN 2030 (2012)

Core Values

E. Preserve rural and agricultural lands and encourage sustainable agriculture.

Agricultural Lands

Goal

7.1 Maui will have a prosperous agricultural industry and will protect agricultural lands.

Objective

7.1.1 Significantly reduce the loss of productive agricultural lands.

Policies

7.1.1.a Allow, where appropriate, the clustering of development on agricultural lands when approved as a CSD [Conservation Site Design] plan or similar approval mechanism.

7.1.1.b Require, where appropriate, the review and approval of CSD plans prior to the subdivision of agricultural land.

7.1.1.c Discourage developing or subdividing productive agricultural lands for residential uses in which the residence would be the primary use and any agricultural activities would be secondary uses.

7.1.1.e Focus urban growth, to the extent practicable, away from productive and important agricultural lands.

7.1.1.f Strongly discourage the conversion of productive and important agricultural lands (such as sugar, pineapple, and other produce lands) to rural or urban use, unless justified during the General Plan update, or when other overriding factors are present.

7.1.1.h Provide incentives for landowners to preserve and protect agricultural lands from development through the use of TDR/PDR, tax credits, easement programs, or similar means.

7.1.1.j Require all major developments adjacent to agricultural lands to provide an appropriate and site-specific agricultural protection buffer as part of a required site plan.

Directed Growth Plan

Rural Growth Area, Policies

8.2.d All development within rural growth areas should avoid encroachment upon prime agricultural land.

Wailuku-Kahului

As shown in Figure 6, Pu‘unani is within the Growth Area for Wailuku, with a portion within the Urban Boundary and a portion within the Rural Boundary.

6. COUNTY OF MAUI, KIHEI-MĀKENA COMMUNITY PLAN (1998)

B. Goals, Objectives, Policies and Implementing Actions

LAND USE

Objectives and policies

p. Prevent urbanization of important agricultural lands.

ECONOMIC ACTIVITY

Objectives and policies

e. Provide for the preservation and enhancement of important agricultural lands for a variety of agricultural activities, including sugar cane, diversified agriculture and aquaculture.

WATER QUALITY ASSESSMENT REPORT

APPENDIX K

Mākena Golf & Beach Club
Water Quality Assessment for Mākena Mauka Project

June 2025

June 20 2025 ***FINAL*** *AECOS* No. 1602

Allen Cattell Ph.D.
AECOS, Inc.

Executive Summary

Marine water quality monitoring has been conducted in Makena nearshore waters continuously since 1998 (Marine Research Consultants {MRC} 1998 – 2017 and AECOS 2018 – current). Monitoring by MRC identified groundwater intrusion with elevated nutrients (primarily nitrate+nitrite) relative to background ocean concentrations at nearshore sites along two transects. The MRC reports listed irrigation with R1 water from the Makena Wastewater Reclamation Facility (WWRF) as a potential source of this subsidy. The *AECOS* monitoring program involved random sampling events that included all four daily tidal conditions. A few nitrate+nitrite subsidies were identified at the same two nearshore coastal areas identified by MRC. No offshore areas subsidies have been identified. A comparison of all MRC and *AECOS* mean salinities, ortho-phosphate, and nitrate+nitrate values demonstrate major differences at nearshore stations 2 and 10 meters from shore and general agreement at distances of 50 and 100 meters from shore.

The Project has the potential to impact the marine water quality through increased areas of irrigation and fertilization (particularly to the renovated South Golf Course) and the increased impervious areas within the development creating more opportunities for stormwater runoff to migrate to coastal waters if not properly managed. These issues are addressed in this report.

We recommend:

- the addition of a water quality transect along Big Beach to monitor possible water quality impacts from the South Golf Course:

Introduction

AREG AC Mākena Propco LLC doing business as Mākena Golf & Beach Club (MG&BC) Owner (Applicant) proposes Mākena Mauka (the Project; Figure 1) a low-density master-planned residential community that will offer market rate housing together with residential workforce housing, with a mixture of rural and single-family lots and multi-family residential units, within an area that has largely been planned for such uses for decades. The project will incorporate the existing 18-hole Mākena North Golf Course and the 18-hole Mākena South Golf Course (to be renovated as part of the land plan), together with a community gathering place, hiking trails, programs to support connectivity, walking, bicycling, and golf cart paths, beach parking for the public, areas reserved for conservation/open space, and areas reserved for public beach access, The Applicant's current vision for the Mākena Mauka land plan includes 652 housing units, including 109 onsite residential workforce housing units, along with approximately 135,000 sf of operational support buildings, which include golf maintenance, staff offices, restaurants, back of house, golf operations and other uses; within the approximately 1,043.71-acre total project area (TMK) Nos. (2)2-1-005:108, (2)2-1-006:036 and -57, (2)2-1-007:068, 092 and 093, (2)2-1-008:078, 079, 081, and 090, and (2)2-1-031:036(Por.)):which includes approximately 473 acres of parcels proposed for residential development (Munekiyo Hiraga, 2024).

The purpose of this report is to review water quality along the coastal nearshore waters off the general Project area and to assess potential effects of the Project on water quality of these Makena coastal waters. Based on our experience, exceeding state criteria for nitrogen, phosphorus, turbidity, and chlorophyll α in Hawaiian nearshore coastal waters is more the common occurrence than the exception. Nutrient enrichment of a specific coastal water body can occur from a variety of causes:

1) groundwater intrusion[1];
2) resuspension of bottom sediments;
3) biological excretion products and biological recycling processes;
4) longshore current transport from other areas; and
5) land surface runoff during storm events (includes enhanced input from stream freshets).

[1] Groundwater, in comparison to marine receiving water, is characterized by very low salinity and typically high soluble nutrient content.

Turbidity is typically elevated by land runoff and by resuspension of bottom sediments due to wind and wave action in shallow nearshore water. Chlorophyll α values can increase in shallow areas due to land runoff and groundwater seepage, providing nutrient sources.

State water quality criteria account for these typical influences by differentiating between "open coastal waters" (nearshore, between the shore and the 183-m [600-ft] depth contour) and "oceanic waters" (offshore, beyond the 183-m depth contour) and distinguishing between "wet" and "dry" coasts (HDOH, 2021, §11-54-06). An exception is made for waters off the Kona coast where special criteria have been developed to account for the considerable groundwater input there (HDOH, 2021, §11-54-06). The majority of Hawaiian coastal waters, including those off Maui, are subject to criteria that were developed nearly 50 years ago and are in need of re-evaluation.

Potential project-related impacts to water quality can arise from:

1) surface runoff and erosion from storm events during Project construction;
2) increased storm-related runoff following build-out due to an increase in impervious surface areas as a result of development;
3) infiltration of nutrients[2] to groundwater from landscape fertilization; and/or
4) infiltration of nutrients to groundwater from use of reclaimed Mākena wastewater reclamation facility (WWRF) R-1 water to irrigate golf course turf.

Existing Coastal Water Quality

Waters south from Nāhuna Point, including Makena Bay and Maluaka Bay (Figure 2), are designated as "Class A, open coastal waters" in the State of Hawai'i, Water Quality Standards by Hawai'i Department of Health (HDOH, 2021) and are included on the HDOH 2024 list of impaired waters in Hawai'i—prepared under Clean Water Act §303(d) (HDOH, 2024)—for nitrate+nitrite, ammonia, total nitrogen, and turbidity. These nearshore waters are listed as a "Category 3" water body, meaning that "there is [sic] insufficient available data and/or information to make a use support determinations [sic]" and as a "Category 5" water body, meaning that "[available data and/or information indicate that at least one or more designated use is not being supported or is threatened, and a Total Maximum Daily Load Study (TMDL) may be required.]

[2] "Nutrients" are nitrogen (nitrate+nitrite) and phosphorus (ortho-phosphate) compounds that promote plant growth, including algal growth in the marine environment. These chemicals are the main ingredients in applied fertilizers.

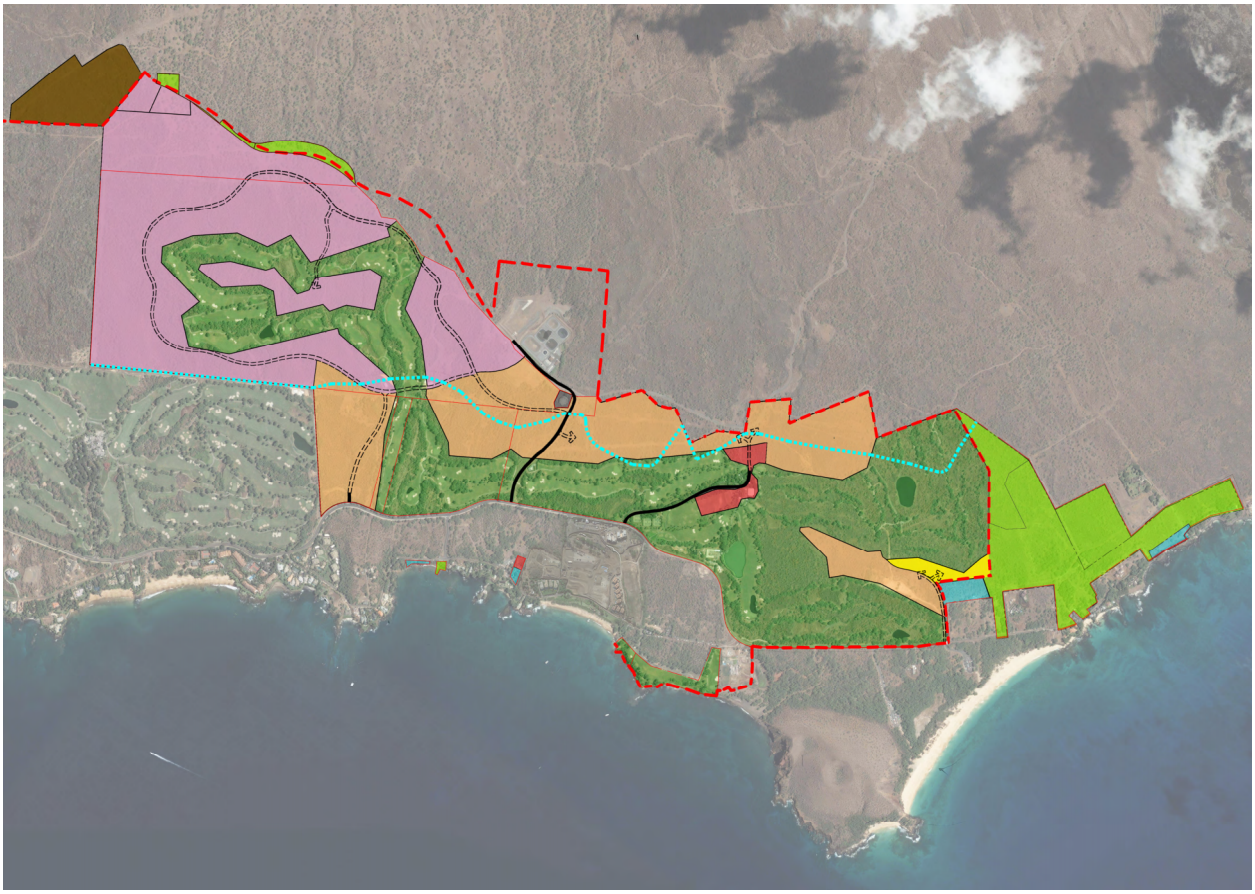

Figure 1. Mākena Mauka Project location map (Munekiyo Hiraga, 2024).

A water quality sampling program has been in continuous operation at MG&BC since 1998 (MRC 2009-2017; AECOS 2018-current) to assess the nearshore waters for the state water quality criteria constituents. The first sampling program by Marine Research Consultants (MRC) included three sampling transects located in nearshore waters just offshore of the resort. A fourth transect was located south of Puʻu Olai in a minimal human-use area to serve as a control (Figure 2). Transect 3A (renamed Transect M-3 in this report), located just offshore of the 16th fairway of the South Golf Course, was added to the sampling program in 2007. This was an alternative to Transect 3 which consistently demonstrated no groundwater input to nearshore coastal waters. Water quality data for MRC transects 1, 2, and 4 from 2009-2017are included in this report.

MRC sampling stations were located along each transect at 0 m, 2 m, 5 m, 10 m, 50 m, 100 m and 150 to 200 m offshore. The specific nearshore location of each transect was determined by refractometer analysis during each sampling event to identify the lowest salinity levels near shore. Transects extended seaward at 90 degrees to the coastline (Fig 2). Surface samples (within 20 centimeters of the surface) were collected at all stations.

In addition, samples were collected at one meter above the bottom at stations 5 m from the shore and seaward.

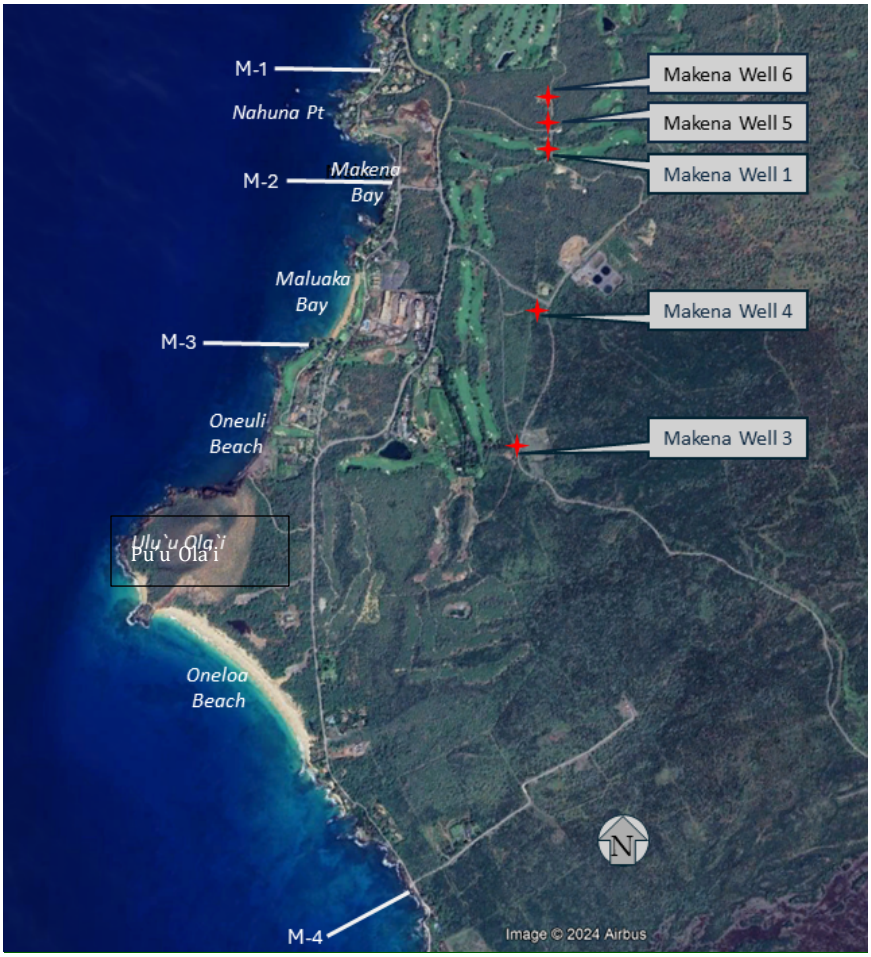

Figure 2. Location of water quality monitoring transects M-1, M-2, M-3, and M-4) and irrigation water supply wells at MG&BC.

Sampling events typically occurred twice a year: once during the Hawai'i water quality standards "wet" season between November and April and again during the "dry" season between May and October (HDOH, 2021). MRC collected Mākena well samples during several sampling events between September 2009 and November 2017 (MRC, 2017). Mākena well samples were analyzed for salinity, temperature, pH, ammonium nitrate+nitrite, ortho-phosphate, total nitrogen, and total phosphorus.

AECOS started Mākena water quality sampling in June 2018 with a revised program and schedule. Quarterly surface samples are collected each year along four transects established by MRC: M-1, M-2, M-3 (termed 3A by MRC), and M-4. Samples are collected at 2 m, 10 m, 50 m and 100 m from shore. No samples have been collected at depth as

coastal surface samples typically represent the best estimate of both groundwater and surface runoff to coastal waters. These fresh waters are less dense than sea water and fan out over the coastal surface, slowly mixing with deeper waters.

MRC and *AECOS* field teams both measured the same water quality parameters: temperature, salinity, pH, dissolved oxygen, nitrate+nitrite, ammonium, total nitrogen, ortho-phosphate, total phosphorus, silicates, turbidity, and chlorophyll α. Water quality parameters of particular interest for the purposes of this report are nutrients (inorganic nitrogen [nitrate+nitrite], and ortho-phosphate) and salinity. Nutrient enrichment of nearshore coastal waters from groundwater intrusion and stormwater runoff can enhance nuisance algae production (DLNR, 2016) and have a harmful impact on corals and other biological components in these waters (Laws et al., 2004; MRC, 2011; *AECOS*, 2016). Changes in salinity can result from stormwater runoff and groundwater seepage to nearshore coastal waters.

Table 1. Analytical methods and instruments used for water quality analyses reported herein.

Analysis	Method	Reference	Instrument

Chlorophyll *α* (Chl. *α*)	SM-10200	SM (1998)	Turner Fluorometer

Nitrogen and phosphorus values in most water quality surveys are typically calculated as geometric means to comply with Hawai'i state water quality regulations (HDOH, 2021). We will be using both averages and geometric mean estimates in this report as we are interested in evaluating potential impacts to Mākena nearshore waters. Average values are typically greater than geometric mean results.

The irrigation wells for golf course and landscaping, located mostly east of the golf course (Figure 2), were monitored for selected water quality parameters during both the MRC program and during the AECOS program (Table 2). Makena wells numbered 1, 3, 4, 5, and 6 are generally used to pump irrigation water into Pond 10. Granular fertilizer is distributed along the golf course and landscaping areas and irrigation occurs from Pond 10 based on environmental water requirements.

Table 2. Mean nitrate+nitrite and ortho-phosphate concentrations in Mākena groundwater.

Statistic	NO_3+NO_2 (µg/L)	PO_4 (µg/L)	Salinity (ppt)
Average	**1700**	**67**	**1.32**
Range	1400 - 1980	18 - 88	1.20 - 1.44
Std. error	*45*	*3.5*	*0.02*

R-1 water from the Mākena WWRF was pumped to Pond 10 until 2016 when the resort was closed. Mākena WWRF has been operating on a low-level basis since. There have been no R-1 water discharges to Pond 10 since 2016. Effluents are presently cleared by evaporation in the Mākena wastewater recovery facility (WWRF) oxidation ponds. The MRC monitoring program measurements were made during WWRF operation. The AECOS program has not measured water quality during any WWRF supply to Pond 10.

MRC Monitoring Program

MRC established transects in locations specifically to capture nearshore groundwater discharges to Makena coastal waters. During each sampling event, refractometers were used to identify specific areas of lowest salinity, which were then used as the 0 m distance from shore station along each transect. The average results and ranges for selected data for the Station 0 m to Station 5 m distance from shore are shown by transect in Table 3.

Notice that there were distinct differences between each transect for these parameters. Ortho-phosphate and nitrate+nitrite values were elevated along Transect M-1 and M-3, while salinity values were low. Also, ortho-phosphate and nitrate+nitrite values decreased rapidly between stations along Transect M-1 and M-3 compared with Transect M-2 and M-4. Salinity values, however, increased rapidly along Transect M-1 and M-3 compared with Transect M-2 and M-4 where there was little increase in salinity values.

Table 3. A summary of MRC average Mākena data at 0 m, 2 m, and 5 m stations between June 2009 and December 2017 during 15 sampling events.

Distance From Shore

Notice the large changes in ortho-phosphate and nitrate-nitrite concentrations for both parameters between 20 and 30 ppt salinity and the lower change in concentrations between 30 and 35 ppt salinity. These changes are characteristic of conditions very close to shore while much smaller changes are observed in coastal waters as distance from shore increases. Nitrate+nitrite values are more closely related to changes in salinity, compared with ortho-phosphate values. Ortho-phosphates are likely to adsorb as well as regenerate from particulate matter in coastal waters.

The MRC nearshore stations demonstrate nitrate+nitrite levels that were elevated relative to typical groundwater concentrations with low salinities along Transect M-1 and M-3 indicating subsidy values from fertilization of the golf course holes landward of these two transects. Figure 3 lists all MRC samples collected between 0 m and 5 m at Transect M-1 and Transect M-3. There are several values exceeding the groundwater average of 1700 µg/L of nitrate+nitrite and represent a distinct subsidy to groundwater nitrate+nitrite concentrations. There is also a strong relation between salinity and nitrate+nitrite concentration by R^2 the coefficient of determination, indicating that 94.5 percent of changes in nitrate+nitrite concentrations are related to changes in salinity.[3]

The MRC nearshore stations demonstrate ortho-phosphate levels that were elevated relative to groundwater concentrations and low salinities along Transect M-1 and M-3 indicating subsidy values from fertilization of the golf course holes landward of these two transects (Figure 4). Subsidy levels for ortho-phosphate were smaller than for nitrate+nitrite and the R determination was somewhat smaller as ortho-phosphate is more reactive by adsorbing to and regenerating from particulate matter.

[3] The coefficient of determination or goodness of fit (R^2 value) in these graphs is an estimate of how much of the variability in mean nutrient results can be attributed to sample salinity. The R^2 values and best-fit lines are shown for the historic data sets.

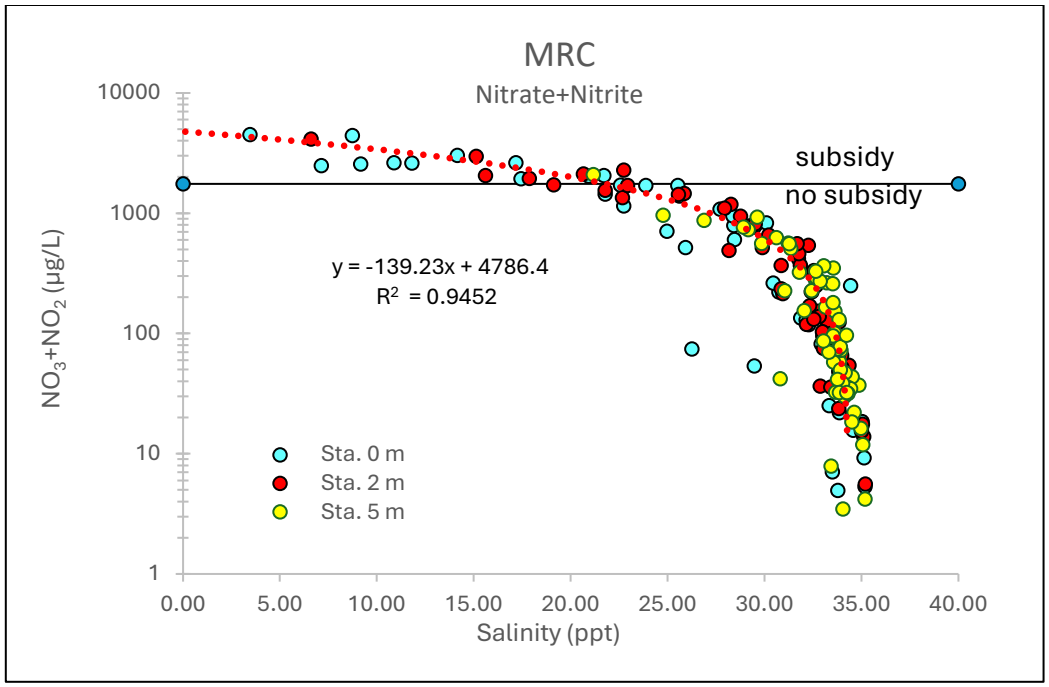

Figure 3. All MRC nitrate+nitrite data points at stations 0 m, 2 m, and 5 m distances from shore.

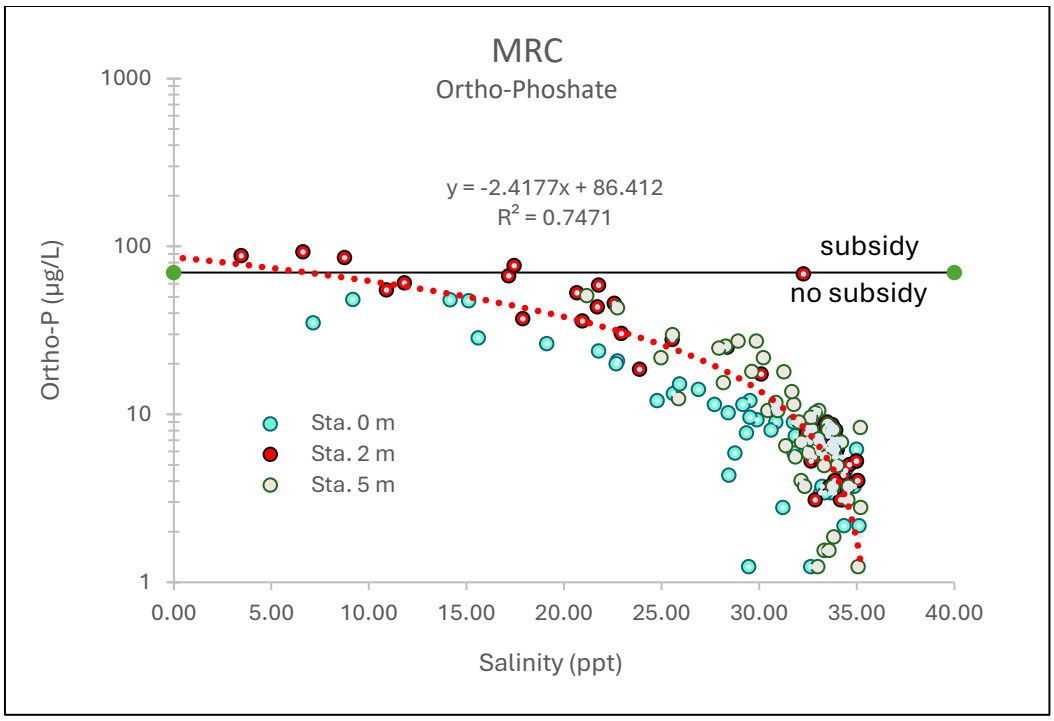

Figure 4. All MRC ortho-phosphate data points at stations 0 m, 2 m, and 5m distances from shore.

Makena golf holes directly landward and inland of some Wailea Golf Course sites at M-1 represent less than 10 acres of area, while the golf course just north of Mākena to Wailea Golf Club Drive is about 140 acres in area. Thus, nitrate+nitrite concentrations along Transect M-1 nearshore waters may be influenced by drainage from both Mākena and the Wailea golf course.

A single fairway on the South Golf Course, Fairway 16, is located just mauka of Transect M-3, where elevated nitrogen was detected near the shoreline (Fig. 3). There is little discharge of elevated nutrients nearshore at M-4. Any nutrient increases at Transect M-4 may be due to nearshore wave action and resuspension of bottom sediments and likely does not exceed groundwater levels, because there is no landward fertilization. MRC nitrate-nitrite concentrations at Transect M-2 did not exceed the groundwater levels for both nutrients.

AECOS Monitoring Program

AECOS' Mākena sampling program began in June 2018 at the following MRC transects: M-1, M-2, M-3 (MRC's 3A), and M-4. Surface samples were collected at stations located 2 m, 10 m, 50 m, and 100 m distance from shore. We sample on a quarterly basis to provide annual mean calculations for yearly comparisons. The primary difference between MRC and *AECOS* programs is that we sample under ongoing coastal conditions, while MRC emphasized low tidal sampling events. Thus, the MRC sampling occurred during ideal groundwater discharge conditions; i.e., low tide. Low tides exhibit maximum groundwater nutrient levels mixing with minimal nearshore water levels. The *AECOS* program samples during a broad view of existing conditions in Makena coastal waters for all tidal conditions.

Average estimates for nitrate+nitrite, ortho-phosphate, and salinity for both MRC (2009 – 2017) and *AECOS* (2018 – current) are shown in Table 4. Nitrate+nitrite and, to a lesser degree, ortho-phosphate geometric mean levels for both MRC and AECOS decrease with distance from shore. Nitrate+nitrite levels along Transect M-1 and M-3 are elevated compared with Transect M-2 and M-4 averages. Means for Nitrate+nitrite, ortho-phosphate and salinity for both data series become more closely matched to each other with distance from shore.

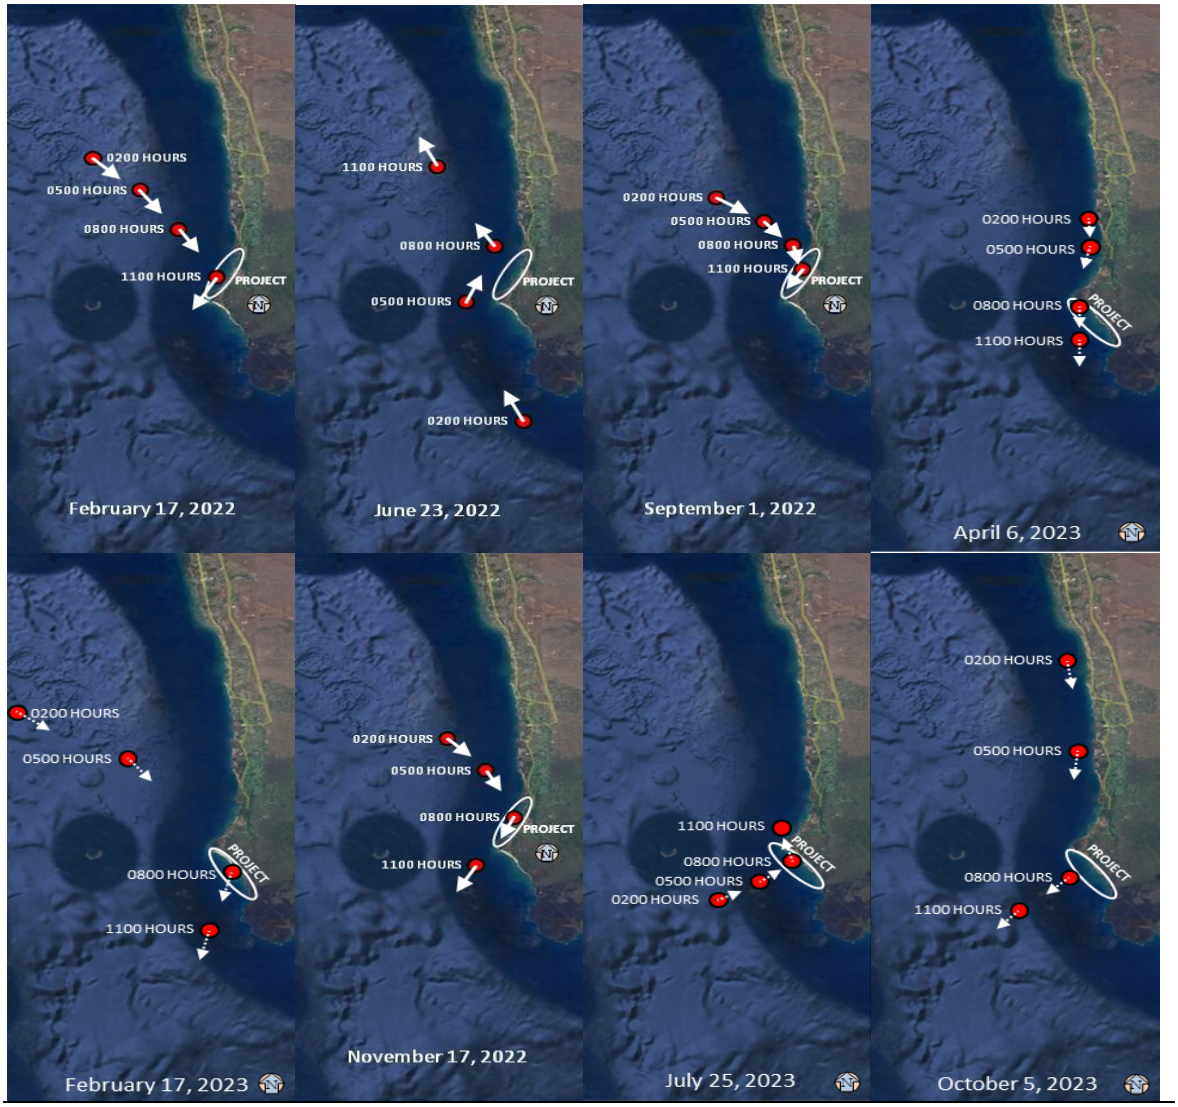

Figure 5. Estimated nearshore currents prior to sampling (0200 & 0500 hours), during sampling (0800 hours), and post-sampling (1100 hours) based on PacIOOS calculations (PacIOOS, 2025).

Nitrate+nitrite and ortho-phosphate distributions at all four transects for all MRC and *AECOS* sampling events are shown in Figure 5 and 7 at 2 m, 10 m, 50 m, and 100 m distance from shore. MRC Nitrate+nitrite and ortho-phosphate values demonstrate larger changes between low salinity values and smaller changes between higher salinities. *AECOS* values for both parameters demonstrate small changes in salinity having been sampled during a number of tidal cycles. Table 4 shows no nutrient interaction with low salinities and demonstrates a regular increase in MRC nitrate+nitrite levels due to low tidal sampling effects and a more clumped distribution of nitrate+nitrite levels for *AECOS* samples.

Table 4. Station by station comparison of MRC (n = 15— 2009-2017) and AECOS (n = 23—2018-2023) nutrient geometric means and salinity averages.

Transect	DFS† (m)	Nitrate+Nitrite (µg/L)		Ortho-Phosphate (µg/L)		Salinity (ppt)

Hui O Ka Wai Ola has been collecting water quality samples at stations across Maui since 2016. summary of the west Maui 25 stations is shown in Table 5 for average values of salinity, nitrate+nitrite, and ortho-phosphate. These stations are located between the Maalaea area and Ahihi-Kinau south of Mākena. These data have been sorted from high to low nitrate+nitrite average concentrations. The greyed sites are located offshore of Mākena. It is apparent that salinity values tend to increase from north to south, while nitrate+nitrite concentrations, and to a lesser extent ortho-phosphate concentrations tend to decrease from north to south. These data give a reasonable comparison of Makena nearshore water conditions for these parameters in the western coastal waters of Maui because of the random monitoring plan that includes all tidal conditions.

Table 5. Hui O Ka Wai Ola west Maui average water quality data for salinity, nitrate+nitrite, and ortho-phosphate.

Mākena Coastal Flow Patterns

There are direct nearshore groundwater discharges along most shoreline areas in Hawai'i. There are also flows just offshore that depend upon a number of ongoing physical conditions---including tidal events, wind conditions, waves, and geologic features. These coastal flows can change direction and speed in short periods of time. There were no ongoing flow modeling programs available in Hawai'i during the MRC sampling program. The PacI00S Regional Ocean Modeling System (ROMS) started producing coastal current information in late 2021 and provides a 7-day, 3-hourly forecast at an approximately 2.5-mile resolution. *AECOS* has been using these data since January 2022 to describe coastal flows in the Mākena area for each quarterly sampling event.

AECOS estimated nearshore flow conditions based on the ROMS model are shown in Figure 5 for 2022 and 2023. Note that these flow conditions are generally from north to south and only occasionally from south to north. There are also a range of flow rates depending upon specific environmental conditions between these sampling events.

The important feature to notice here is that these coastal flows at distances of 5 m to 10 m and further from shore can travel large distances—many meters in a few hours—while nearshore areas up to about several meters from shore may receive groundwater drainage for up to 1 m per day of possible discharge. Thus, groundwater seepage in Mākena is generally most apparent in nearshore waters, before merging with coastal flow patterns.

Other Thoughts about Coastal Water Quality

Based on our experience, exceeding state nutrient criteria—the nitrogen and phosphorus components—and criteria established for turbidity and chlorophyll α in Hawaiian nearshore coastal waters is more the common occurrence than the exception. Turbidity is typically elevated by land runoff and by resuspension of bottom sediments due to wind and wave action in shallow water near shore. State water quality criteria account for these typical influences by differentiating between "open coastal waters" and "ocean waters" and distinguishing between "wet" and "dry" coasts (HDOH, 2021, §11-54-06). An exception is made for waters off the Kona coast where special criteria have been developed to account for the considerable groundwater input there (HDOH, 2021, §11-54-06). The majority of Hawaiian coastal waters, including those off Maui, are subject to criteria that were developed nearly 50 years ago and in need of re-evaluation.

Water Supply Wells

AECOS is tracking monthly MG&BC turf fertilization amounts and irrigation rates (data provided by MG&BC) along with nutrient concentrations in the irrigation supply wells shown in Table 6 below. Mākena irrigation wells, located several hundred feet below land surface, are sampled during each quarterly sampling event.

Table 6. Annual geometric mean soluble nutrient concentrations and salinity values in well water for golf course and landscaping irrigation during *AECOS* sampling events.

Year	PO_4 (µgP/L)	NO_3+NO_2 (µgN/L)	NH_4 (µgN/L)	Salinity (ppt)

Nitrate+nitrite averages are high compared with both ortho-phosphate and ammonium in these well waters. Only nitrate+nitrite in the groundwater is likely to be detected as it seeps into nearshore marine waters where it mixes into the nearshore seawater. Ortho-phosphate and ammonium, would be diluted to non-detectable levels very near to shore.

Sources of Groundwater Nutrients in Mākena Coastal Waters

The mean distribution of nutrients, especially nitrate+nitrite, along all transects demonstrate decreasing concentrations with distance from shore, and as might be expected, are mirrored by increasing salinity offshore. This information tells us that groundwater seepage/intrusion is a source of nitrate+nitrite in the nearshore waters. The nutrients in groundwater at MG&BC have two possible origins: (1) a remote source: present in groundwater that originates upslope of the resort and that can be measured in well water; and (2) a local source: seepage of MG&BC excess irrigation water into the groundwater. Brackish water pumped from the wells is used to irrigate MG&BC grounds, the North Golf Course (NGC) and five holes of the South Golf Course (SGC). The

MG&BC grounds, the North Golf Course (NGC) and the five holes of the South Golf Course (SGC) encompass approximately 100 ac (40.5 ha) of MG&BC property. These areas are irrigated and fertilized on a regular basis using water from Makena Well 1, Makena Well 3 (Seibu Well 3), Makena Well 4 (Seibu Well 4), Makena Well 5 (Seibu Well 5) and Makena Well 6 (Seibu Well 6) (Fig. 2). Water supplied from Seibu Well 1 is used to irrigate landscape vegetation along Mākena Alanui Road.

The Mākena South Golf Course (SGC), closed in 2008, will be renovated as part of the Mākena Mauka Project. Though five of the SGC holes are still irrigated regularly, the renovated SGC will cover an area of about the size of North Golf Course once completed. It is assumed herein that fertilizer concentrations and irrigation amounts will be similar to NGC conditions.

Irrigation and Fertilizer Tracking

During normal MG&BC operations in the proposed Project, R-1 water from WWRF was pumped into Pond 10, where it mixes with well water, and then used to supply water for irrigation purposes. At the present time, the WWRF is not fully operational because MG&BC has been closed for redevelopment since 2016. Only a controlled-release nitrate+nitrite fertilizer is used to fertilize the North Golf Course turf and five holes of the South Golf Course at the present time; phosphorus-containing fertilizers are used several times a year in small quantities.

Water and nutrients not taken up by golf course turf and other vegetation during irrigation filter down through the soil to eventually reach local groundwater. We can assume that this excess irrigation water does not remix with water drawn from the wells for at least two reasons: 1) irrigation occurs mostly downslope of all wells with excess irrigation water moving seaward upon reaching groundwater; and 2) well water is drawn from a depth of 200 ft or more below ground, far below the groundwater surface. Any excess residual nutrient concentration, that is greater than average groundwater concentration, are expected to dilute as these waters seep towards nearshore coastal waters.

Most ortho-phosphate in irrigation water not taken up by the turf grasses is adsorbed to subsurface soil particles (Busman et al., 2002; Laws et al., 2004) and effectively lost to the groundwater nutrient pool. Nitrogen on the other hand, may change form in subsurface soils and groundwater, but is typically present as soluble nitrate+nitrite in groundwater. Groundwater movement is towards the ocean shore, so eventually this water with its soluble nutrients enters nearshore waters, resulting in nutrient enrichment or subsidy.

We track turf and landscape fertilization/irrigation data provided by MG&BC monthly. Nutrients are measured in irrigation supply wells on each quarterly sampling event, and

averaged over the year, are assumed to be representative of the nutrient concentration of the irrigation water being applied. However, most of the nutrients are taken up by turf grass and other plants (or otherwise lost). A U.S. Geologic Survey report estimates that only about 20% (as an average for nitrogen fertilizer applied on Maui golf courses) actually reaches the groundwater (USGS, 2018) and we refer to this as the "residual" or "subsidy" concentration.

Table 7 presents a comparison of estimated groundwater "residual" concentrations with nearshore (2-m stations) nitrate+nitrite concentrations. In this table, the residual is given for each monitoring year as an annual mean (n=16). The residual concentrations at each 2-m station are calculated as expected concentrations utilizing the inverse relationship that exists between salinity and nitrate+nitrite in these waters.

Table7. Estimated arithmetic means for annual nitrate+nitrite fertilizer residual amounts and calculated total daily nitrate+nitrite subsidy at 2 m stations on monitoring transects.

	Nitrate+Nitrite Residual	Station nitrate+nitrite subsidy			
Date	**Amounts**	**M-1**	**M-2**	**M-3**	**M-4**
Year	**Annual (µg/L)**	**Nitrate+Nitrite (µg/L)**			
2018	397	0	0	47	0
2019	237	27	11	40	0
2020	316	9	0	51	0
2021	687	0	0	4	0
2022	678	0	0	0	0
2023	509	11	0	0	0
Grand Mean	**471**	**8**	**2**	**24**	**0**

We obtain a rough estimate of the nitrate+nitrite residual to the nearshore waters by first calculating the salinity reciprocal (*Sw*) for the Makena well data and this becomes our salinity factor for the contribution of groundwater seeping out at the shore. The amount of nitrate+nitrite expected in the nearshore from groundwater should be a function of the proportion of groundwater present, calculated using the equation:

$$Expected\ groundwater\ contribution = \frac{Ss\ x\ C}{Sw}$$

Where:

Ss = Salinity reciprocal at 2 m stations;

C = Mean monthly nitrate+nitrite concentration for all wells;

Sw = Mean salinity reciprocal for Mākena wells.

Utilizing the inverse relationship between salinity and nitrate+nitrite in these waters, a nitrate+nitrite residual at the shore is obtained by subtracting this calculated expected contribution from the actual (measured) nitrate+nitrite concentration on 2 m station. Although transect M-4 is not in the same watershed as MG&BC, we make the assumption that the groundwater in that watershed can be represented by the Mākena wells. Negative values are sometimes generated, but as these are meaningless, they are presented as zero (no residual) in Table 7.

Of course, we have no direct knowledge of when a fertilizer application on the land might be expressed in groundwater seeping out at the shore, if at all. The residuals shown in Table 7 are certainly very rough and at best may be an indication of the magnitude of the groundwater influence. The lowest annual mean fertilizer residual estimate occurred in 2019 when nitrate+nitrite concentrations were highest at all 2 m stations except at Transect M-3 and M-4 (*AECOS*, 2019). The highest mean fertilizer residual amount occurred in 2021 and 2022 when nitrate+nitrite concentrations were lowest at all 2 m stations (Table 3). Many more samples will be required before this approach can generate statistically meaningful results.

Fates of Groundwater Nutrients in Mākena Coastal Waters

Nutrients infiltrating to coastal waters have important implications regarding biological assemblages in these waters. For example, growth of marine benthic algae in Hawaiian coastal waters is typically regulated by nutrient supply, usually dissolved forms of inorganic nitrogen (nitrate, nitrite, and/or ammonium) or phosphorus (ortho-phosphate) and referred to as dissolved inorganic nitrogen (DIN) and dissolved inorganic phosphorus (DIP). Typically, in pristine coastal waters, either DIN or DIP occurs in insufficient concentration to sustain runaway algal growth (Atkinson and Smith, 1983; Smith, 1984; Larned, 1998; HDLNR, 2020). Outbreaks of excessive amounts of algae off West Maui have been attributed to elevated concentrations of both DIN and DIP in sewage effluent injected into groundwater and migrating to nearshore waters (Laws et al., 2004; Dollar and Andrews, 1997; Dailer, 2010; MRC, 2011). No such algal outbreaks have been recorded for nearshore waters off MG&BC (MRC, 2006; *AECOS*, 2016, 2018, 2020). That excessive algal growth has not been seen in waters off Mākena may be due to several factors, including a limit on the supply of DIP or DIN in these coastal waters plus generally rapid flows of nearshore coastal waters.

Surface Water Runoff

We have listed five years of rainfall summaries from two gauges in the Makena area (Table 8): Mākena Golf Course 249.1 rainfall gauge and Ulupalakua Ranch 250.2 rainfall gauge (Giambelluca *et al*. 2025). The Mākena golf course gauge was located on Mākena

North Golf Course at a height of 107 ft above mean sea level. The Ulupalakua Ranch gauge is located east near Highway 37 at 1869 ft. above mean sea level (Figure 8).

The average amount of rainfall in the Makena area is small, less than 9 inches per year at the Mākena gauge and about twice as much at the Ulupalakua gauge. Also, the number of days of rainfall is greater at the Ulupalakua Gauge.

Table 8. Rainfall summary for Makena Golf Course 2.49 rainfall gauge and Ulupalakua Ranch 250.2 rainfall gauge between 2018 and 2023.

Year	Gauge	Rainfall Days	Annual Total (in)	Highest Value (in)	Days >1.00 in (in)
2018	Mākena	31	12.87	1.16	4

Project Water Quality Considerations

Potential effects to coastal water quality resulting from the proposed Project can be divided into two phases: (1) Project construction and development; and (2) Project operation and maintenance. Potential water quality impacts during construction and development will primarily be associated with surface runoff from storm events when soil erosion potential is highest. Potential impacts during operations/maintenance phase will also include surface runoff effects due to increased impervious surfaces (asphalt, concrete, roofs) which could accelerate runoff delivery to coastal waters.

Additionally, an increase in WWRF R-1 water volume may result in additional unused nutrients reaching groundwater and eventually adjacent coastal waters.

Figure 8. Location of Mākena Golf Course gauge 249.2 and Ulupalakua Ranch gauge 250.2

Project construction and development

Nearshore coastal waters will be most susceptible to water quality degradation from storm runoff during Project construction, especially during early grading and grubbing activities. Impacts could include soil erosion resulting in sedimentation and increased nutrient levels delivered off the shore. Increased sediment loading of coastal waters can have negative effects to fish, coral, and macro-invertebrate communities in these waters (see *AECOS*, 2016).

Best management practices (BMPs) during construction to prevent storm and sediment runoff to nearshore waters include temporary sediment retention basins, diversion berms and swales, silt fences, inlet and slope protections. These BMPs follow Maui Department of Public Works Rules for Design of Stormwater Treatment, Best Management Practices and State of Hawaii, Construction Best Management Practices Field Manual (HDOT, 2008.).

A National Pollution Discharge Elimination System (NPDES) stormwater permit will be required for Project construction to ensure that water quality is not degraded in nearshore waters off the Project site. As part of this permit a Stormwater Pollution Protection Plan (SWPPP) must be prepared and approved by the HDOH Clean Water

Branch. The SWPPP has two major requirements: (1) providing a site description that identifies sources of pollution to stormwater discharges; and (2) identifying and implementing appropriate measures to reduce pollutants (sediments, nutrients) in stormwater discharges to ensure compliance with terms and conditions of the permit.

It is not possible to predict Project construction effects on nearshore water quality, since the magnitude or timing of future major storm events cannot be determined. The Project is located in a low average rainfall area (about 9 inches per year), which minimizes the risk of major runoff occurring during the construction phase. Maintaining nearshore water quality during construction depends upon the effectiveness of the SWPPP and BMPs.

Storm Runoff

The proposed Project drainage plan (SSFM, 2024) includes grated drain inlets and/or catch basins, area drains, underground drain lines, retention basins, bioretention basins, and underground retention systems throughout the development to minimize runoff to nearshore waters. The retention devices not only minimize water flow through the Project area, but they also trap much of the water-borne sediments and associated nutrients. Project landscaping will include grass swales, bioswales, and vegetated buffers to further reduce runoff.

A sustainability report has been prepared for the Project recommending the use of Low Impact Design (LID) measures, to further reduce storm runoff to nearshore waters (Cording, 2025). The report addresses the potential impacts of Marine Water Quality Degradation and recommends a mitigation plan inclusive of stormwater management planning, groundwater protection and suggestions to recharge the nearby groundwater resource.

Surface flows from offsite *mauka* will be addressed by Future Keyline design features and LID improvements to the Project removing nutrients and sediments and reducing velocity and total runoff volume.

While predicted reductions in peak runoff to nearshore waters are based solely on modeling results and theoretical estimates of LID efficiencies, drainage control measures indicate that there will be a significant reduction in runoff, nutrients, and sediments from the Project parcels compared with existing conditions. Runoff originating *mauka* of the Project will be reduced during a 1-year storm, while 50-year and 100-year storm runoff will mostly pass through the Project and discharge to nearshore waters.

Fertilization/Irrigation

Influx of nutrients to nearshore waters resulting from Project irrigation/fertilization and the added resort R-1 water production, are potential concerns regarding both marine water quality and biology. Potential increased nutrient supply to nearshore waters can promote benthic algal growth as evidenced in coastal waters off west Maui.

Project operation is anticipated to generate approximately 310,000 gpd of secondary R1 water (SSFM, 2025). To the extent that R-1 water is used in irrigation of the golf course and landscape of the resort grounds, there is at least the potential for an increase in nutrients infiltrating via groundwater to adjacent nearshore waters.

Irrigation/Fertilization Calculations

Pond 10 is the 5-million-gallon irrigation system for MG&BC. During normal Mākena operation, Pond 10 will contain 4,470,000 gallons of groundwater (nitrate+nitrite concentration = 1,700 µg/L) and 310,000 gallons of Mākena WWRF R-1 water (SSFM, 2025) with nitrate+nitrite concentration of 6,290 µg/L (Water Tectonics, 2024). Both groundwater and R-1 water resources are renewed daily. The combined groundwater (1,700 µg/L nitrate+nitrite) and mixed diluted R-1 water (365 µg/L nitrate+nitrite---after dilution to Pond 10 volume) for a total 1.979 µg/L nitrate+nitrite concentration and plus daily landbased nitrate+nitrite fertilizer of 446 µg/L, a 20 percent fertilizer residual estimate (USGS, 2018), for a grand total of 2,425 µg/L of nitrate+nitrite residual discharged to groundwater.

The USGS estimates that about 20 percent of golf course fertilizer is unused and remains in groundwater (USGS, 2018). Thus, an estimated total of 2,425 µg/L of nitrate +nitrite, needs to dissolve to a groundwater concentration of 1,700µg nitrate+nitrite, a change of 725µg/L, by the time it reaches Mākena coastal waters — a distance based on the difference between fertilization area and nearshore coastal waters

Introduction

AREG AC Mākena Propco LLC proposes the development of Mākena Mauka, a low-density master planned residential community within the Mākena area of East Maui (area often referred to as Mākena Resort). Mākena Mauka referred to herein as the "Project" will offer market rate housing together with residential workforce housing with a mixture of rural and single-family lots and multi-family residential units all located mauka of Mākena Alanui Road (Figure 1).

Due to the size of the Project and the potential impacts from the use of county lands associated with proposed roadway improvements, use of Shoreline Setback Area lands, and an anticipated Community Plan Amendment (CPA) request, an Environmental Impact Statement (EIS) is being prepared. In June 2024, an EIS Preparation Notice (EISPN) was published, with an anticipated EIS to be released in the summer of 2025 (Munekigo Hiraga, 2024). *AECOS* was contracted to conduct marine surveys of the waters adjacent to the Project location to support the EIS and completed field surveys in 2016 and 2019 (*AECOS*, 2016 and 2020). In March 2025, we conducted surveys to complement our previous surveys and provide updated information on marine environments in the area. This report details our 2025 findings.

Project description

Mākena Mauka is proposed as a low-density master-planned residential community that will offer market rate housing together with residential workforce housing, with a mixture of rural and single-family lots and multi-family residential units, within an area that has largely been planned for such uses for decades. The project will incorporate the existing 18-hole Mākena North Golf Course and the 18-hole Mākena South Golf Course (to be renovated as part of the land plan), together with a community gathering place, hiking trails, programs to support connectivity, walking, bicycling, and golf cart paths, beach parking for the public, areas reserved for conservation/open space, and areas reserved for public beach access. The Applicant's current vision for the Mākena Mauka land plan includes 652 housing units, including 109 onsite residential workforce housing units, and approximately 135,000 sf of operational support buildings, which include golf maintenance, staff offices, restaurants, back of house, golf operations and other uses; within the approximately 1,041.47-acre total project area which includes approximately 473 acres of parcels proposed for residential development.
(Munekigo Hiraga, 2024).

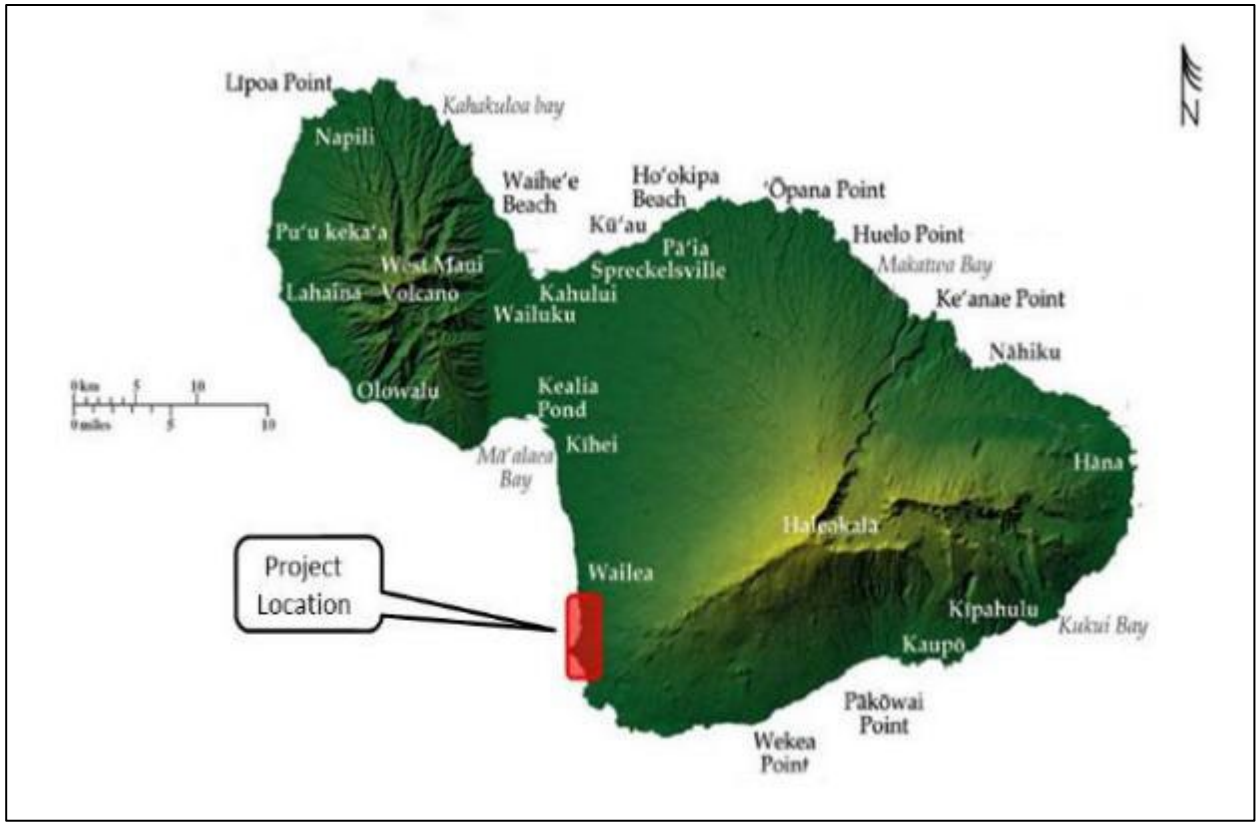

Figure 1. Project location in Mākena, East Maui.

Background Information

NOAA-NOS benthic habitat maps (Battista et al., 2007) provide physiography (i.e., reef flat, channel, reef crest, fore reef, and bank/shelf) and biological cover (i.e., % coral, % macroalgae, % turf, % coralline algae, and uncolonized bottom) of thenearshore environments. The NOAA-NOS habitat off the Project area includes the following categories of bottom types: uncolonized sand, hard bottom with coral cover between 10 - 50%, coral between 50 – 90%, hard bottom with turf between 10 - 50%, turf between 50 – 90%, and hard bottom with macroalgae between 10 - 50%, and macroalgae between 50 - 90%.

The shore and intertidal areas off Mākena consist predominantly of a series of basalt outcrops separating wide crescent-shaped sand beaches. The beaches are composed of fine white calcium carbonate sand extending seaward into the subtidal zone. In some areas, a sand formation continues seaward as gentle sloping sand bottom. The most prominent geological feature in this area is the cinder cone, Pu'u Ola'i, that separates Oneloa (Big Beach) and to the south and Oneuli Beach to the north. Mākena Bay is somewhat atypical of the coastal region,

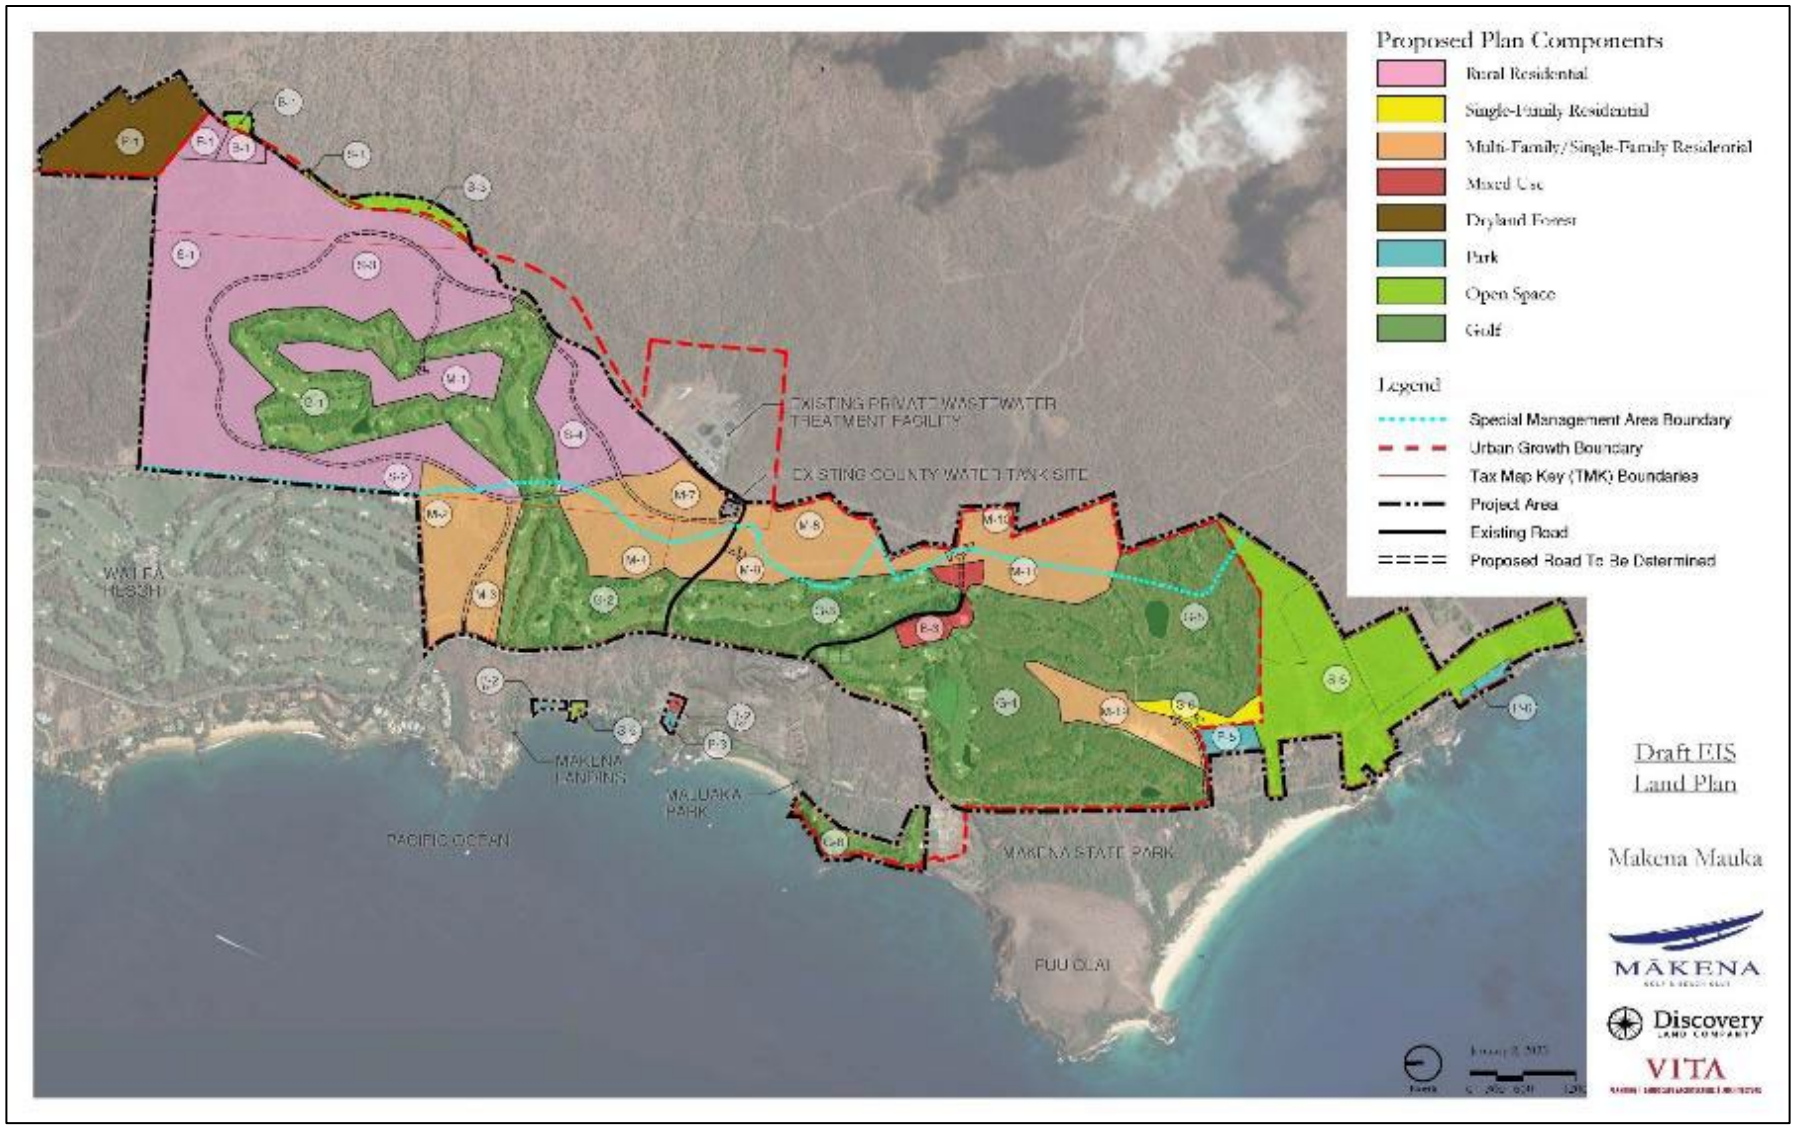

Figure 2. Mākena Mauka Conceptual Land Use Plan (Munekigo Hiraga, 2024).

as the area is more sheltered from wave effects than the open coastal areas, and bottom composition contains more terrigenous sediment than seen in other locations off this coast (MRC, 2006). Seaward of the intertidal zone, bottom composition varies between sand channels and limestone reef platform. The submerged portions of the basalt headlands consist of jagged, steep-sided rock fingers that terminate in sand bottom. There are numerous depressions and undercut ledges associated with these fingers at the shore.

Biological assessment surveys in the Project area were conducted in 2005, focused offshore of the Mākena Resort (MRC, 2006). In 2016, *AECOS* conducted marine biological surveys at 12 stations offshore Mākena (*AECOS*, 2016). Our 2016 survey found the dominant marine bottom types in the area to be sand and limestone pavement. Overall, coral cover averaged 7% of bottom cover across our survey area. Macroinvertebrate, turf algae, CCA, and rubble made up small portions of the bottom composition, all less than 3% of each station (*AECOS*, 2016). This latter finding was consistent with the earlier 2005 surveys (MRC, 2006). Our 2019 survey found that, overall, the offshore coral reef has relatively low coral cover (mean of 7.25%) with a size class distribution in which the preponderance of coral heads are in the smallest size class (<10 cm). Such a distribution suggests either a recent, severe disturbance or frequent recurrences of moderate disturbances, following which recruitment and growth have been relatively recent processes. Other factors include the environmental regimes to which coral is exposed (e.g., shifting sand bottom).

Methods

AECOS biologists conducted surveys to inventory marine bottom assemblages in the nearshore off the Project area on March 21, 22, and 23, 2025. Using both SCUBA and snorkel equipment, we conducted orthomosaic mapping and collected data on benthic composition, coral abundance and size-class distribution, coral species composition, fish abundance, and presence of Endangered Species Act (ESA)-listed species. Orthomosaic maps are geometrically corrected aerial images that provide a two-dimensional view of an area, These orthomosaics can be used for detailed physical referencing to monitor changes in coral health and growth over time (See Appendix C for representative orthomosaics of the Project area). Survey methods for each location are described following. Depths in the survey area ranged from 7 m (24 ft) to 14 m (45 ft). On March 21, our biological survey began at 8:00 AM, four hours and 33 minutes before a predicted 0.04 low tide relative to mean lower low water (MLLW); on March 22, our survey began at 8:00 AM, five hours and fifty-seven minutes before a predicted 0.11 low tide relative to MLLW, and on March

23, our survey began at 8:00 AM, 90 minutes after a predicted 0.42 low tide relative to MLLW (Makena, Station ID: 1615202; NOAA-NOS, 2025). An inventory was made for corals, "invasive" species, seagrass, marine protected species (HDLNR, 2009, 2014, 2015; USFWS, 2019), and non-coral macro-invertebrates. Underwater visibility during the March 2025 survey varied between stations from about 6 m (20 ft) to 18 m (60 ft).

Transect placement

Consistent with our 2016 and 2019 surveys, we utilized NOAA-NOS benthic habitat maps (Battista et al., 2007) to identify the dominant composition of the bottom in the Project area: 1) unconsolidated sediment (sand), and 2) coral reef/hard bottom (rock and boulders). For our 2025 survey efforts, we separated the NOAA-NOS benthic habitats to differentiate between coral reef hard bottom areas and other hard bottom areas. Our survey stations names indicate this distinction: coral hard bottom stations named "CHB"; hard bottom stations named "HB" and unconsolidated stations named "UNC". Survey stations for each of these habitat types were selected using a stratified random approach. A random number generator was used to identify x- and y-coordinates on a grid generated by Adobe© Photoshop© placed over this map of geomorphological structure types.

Transects were laid parallel to depth contours. The results of all transects are analyzed individually and collectively as a group. Consistent with our previous surveys, in general, our transect results revealed that the maps of bottom type were not always accurate (e.g., "hardbottom" areas in fact include some "unconsolidated/sand" areas and "unconsolidated sediment" areas in fact contain "hardbottom"). As a result, we grouped all transects together for analysis rather than group by habitat type. Due to strong currents causing hazardous diving conditions, one station in the unconsolidated habitat type was removed from our survey effort. A total of 15 stations (Figure 3) was assessed based on the following protocol.

The Rapid Ecological Assessment (REA) methods used by NOAA Pacific Islands Fisheries Science Center (PIFSC) are comprehensive, fine-scale, site-specific surveys. NOAA PIFSC monitors coral reef health at about 40 islands and atolls, using standardized survey methods to assess corals, algae, other invertebrates, and fishes in marine benthic habitats. These methods are used consistently across the Pacific Islands region to enable comparative ecosystem analyses across diverse biogeographic, environmental, oceanographic, and socioeconomic gradients. For this reason, our survey methodology was based on the REA. At each of our survey stations, two 25-m lines were set down in single file, separated

by a 5-m segment between the adjacent ends[1]. The lines were then used to quantify bottom complexity, benthic composition, coral abundance, coral size class, and fish assemblage composition as described below.

Figure 3. Location of 15 transect survey stations offshore of the Mākena area.

[1] It is unclear to us why the REA uses two 25-m lines in the manner described. This layout is essentially one 50-m transect station because the two 25-m transects are linked and not independent of each other as required for statistical analyses of the resulting data. Transect data are analyzed by station herein.

Benthic composition

The point intercept method (also termed a "line-point intercept" method) was used to assess benthic composition at each survey station. This protocol uses marks on the transect line as sample points. At 0.5-m intervals, the nature of the bottom was identified and assigned to one of the following categories: sand, limestone rubble, limestone boulder, limestone, live coral, turf algae, macroalgae, or macroinvertebrate. Benthic composition using the point-intercept method was recorded for each of the two 25-m lines, which generated 102 points per transect). Benthic percent cover was calculated by dividing the total number of points for a category by the total number of points sampled (times 100).

Coral abundance and size-class distribution

Biologists gathered coral abundance and size-class data from five evenly spaced segments (each a 2.5 x 1 m quadrat) along each 25-m line. Within each 2.5 m^2 quadrat, any live coral whose center is included, was identified and assigned to a size class: 1- to 5-cm; 6- to 10-cm; 11- to 20-cm; 21- to 40-cm; 41- to 80-cm; 81- to 160-cm; or >160-cm. Bleaching and any signs of disease were also recorded. Coral abundance was determined as the number of individual heads observed for each transect, divided by the total area surveyed per transect, resulting in the number of individual corals per m^2. Coral abundance and size class was surveyed at each station (two 25-m lines with 12.5 m^2 coral survey area each), producing a total survey area of 375 m^2.

Orthomosaic

Five weighted triangles were placed roughly 12 to 13 m apart along a 50-m transect at each station. The triangles provided the diver a general direction and guidance along the correct course (the next triangle was visible from the previous one), as well as mark the start and finish of the transect. Using two GoPro cameras mounted 0.6 m apart on an assembled PVC rig, photographs were taken every 0.5 seconds in time lapse mode while swimming slowly along the surface from the last triangle to the first. The cameras were angled directly downward and outfitted with a red filter for underwater color enhancement. Approximately 450 images were collected per camera at each transect and processed using Agisoft® software. Triangles were a fixed length (0.44 m along the hypotenuse) and used to preserve scale along the length of each orthomosaic.

Fishes

At each survey station, pairs of divers recorded the number and species of all fishes observed within visually estimated vertical cylinders 15 m (50 ft) in diameter. At the start of a survey dive, one diver moved to the 7.5-mark and one diver moved to the 22.5-m mark on the 25-m line; these marks serve as the centers of Stationary Point Count (SPC) cylinders. During a 5-minute timed period, the diver recorded the fish species observed within or passing through their visual "cylinder" (i.e., within 7.5 m or 25 ft of the observer).

Fish abundance was calculated by normalizing fish counts from each station to 100 m^2 (1076 ft^2). Species richness (S) was determined as the number of species observed for each transect. Species diversity was calculated using the Shannon-Weiner diversity index (H') where p_i is the proportion of all individuals counted that were of species i using the equation:

$$H' = -\sum_{i=1}^{S} p_i \ln p_i$$

Results

Benthic composition

The results of the point-intercept surveys are presented in Figures 4 and 5. The dominant bottom type across the transects is sand (with a total of 59.7%; Fig. 6). Turf algae and coral make up the common bottom types across the survey areas, at 17% and 10%, respectively. Invertebrates (other than coral) make up a small portion of benthic composition across the 15 survey stations, under 1% of the total. In general, these results are consistent with findings from our 2019 surveys (*AECOS*, 2020).

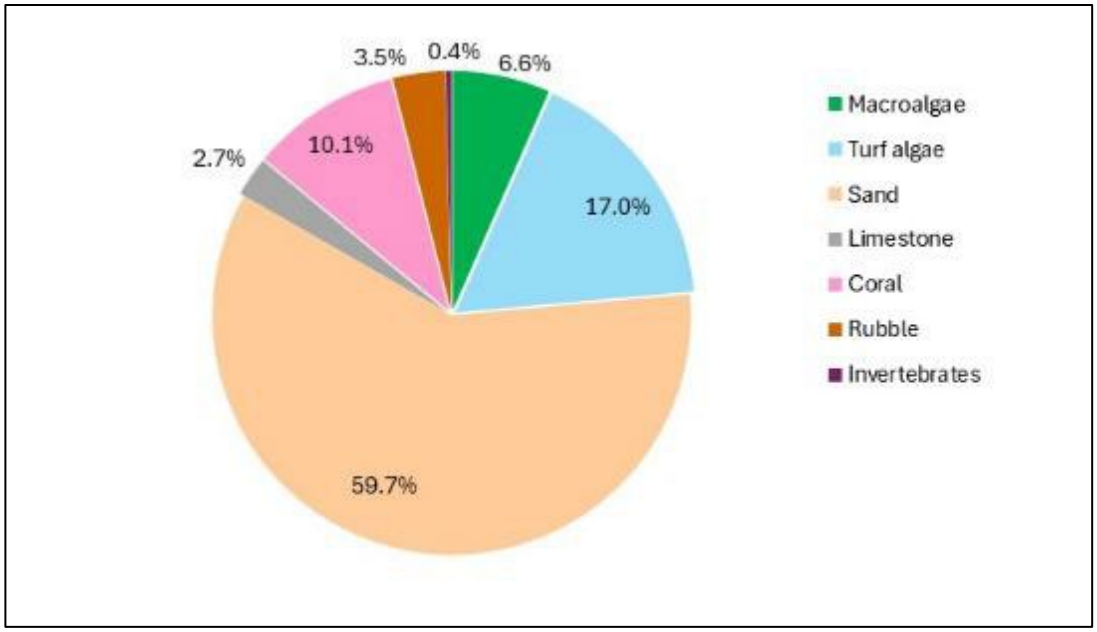

Figure 4. Mean percent benthic cover across survey area, as measured using point-intercept method at 15 survey stations.

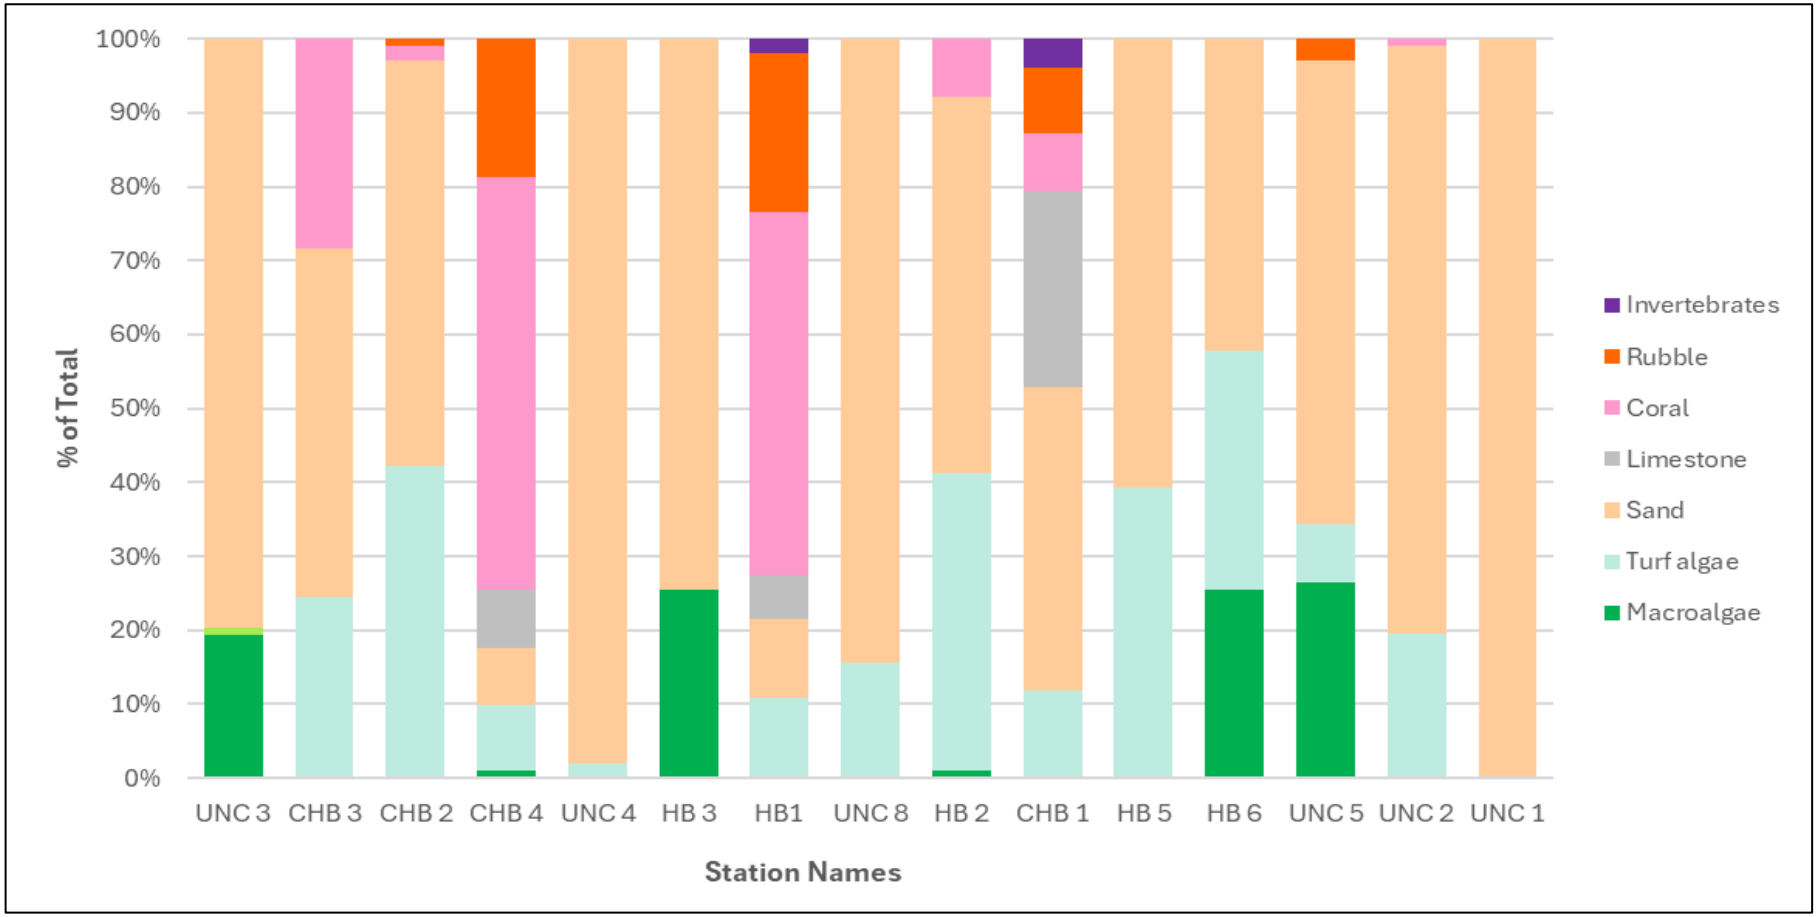

Figure 5. Percent benthic cover as measured using point-intercept at 15 survey stations. "UNC" = unconsolidated; "CHB"=coral hard bottom; and "HB"=hard bottom

Coral abundance and size class distribution

Coral abundance determined at each survey station is presented in Table 1. The total number of coral colonies was 1322. Coral abundance ranges from 0 colonies/m^2 to 18.16 colonies/m^2 and mean coral abundance was 6.52 colonies/m^2.

Table 1. Total number of coral colonies and coral colony abundance (mean colonies per m^2) counted at 15 survey stations.

Coral size-class distribution — Results of the coral size-class survey are presented in Table 2 and Figure 6. A total of 1322 coral colonies representing at least ten coral taxa (*Montipora capitata*, *M. patula*, *Pocillopora* sp. *Poc. meandrina*, *Poc. damicornis*, *Porites lobata, P. evermanni, P. brighami P. compressa*, and *Leptastrea* sp.) were recorded across the survey stations. By far, the most common coral was *Porites* spp., with 1131 colonies (80% of the total). Corals in all size classes were observed. The most common colony size was the 1- to 5-cm class (58% of the total). Very large (>161 cm) colonies of two taxa (*P. compressa* and *Porites* spp.) were observed at three survey stations (Stations CH2, CH3, and CH4). These results from this coral size class survey are consistent with our findings from previous surveys in the area (*AECOS*, 2016).

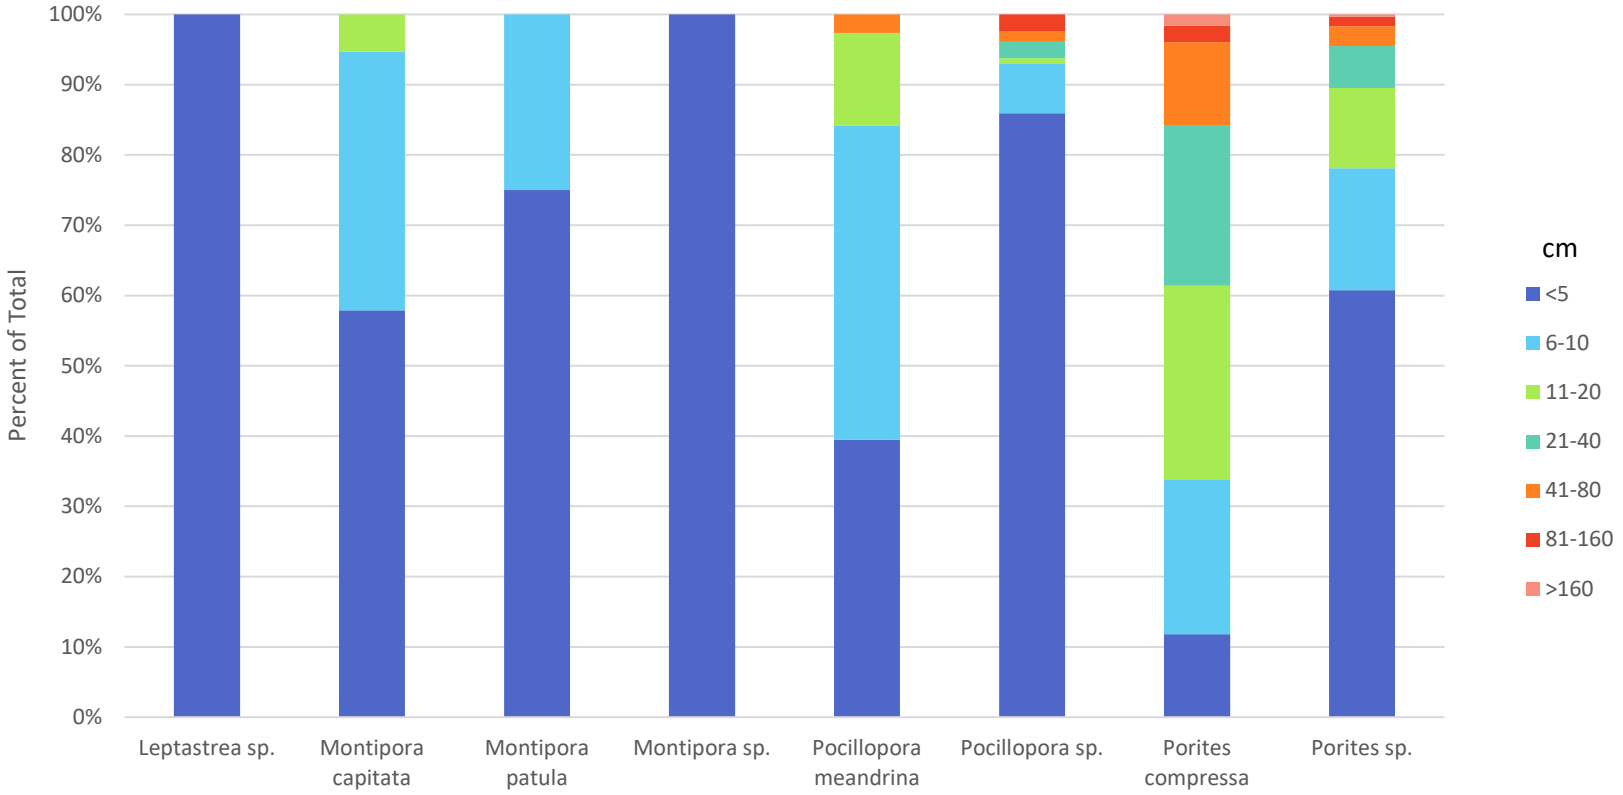

Figure 6. Percentage of coral colonies in size classes (cm) for all 15 survey stations.

Fish species abundance, richness, species diversity

Fish abundance — The total number of fishes counted was 1092. Table 3 presents the number of fishes counted for each station. Fish counts ranged from 2 individuals per station to 158 individuals per station and were generally low at unconsolidated bottom stations (Stas. UNC1, UNC2, UNC3, UNC4, UNC5 and UNC8) and higher at coral hard bottom and hard bottom stations with some topographical relief. Mean number of fishes counted across the survey area was 73 individuals per station.

Fish abundance normalized to 100 m^2 is presented in Table 4. Mean fish abundance across the survey area was 10.3 fishes per 100 m^2. The maximum abundance was 22.3 fishes per 100 m^2, at Station CHB4. The lowest fish abundance was at Stations UNC2 and UNC3, both with 0.3 fishes per 100 m^2.

Fish species richness and diversity — A total of 43 fish species was observed across 15 stations. Well-represented genera across the survey area include wrasses (Labridae) surgeonfishes (Acanthuridae), damselfishes (Pomacentridae) and butterflyfishes (Chaetodontidae). Fish species richness and diversity for each survey station are presented in Table 5. Species richness varied between 1 and 15 species per station, with the highest species richness observed at hard bottom stations. Overall mean species richness across the entire survey area was 9.71 fish species. Fish diversity across the stations ranged from 0 to 2.33, with the greatest diversity occurring at Station CHB1 (Table 5).

Relative abundance of marine biota

Photos from across the survey area are provided in Appendix A. A listing with relative abundance values of algal, coral, macroinvertebrate, and fish taxa present in the Project area in our 2016, 2019 and 2025 surveys is provided as Appendix B.

Algae — A total of 12 algal taxa were identified across the survey area. Macroalgae were uncommon throughout the 15 stations. Species observed include *Neomeris* sp., *Dictyota* sp., *Padina sanctae-crucis*, *Halimeda opuntia*, and

various coralline algae (*Hydrolithion* spp. and *Sporolithon erythraeum*). Meadows of *Halimeda kanaloana* were observed on the sand bottom areas.

Coral — A total of 10 coral taxa (*Montipora capitata*, *M. patula*, *Pocillopora* sp. *Poc. meandrina*, *Poc. damicornis*, *Porites* spp. (massive), *P. compressa*, and *Leptastrea* sp.) were recorded across the survey stations (Table 6). Six of these were recorded at Stas. CHB1 and HB1. Live coral was recorded at each Station. The most common coral is *Porites* spp. (76% of the total), followed far behind by Pocilloporids and *P. compressa* (around 9% each).

Macroinvertebrates — A total of 30 macroinvertebrate taxa (not including hard corals) was identified across the survey stations. Comparable to our previous surveys in the area, sea urchins (*Echinometra mathaei, E. oblonga*, *Colobocentrotus atratus*, *Heterocentrotus mammillatus*, *Diadema paucispinum*, *Echinothrix calamaris Pseudoboletia indiana*, and *Tripneustes gratilla*) are the most common macroinvertebrates observed. Other invertebrates, including vagabond boring sponges (*Spirastrella vagabunda*), sea cushion (*Culcita novaeguineae*), sea star (*Linckia guildingi*), trembling nudibranch (*Goniobranchus vibrata*), gold lace nudibranch (*Halgerda terramtuentis*), and teated sea cucumber (*Holothuria whitmaei*) occur occasionally.

Fishes — A total of 43 fish taxa was recorded across the survey stations, with 15 of these observed at CHB1 and HB1. As expected, in locations with topographical complexity, fishes were present. Mixed schools of Acanthurids, including brown tang (*Acanthurus nigrofuscus*), yellow tang (*Zebrasoma flavescens*), and goldring surgeonfish (*Ctenochaetus strigosus*) were prevalent. Small planktivorous damselfish, including *Chromis vanderbiliti, C. agilis, C. hanui, C. ovalis, Chromis* sp. were abundant, as also noted by the 2005 (MRC, 2006), 2016, and 2019 surveys (*AECOS*, 2016; 2020).

Discussion

Comparison of previous findings

Results from this 2025 survey show a similar species assemblage, coral community, and size class distribution as in our 2016 and 2019 surveys (*AECOS*, 2016; 2020) and the MRC survey in 2005 (MRC, 2005). In each of our survey efforts, the most common coral was *Porites* spp. Corals in all size classes were observed, and the most common colony size was the 1- to 5-cm class. At each survey event, large (>80 cm) colonies of two taxa (*P. compressa* and *Porites* spp.) were observed. Additionally, coral cover is comparable between our three survey efforts (both 2016 and 2019 had a mean of 7.2%; our 2025 result is 6.5%).

Presence of coral bleaching was not observed in our 2016 survey but was noted in the 2019 survey due to a widespread coral bleaching event[2]. In 2019, coral bleaching was observed by our survey team with varying expression across taxa. All *Poc. meandrina* colonies displayed either partial or full bleaching; some colonies appeared pale in color while others were stark white, indicating that all symbiotic algae had been expelled. Other colonies showed signs of fluorescing bright yellow or purple. Fluorescent pigments might serve as protection for coral tissues in environments with intense light, functioning as a sort of "sunscreen" to regulate the light environment of the coral and help reduce bleaching stress (Salih et al., 2000). *Montipora* and *Porites* colonies appeared to be among the least affected, although we did observe several *Porites* colonies pale in color and partially bleached. These findings were similar to coral bleaching surveys recorded by NOAA Fisheries.[3] In our 2025 survey, bleaching was not notable.

Fish abundance was similar between the 2016 and 2019 survey efforts, with 16.7 fishes/100 m^2 at our 2016 survey, and 17.1 fishes/100 m^2 during the 2019 survey. In our 2025 survey, fish abundance across the survey area was 10.3 fishes per 100 m^2. Fish species richness and diversity measured in 2016 were lower (11.6 and 1.5), than that of 2019 survey (17.1 and 1.99, respectively). In 2025, mean species richness across the entire survey area was 9.71 fish species and diversity was 1.49.

Protected and Listed Species

One federally protected marine species was observed in our survey: green sea turtle (*Chelonia mydas*). Other state- and federally-listed (endangered or

[2] https://hawaiicoral.org/

[3] https://www.fisheries.noaa.gov/science-blog/coral-bleaching-2019-survey-update-leeward-maui

threatened; HDLNR, 2015; USFWS, nd) marine species—hawksbill sea turtle (*Eretmochelys imbricata*) and monk seal (*Neomonachus schauinslandi*)—may occur in the general vicinity of the Project considering the distribution of these species throughout the Islands but were not observed by us.

Invertebrates — Coral species are protected by Hawai'i State regulations that prohibit damage to "any stony coral by any intentional or negligent activity causing the introduction of sediment, biological contaminants, or pollution into state waters" (HDLNR, 2014). On August 27, 2014, NOAA issued a final rule for listing 20 coral species as threatened under ESA (NOAA-NMFS, 2014), but none of these listed coral species occurs in Hawai'i.

Hawai'i Department of Land and Natural Resources (HDLNR) regulates taking of shellfishes such as pearl oysters (HDLNR, 1987) and '*opihi* (HDLNR, 1989). One '*opihi* species (*Cellana exarata*) and black-lipped pearl oyster (*Pinctada galtsoffi*) were observed in our survey. Rules are in place for regulating the take of certain fishes (Table 8; HDLNR, 2019). Fishing activity is not a part of the Project, but it is anticipated that the proposed coastal development will increase the number of ocean users, including fishermen. Table 8 lists the regulated fish species for Maui. For the species listed in Table 7, there are minimum sizes and seasonal regulations, outlined by the state of Hawai'i Division of Aquatic Resources (HDLNR, 2019).

Table 7. Regulated fish species on Maui (HDLNR, 2019).

Common name	*Species*

Sea turtles — The distinct population segment (DPS) of green sea turtle (*Chelonia mydas*) that occurs in Hawaiʻi is federally-listed as a threatened species (USFWS and NOAA-NMFS, 2015a, b; USFWS, 2019). It is also listed as threatened under state regulations (HDLNR, 2014).

Threats to the green sea turtle in Hawai‘i include: disease and parasites, accidental fishing take, boat collisions, entanglement in marine debris, loss of foraging habitat to development, and ingestion of marine debris (NMFS-USFWS, 1998). Destruction and alteration of green turtle nesting and foraging habitats is occurring throughout the species' global range, especially by coastal development, beach armoring, beachfront lighting, vehicular/pedestrian traffic, invasive species, and pollution from discharges and runoff. Coastal development increases artificial lighting, which may disorient emerging hatchlings, causing them to crawl inland towards lights instead of seaward. Coastal development improves beach access for humans, resulting in more vehicular and foot traffic on beaches, causing compaction of nests and reducing emergence success. Adult green turtles forage in shallow nearshore areas and coral reefs. Contamination from effluent discharges and runoff has degraded these habitats, and invasive species may reduce native algal species preferred by green turtles or could exacerbate susceptibility to, or development of disease (NMFS & USFWS, 2007a; Guimaraes dos Santos et al., 2010). Fibropapillomatosis, a disease characterized by the presence of internal and/or external tumors that may grow large enough to hamper swimming, vision, feeding, and potential escape from predators continues to be a major threat to green sea turtles. Extremely high incidence has been reported in Hawai‘i, where affliction rates peaked at 47-69% in some foraging areas (Murakawa et al., 2000).

The green sea turtle diet consists primarily of benthic macroalgae, which the shallow reefs of the main Hawaiian Islands provide in abundance. Red macroalgae generally make up 78% of their diet, whereas green macroalgae make up 12% (Arthur and Balazs, 2008). The single most consumed algal species is *Acanthophora spicifera*, which is an introduced species first recorded in Hawai‘i in 1950 (Huisman et al., 2007). Little algal cover was observed across the survey stations and no *A. spicifera*. Despite the lack of preferred foraging resources, four green sea turtles were observed during our underwater surveys in 2019 and 2025. Additionally, green sea turtle basking sites at Mākena Landing and Mokuha have been recorded (NOAA-PIFSC, 2010).

Hawksbill sea turtle (*Eretmochelys imbricata*) is much less common than green sea turtle in Hawaiian waters. Hawksbill turtle is distributed across the Pacific, Indian, and Atlantic oceans. The global population has declined by more than 80% over the last 30 years and all hawksbill turtle populations were listed as endangered under the ESA in 1978. Hawksbill turtle faces many of the same threats affecting green sea turtle. In addition, there remains a commercial market for hawksbill shell products, despite protections afforded this species under U.S. law and international conventions (NMFS and USFWS, 2007b).

As with green turtle, hawksbill forage grounds and natal nesting areas are frequently located in different island groups, and residents of a given island group may originate from multiple natal nesting areas (NMFS & USFWS, 2007b). However, tagging studies suggest that hawksbill nesting in Hawai‘i remains within the MHI (main Hawaiian Islands). Genetic samples collected and analyzed suggest that Hawai‘i’s hawksbill sea turtle may be genetically and geographically distinct from other populations in the Pacific (Dutton and Leroux, 2008). Parker et al. (2009) report that the tracks of nine post-nesting tagged females have all remained within the MHI, further supporting the possibility that Hawai‘i’s hawksbill sea turtle may be a discrete central Pacific population.

Nearly all hawksbill nesting and foraging in Hawai‘i occurs in the MHI. Females nest in a variety of habitats including black and white sand beach, small pocket coves covered in cobbles or rugged lava, and in beach vegetation. Since monitoring began in 1989, hawksbill nesting activity has been confirmed at 22 sites in the MHI: 13 on the Island of Hawai‘i, 8 on Maui, and 1 on Moloka‘i. Nesting may occur on the windward coast of O‘ahu. Over 90% of the documented hawksbill nesting activity in Hawai‘i occurs along the Ka‘ū Coast of the Island of Hawai‘i. Regular nesting also occurs on Maui and Moloka‘i. According to satellite tracking, the Hamakua Coast of the Island of Hawai‘i appears to be an important foraging area for hawksbill sea turtle.

Hawksbill nesting activities were first documented on Maui in 1991 at Kealia. Hawksbill turtle nesting has been documented at Little Beach and Oneloa (King, 2015). The most likely impact to hawksbill turtles may come in the form of increased useage of Maluaka Beach and the nearshore environment. This area may be used by post-recruitment juvenile and adult hawksbill turtles sheltering and foraging in and near the beach Data are insufficient to estimate hawksbill density in Hawaiian waters off the Project area.

As with green turtle, destruction and alteration of habitat, as well as direct harvest are considered the major threats to the hawksbill. Climate change also appears to be a growing threat. Destruction and alteration of hawksbill nesting and foraging habitats is occurring throughout the species’ global range, especially through coastal development, beach armoring, beachfront lighting, vehicular/pedestrian traffic, invasive species, and pollution from discharges and runoff. The adverse impacts of these threats described for green sea turtle are the same for hawksbill sea turtle (NMFS & USFWS, 2007b). The Project does not involve any alteration of the shoreline, beach armoring, beachfront lighting, etc., thereby minimizing Project-related impacts to sea turtles.

Monk Seal — The endangered Hawaiian monk seal (*Monachus schauinslandi*) is known to occur in the waters off Makena. The majority of Hawaiian monk seal

sighting information collected in the main Hawaiian Islands is reported by the general public and, therefore, highly biased by location and reporting effort. The only truly systematic monk seal count data available for the main Hawaiian Islands are from aerial surveys conducted by the Pacific Islands Fisheries Science Center (PIFSC) in 2000, 2001, and 2008 (Baker and Johanos 2004, PIFSC unpublished data). No Hawaiian monk seals were sighted in the Mākena area during these three complete surveys of Maui.

Reports by the general public, which are non-systematic and not representative of overall seal use of main Hawaiian Island shorelines, have been collected in the main Hawaiian Islands since the early 1980s. For the purposes of the report from PIFSC[4], a sighting is defined as a calendar day during which an individual seal is documented as present at a specific location. The PIFSC report summarized all documented sightings of Hawaiian monk seals in the Makena area, from Palauea Beach to `Ahihi Cove, on the island of Maui for the years 2015 through 2024 (Johanos, 2025*a*-*c*). There have been 206 reported sightings of monk seals from Palauea Beach to ʻAhihi Cove from 2015 to 2024 (Table 8). Sighting locations were recorded based on reported location and were generated from a list of standardized location names and include ʻAhihi Cove, Big Beach, Bubble Cave, Five Graves, Little Beach, Mākena Cove, Mākena Landing, Maluaka Beach Park, Oneʻuli Beach, Palauea Beach, Poʻolenalena Beach, and Puʻu Olai. Of the total sightings, 76 reports can be attributed to 14 uniquely identifiable seals (Table 9). No monk seal births have been documented in the area from Palauea Beach to ʻAhihi Cove.

Critical habitat for Hawaiian monk seals has been designated (NOAA-NMFS, 2015). Hawaiian monk seal critical habitat includes the seafloor and marine habitat to 10 m above the seafloor from the 200 m depth contour through the shoreline and extending into terrestrial habitat 5 m inland from the shoreline between specified boundary points. The waters offshore of the Project area are designated monk seal marine critical habitat. The shore in the Project area falls within boundary points MA101 to MA102 (South of Kīhei Boat Ramp through ʻAhihi Bay; 20°42′27″ N to 20°37′39″ N) and is therefore included in monk seal terrestrial critical habitat (NOAA-NMFS, 2015).

Impact Assessment

Indirect Impacts

Indirect impacts to the biological assemblage of the reef off Makena are expected in the short-term during construction, as well as long-term due to development and increased coastal use. The proposed development would increase both the amount of impervious surfaces and land-based vehicle and machinery activities near and along portions of the coast. This could result in an increase in storm water run-off and pollutants entering the ocean. Sedimentation, as a result of both natural processes and human activities, can significantly impact coral population structures and be one of the main drivers of reef degradation (Rogers,

1990). Increased sediment loading of coastal waters can increase water turbidity and lead to lower light available for photosynthesis (Rogers, 1990; Philipp and Fabricius, 2003), increase nutrients (Fabricius, 2005), reduce feeding surfaces responsible for catching prey (Telesnicki and Goldberg, 1995), and in extreme cases, bury entire coral colonies (Jokiel et al., 1993). Coral reproduction and recruitment can also be affected by terrestrial runoff (Fabricius, 2005). Nutrient enrichment has been shown to affect fecundity, oocyte size, fertilization rate, and embryo development in acroporid corals (Ward and Harrison, 2000; Harrison and Ward, 2001; Cox and Ward, 2002) and sedimentation has been shown to affect processes such as larval settlement, recruit survival, and juvenile growth (Rogers, 1990; Te, 1992; Gilmour, 1999; Fabricius, 2005).

Table 9. Number of sightings of uniquely-identified Hawaiian monk seals reported off Mākena, between Palauea Beach and ʻAhihi Cove (2015 to 2024).

Seal ID	Sex	Sightings	Survival Status
R00K	Female	2	Alive 2024
R308	Female	5	Alive 2024

RS06	Male	3	Alive 2024
RV16	Female	6	Last sighted 2018
RW12	Male	4	Alive 2024
Total		**76**	

Overall, the offshore coral reef has relatively low coral cover, with a size class distribution in which the preponderance of coral heads is in small size classes (<10 cm). Such a distribution suggests either a recent, severe disturbance or frequent recurrences of moderate disturbances. After such disturbances recruitment and growth have been relatively recent processes. Other factors include shifting sand beds and sand scour due to wave action.

The potential exists for Project-related activities to impact the offshore reef community. Proper construction best management practices (BMPs) must be implemented, and a water quality monitoring plan should be developed to ensure Project activities do not degrade marine water quality off the development. We also suggest biological monitoring programs be developed to track densities and distribution of macroalgae, macroinvertebrates, and changes in the health of corals.

Listed and Protected Species

Adult green turtles forage in shallow nearshore areas and coral reefs off Makena. A total of 29 green sea turtles were observed in our 2019 survey of the Project area: 4 during our underwater survey and 25 during our shore survey. During our 2025 survey, 2 green turtles were observed during out underwater surveys. Additionally, during our 2019 survey event, one macroalgal species (*Ulva* sp.) consumed by green turtles was observed on the shoreline and offshore Makena. Contamination from effluent discharges and runoff from the Project area has the potential to degrade these habitats, and invasive species may reduce native algae species preferred by green turtles or could exacerbate susceptibility to, or development of disease.

Future Biological Monitoring

As previously recommended, biological monitoring should be undertaken, focused on the specific biological components of particular interest to the resource and permitting agencies and beginning immediately before the start of construction. If preventable degradation of this marine ecosystem starts to occur, the long-term viability of the Project could be diminished. Fixed quadrat or transects should be placed in locations representative of the best coral growth off the coast in the Project vicinity and need not be set up in relation to an ongoing water quality monitoring program (*AECOS*, 2019) or previous biological monitoring efforts (MRC, 2006; *AECOS*, 2016; this report).

At these monitoring locations, the following should be quantified: (1) coral colony size-frequency (size, diversity, new recruits, large colonies, health, bleaching conditions); (2) diversity, size, density, and biomass of fishes; (3) algae (including crustose coralline algae) and seagrass; and (4) non-coral macro-invertebrates greater than 3 cm. To capture long-term trends, monitoring frequency should be annually for a period of at least ten years. Long-term coral monitoring programs (see Coles & Brown, 2007) suggest including a provision to undertake special event-driven surveys (for example, after a tsunami, significant land runoff event, or massive bleaching event) as important to demonstrate the impact of events unrelated to the Project itself. Additionally, control stations

should be included in the monitoring effort to capture non-Project-related influences to the marine environment (ie warming event or large storm event).

Enhanced macroalgae growth is a potential indirect impact from further development along this coast. This problem does not exist at present, and the likelihood is regarded as small. However, monitoring for such events would be beneficial. Monitoring would need to be in shallow water, but determining exact locations is difficult in the absence of any past or present problems. We suggest resort management become attuned to unusual events at the shore and report these to the biological monitoring team. For their part, the biological monitoring team, during the annual offshore monitoring survey, include a walk along the entire relevant shore noting qualitative abundances of algae species in the littoral zone or washed up on beaches, in addition to quantification during in-water reef surveys. Over time, these notes should reveal whether changes are occurring. If changes do occur or resort management reports excessive algae or other biota washing up on the shore, an investigation should be conducted and a more quantitative monitoring effort implemented.

Appendix A

Representative photos taken from across 15 survey stations in the Mākena Mauka Project area and vicinity, Makena, Maui, March 2025.

At Station CHB1, limestone pavement with scattered coral heads makes up the bottom type. Large patches of coral outcrops are common.

At Station CHB2, sand, limestone pavement are the dominant bottom types. Coral outcrops are rare.

Coral makes up the majority of the bottom type at Station CHB3 Sand channels dissect the coral patches.

At Station CBH4, coral makes up most of the bottom type. Large outcrops of *P. compressa* are common.

At Station HB1, coral makes up the majority of the bottom type

At Station UN2, sand makes up the bottom; corals are uncommon.

At Station HB2, limestone pavement with coral outcrops is the dominant bottom type. The triangle used for our ortomosiac mapping is shown in the bottom photo.

At Station UC3, sand makes up the bottom; corals are uncommon. Meadows of the green alga, *Halimeda kanaloana* occur in the sand.

At Station UC4, sand makes up the bottom, with patches of the green alga, *Halimeda kanaloana*. Corals outcrops commonly occur.

At Station UC8, sand and limestone pavement make up the bottom. Meadows of the green alga, *Halimeda kanaloana*.

Appendix B

Inventory of marine biota observed in the Mākena Mauka Project area and vicinity, Makena, Maui, March 2025.

PHYLUM, CLASS, ORDER, FAMILY *Species*	Common name	Status	Abundance
	ALGAE		
CYANOPHYTA	CYANOBACTERIA		
Leptolyngbya crosbyana		Ind.	U
Lyngbya majuscula		Ind.	C
Symploca hydnoides		Ind.	U
CHLOROPHYTA	GREEN ALGAE		
Caulerpa serrulata	saw caulerpa	Ind.	U
Halimeda kanaloana		End.	A
Halimeda opuntia			U
Neomeris sp.			U
RHODOPHYTA	RED ALGAE		
Ahnfeltiopsis concinna			C shore
Hydrolithon gardineri		Ind.	O
Hydrolithon onkodes		Ind.	R
Hydrolithon reinboldii		Ind.	O
Sporolithon erythraeum	patchy red coralline algae	Ind.	O
OCHROPHYTA	BROWN ALGAE

KEY TO SYMBOLS USED:

Abundance categories:

R – Rare – only one or two individuals observed.
U – Uncommon – several to a dozen individuals observed.
O – Occasional – seen irregularly in small numbers
C – Common -observed everywhere, although generally not in large numbers.
A – Abundant – observed in large numbers and widely distributed.

Status categories:

End. – Endemic – species found only in Hawai‘i
Ind. – Indigenous – species found in Hawai‘i and elsewhere
Nat. – Naturalized – species were introduced to Hawai‘i intentionally or accidentally.

1. EXECUTIVE SUMMARY

Purpose of Report

The purpose of this report is to provide an assessment of water resources within the Mākena Mauka project area (referred to herein as "MMP", "Mākena Mauka", or "the project") that lie within the Kamaʻole Aquifer System Area (ASA)[1], the Wailea Surface Water Hydrologic Unit (SWHU), and the Moʻoloa SWHU[2] in the Wailea area on the leeward Haleakalā portion of the Island of Maui. Mākena Mauka is a low-density, master-planned residential community featuring market-rate and workforce housing, with a mix of rural, single-family, and multi-family units. Planned for such uses for decades, the project integrates the existing Mākena North and South Golf Courses (with renovations to the South Course) and includes community amenities such as gathering spaces, hiking trails, pedestrian and bike-friendly pathways, public beach parking, and designated conservation areas. The land plan consists of 652 housing units—including 109 onsite workforce units—and approximately 135,000 ft^2 of operational support buildings for golf operations, maintenance, staff offices, and related uses. The 109 workforce units are planned to be supplied by the Maui Department of Water Supply (MDWS), while the rest of the water demands will be supplied by a private water system. The total project area covers approximately 1,044 acres, with 473 acres designated for residential development. Since the project anticipates making improvements in various County and State right of ways, Mākena Golf & Beach Club Owners, herein referred to as "the Client," is preparing an Environmental Impact Statement (EIS) to satisfy Hawai'i Revised Statutes (HRS) 343. This report informs the ground and surface water resources portions for the future EIS.

The report is partially based on information relayed to Akinaka and Associates, Ltd. by the Client for analysis. Additional historical and the latest best ground and surface water information available for the hydrologic units of ground water (Kamaʻole ASA) and surface water (Wailea SWHU and Moʻoloa SWHU) are included in this report. Additionally, since

[1] The Kamaʻole ASA [60304] is a ground water hydrologic unit as defined in the 2019 WRPP [4].
[2] Wailea (6110) and Moʻoloa (6109) SWHU are surface water hydrologic units as defined in the 2019 WRPP [4]

improvements in Mākena Mauka are anticipated to be partly serviced by the MDWS through their Central Maui System (CMS) the ground water hydrologic units of ʻĪao, Waiheʻe , Haiku, and Waikapū ASAs that provide ground water to the CMS and allocations from the ʻĪao-Waikapū Ditch for the CMS are also reviewed in this report.

The State Commission on Water Resource Management (CWRM) is the regulatory body in Hawaiʻi that ultimately manages the ground and surface water resources at the source statewide through the setting of SY, interim instream flow standards (IIFS), monitoring monthly pumpage and diversions from these sources, and approving well and pump installation, stream diversion, and stream channel alteration permits. Additionally, CWRM determines the reasonable and beneficial allocations through water use permits (WUPs) in areas duly designated as water management areas. The Kamaʻole ASA and Wailea & Moʻoloa SWHUs are **not** designated water management areas and as such any wells or stream diversions in those hydrologic units do not require a WUP.

The current SY of the Kamaʻole ASA is 11 million gallons per day (Mgd) and reflects the historically dry and brackish conditions of this large leeward aquifer area. Pumpage (statewide) and allocations (in ground water management areas (GWMA)) are managed on a 12-month moving average (12-MAV) basis.[3] The current 12-MAV pumpage from the Kamaʻole ASA as of January 2025 is 3.660 Mgd, which is 7.340 Mgd lower than and constitutes 33% utilization of the Kamaʻole ASA's (60304) 11 Mgd SY. Based on this and the historically dry and brackish conditions of the Kamaʻole ASA the utility of the hydrologic unit as a water source does not appear to be threatened by current pumpage from the aquifer.

Potable demands for the general Mākena area are currently serviced through the MDWS CMS while future alternative sources are being explored (i.e., local reverse osmosis (RO) or future Haiku ASA sources to feed into the MDWS CMS). The CMS serves the Kīhei-Mākena Community Plan districts within which the MMP resides. According to the County of Maui MDWS 2023 Maui Island Water Use and Development Plan (WUDP) [1], the CMS

[3] 12-month moving average, or 12-MAV, is a rolling 12-month period such that at any point in time the previous 11 months of pumpage are made part of the average to cover complete annual seasonal variations. This is the statistic the CWRM uses to manage pumpages against SY.

provided 12.462 Mgd of water to the Kīhei-Mākena Community Plan area (or Kama‘ole ASA) in 2014.[4] The total average daily water use demand without RO recovery for the MMP is estimated to be 0.917 Mgd while the maximum/peak daily demand is 1.375 Mgd. Excluding golf course demands, the average water use demand is estimated to be 0.528 Mgd and maximum/peak day demand is 0.792 Mgd, which are consistent with recent developments in Maui (see Appendix N). Water meter records from 2024 from recently built multi-family projects in Wailea show annual consumption of 0.659 Mgd for Makali’i (built in 2022) and 0.688 Mgd for Keala O Wailea (built in 2018). Neither of these two projects were LEED certified so additional conservation savings could be realized. These usage figures are generally consistent with MDWS Water System Standards Table 100-18 as well.

The total average water demand with RO recovery is 1.038 Mgd and maximum/peak day water demand is 1.557 Mgd. Ninety-four percent (94%) of the demand will be met by a private water system pumping from the Kama’ole ASA and treated with RO. Due to a RO recovery efficiency of 65%, 1.464 Mgd will be required to be pumped to meet the maximum/peak demand. The rest (6%) of water demand is for the development’s affordable housing, which will be supplied completely by the MDWS CMS. Table 1 summarizes these demands by category.

[4] Table 8-10 MDWS Maui Island WUDP [1]

Table 1. Demand Summary for the Mākena Mauka Project with RO Recoveryby Category

Category	Total Average Demand GPD (with RO Recovery)	Total Maximum/peak Demand GPD (with RO Recovery)
Potable Residential Housing (supplied by private water system)	**345,846**	**518,769**
Potable Affordable Housing (supplied by MDWS CMS)	**61,640**	**92,460**
Non-Potable Irrigation (supplied by private water system)	**630,190**	**945,285**
Total Average Demand	**1,037,676**	**1,556,514**

MDWS can meet the affordable housing potable water needs of the MMP within the CMS from various sources that serve the CMS, and MMP is capable of meeting their other average water demands through a private water system as follows:

- First, MMP plans to rely primarily on private brackish wells as their source to minimize reliance on County water. Akinaka estimates a maximum pumpage of 1.464 Mgd for their uses (see Appendix N). Considering other planned projects in the area and the DHHL reservations, the total additional average pumpage would be within the total 11 Mgd SY established by CWRM for the Kama'ole ASA. Only the planned affordable housing –about 6% of their maximum day water demand or 0.092 Mgd—will be supplied by the MDWS CMS.

- Second, the actual reported non-caprock use from the ʻĪao ASA, where the CMS is mainly sourced from, is 13.157 Mgd based on a 12-MAV as of January 2025, typically the lower pumpage time of the year. This is 6.843 Mgd below the 20

Mgd SY for the ʻĪao ASA and 2.694 Mgd below the current total allocations that count against SY. This is in part due to conservation efforts of the MDWS where metered water use in the CMS has declined over 4% from 2006 to 2020 while water meters increased by 14% from 2006 to 2020 (based on MDWS annual reports). Other non-MDWS allocations amount to 0.026 Mgd, leaving the MDWS with 2.688 Mgd of unused allocation as of January 2025 that could be re-allocated within the MDWS CMS. Under HRS 174C-48, the CWRM must also delegate to the county boards of water supply the authority to allocate the use of water for municipal purposes, subject to the limits of water supply allocated to the county boards of water supply in their role as water purveyors. Therefore, it would appear MDWS and the ʻĪao ASA alone have enough cushion between actual pumpage vs. allocated use to manage and provide for the MMP future needs within the MDWS current allocations.

- Third, the CMS is also supplied by other ASAs, primarily the Waiheʻe ASA (60103), which is currently pumping 69% of its 8 Mgd SY and permitted surface water use from the CWRM designated Na Wai Eha surface water management area. For Waiheʻe ASA, there is a new capital improvement project (CIP) for a 0.5 Mgd Waiheʻe well anticipated to be online by FY28 and for Na Wai Eha.

- Fourth, two additional future ASA sources to increase source supplies are identified in the MDWS 2023 Maui Island WUDP are: 1) from the Haiku ASA that is currently pumping only 3% of its 24 Mgd SY and 2) from the Waikapū ASA, currently pumping only 1% of its 3 Mgd SY. MDWS is currently pursuing feasibility studies required under the East Maui Consent Decree to implement the source strategy for the Haiku ASA, while strategy #3 of the Maui Island WUDP for the Waikapū ASA (60101) adjacent to and south of the ʻĪao ASA is to adapt pumpage of constructed wells in Waikapū ASA with guidance from the 2015 USGS groundwater flow model results.

- Fifth, MMP will be designed to use County R-1 recycled water when available, which will reduce the need for groundwater pumping.

- Sixth, through imported return-irrigation recharge, use of imported R-1 recycled water will help minimize groundwater salinity increases within the project area.

- Seventh, at full build out, the MMP reverse osmosis (RO) treatment process to meet new non-affordable housing related potable demands is expected to produce 181,569 GPD of RO concentrate that can be mixed with brackish well water to offset well pumpage. Overtime, combined with recycled R-1 water availability from the County, there will be an inverse relationship between residential occupancy and the amount of non-potable groundwater pumping required for golf course irrigation.

- Eighth, conservation measures, primarily through Leadership in Energy and Environmental Design (LEED) certified construction for buildings greater than 500 square feet, will be incorporated into the MMP development to continue and further the conservation efforts that have proven effective in the ʻĪao ASA.

Thus, for the reasons stated above, the wells pumping from the Kama'ole ASA and the MDWS CMS can meet the future potable and non-potable average and maximum/peak day demands of the MMP improvements. However, the cumulative maximum/peak day demand for MMP along with other future planned developments and DHHL reservations will be nearing the Kama'ole Aquifer System Area sustainable yield of 11 Mgd.

It is important to note and consider there are recently released U.S. Geological Survey (USGS) scientific studies [2] [3] that predict lower recharge that could result in lowered ground water availability in the future as evidenced by declining rainfall and stream flow over the past several decades. However, these predictions are for mid-to-end of century years (2071 to 2099 (47 to 75 years) with several different scenarios and models. It is not clear if the impacts are correlated more with upper recharge and SY range estimates

specified in the CWRM Water Resource Protection Plan (WRPP) [4] rather than the conservative minimum values that are used. The CWRM will be reviewing these new predictions in an update to the 2019 WRPP and determine if revising current recharge and SY range estimates are required to accommodate these future recharge predictions.

This report also determined the water demands of future development projects in the area to ensure that the cumulative impacts of these projects (including MMP) will not overpump the Kama'ole ASA and the ASAs that CMS is tapping from. In the Kama'ole ASA, we estimate the future pumpage to rise to a maximum/peak of 8.190 Mgd. Including DHHL reservations would increase the maximum/peak pumpage to 10.737 Mgd. Although this would be below the SY of 11 Mgd, this would raise the pumpage to greater than 90% of the SY, which is something that could initiate designation of a GWMA under the CWRM.

To mitigate impacts, MMP will be looking to reduce water demands. They will be ensuring LEED certified construction for buildings 500 square feet and larger and shall implement the following measures:

- Low flow faucets, fixtures, and toilets.
- Utilize R-1 water when available
- Encourage pool evaporation covers.
- Use of non-potable water for landscaping.
- Irrigation systems that use drip lines and moisture sensors.
- Irrigation scheduling during morning and evening hours to avoid high-evaporation times of the day.
- Xeriscaping and use of drought tolerant plants in landscaping, while encouraging native species.
- Rainwater/stormwater catchment and reuse.

2. INTRODUCTION

2.1. Scope

The scope of this report is to primarily:

- Research existing available information including existing utilities and reports within the proximity of the MMP area;
- Provide analysis of water resources portion of the EIS for the MMP;
- Review past reports and public information available at Department of Land and Natural Resources CWRM and other appropriate agencies primarily regarding the status of the Kama‘ole ASA ground water availability.

3. MMP WATER NEEDS

Appendix N summarizes the water demands for MMP. It is based on Table 2 in the November 2025 Water Resource Assessment for the Mākena Mauka Project from Tom Nance Water Resource Engineering (TNWRE) [5] as well as estimates using average consumption demand from Table 100-18 from the MDWS Water System Standards [6]. The total estimated maximum/peak demand for MMP is 1,374,945 gpd. However, MMP is planning to develop their own privately owned and operated water system to supply around 94% of their water demand. The Client plans to use three wells on their property to pump brackish water for their supply, using RO to treat the water for potable demands and leaving the water untreated for irrigation demands.

Of the total maximum/peak demand to be supplied privately, 429,660 gpd will be used for potable use and 945,285 gpd will be used for irrigation. The water planned for potable use must go through RO treatment with 65% recovery, meaning 65% of the water that goes through the treatment is suitable for potable use while the rest (35%) is disposed as brine waste. Thus, it requires the wells to pump up to 518,769 gpd, so that 337,200 gpd (65% of 518,769 gpd) can be yielded for potable use through RO. In total, this requires the wells to pump a total of 1,464,054 gpd or 1.464 MGD of brackish water

from the Kama'ole ASA. This additional pumping by itself would still be well below the aquifer's 11 MGD SY.

The estimated maximum brine waste requiring disposal would be 181,569 gpd (35% of 518,769). TNWRE believes that the brine would likely be too saline for irrigation but may be appropriate for golf course irrigation. However, the DOH maintains that RO reuse cannot be reused for irrigation, and if this stance remains, a disposal well would ultimately be required. Currently, the Client plans to dispose of the waste in a 400,000-gallon lined basin at their own existing private wastewater treatment facility. The RO waste would be allowed to evaporate, leaving behind the salt. These salts would then need to be periodically hauled off to a landfill for disposal. In addition, the Client will consult with the State DOH to assess whether the waste could instead be mixed with irrigation water for the golf course for irrigation purposes.

The total maximum/peak demand that is estimated to be supplied by MDWS CMS is 92,460 gpd or 0.092 Mgd. MMP is already connected to the CMS via a 4" County water line at TMK 2-1-005:108, and this amount of additional pumping will not stress the ʻĪao ASA, where the majority of CMS water comes from, past its SY.

Additionally, the affordable housing project within MMP, which is slated to be 100 percent affordable under section 2.96 of the Maui County Code, is exempt from the "Show Me the Water" requirement under section 14.12 of the Maui County Code. This exemption applies to "subdivisions that will not be regulated as a public water system under department of health rules" and "residential development projects with 100 percent affordable housing units and are within the service area of the department's central or west Maui water system. Consequently, the MMP affordable housing project will be exempt from the "Show Me the Water" requirement and will be served by the MDWS CMS. The remainder of the development will be supplied by a private water system.

4. EXISTING WATER SUPPLY ENVIRONMENT

4.1. Location

Exhibits 1, 2, & 3 are summary maps of the ground and surface water supply and regulatory regimes within which the proposed 1,044 acres of the MMP improvements reside (see also **Appendix A**). Mākena Mauka lies within the Kamaʻole ASA (60304), the Wailea SWHU (6110), and Moʻoloa (6109) SWHU and includes western portions of the Leeward Haleakalā Watershed Restoration Partnership (LHWRP) that are mostly outside Papa'ainui Tract of the Kahikinui Forest Reserve [7] and bordering Department of Hawaiian Home Lands (DHHL) at its most mauka limits. Good historical references for the geology, hydrology, and water distribution systems in the Kamaʻole ASA, the Wailea SWHU, and the Moʻoloa SWHU can be found in Yuen 1990 [8], Stearns [9] [10], Lau [11], and more recently the CWRM's 2019 WRPP [4] and the MDWS 2023 Maui Island WUDP [1]. More detailed localized descriptions of climate, ground water, and surface water sources within the project area are discussed in the following sections of this report.

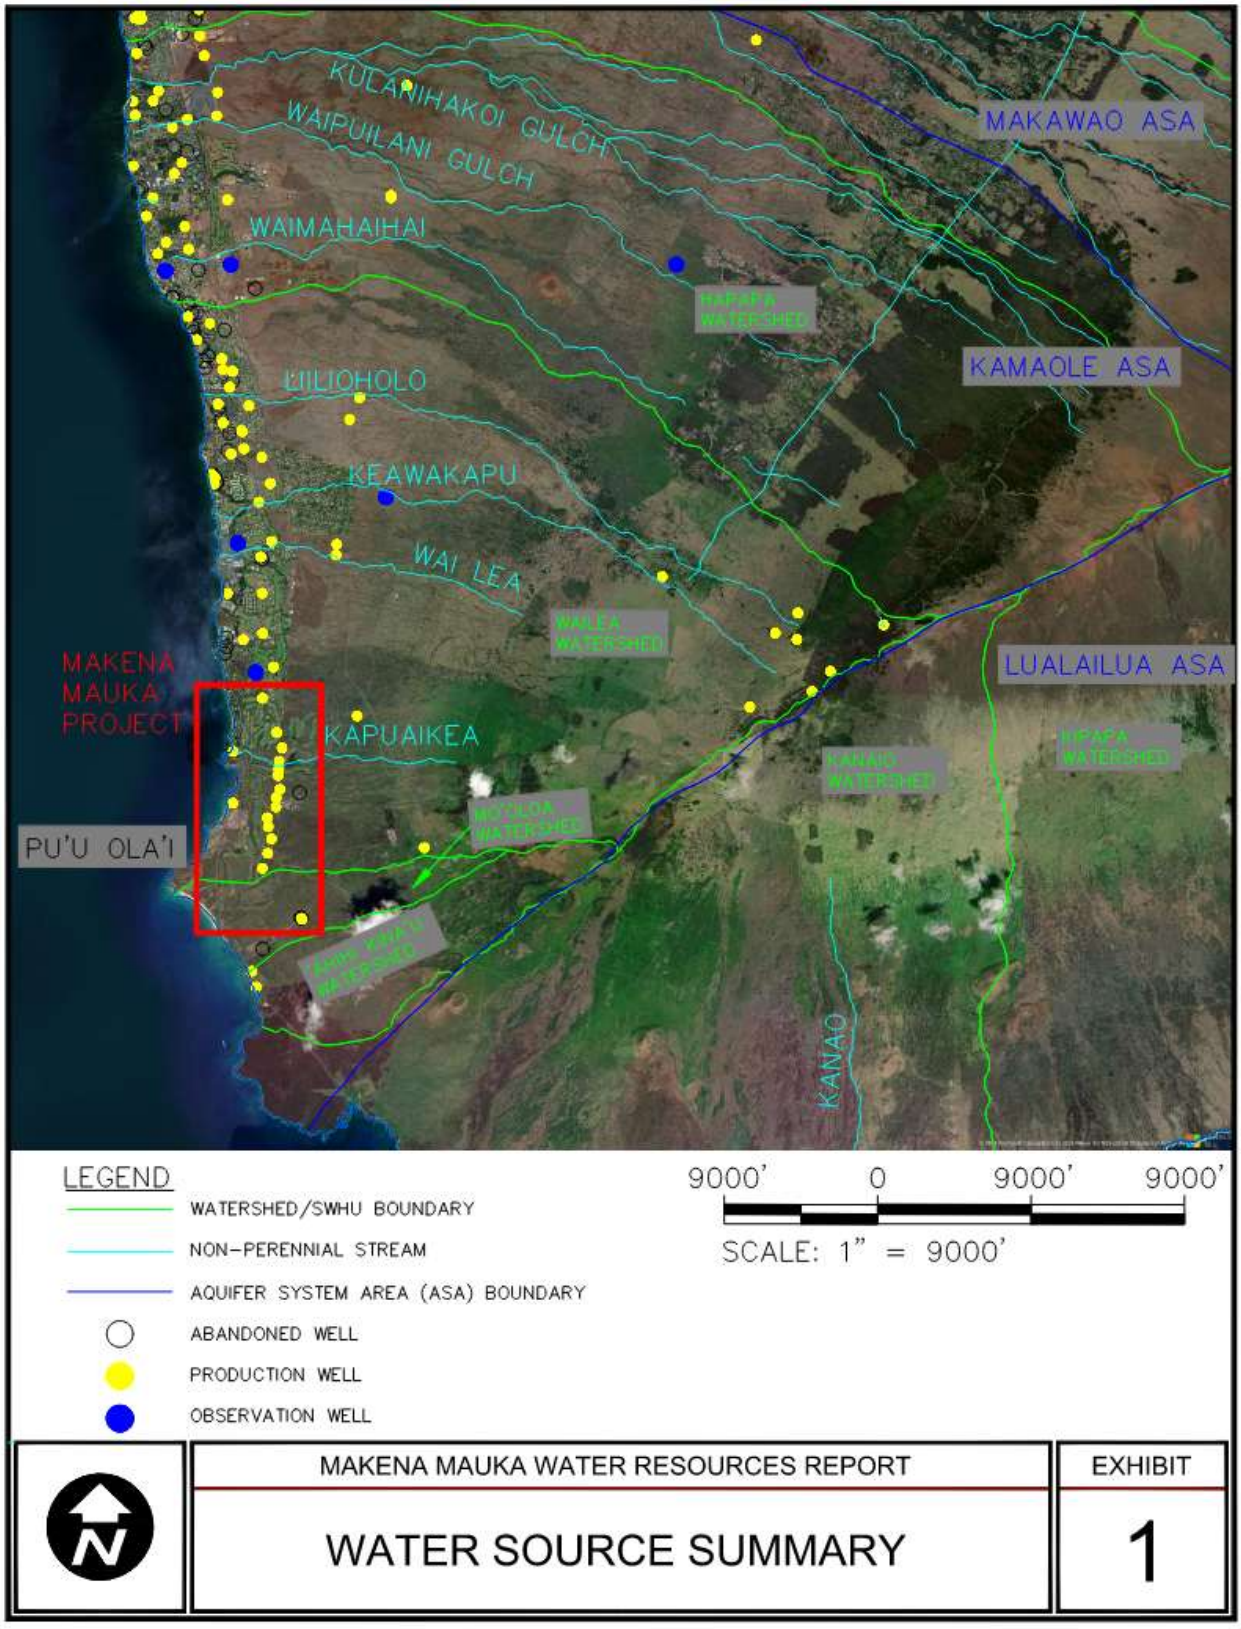

Exhibit 1. Water Source Summary Map

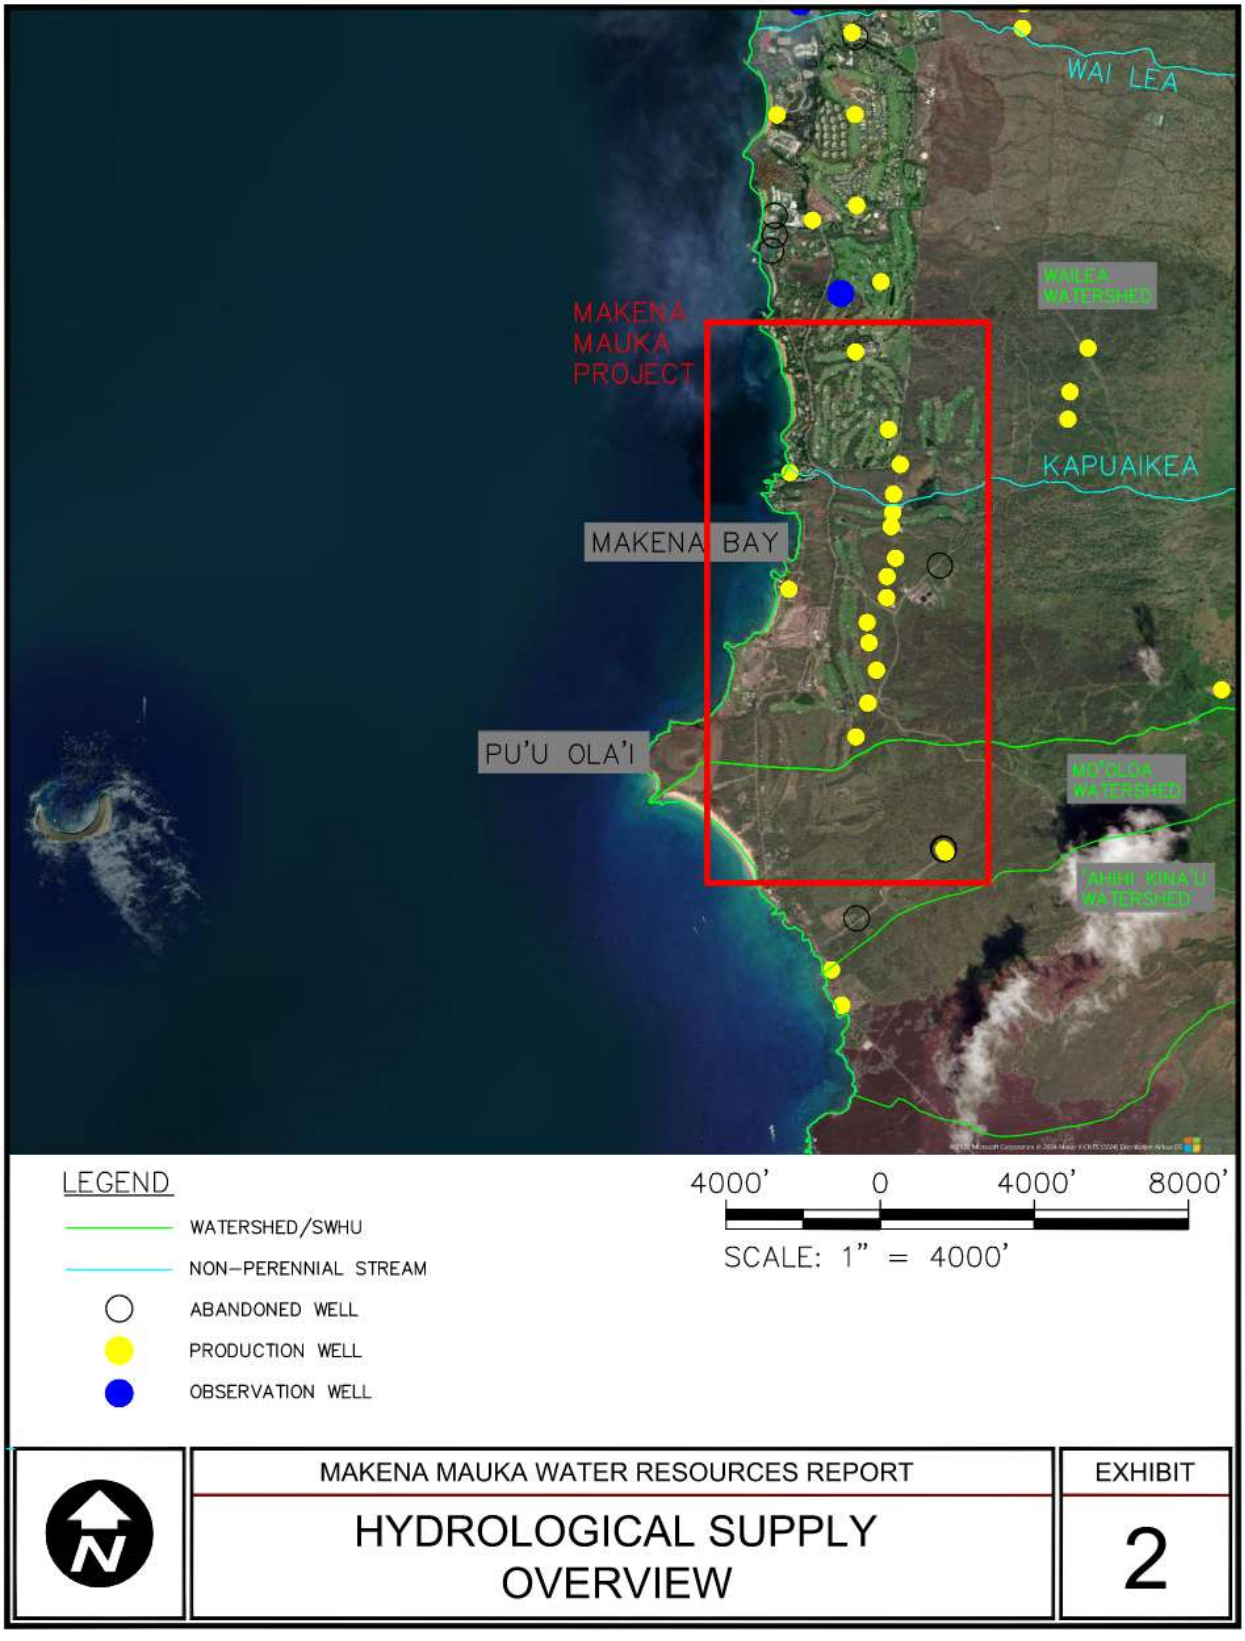

Exhibit 2. Hydrological Supply Overview

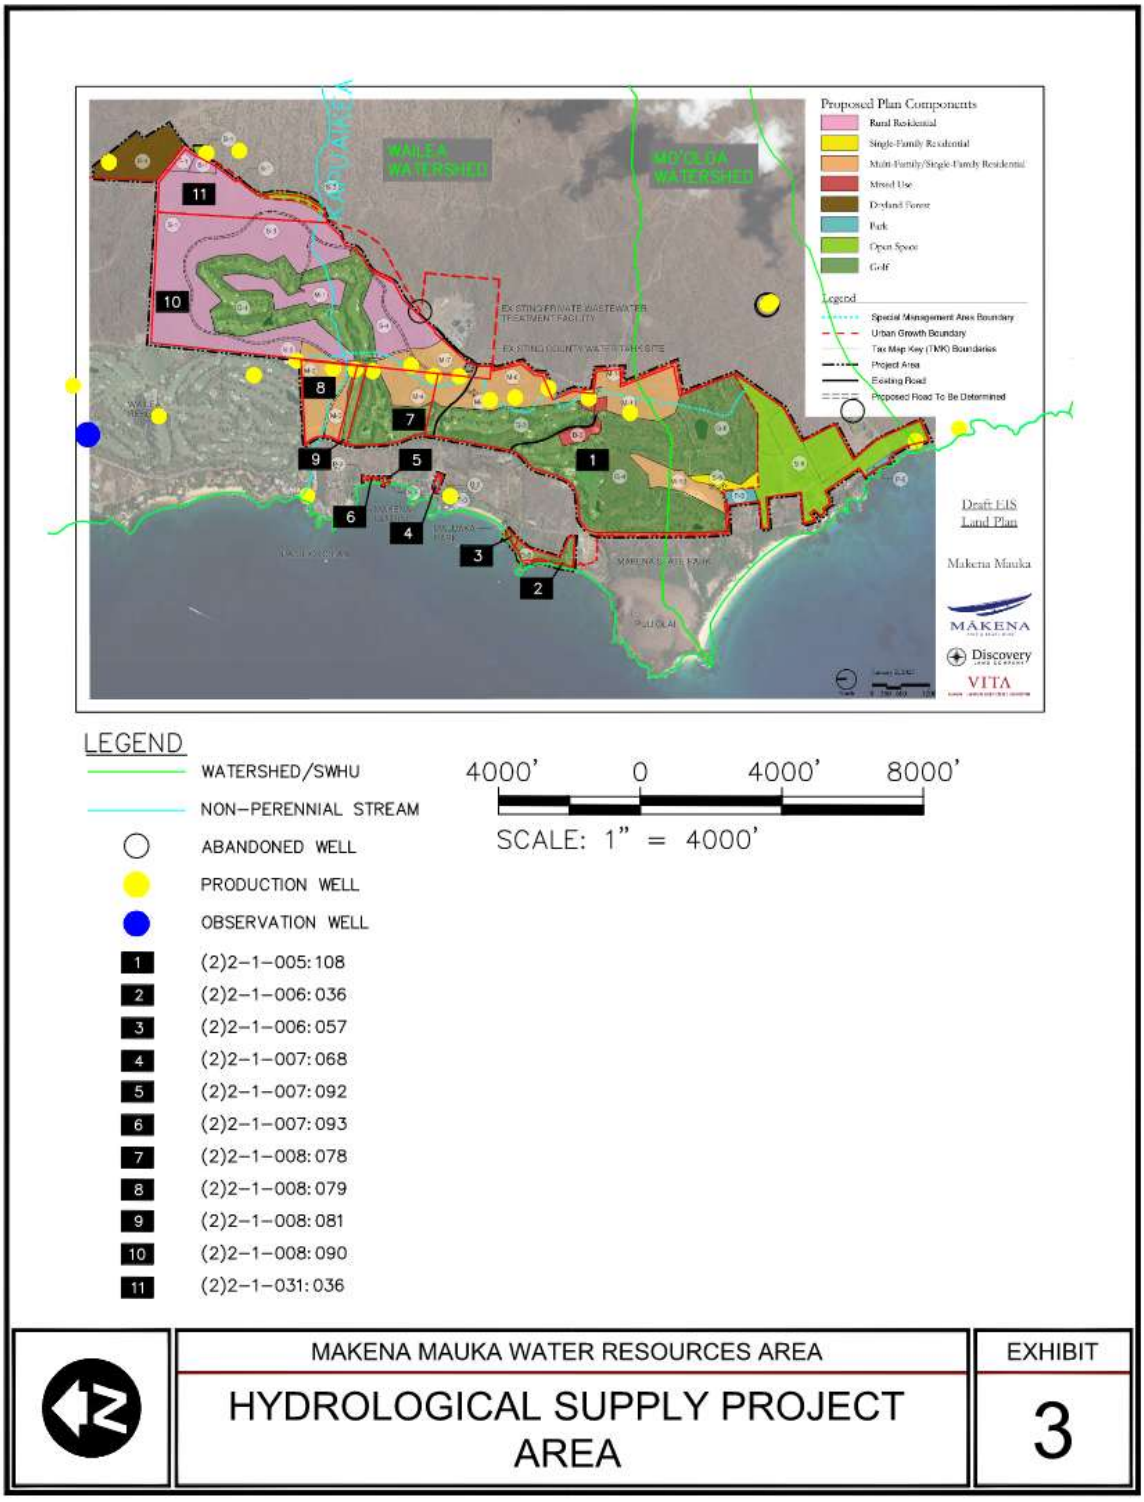

Exhibit 3. Mākena Mauka Project Area Water Source Map (modified Fig. 1 TNWRE [5])

4.2. Climate

The hydrologic water cycle and local climate are the fundamental source for all water of an area. Rainfall (RF) and evapotranspiration (ET) are reviewed in the following sections showing that spatial variations in rainfall and potential evapotranspiration (PET) vary significantly over the region and in the MMP area. Climate change is also a significant issue of concern, and it should be noted there are future pending predictions that raise the uncertainty of how much the climate will remain consistent with long-term trends in the region and the project area. Predicted climate changes could affect the availability of ground water for various drinking and irrigation needs of the MMP while the surface water effects will be more related to water quality and intermittent storm flood events in the historically dry area.

Table 2 summarizes the general climate through RF, ET, and PET ranges for the hydrologic units and MMP areas to show and quantify the "dryness" of the area, which is exemplified by maximum PET exceeding rainfall by approximately five (5) times. **Appendix A** photos show the dry conditions of the project area parcels next to or containing well irrigated golf turf area. **Appendix B and C** provide areas detailed in **Table 2** with more detailed discussions of these parameters explained in the respective following sections of this report.

Table 2. Annual Mean (inches) Ranges

	Annual Mean (inches) Range					
	RF[1]		ET[2]		PET[3]	
Area/Gage	Min	Max	Min	Max	Min	Max
Kama'ole ASA[4]	11	41	3	49[9]	35	285
Red Hill[5]		41[10]	13 – withing range		177 – within range	
Wailea SWHU[6]	11	36	3	45	35	227
Polipoli Spring		36[11]	23 – within range		76 – within range	
MMP[8]	13	16	23	45	79	138
Mākena	5	30	N/A	N/A	N/A	N/A

Notes:
[1] RF = Rainfall
[2] ET = Evapotranspiration
[3] PET = Potential Evapotranspiration
[4] ASA = Aquifer System Area, which is a ground water hydrologic unit
[5] Red Hill is located at HaleNet SKN 339.6
[6] SWHU = Surface water hydrologic unit
[7] Polipoli Spring location is SKN 339.6 gaging system
[8] MMP = Mākena Mauka Project
[9] A 67-inch data point is an anomaly, and all other data is below 41 inches
[10] Annual average since 1955
[11] Annual average since 1990
[12] NOAA Sta – USC00515842 at Mākena Golf Course from 1982 to 2024

4.2.1. Rainfall

RF is spatially variable because of the islands' topography and the persistent northeasterly trade winds. The Hawai'i Climate Data Portal [12] (URL: https://www.hawaii.edu/climate-data-portal/data-portal/) website provides the best estimates for mean RF ranges based on complete historic RF gage records statewide and near Mākena Mauka (see **Appendix B**).

Generally, mean annual RF historical data from seven (7) active and twelve (12) discontinued RF stations spanning various periods over the years between 1903 to the present within the Kama'ole ASA demonstrate the dryness of the region. Along the Kama'ole ASA coastline from Kenolio Park to La Perouse Bay the mean annual RF is approximately between 11 to 14 inches while the maximum near the top of Haleakalā at the active HaleNet SKN 339.6 station is 41 inches. Therefore, the range of mean annual RF in the Kama'ole ASA is roughly between 11 to 41 inches while the mean annual RF of

the Wailea SWHU within the Kama'ole ASA ranges between 11 to a max of 36 inches at the active Polipoli Spring SKN 267.2 station.[5]

Additionally, National Oceanic and Atmospheric Administration (NOAA) has a precipitation gauge on Mākena Golf Course in the project area measuring daily RF data since May 1, 1982 as shown in **Exhibit 4**. This gives a more direct localized sense of what the RF is within the MMP. Like the surrounding region, MMP is a very dry area with annual RF ranging from 5 to 30 inches over the 32-year period since 1982, and the average annual RF is 14 inches.

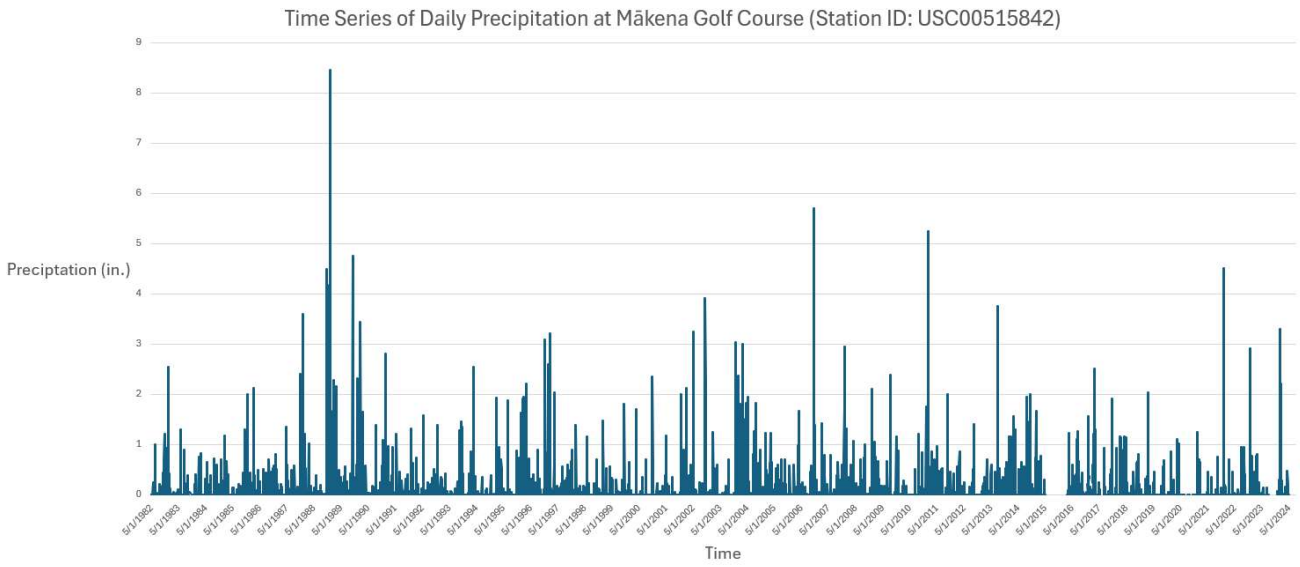

Exhibit 4. Time Series of Daily Precipitation at Mākena Mauka Golf Course

[5] For comparative purposes between older vs. newer methods and additional data, it should be noted that the older annual mean rainfall rate isohyets from the 1986 Rainfall Atlas of Hawai'i, Giambelluca [47] mean annual rainfall was under 16 inches along the Wailea coastline to under 49 inches near summit of Haleakalā.

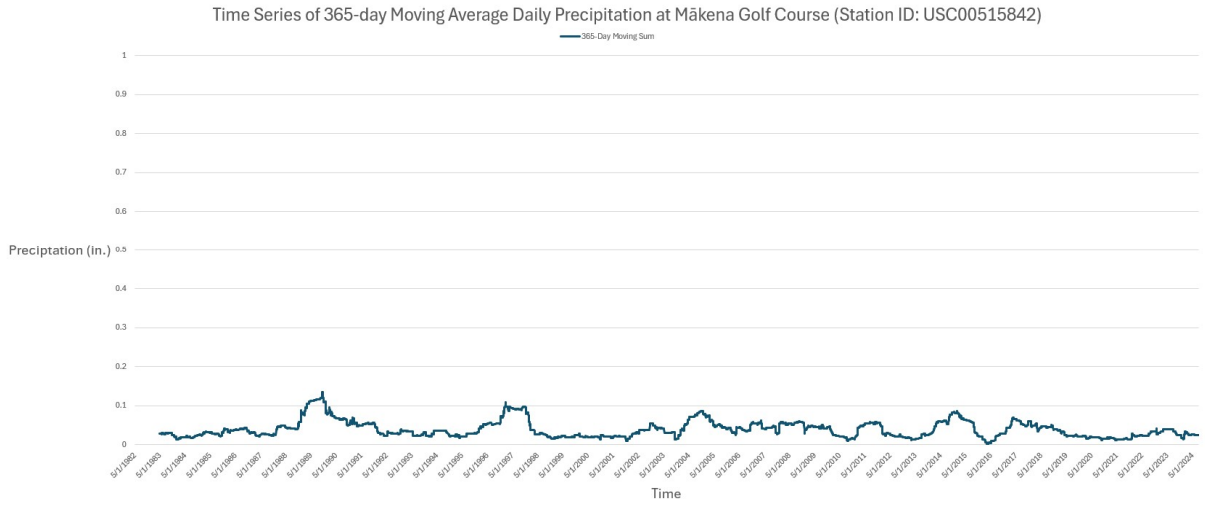

Exhibit 5. Time Series of 365-Day Moving Average Daily Precipitation at Mākena Golf Course

The complete time-series of the daily precipitation highlights large storm events very well and the time series of the 365-day moving average (**Exhibit 5**) visually depicts the daily dryness much more accurately, showing less than 0.2 inches/day. There is usually little to no rain in the MMP area on a daily basis.

It is important to note there are also recent uncertainty analysis based on observed declines in RF from 1920-2012 based on analysis by Frazier and Giambelluca [13]. This will be addressed in the SY Section 3.3.2 of this report.

4.2.2. Evapotranspiration

ET is the combination of evaporation off a water surface exposed to the atmosphere and transpiration, which is the process where vegetation takes up soil-moisture water through its root system and releases additional water vapor into the atmosphere. Again, the Hawai'i Climate Data Portal [14] (URL https://www.hawaii.edu/climate-data-portal/evapotranspiration-atlas/) website provides the best maps for estimates of various actual mean ET and mean annual PET ranges near

Mākena Mauka (see **Appendix C**). **Table 2** summarizes the ET ranges for the various hydrologic units and the project area.

Actual annual mean ET ranges from 3 to 67 inches along the same coastal segment of the Kama‘ole ASA as described previously in the Rainfall Section 3.2.1 to 13 to 67 inches near the active rain gage station at the HaleNet SKN 339.6 station near the Red Hill summit of Haleakalā. Therefore, the range of mean annual ET in the Kama‘ole ASA is roughly between 3 to 67 inches while the mean annual ET of the Wailea SWHU within the Kama‘ole ASA ranges between 3 to a max of 45 inches at the active Polipoli Spring SKN 267.2 station. However, the 67-inch estimate is an anomaly near the intersection of E Lipoa Street and Liloa Drive approximately 2.7 miles north of the MMP area. In fact, there are two large swimming pools just makai and mauka of the intersection.[6] The next highest ET nodal estimate is approximately 49 inches with the remaining estimates all lower than the 49-inch estimate in the Kama‘ole ASA. Therefore, it is reasonable to say the more accurate range of actual annual mean ET is between 3 to 49 inches within the Kama‘ole ASA. These estimates are relatively low due to the dryness of the area where there is normally little water to evaporate or transpire, which the 67-inch anomaly clearly demonstrates.

Evaporation from a pan evaporation station where water is always present combined with land cover and vegetative correlation coefficients that multiply additional transpiration effects based on type of vegetation and soil characteristics can help to estimate the *PET* if water were always available through additional RF or irrigation. The Penman-Monteith PET model gives the highest maximum PET if water was always present. Based on the online tool, the mean annual PET range for the Kama'ole ASA is roughly 35 to 285 along the same coastal segment, as described previously in the RF Section 3.2.1, to 177 inches near the active rain gage station at the HaleNet SKN 339.6 station near the Red Hill summit of Haleakalā. Therefore, the range of mean annual PET in the Kama‘ole ASA is roughly between 35 to 285 inches while the

[6] The two pools are located at the Haggai International Institute and the Kihei Aquatic Center that explain the high ET rate.

mean annual PET of the Wailea SWHU within the Kama‘ole ASA ranges between 35 to 227 near the coast to 76 inches at the active Polipoli Spring SKN 267.2 station in the upper elevations of the area.

It should also be noted that based on older annual adjusted mean pan evaporation rate isopleths from the 1985 Ekern report [15] potential ET was estimated to range from 90 to 70 inches along the Kama‘ole ASA coastline from Kihei to the Mākena Mauka areas, respectively.

Generally, PET is 3 to 10 times the available RF in areas within the project area, which is why it is necessary to augment RF to meet annual irrigation needs.

4.2.3. Climate Change

Climate change is occurring in the Hawaiian Islands. Shifting and declining patterns in RF [13] and streamflows [16] are proof of this, which can then affect available ground and surface water in the future. Ground water availability has the advantage of having large storage capabilities to buffer these changes compared to streams and surface water availability. This is why dams for surface water reservoirs can and have been used in the past to function as buffers to capture and store large RF event runoff that can be used during drier times of the year.

Studies on future climate scenarios have been and continues to be developed. The USGS Oki study on declining trends of streamflow [16] and more recently by Kāne Mair [17] show that climate change may have significant impacts on water availability in Hawai’i.

4.3. Ground Water Availability and Impacts

4.3.1. Occurrence of Ground Water in the Kama‘ole ASA

The nature and occurrence of ground water is well established in Hawai’i. Much of the regional geology and hydrology of the Wailea region has its origins from Stearns [9] [10] and later more detailed studies by Rosenau [18] and Dale [19]. The 2019 WRPP [4]

is a good summary of the various seminal studies that support this conceptual model of Hawaiian aquifers. The traditional conceptual diagram showing the basal, dike complex, perched, and caprock aquifer zones are shown in **Exhibit 6.**

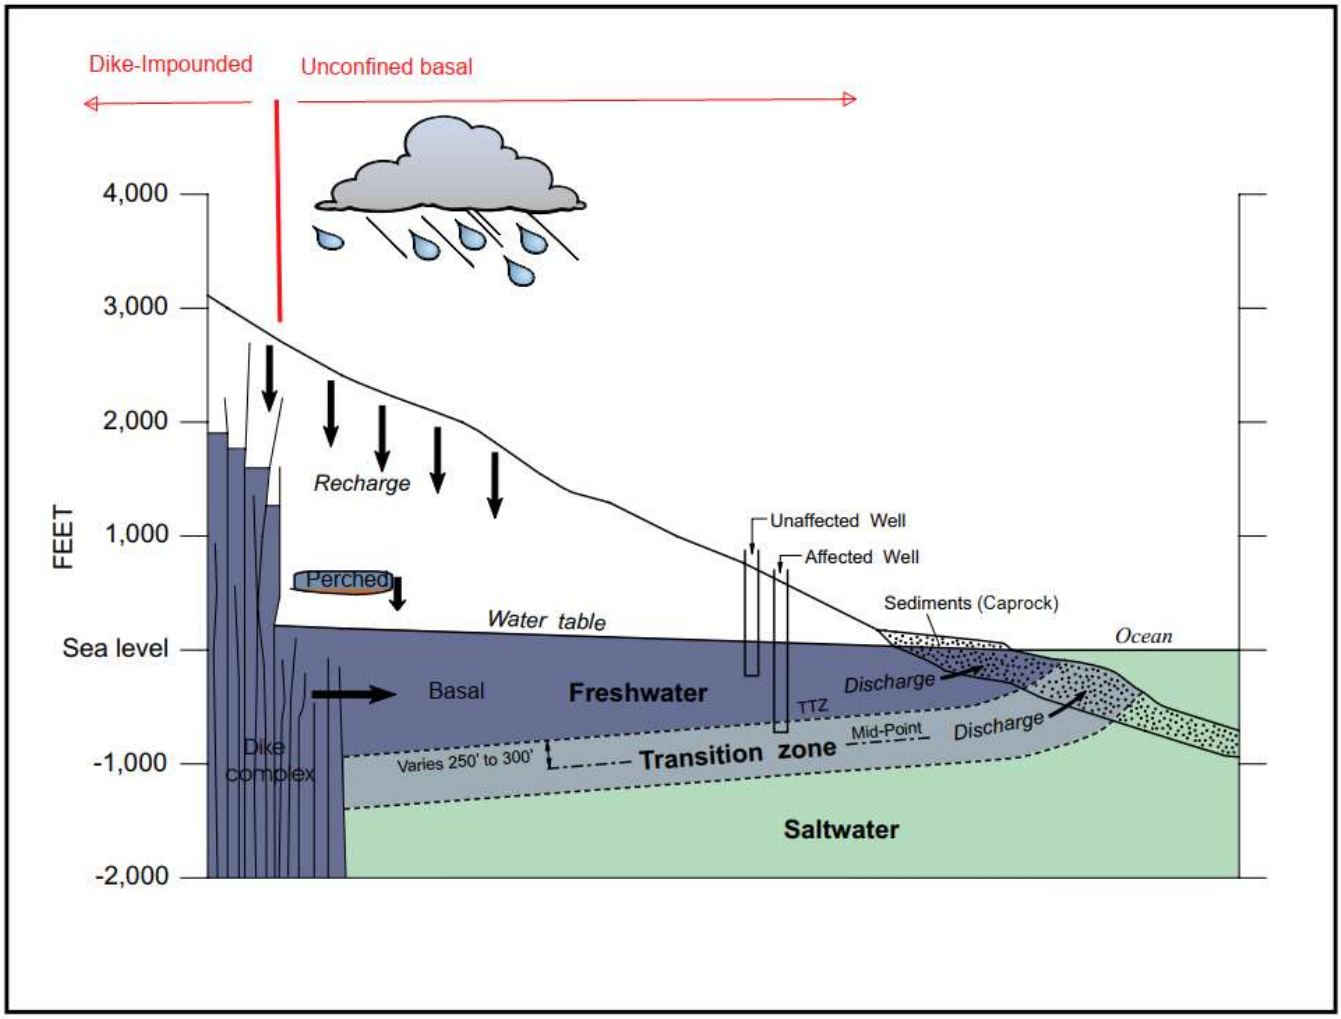

Exhibit 6. Ground Water Occurrence in Kamaʻole ASA
(modified from CWRM https://files.hawaii.gov/dlnr/cwrm/maps/hydrodisplay.pdf)

Recent deep monitor wells have found deep-confined freshwater underlying both the basal and saltwater aquifer zones on the Big Island in both the Hilo and Kona areas. However, there are no deep monitor wells on Maui or the Kamaʻole ASA that have encountered such a zone and it is not currently an issue. The majority of ground water occurrence within the Kamaʻole ASA is basal with its most inland boundary

terminating near the high-level dike impounded complex in the Haleakalā rift zones as shown in **Exhibit 7** [20].

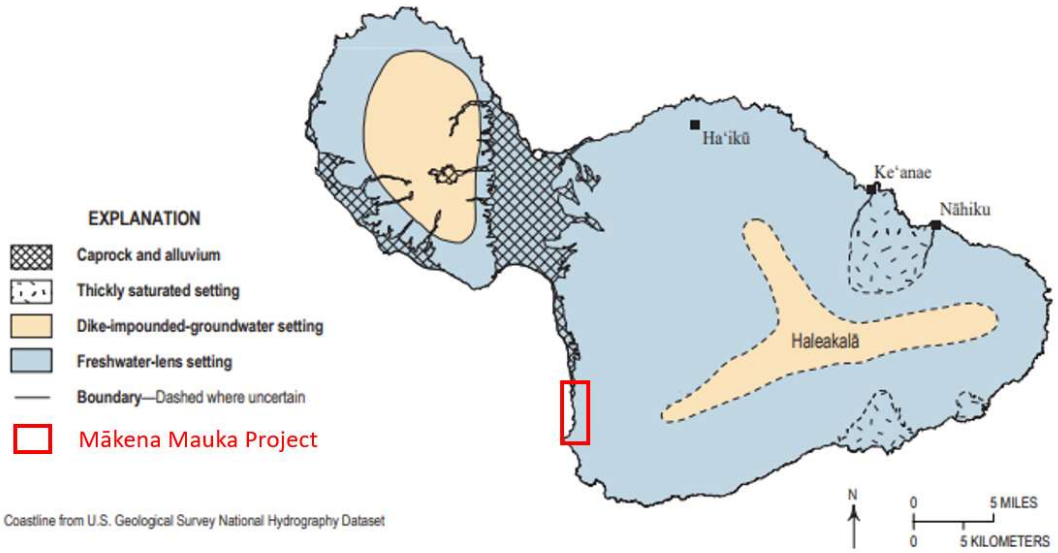

Figure 41. Map of the principal groundwater settings on Maui, Hawai'i. Modified from Izuka and others (2018).

Exhibit 7. Geologic based groundwater occurrence on Maui (modified Fig. 41 Izuka & Rotzoll [21])

Basal aquifers in Hawai'i typically have tremendous storage compared to high-level dike complex and perched aquifers. As such, they can sustain large pumping with little reduction in water levels. However, basal aquifers are more susceptible to saltwater intrusion from the underlying saltwater upon which the less dense freshwater floats. This saltwater intrusion into wells and the basal aquifer are not a concern in high-level dike complex and perched aquifers unless geothermal activity is present. There is no such evidence of geothermal activity in the Kama'ole ASAs. Based on CWRM well data information, the basal lens in the Kama'ole ASA ranges up to approximately +10 ft above mean sea level (msl), but most recorded water levels are under +5 ft msl (see **Appendix D**). Water-level data in the project area range between 1-3 ft above sea level, so the ground water is at a depth well below any typical excavation required for construction of a residential project. Any new well drilling near or within the project area must go down to that elevation to encounter the basal aquifer. The reasons for the

relatively thin basal lens are that 1) most wells are drilled near the coastline where the lens is thinnest and 2) the general lack of significant caprock to impede ground water discharge to the ocean to increase ground water levels and storage (see **Exhibit 7** and **Appendix E**).

The Kama'ole ASA lies within the larger Central Aquifer Sector Area as shown in **Exhibit 8** below.

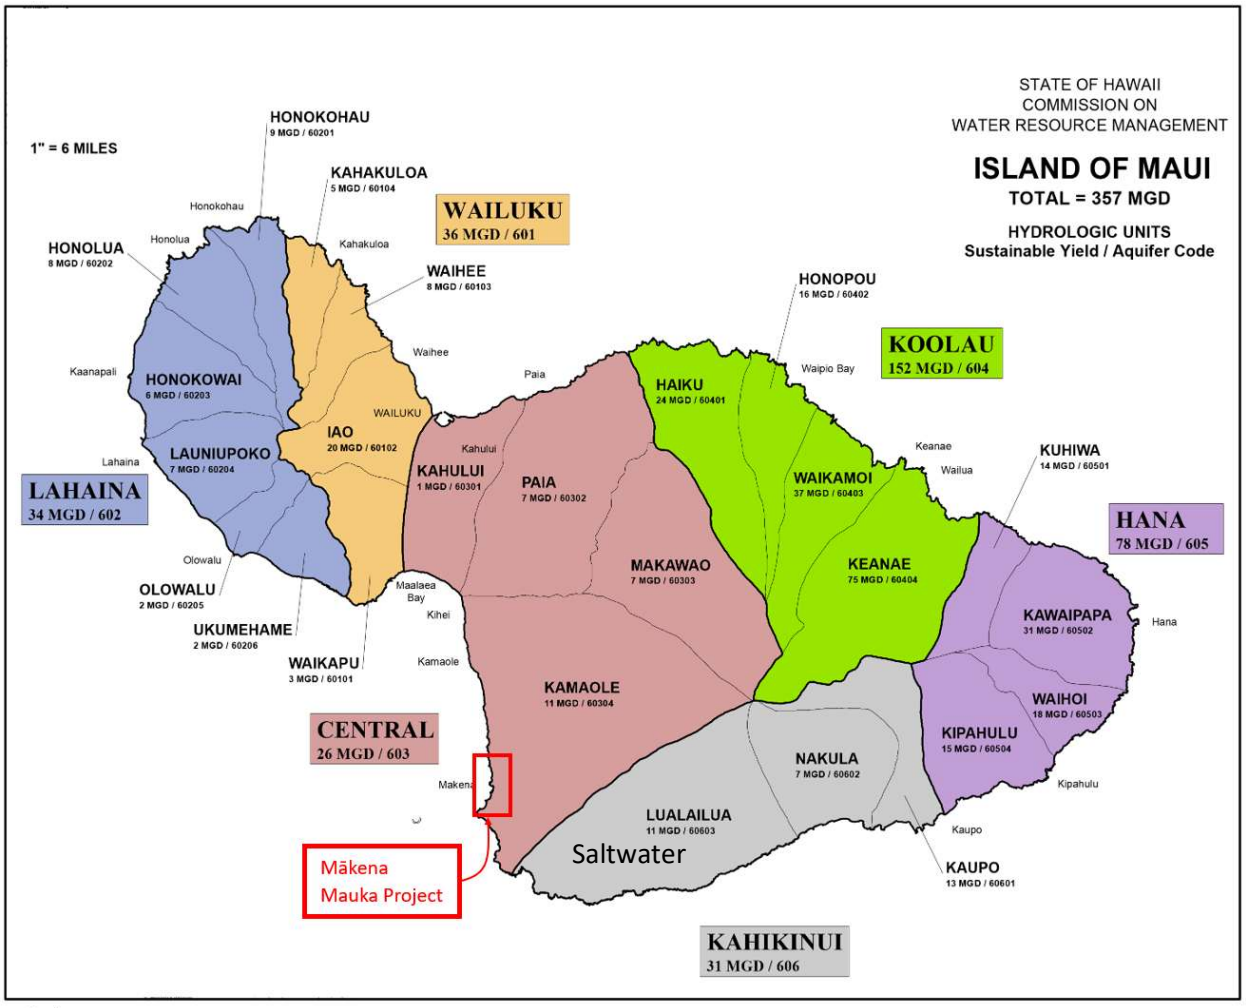

Exhibit 8. Ground Water Hydrologic Units for Maui (WRPP [4]) and Mākena Mauka Location

Covering an area of 91.4 mi^2 (including 2.2 mi^2 of caprock near the coast) the Kamaʻole ASA extends from the mauka to Red Hill at the top of Haleakalā. The caprock is very thin near the coast and only exists in the northern coast of the ASA (See **Exhibit 7** and **Appendix E**) and is composed mostly of Hana volcanics [11]. It is within these boundaries that localized water budgets estimating recharge that contribute to SYs are computed in the management scheme of setting water availability for ASAs statewide [8], [22], [4].

4.3.2. Sustainable Yield

SY under the State Water Code, HRS 174C-3 is defined as:

> *"Sustainable yield" means the maximum rate at which water may be withdrawn from a water source without impairing the utility or quality of the water source as determined by the commission.*

SY is the measure against which available water is managed and determined by the CWRM, especially within GWMAs such as the ʻĪao ASA.

The CWRM currently determines ground water SYs in the 2019 WRPP [4] of the Hawai'i Water Plan (HWP) using the Robust Analytical Model (RAM) model(s).[7] The CWRM normally selects the minimum from a range of SY estimates to address the precautionary principle unless there are groundwater numerical models, data from deep monitor wells and sufficient historical pumpage and chloride records to support a higher SY than the minimum estimated by recharge ranges and RAM. Numerical models have the advantage of estimating future temporal, spatial, and quality changes if sufficient observed data exists and require calibration analysis with assumed geologic boundaries to match observed steady states (if they exist) of water levels, pumpage, and chlorides

[7]The CWRM uses the analytical Robust Analytical Model (RAM) [52] or RAM2 [51] approved by CWRM [4]. More detail on this approach is discussed in the 2019 WRPP [4] and why it is useful for planning and regulatory purposes and forms the foundation for most SY estimates in the state when compared to the more complex numerical models.

to make future predictions reasonable. If calibrated and validated, numerical models can help estimate impacts to ground water resources for various scenarios of pumpage or recharge. A numerical model [23] has been developed specifically to assess ʻĪao, Waiheʻe, and Waikapū ASAs but not for the Kamaʻole ASA. The current best conservative estimate of SY for the Kamaʻole ASA is 11 Mgd from a range of 11-16 Mgd [4], which is 44% of the minimum recharge range estimated between 24-37 Mgd [4] for the area. The SY is a daily use figure averaged annually and the CWRM uses a 12-month moving average of pumpage to assess the impact on the aquifer resource.

Since drinking water is supplied to the Mākena area from the MDWS CMS, then the primary sources of the ʻĪao (60102) and Waiheʻe (60103) ASAs for this distribution system are also important to consider. Also, according to the MDWS 2023 Maui Island WUDP [1], the Haiku ASA (60401) will play a key role planning for future growth and relieving current reliance on the ʻĪao and Waiheʻe ASAs for drinking water.

The current best estimate of SY for the ʻĪao ASA is 20 Mgd from a range of 10-28 Mgd [4], which is based on a significant amount of data and analysis.[8] The current best estimate of SY for the Waiheʻe ASA is 8 Mgd from a range of 6-15 Mgd [4], based on similar related analysis with the ʻĪao ASA. Lastly, the current best conservative estimate for the Haiku ASA is 24 Mgd based on a range of 24-27 Mgd.

Normally, the minimum of the estimated SY range is selected as the SY to be conservative as discussed in more detail in the 2019 WRPP [4]. The latest published recharge studies by Engott [24] based on the online RF and ET data described above provided the basis for updated recharges for the Kamaʻole, ʻĪao, Waiheʻe, Haiku, and the Waikapū ASAs. More details of these latest assumptions for the best estimate of minimum recharges for the Kamaʻole, ʻĪao, Waiheʻe , Haiku, and Waikapū ASAs can be found in the 2019 WRPP [4]. However, the more recent recharge estimates use a more

[8] In accordance with the 2019 WRPP , the alternative minimum SY for ʻĪao and Waiheʻe were based on complete historical data record from production wells, monitor wells, three (3) deep monitor wells, the RAM2 model, and pre-2019 USGS/MDWS numerical models [23] [50]. Post-2019 USGS numerical and recharge models also cover various pumpage scenarios that indicate the reasonableness of the current ʻĪao and Waiheʻe SYs [21] [26] [54].

detailed soil-moisture storage model that is not as conservative as the older annual recharge estimates made in the original 1990 WRPP [8] that overestimate the effects of ET. The current 2019 WRPP still uses older annual average recharge estimates for most SY estimates to address the precautionary principal policy of the CWRM including the Kama‘ole ASA. This original older method significantly overestimates ET and is typically still more conservative than the newer recharge methods that observed and predicted reduced RF in the future. **Table 3** provides a summary of this discussion in the pumpage Section 4.3.3 of this report.

Despite the breadth of data, research, and public involvement for the CWRM approval process that back up the current and reasonable minimum SYs within the 2019 WRPP there are two (2) significant uncertainties to SYs in all ASAs statewide:

- First, in January 2022, the USGS presented unpublished analyses to the CWRM that considers future climate change scenarios where recharge is predicted to be significantly reduced; hence, possibly reducing estimated SYs [17]. However, it is not clear if this reduction is related to the more recent and higher estimates of the recharge range rather than the minimum recharge used based on older but more conservative recharge calculations and estimates.
- Second, the 2019 WRPP acknowledges the emerging issue of ground water dependent ecosystems (GDE) that have not been explicitly addressed in establishing SYs. Although targeted as a test case in the Keauhou ASA (80901) [25] to assess how to address this GDE issue, current policy of the CWRM appears to have moved this issue into more recent regulatory approvals statewide for all well construction permits.

4.3.3. Well Sources, Pumpage, Water Levels, and Salinity

According to the CWRM well index database as of January 2025, there are 149 known well sources with a total installed pumping capacity of 21.563 Mgd in the Kama‘ole ASA that are not abandoned or lost (see **Exhibit 1** and **Appendix D**). All wells not sealed are required to report total pumpage, water levels, and salinity to the CWRM monthly as defined under HAR 13-168-7. Most of the ground water data comes from well sources within 3 miles of the coast in the Kama‘ole ASA.

The historical pumpage for the Kamaʻole ASA is summarized in **Exhibit 9** and **Appendix F**. Similar pumpages for ʻĪao (**Exhibit 10/Appendix G**), Waiheʻe (**Exhibit 11/Appendix H**), and Haiku (**Exhibit 12/Appendix I**) ASAs are included in this section as these aquifers would provide potable water for MMP via the MDWS CMS as specified in the MDWS 2023 Maui Island WUDP.

Although the MDWS CMS does not have any sources in the Waikapū ASA, pumpage information is also included as it is also a potential future alternative source for potable water (**Exhibit 13/Appendix O**). Additionally, scenario 3 of the numerical modelling efforts [26] by MDWS and USGS show that Waikapū ASA could be pumped as high as 4.117 Mgd, while the ʻĪao ASA is pumped to ground water use permit allocated amounts of 19.064 Mgd and Waiheʻe ASA is pumped to 5.039 Mgd with chlorides remaining below the EPA secondary guidelines of 250 mg/l in all modelled production wells with the exception of 1 source (see **Exhibit 14).**

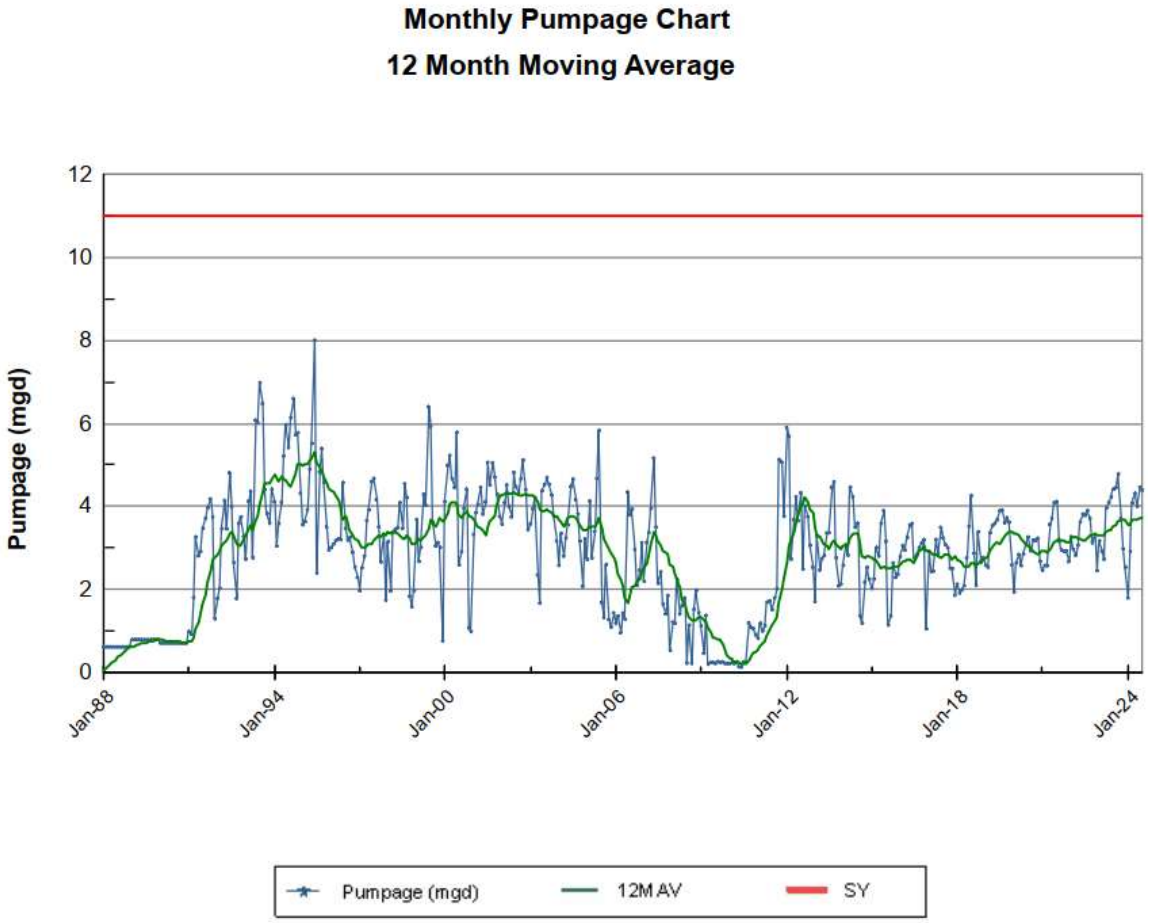

Exhibit 9. CWRM Historical Kama‘ole ASA Pumpage as of January 2025 (See **Appendix F**)

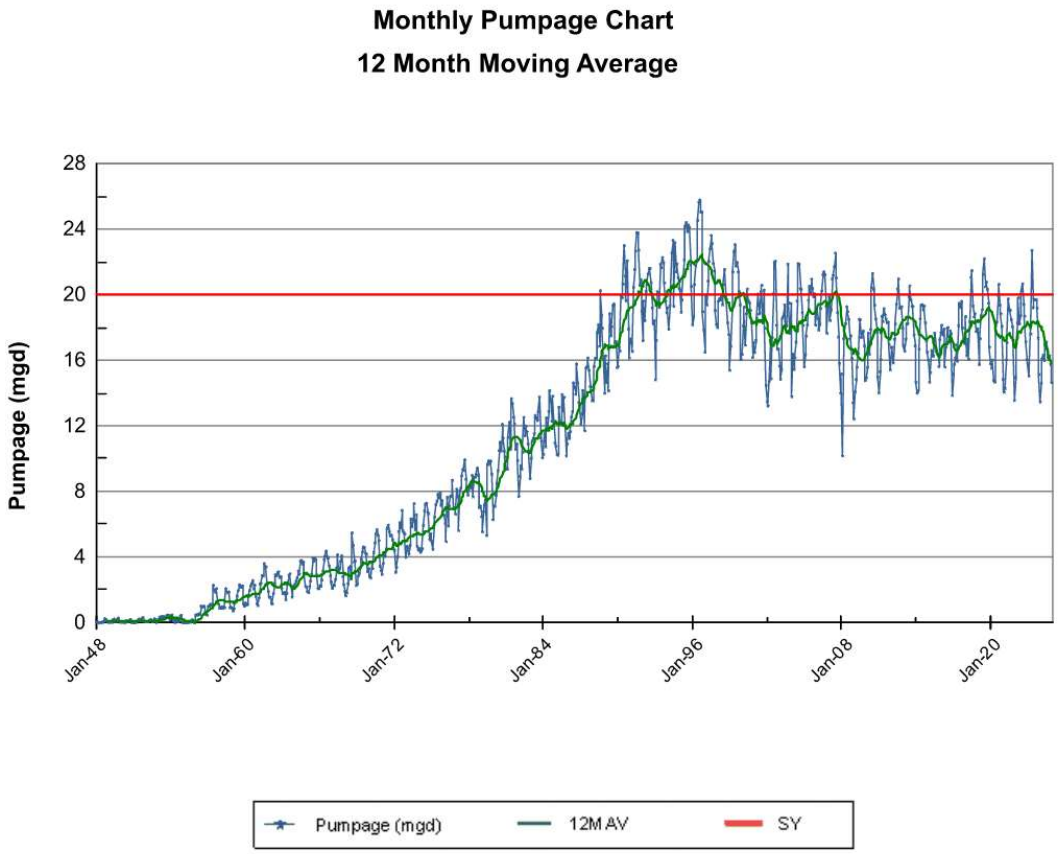

Exhibit 10. CWRM Historical ʻĪao ASA Pumpage as of January 2025 (See **Appendix G**)

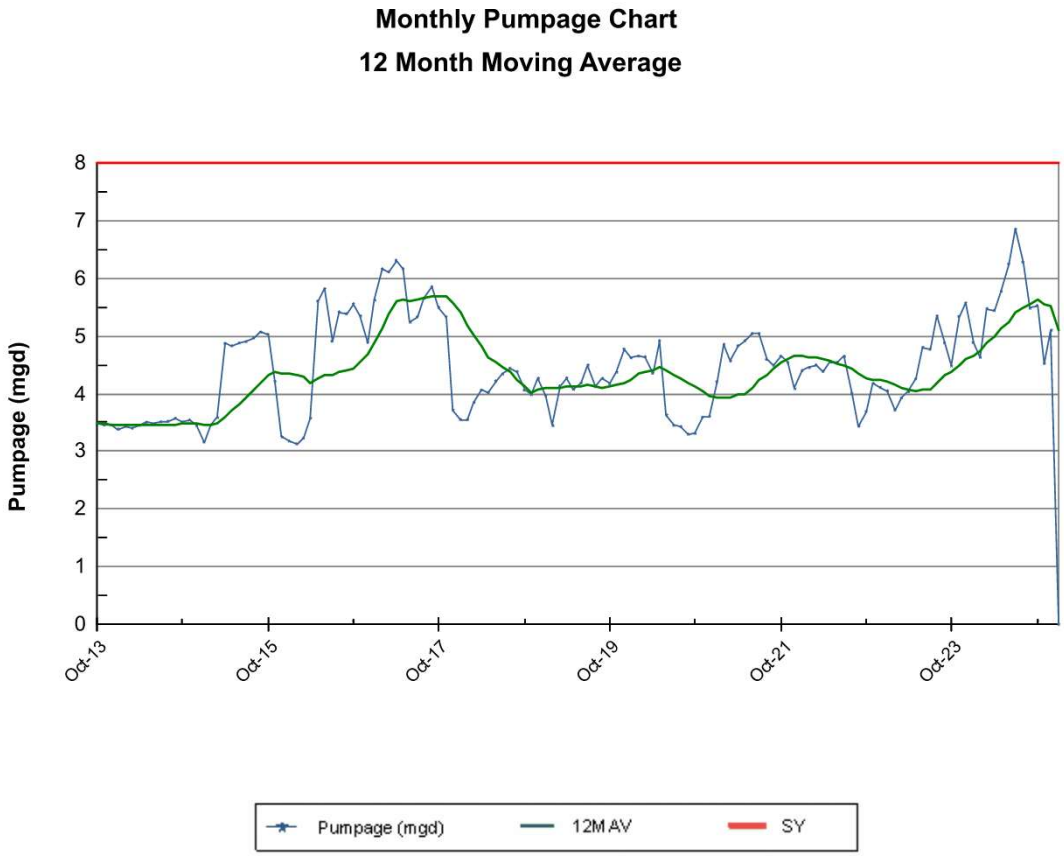

Exhibit 11. CWRM Historical Waiheʻe ASA Pumpage as of January 2025 (See **Appendix H**)

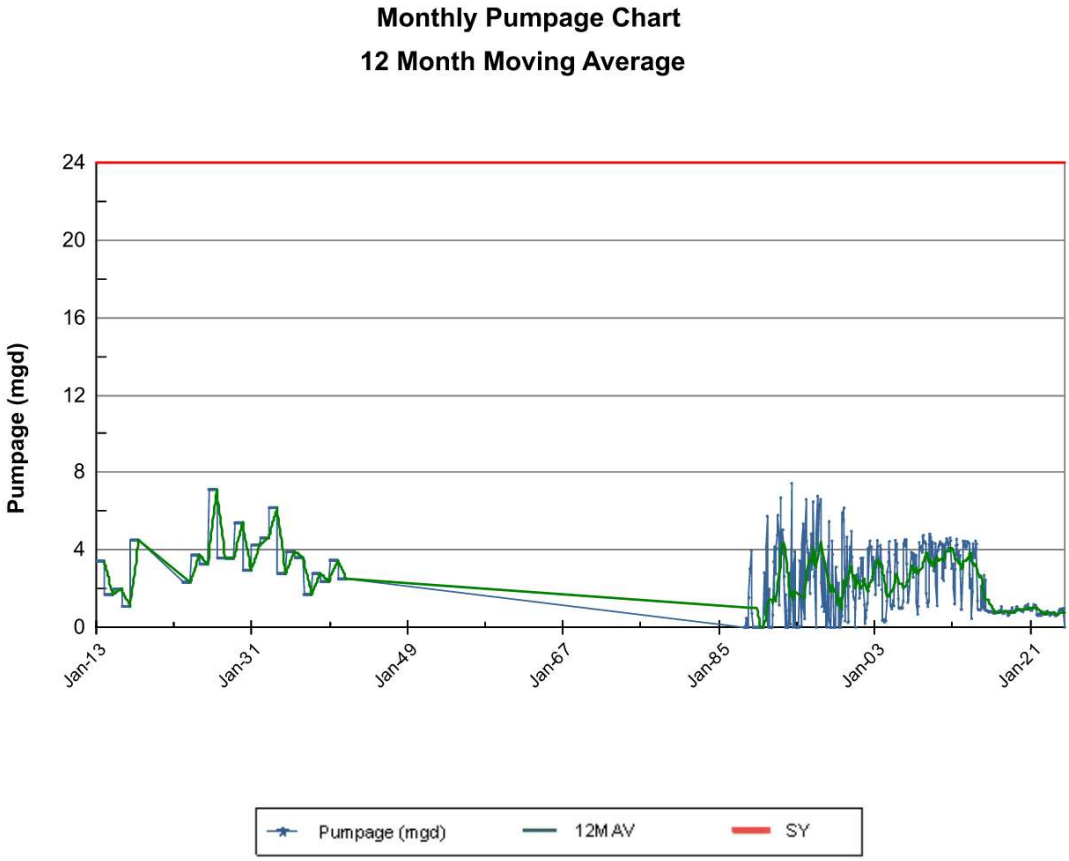

Exhibit 12. CWRM Historical Haiku ASA Pumpage as of January 2025 (See **Appendix I**)

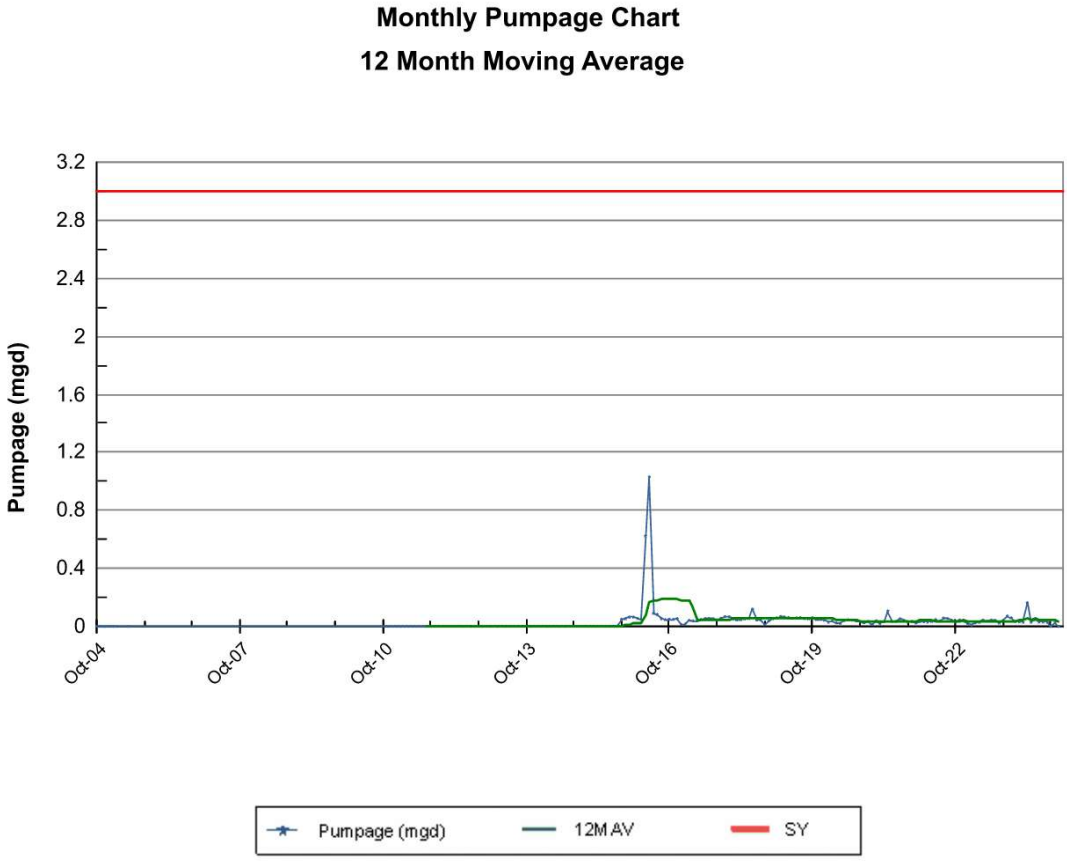

Exhibit 13. CWRM Historical Waikapū ASA Pumpage as of January 2025 (See **Appendix O**)

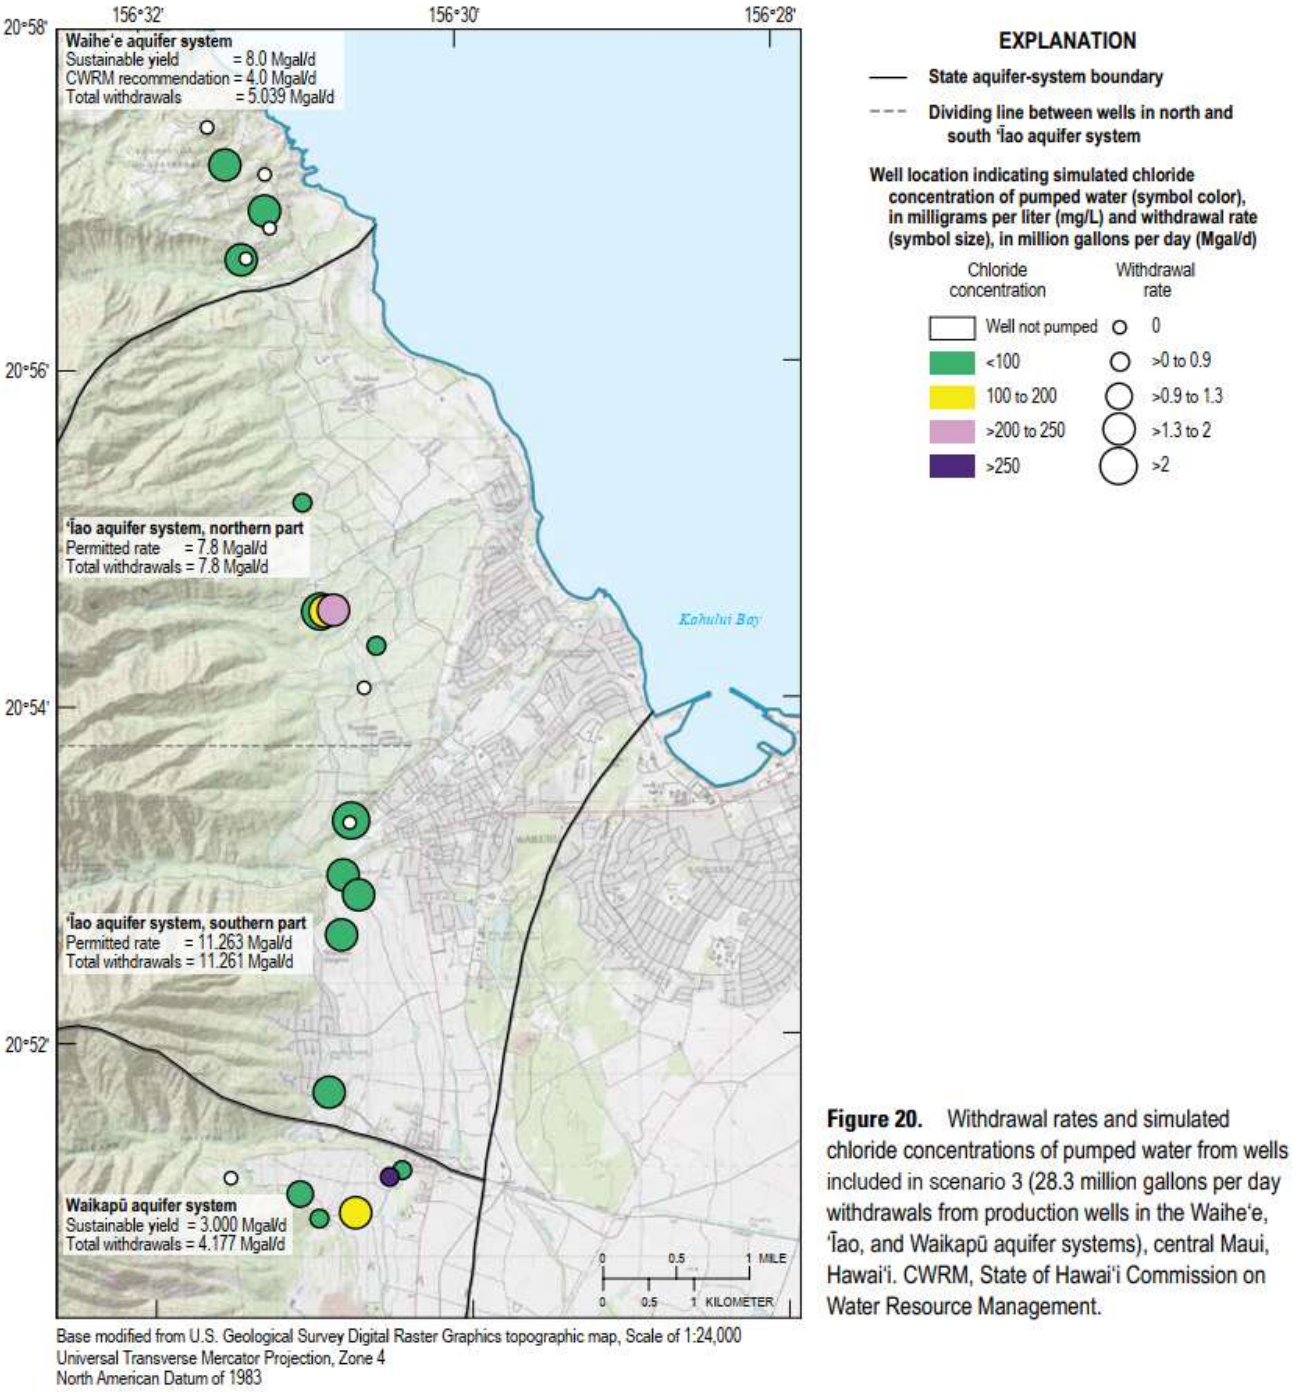

Figure 20. Withdrawal rates and simulated chloride concentrations of pumped water from wells included in scenario 3 (28.3 million gallons per day withdrawals from production wells in the Waihe'e, 'Īao, and Waikapū aquifer systems), central Maui, Hawai'i. CWRM, State of Hawai'i Commission on Water Resource Management.

Exhibit 14. Fig 20. from MDWS/USGS Numerical Model Scenario 3 Chloride Results [26]

The CWRM tracks total pumpage against SY by using the 12-MAV to protect the ASA based on current pumpage. The 12-MAV is a rolling 12-month period such that at any particular month the previous 11 months of pumpage are made part of the average to cover complete annual seasonal variations. **Table 3** is a summary of the current pumpage vs. SY in Kamaʻole, ʻĪao, Waiheʻe, Haiku, and Waikapū ASAs.

Table 3. SY vs. Pumpage

	Mgd					
ASA[1]	Recharge Range	SY[2]	12-MAV[3]	Unused SY	% SY Used	As of WUR Date
Kama'ole	24-37	11	3.805	7.195	35%	12/31/2024
ʻĪao [4]	15-42	20	13.157	6.843	66%	12/31/2024
Waiheʻe [5]	12-30	8	5.518	2.482	69%	12/31/2024
Haiku	54-61	24	0.837	23.277	3%	12/31/2024
Waikapū	6-18	3	0.037	2.968	1%	12/31/2024
Total	111-188	66	22.517	43.483	34%	

Notes:

[1] ASA = Aquifer System Area, which is a CWRM ground water hydrologic unit as defined in the 2019 WRPP

[2] SY = Sustainable Yield as defined by HRS 174C-3, 31(i)(2), & 2019 WRPP

[3] 12-MAV = 12-month moving average for non-caprock sources which do not count against SY, including high-level dike sources

[4] ʻĪao is a designated ground water management area where the SY is an alternative minimum due to data record, multiple deep monitor wells, RAM2, and a numerical ground water model developed and used by the USGS and MDWS.

[5] Waiheʻe has an alternative minimum SY due to data record, a deep monitor well, RAM2, and a numerical ground water model developed and used by the USGS and MDWS.

The current 12- MAV pumpage from the Kamaʻole ASA as of January 2025 is 3.805 Mgd (see **Appendix F**), which is 7.195 Mgd lower than and using only 35% of the Kamaʻole ASA's 11 Mgd SY (or 10-15% of the recharge range). Thus, based on actual use it would appear there is ample ground water available for reasonable and beneficial uses within the Kama'ole ASA at this time. It is important to note that the CWRM approved a reservation of 2.547 Mgd to DHHL from the Kama'ole ASA on September 18, 2018 for potable needs and this should be considered as future pumpage against the SY. The DHHL reservation raises the authorized planned use in the Kama'ole ASA to at least 58% of the 11 Mgd SY, which indicates that the utility of the Kamaʻole ASA ground water

is still not threatened and could provide reasonable and beneficial irrigation water on a sustainable basis.

Water levels in the Kama‘ole ASA range up to approximately +10 ft above mean sea level (msl) but most recorded water levels are under +5 ft msl (see **Appendix D**). Near and within the project area water levels are expected to range between 1-3 ft above mean sea level. Unfortunately, monthly water-level reporting is not as robust as monthly pumpage reporting and there is little reporting from most wells in the Kama‘ole ASA including observation monitor wells of: 1) USGS Observation Wells Kihei Fire Well Nos. 6-4427-006 to 008; 2) Kalama Beach Well Nos. 6-4327-008 to 010; and the 3) County Observation Kihei Injection Well No. 6-4426-001 (personal communication with CWRM staff).

CWRM staff directly collect water-level data from the more inland Waiohuli Observation Well No. 6-4422-001 (see **Exhibit 15**). The USGS drilled the well and recorded water levels between +6 to +5 ft msl from 2001 to 2003 [27]. This indicates a decreasing trend of 0.07 ft/yr over the past 23 years.

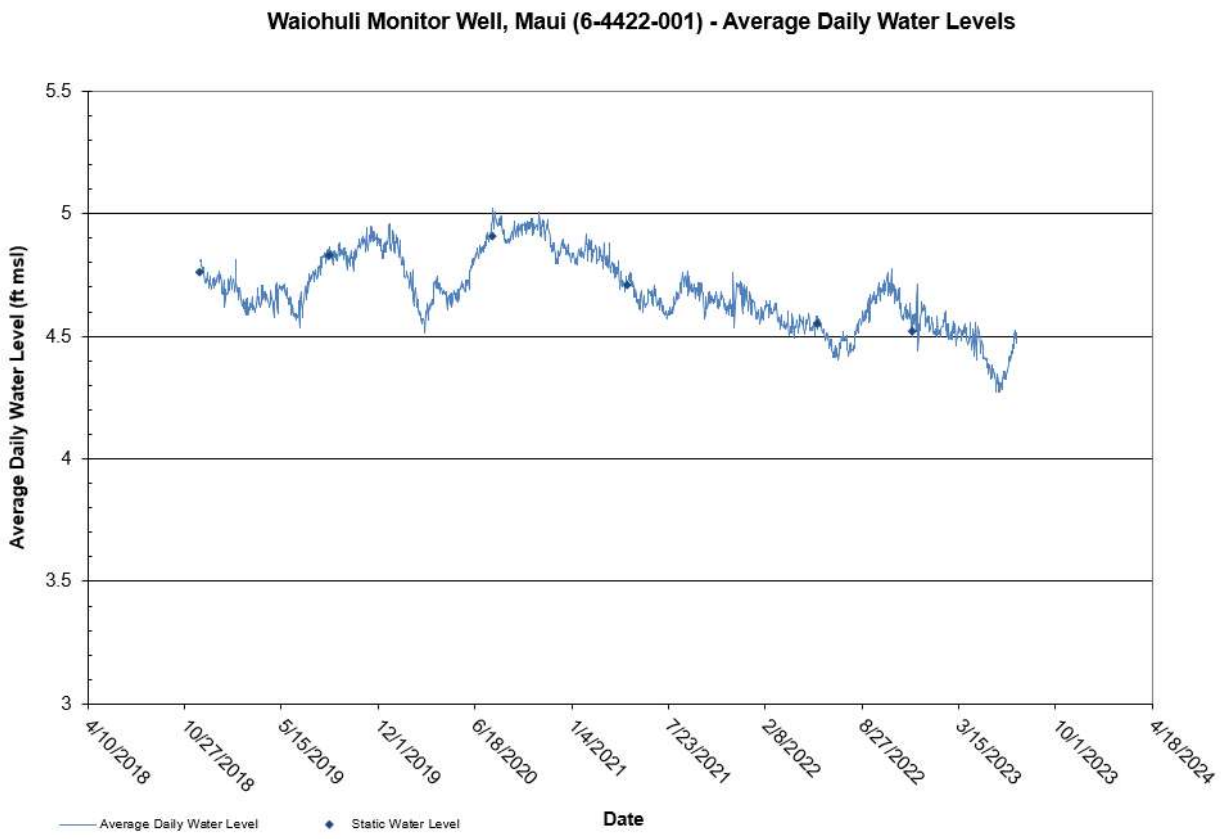

Exhibit 15. CWRM Waiohuli Monitor Well Water-Level Data through July 2023

The trend may be due to larger hydrologic changes from island wide climate change, diminished importation of surface water from East Maui into the Upcountry Maui Irrigation System and the adjacent Makawao, Pāʻia, and Kahului ASAs, the closure of HC&S Sugar operations in 2016, or a cumulative impact from all these events.

CWRM has collected data (**Exhibit 16**) for Maui Meadows Observation Well 6-4225-001, which is a more proximal observation well just under a mile north of the MMP (see **Exhibits 1 & 2**). Water levels are lower at this site as it is nearer to the coast, and it has a similar trend to Waiohuli (**Exhibit 15**) since 2020 except for a significant rise during the summer.

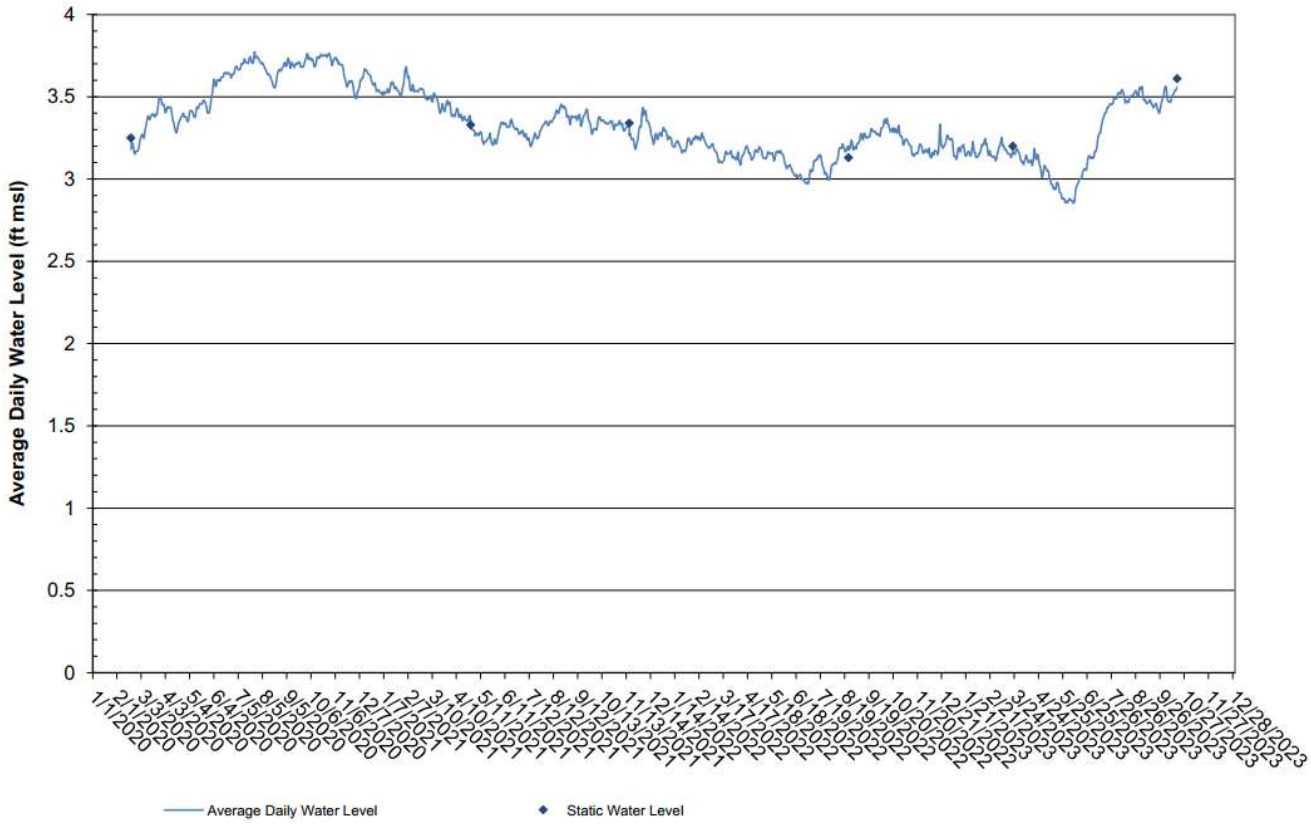

Exhibit 16. CWRM Maui Meadows Monitor Well Water-Level Data January 2020 through July 2023

It is highly unlikely that pumping from the existing and new well sources near the coast in the MMP vicinity would have any impact towards the inland area of the Kama‘ole ASA. Instead, once a commensurate amount of coastal discharge is captured by irrigation pumpage near the coast, water-level impacts will cease to extend inland within the Kama‘ole ASA from the MMP irrigation well sources. Given the Kama‘ole ASA shoreline is 16.6 miles long, uniform coastal discharge estimates would range between 1.446 to 2.229 Mgd/mile based on recharge estimates (see **Table 3**). At this rate, the natural discharge along the MMP coastline (5 miles) would be approximately 7 to 11 Mgd. However, assuming uniform coastal discharge, the SY of the Kama‘ole ASA would suggest that ground water discharge along the MMP coastline should be limited to a total of 1.79 Mgd, or 30% to 46% of the recharge range of the natural ground water

coastal discharge to the area.[9] As of January 2025, the reported actual 12-MAV pumpage from wells within and mauka of the MMP coastline is 0.844 Mgd (see **Appendix R**), which suggests current localized pumpage at the MMP is currently within sustainable localized coastal discharge limits. Even so, spreading out the distribution of localized pumpage stresses north and south of the MMP to minimize further impacts on water levels, chloride concentration, and coastal discharge would be good management practice.

Some of the irrigation pumpage will also have mitigated impacts due to return-irrigation recharge contributions back to the aquifer; however, efficient irrigation practices would limit return irrigation by avoiding overwatering. Soil-moisture-sensor based irrigation is one example of efficient irrigation that while promoting efficient use of water would reduce return-irrigation recharge benefits to the aquifer.

Much of the ground water chloride and water-level data in the Kama‘ole ASA comes from well sources within 3 miles of the coast where most have chloride concentrations that exceed the U.S. Environmental Protection Agency (EPA) Secondary guideline of 250 mg/L (https://www.epa.gov/sdwa/secondary-drinking-water-standards-guidance-nuisance-chemicals). The initial chlorides encountered from wells within the MMP and outside the MMP owned by Wailea Golf Course averaged 536 Mg/L, showing these wells are naturally brackish and making the utility of the Kama‘ole ASA as an irrigation water supply near the coastline (see **Appendix D**).

Despite the brackish nature of wells in the vicinity of MMP, saltwater upconing and intrusion are still concerns to maintain the irrigation utility of ground water wells as the upper tolerance limit for most plants is generally 1,000 mg/L and well depths and pumpage rates will need to follow the CWRM’s 2004 Hawai’i Well Construction and Pump Installation Standards (HWCPIS [28]). The two major protection components of the CWRM 2004 HWCPIS are: 1) limits the depth of new wells to ¼ the depth of the

[9] The Kama‘ole ASA RAM D/I, or simply pumpage to recharge, ratio of 44% used to calculate SY lies within this range and shows that a minimum of 54% to 70% ground water discharge would always continue to ocean under the current 11 Mgd SY limit.

basal lens based on the original water-level encountered during the initial well construction and 2) well (step-drawdown) and aquifer (long-term) pump testing. The average of reported initial water-levels encountered by 20 wells within the vicinity of the MMP (see **Exhibits 2 & 3** and **Appendix D**) is approximately +2 ft above mean sea level (msl). Thus, new wells drilled should anticipate a drilling depth limit of approximately -18 ft msl to keep the bottom of the well bore sufficiently above the transition zone to protect against upconing. The pump tests to assess water level and chloride changes are predicated on the size of the pump to be installed. However, well pump capacities below 50 gallons per minute (gpm) do not require testing as the impacts from these capacities are generally less than natural tidal and barometric variation and impacts to ground water-levels and changes to chlorides at this pumping rate are rarely observed.

4.3.4. Ground Water Contamination Concerns

The State of Hawai'i (SOH) Department of Health Groundwater Protection Program Safe Drinking Water Branch (DOH SDWB) provides groundwater contamination maps through their online viewer located at https://health.hawaii.gov/sdwb/groundwater-contamination-viewer/. The intent of these maps is to identify only those wells with current detectable levels of groundwater contamination as shown in **Exhibit 17** for the island of Maui with the MMP area.

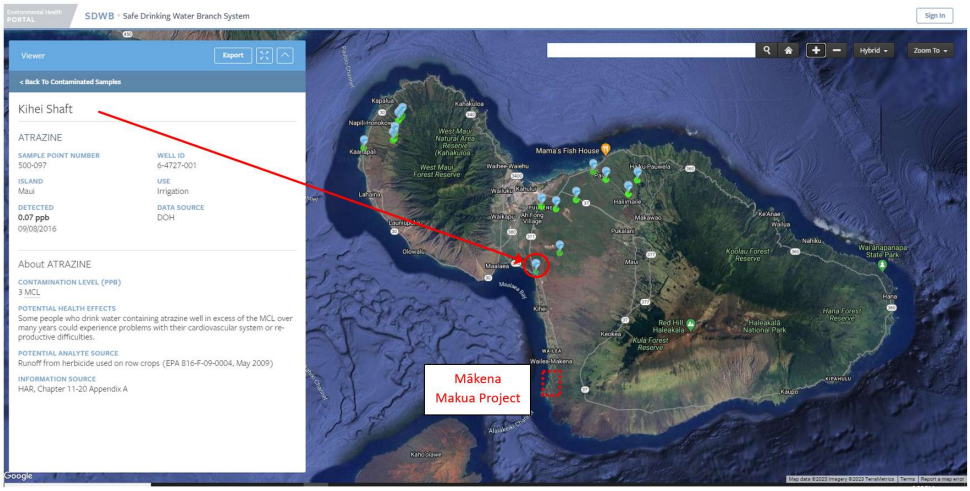

Exhibit 17. DOH Groundwater Contamination Map
(source: https://eha-cloud.doh.hawaii.gov/sdwb/#!/viewer)

There are no reported contaminants in the MMP area or the Kama‘ole ASA. The closest detect has been 9 miles north of the MMP at the Kihei Shaft (Well No 6-4727-001) owned by Alexander & Baldwin, Inc. for the herbicide atrazine. The 2016 0.07 ppb detection is under the 3-ppb maximum contaminant level (MCL), from this irrigation well.

However, there are concerns regarding elevated levels of nitrate and nitrite, ortho-phosphate, turbidity, and chlorophyll α based on a 2024 annual water quality monitoring report for the Client by AECOS, Inc. [29]. The AECOS report recognizes that outbreaks of excessive amounts of algae off West Maui have been attributed to elevated concentrations of both dissolved inorganic nitrogen (DIN) and inorganic phosphorus (DIP) in sewage effluent injected into groundwater and migrating to nearshore waters but that no such algal outbreaks have been recorded for nearshore waters off the MMP area.

The AECOS report states that the nutrients in groundwater near Mākena have two possible origins: (1) a remote source: present in groundwater that originates upslope of the resort and that can be measured in well water; and (2) a local source: seepage of MG&BC excess irrigation water into the groundwater [29]. There are no

cesspools in the immediate area around the MMP (see **Appendix J**) that would be a source concern of nutrient or microbiological ground water contamination. However, the two to three annual discharges of R-2 effluent into the unlined basin (See Section 3.6.1) may be a source of nutrient contamination.[10] MMP intends to be sewered to its own privately owned and maintained Mākena Wastewater Reclamation Facility and while there is no current estimate of wastewater demands; a preliminary engineering and drainage report (PEDR) will be prepared to assess the wastewater needs of the project .

Finally, it should be acknowledged that pumpage from current and future wells within and around the MMP should reduce the mass loading of nutrient contamination to the aquifer so long as good irrigation and fertilization practices are followed (See **Appendix K** for DOH guidelines).

4.4. Surface Water Availability and Impacts

4.4.1. Occurrence of Surface Water in the Wailea and Mo‘oloa SWHUs

The MMP lies within the Wailea SWHU (6110) and Mo‘oloa SWHU (6109) drainage area of the greater Kahikinui Region (see **Exhibit 18**).[11] It is one of thirty-five drainage areas in the region and covers an area of 35.76 mi^2. The Intermittent riverine of Keawakapu transect the MMP mauka to makai is within the Wailea SWHU (see **Exhibit 3**). This is not a significant source of surface water and will be left undiverted.

[10] R-2 effluent is recycled water that has been oxidized and disinfected to remove contaminants making the resuse water available for landscape irrigation such as landscape, golf course, parks and certain agricultural crops.
[11] The Wailea SWHU (6110) and Mo‘oloa SWHU (6109) as defined in 2019 WRPP [4] and is shown in Exhibit 1.

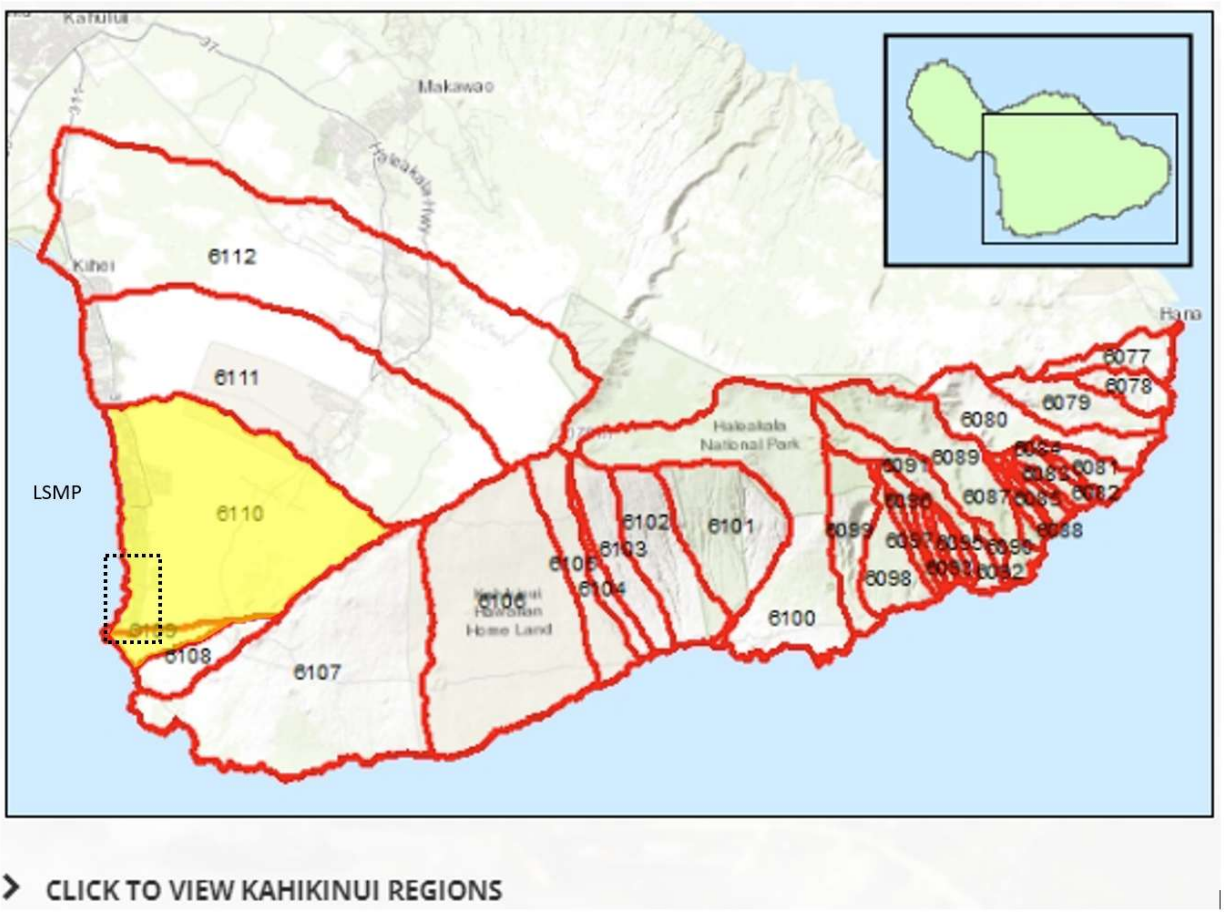

Exhibit 18. CWRM Wailea and Mo'oloa SWHU, Kahikinui Region
(Source : https://dlnr.hawaii.gov/cwrm/surfacewater/ifs/maui/)

4.4.2. Interim Instream Flow Standards

The CWRM has the duty to reasonably protect instream flows. This is done through interim and permanent instream flow standards (IIFS & IFS) that identify minimum flows that must pass through a specific point or reach of a stream.

There are no Instream Flow Standard Assessment Reports (IFSARs) available from the CWRM for any of the Kahikinui Region of the dry leeward side of Haleakalā including the Wailea Watershed/SWHU (6110) and Mo'oloa SWHU (6109). Based on communications with CWRM staff, there are no pending plans to do IFSARs or update

IIFSs since streams are historically intermittent in this dry area. Further, the USGS has no surface water monitoring stations in the region.

Like ground water, an uncertainty to consider related to climate change is that results from USGS Oki study [16] show that long-term stream baseflow trends have been declining since 1913 – 2002 statewide. This will impact surface water availability more than ground water as ground water has much greater storage capacity in aquifers. Although it shows a significant decreasing trend in streamflows statewide from the 1940's, the report itself also concludes further study is needed to see if this observation may be part of a long-term cycle that may return to a wetter period similar to the years between 1913 and 1940's. Since the MMP is already in a dry area with no perennial streams this is likely to have insignificant impacts on the area with respect to water availability and IIFS/IFS.

4.4.3. Diversions

According to CWRM, there are four surface water diversions with no declared water uses that were registered with CWRM within the Wailea and Mo'oloa SWHUs [30] [31]. These diversions identified by CWRM are approximately 8-11 miles mauka upcountry with locations shown in **Exhibit 19**. These divert surface water from Waihou (1116), Waikaalu (1117), an unmapped spring on Ulupalakua Ranch (1118), and Polipoli (1075) springs. There are seven other ground water tunnels near these diversions not shown **Exhibit 19** but listed in **Appendix D** and are identified as the Cornwall Tunnel (4020-002), Waikaalu Spring (3920-002), Polipoli Tunnel (4019-001), Morton Tunnel (4020-003), Waihou Spring (3921-001), Waikaukane Tunnel (4020-001), and Waikaahi Tunnel (4021-001) that may be confused with these four surface water springs. No reported flows from these diversions or tunnels have been made to the CWRM for irrigation and livestock watering and some domestic supply for remote camps.

Given the distance and non-reporting of flows, the MMP is not expected to impact these registered mauka diversions.

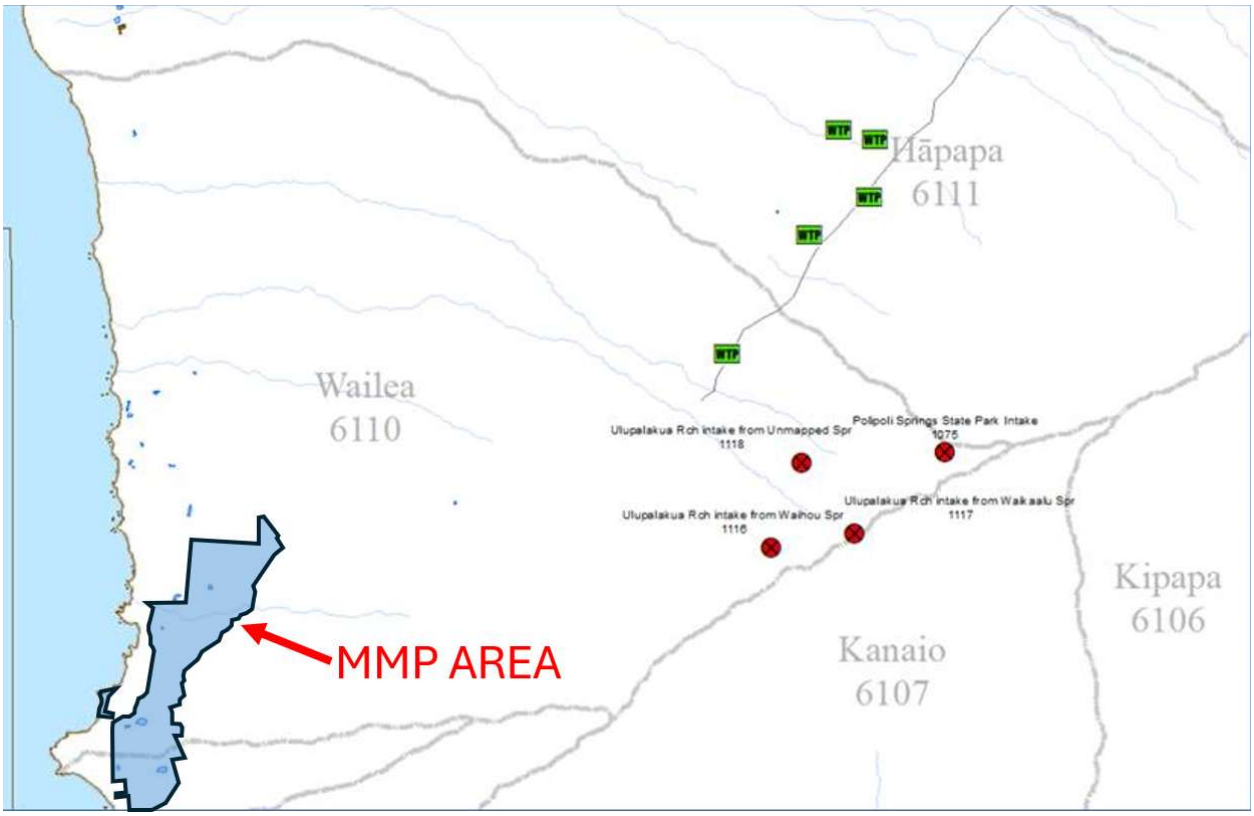

Exhibit 19. CWRM Wailea SWHU, Registered Diversions

4.4.4. Springs and Wetlands

Naturally occurring artesian springs and wetlands are considered surface water under the CWRM management (174C-3, HRS & 2019 WRPP [4]). There are significant wetlands of interest 0.8 to 5.4 miles north of the MMP from Auhana Road to the intersection of Pi'ilani Highway where there exists Kealia Pond and streams and wetlands in what is called the Kula Kai Area. [12,13] However, there are no anticipated impacts from the MMP on these northern drainage areas.

[12] Approximately 6 miles north of MMP in the Kahului ASA (60301).

[13] Beginning approximately 1.5 miles north of MMP with 13 ephemeral and intermittent streams (Keahuaiwi, Waiakoa, Ohukai, Kulanihakoi, Ko'ie'ie, Waiohuli, Waipuilani, Kawililipoa, Lā'ie, Kēōkea, Waimahaihai, Kīhei, Kaluaihakoko) (see https://savethewetlands.org/south-maui-gulches-and-streams/). None of these are monitored by the USGS streamflow data network.

Further review of published reports from the USGS [9] [10] and DLNR [32] and other professional hydro-geologist reports [33] [34] did not reveal significant springs in or near the MMP though the presence of small seeps is mentioned. A 2016 Master of Science Thesis using thermal imaging to locate significantly cooler coastal discharge indicated a significant spring source visible at low tides inside the southern corner of Kihei Boat Harbor, which is on the north side of the MMP; otherwise, there were no significant plumes revealed [35].

Further research of older published reports of from the USGS [9] [36] and DLNR [37] and other professional hydro-geologist reports [33] [34] for the Mākena area did not reveal significant springs in or near the MMP though the presence of small seeps along the coastline near sea level is mentioned in the 1969 Bowles reports. Bowles reported: "*On April 4 and 5, a traverse was made along the coastline from Keawakapu to Makena. Water samples and temperature data were collected in order to further delineate ground water flow through the property. The traverse as made between 11 a.m. and 12 noon during the lowest stage of the diurnal tides for that month. No large basal springs were located, however, numerous small seeps were found.*" Seeps are slow and intermittent while springs are faster continuous flow. Since the project is located near or above the 100-ft contour elevation and the seeps are near sea level, it is not anticipated that any land or excavation disturbances in the project area would impact these coastal seeps.

A more recent 2016 Master of Science Thesis [35] using thermal infrared imaging in conjunction with radon monitoring spatially located submarine discharge anomalies to qualify submarine groundwater discharge (SGD) on regional and local scales. On the regional scale, significant SGD was observed beginning 3 miles north of the Wailea project area in Ma'alaea Bay Kihei and 3.3 miles south of the project in Ahihi Bay and increasing towards the Ahihi-Kinau Area Reserve (see **Exhibit 20**). Therefore, regional scale anomalies indicate less potential for significant SGD in the MMP area. However, on the smaller local scale the study did observe a significant cooler plume visible at low tides inside the southern corner of the Kihei Boat Ramp (see **Exhibits 20 &**

21). This cooler plume is on the north makai corner of the MMP area but appears to be significant only during low tides and could be classified more like a large seep since the flow seems to be dependent on the tides. It is not known if this is a natural source or was created or modified by the construction of the boat ramp. Also, it is known that water from boat washing discharges into the area of the plume and may be related to the temporary cooler water spot observed. Regardless of the origin, this potential spring source seems to flow only at low tides and when the higher hydrostatic pressure from high tides exists and diminishes the cooler water anomaly. Otherwise, no other significant plumes were included in this reference or revealed in the MMP area.

Based on published hydrologic reports it is anticipated there will be little to no impact on springs, wetlands, and coastline seeps from the MMP

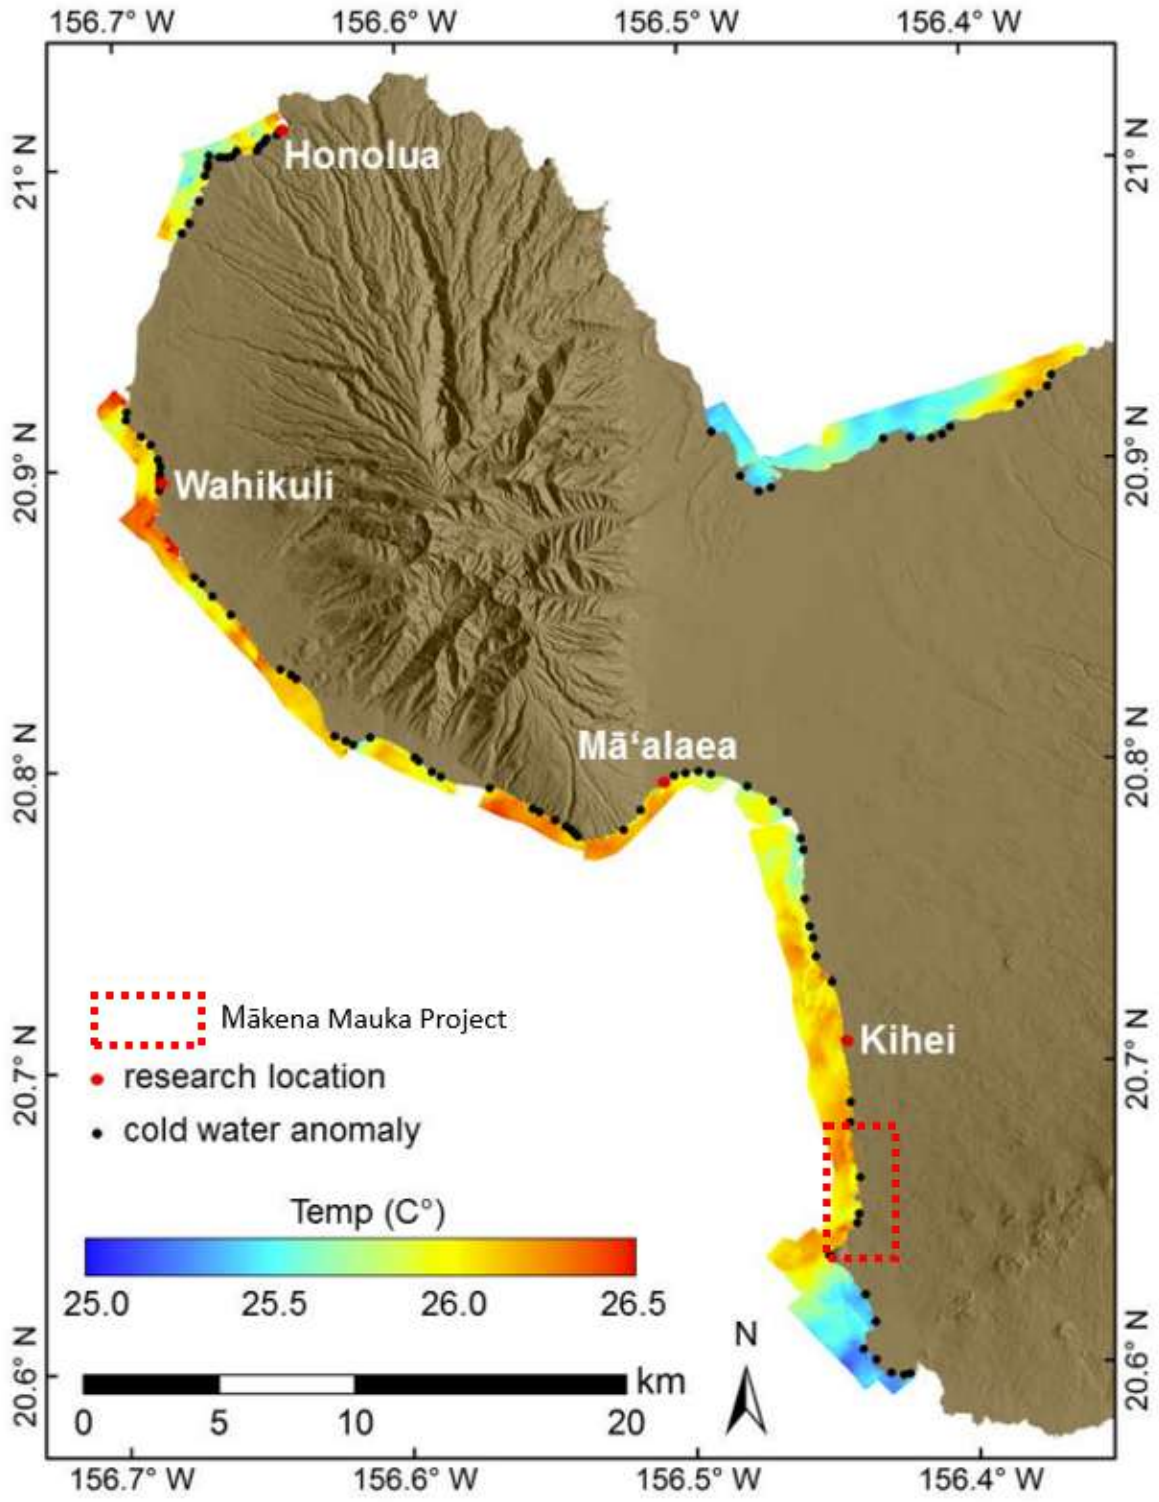

Figure 8: Regional scale TIR imagery of Maui obtained 07-08 June 2014 showing locations of potential SGD.

Exhibit 21. Local Thermal Imaging of Potential SGD at Kihei Boat Ramp (Fig 10. from Kennedy, [35])

4.4.5. Surface Water Quality Issues

The State Department of Health, Clean Water Branch (DOH CWB) and U.S. Army Corp of Engineers (USACE) are the responsible entities in regulating surface water quality issues statewide under the Clean Water Act. There are 19 active National Pollutant Discharge Elimination System (NPDES) permits within the Kamaʻole ASA [38].

The main concern for surface water quality is runoff from storm events where contaminant concentrations increase. The proposed MMP is not expected to significantly add to nutrient loads in surface water during storm events given 1) the MMP's relatively small size relative to the overall drainage area, 2) the use of LEED certification in individual MMP design and maintenance, and 3) compliance with the County's recent stormwater quality runoff regulations.

4.5. MDWS CMS

Figure ES.3 Wailuku and Central Aquifer Sectors, Maui Department of Water Supply Central Maui System

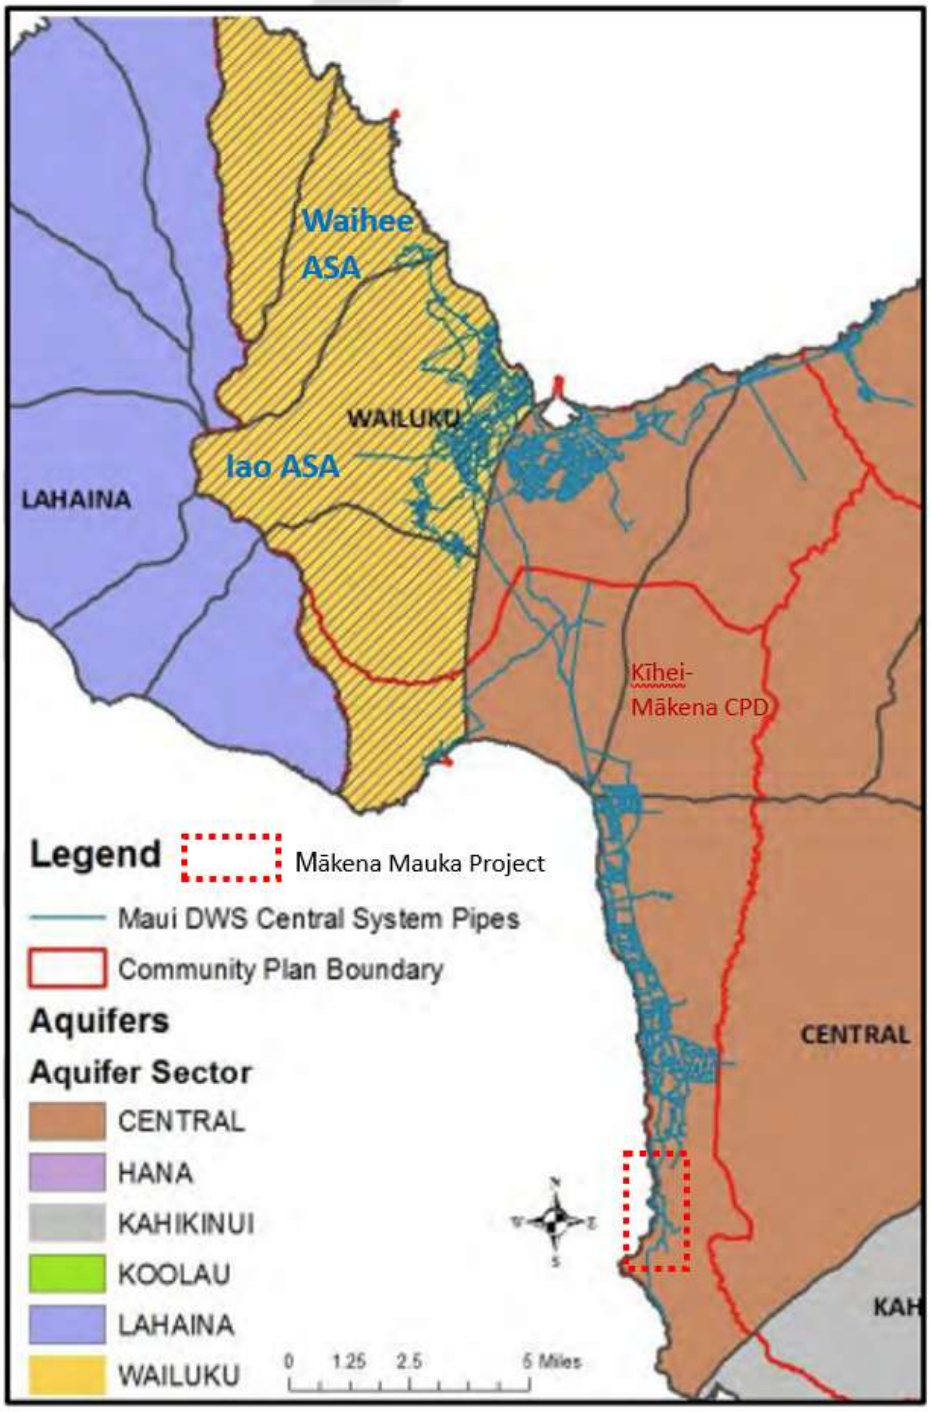

Exhibit 22. MDWS CMS (PWS 212) (modified from Maui Island WUDP [1])

Exhibit 22 is a source and transmission map detailing the general areas served by the MDWS CMS. The MDWS CMS provides ground and surface water for both potable and non-potable needs in and or from the ASA of Haiku (60401), Pāʻia (60302), Kahului (60301), Waiheʻe (60103), ʻĪao (60102), Waikapū (60101), and Kamaʻole (60304). These hydrologic unit areas historically and currently closely entwine water imports and exports between these areas. Surface water sources from ʻĪao and Waiheʻe also contribute to the CMS. There are no MDWS sources in the Kamaʻole ASA, but the area is dependent on the CMS for its potable needs.

The MMP is part of the MDWS CMS service area having been one of the original partners (along with MDWS and others) in bringing the transmissions lines from Central to South Maui, later building three MDWS water tanks to service Wailea, and installing all MDWS water distribution lines to the MMP parcels.

4.5.1. CWRM ʻĪao Allocations

Since the MMP plans to obtain around 7golffdd% of its maximum/peak day water demands (0.092 Mgd) from the MDWS CMS while exploring other source options as discussed, ground water use permits (GWUP) that limit the 12-MAV pumpage from individual wells in the ʻĪao ASA (60102) GWMA (see **Exhibit 10**) are relevant to the MMP and are discussed in this section.

There are currently fourteen (14) wells under twelve (12) basal ground water use permits (GWUPs) for a total allocation of 19.089 Mgd (see **Appendix L**) in the ʻĪao

GWMA.[14] Therefore, 0.911 Mgd is currently available for allocation from the basal ʻĪao GWMA.

If more ʻĪao ASA ground water allocation is required by MDWS for the MMP then a ground water use permit application (GWUPA) must be submitted by MDWS. However, according to the CWRM January 2, 2025, Monthly Bulletin (**Appendix M**), there are five (5) pending GWUPAs totaling 0.982 Mgd, the bulk of which is MDWS' GWUPA 852 for 0.841 Mgd from the high-level Kepaniwai Well (5332-002), which would not count against SY. Therefore, there are four (4) pending requests totaling 0.222 Mgd that can be accommodated by the currently available 0.911 Mgd from the ʻĪao GWMA.

Also, four (4) of these applications have been pending for more than 8 years with no clear movement forward, while the recently published GWUPA 1187 for a county park irrigation water from a new well has been requested. Even MDWS's GWUPA 852 path forward is not addressed in the MDWS Maui Island WUDP. However, GWUPA 852 could be amended and moved forward for CWRM consideration without having to wait for the other long-pending GWUPAs. Regardless of the status of all the published pending GWUPAs for ʻĪao there is sufficient allocation available for the MMP from the ʻĪao GWMA should all these pending applications be approved as requested.

A flowchart of the GWUPA process can be found at the CWRM website at https://files.hawaii.gov/dlnr/cwrm/forms/dgwup.pdf. It is statutorily a 90- to 180-day process to appear before the CWRM for decision making but has proven to be very contentious and takes much longer, as is shown in the CWRM Monthly Bulletins.

MDWS appears to be managing their current GWUPs in ʻĪao adequately. Actual reported pumpage from the ʻĪao ASA basal and high-level dike areas as of June 2024, is currently 16.395 Mgd based on a 12-MAV, which is 3.605 Mgd below the 20 Mgd SY for the ʻĪao ASA and 2.694 Mgd below the current total non-caprock allocations that count

[14] Three (3) allocations from high-level sources currently do not count against the ground SY as they were instead combined with and considered for impacts to interim instream flow accounting by virtue of the CWRM decision and order from Na Wai Eha CCH MA0601-1 for GWUP 691: ʻĪao Tunnel (Puako) 5330-002 and GWUP 920 ʻĪao Tunnel (Kepaniwai) 5332-005 & GWUP 921 Kepaniwai well 5332-005. This may change in future CWRM decisions.

against SY. This is in part due to conservation efforts of the MDWS where metered water use in the CMS has declined by over 4% from 2006 to 2020 while water meters increased by 14% from 2006 to 2020 (based on MDWS annual reports) and by leak detection and water auditing analysis performed by MDWS.

Under HRS 174C-48, the CWRM must delegate to the county boards of water supply the authority to allocate municipal use of water within their distribution systems, subject to the limits of water supply allocated to the county boards of water supply in their role as water purveyors. Other non-MDWS allocations in ʻĪao ASA amount to 0.026 Mgd, leaving the MDWS with 2.688 Mgd of unused allocation that could be allocated within the MDWS CMS. Therefore, it would appear MDWS and the ʻĪao ASA alone have enough cushion between actual pumpage vs. allocated use to manage and provide for the MMP future needs within the MDWS current allocations, long-pending competing GWUPAs notwithstanding.

The CMSA is also serviced by other ASAs, primarily the Waiheʻe ASA (60103), which is pumping only 51% of its SY of 8 Mgd. Third, the MDWS 2023 Maui Island WUDP identifies the primary alternative source strategy for CMS, as well as MDWS Upcountry System, as developing more water from the Haiku ASA that is pumping only 3% of its 24 Mgd SY. MDWS is currently pursuing feasibility studies required under the East Maui Consent Decree to implement this source strategy.

The MDWS CMS also incorporates a single microfiltration surface water treatment plant, the ʻĪao Water Treatment Facility, which is currently able to produce an average of approximately 1.7 Mgd of drinking water from the ʻĪao-Waikapū Ditch. According to the Maui WUDP [1], MDWS plans to increase capacity of the treatment facility for wet season use and new capacity has already been added to treat up to 3.2 Mgd in the future to be consistent with the CWRM Na Wai Eha surface water allocations

totaling 3.2 Mgd.[15] The latest 12-MAV of reported use from for the ʻĪao-Waikapū Ditch as of August 2024 is 1.894 Mgd.[16]

Other alternatives are also available to relieve the need for additional allocation from MDWS CMS. MMP will also be designed to use County R-1 when it becomes available for non-potable needs. Conservation measures will be incorporated into the MMP development to continue and further the conservation efforts that have proven effective in the ʻĪao ASA by MDWS. Existing ground water sources in the project area may have additional capacity brought about by conservation of existing users. Lastly, new ground water sources could be drilled for non-potable uses to reduce the reliance on the CMS source or existing unused wells near the MMP for irrigation needs without impacting the Kamaʻole ASA. Thus, the MDWS CMS should be able to meet the future potable demands of the MMP within the current MDWS allocations, though supplementing the irrigation demands of the MMP through other non-potable sources would further lessen demand of the MDWS CMS.

4.6. Alternative Water Sources

Alternative water sources are those other than the available natural ground or surface water sources covered in Sections 3.3, 3.4, and 3.5 of this report.

4.6.1. Wastewater Reclamation Facilities (WWRF)

Presently, the Mākena WWRF does not produce R-1 quality effluent and the WWRF R-2 effluent discharges into an unlined basin two to three times a year. Discharge amounts varied from 50,000 gallons from the reuse tank to 96,000 gallons directly from the clarifier. In the past, the Mākena WWRF used to produce R-1 effluent that was pumped into No. 10 Lake, where it mixed with well water, and then was used

[15] The total of 3.2 Mgd consists of surface water use permits SWUP.2178.6 for existing uses of 1.784 Mgd & SWUP.2179.6 for future new uses of 1.416 mgd from the ʻĪao-Waikapū Ditch.
[16] As reported to CWRM from MDWS as of January 2025.

to supply water for irrigation purposes. So, this is an underutilized alternative water source.

Also, the Kīhei WWRF serves the South Maui area from Wailea to Sugar Beach with an R-1 production capacity of 8.0 Mgd (Table 14-20 [1]) but the average dry weather flow to the WWRF for FY2024 is only 3.831 Mgd. As of FY2024 it is estimated that 2.005 Mgd of excess R-1 is available. The MMP may be designed to use and accept any available County R-1 water for the new MMP parcels should they need to augment or replace their own Mākena WWRF reuse abilities.

4.6.2. New MDWS Infrastructure Supply

The only current MDWS CIP to increase the CMS infrastructure supply is a 0.5 Mgd Waiheʻe ASA Well by FY28. Current SY, pumpage and monitoring data from CWRM for the Waiheʻe ASA indicate that this should be a reasonable source though it must be monitored closely as more than one-half (1/2) total pumpage is concentrated in the southern half of the ASA.

Additionally, the ʻĪao surface water treatment plant has the potential to increase their current limited use of ʻĪao ditch water. Presently, MDWS is awaiting their official approved surface WUP from the Na Wai Eha Contested Cased Hearing (CCH-MA15-01) decision for 3.2 Mgd.[17] MDWS is presently limiting their use of ʻĪao-Waikapū ditch water to 3.2 Mgd on a daily basis but was hoping this 3.2 Mgd limit will be on the more flexible moving average annual basis. So long as the interim IIFSs are met there are times when more than 3.2 Mgd on a daily basis can be taken so long as the average annual remains below 3.2 Mgd. The moving average annual basis will allow MDWS to make use of high flows and get credit for when less than 3.2 Mgd can be diverted so long as the IIFS minimum is satisfied. For example, at times the treatment plant cannot take ditch water when ditch water turbidity is too high and must shut down to avoid

[17] See https://dlnr.hawaii.gov/cwrm/newsevents/cch/cch-ma15-01/

damage to the filtration system, yet this non-diversion event cannot be credited towards the average annual need of 3.2 Mgd. However, the Supreme Court issued an opinion in June 2024 and approved Na Wai Eha surface WUPs should be issued as prescribed by the CWRM on a daily rather than a 12-MAV basis.[18] To date, Na Wai Eha surface WUPs have not been issued.

4.6.3. Desalination

Brown and Caldwell (B&C) performed a desalination feasibility study for the MDWS in 2024, and the following information is a summary of their presentation at the 2025 Pacific Water Conference. B&C estimates that the MDWS CMS will need an additional 7-11 Mgd of water by 2040. They recommend three desalination sites in the Kama'ole ASA – two in the Kihei area and one in the Wailea area - using brackish groundwater as the source. Their suggested plant would be a 0.5 Mgd capacity (expandable to 2 Mgd) RO facility powered with solar energy and sited with a deep injection well to dispose of the brine waste. In terms of cost, the 0.5 Mgd facility is estimated to cost $119 million with annual operating costs of $2 million. The expanded 2 Mgd facility is estimated to cost $261 million with annual operating costs of $3 million. Both facilities would produce water at a unit cost of $25/1000 gallon. In comparison, MDWS single family dwelling monthly billing rates beginning at $2.13/1000 gallons for the first 5,000 gallons to a maximum of $8.12/1000 gallons for usage amounts over 35,000 gallons.

Maui Island WUDP identifies three crucial issues with desalination: 1) cost; 2) pesticide contamination in brackish source water for desalination; and 3) disposal of the reject brine water [1]. However, the Shores of Kohanaiki in Keauhou, Hawai'i has successfully addressed these issues. The Shores of Kohanaiki is an exclusive housing and golf course development like the MMP that desalts brackish ground water for golf

[18] See https://files.hawaii.gov/dlnr/cwrm/cch/cchma1501/2024-SCOT-21-0000581.pdf

course irrigation needs and injects the reject brine deep into saltwater below the thin brackish basal aquifer in the Keauhou ASA. It has been operating and monitoring ground water since 2007 without observing any negative impacts to the resource or marine environment.

MMP is planning to supplement all of their irrigation needs with 65% RO recovery desalination of brackish well water according to TNWRE [5] from their own water system. This would require them to pump a maximum/peak of 1.464 Mgd to supply 1.282 Mgd of potable and irrigation water demand (**Appendix N**). The report also estimates the generation of a maximum/peak of around 0.182 Mgd of concentrate from RO treatment at full build-out that would require disposal. The report states DOH's current position is that it cannot be reused for irrigation (though the mixing with brackish ground water could potentially be appropriate for golf course irrigation if DOH changes its position) and a disposal [injection] well would need to be installed for proper disposal [5].

4.6.4. Conservation

Conservation is considered an alternative source by using water more efficiently to reduce water demands and thereby increasing the availability of supply. Current conservation efforts by MDWS in the ʻĪao ASA have shown to be effective as the MDWS metered water use in the CMS has declined over 4% since 2006 to 2020 while water meters increased by 14% from 2006 to 2020 (based on MDWS annual reports). The 12-MAV for the ʻĪao ASA has declined by more than 17% from 2006 to 2023 based on reported pumpage to the CWRM.

Conservation is a recommended strategy for all regions serviced by MDWS for both agricultural and non-agricultural uses under the MDWS WUDP [1]. Additionally, MDWS recently adopted its Water Shortage and Conservation Plan (WSCP) [39] in April of 2024. The WSCP follows the American Water Works Association's (AWWA) guidelines of AWWA-M52 [40] for Conservation Planning and AWWA-M60 [41] for Drought

Preparedness and Response. The main long-term goal of the WSCP is an overall 20% reduction of per capita water demand by 2040 in all their service systems. This includes the CMS that will service MMP's potable needs.

Conservation can be characterized as **demand side strategies** that generally promote reduction in water use, and **supply side strategies** that focus on water system efficiency and loss control from source to end use. Demand-side management options are usually programs undertaken by a water utility to encourage the use of efficient and low-flow fixtures and appliances or practices by its customers, or to encourage customers to shift their time of use. Such programs often provide direct installation or incentives such as rebates to encourage the purchase of efficient fixtures or appliances. As described in the MDWS 2024 WSCP, MDWS has implemented replacement and rebate incentive programs to increase use of Advanced Metering Infrastructure (AMI) smart meters, rain barrels, low flow showerheads, ultra-high efficiency toilets (WaterSense® certified 1.28 gals per flush vs. older 3.5 gals per flush), and other low flow fixtures. Other products such as Smart Rain, a smart leak detection system for irrigation systems, are estimated to save 25-30% of water annually. Products such as Smart Rain optimize water usage and reduce waste by automatically adjusting watering schedules based on real-time conditions and cutting off water flow in the event of a leak. Utilizing this technology, moving forward reduces future demand and retrofitting existing subdivisions, such as Wailea Palms has done, will lead to major water savings.

MDWS also provides public outreach to raise customer awareness and feedback through online educational conservation content, feedback surveys, and QR codes on the monthly water billing to link to MDWS news and water savings tips including a comprehensive landscaping water conservation handbook [42] as irrigation is a significant portion of average domestic demand.

Other demand components focus on regulatory controls (e.g., 2024 MDWS WSCP recommends a new ordinance requiring WaterSense low flow fixtures for new developments, tiered rate structure modification, etc.) and continued MDWS

educational outreach programs to instill a conservation mindset and support other programs. MDWS is working on a conservation bill that would restrict domestic irrigation to no more than 3 days a week and between the hours of 8a-6p. If passed, this would save an estimated 6 Mgd from and for MDWS customers alone and would additionally result in significant irrigation savings from private wells.

Supply side measures include water audit/non-revenue water analysis, leak detection and meter maintenance and replacement [1]. Smart meters or other AMIs will take another 2 years to fully implement for existing users.

MDWS conducts annual water audits following the AWWA M36 [43] and uses the AWWA Free Water Audit Software © in compliance with the CWRM published Hawai'i Water System Audits and Water Loss Control Manual and the 2016 Hawai'i State Legislature Act 169. CWRM reviews and validates these annual water audits and considers them to be acceptable.[19]

Although not currently part of MDWS conservation programs, MDWS is working towards an ordinance to address concerns about evaporation losses from residential pools. It is unknown at this time the amount of new and existing pool area for MMP that would translate into a range of a total additional demand based on the evaporation atlas [14] rates for the MMP area. The following LEED guidelines will help to reduce these pool losses and if MDWS's overall goal of 20% reduction in average daily demand for new projects can be realized then the total domestic demand could approximate 654,000 gpd. MMP specifically has committed to adhere to LEED certification for all buildings greater than 500 square feet within the SMA (phase 1) lands.

Although conservation appears to have contributed to reducing pumpage from the ʻĪao ASA, MDWS would rather increase supply through CIP projects that increase system capacity. MDWS does not want to rely on individual customer responsible

[19] Personal communication with CWRM State drought coordinator.

behavior without ordinances in place that can allow MDWS to turn off water meters per DWS Rules and Regulations, Section 3-10, to enforce such an ordinance.

4.6.5. Storm Water

The MDWS Maui Island WUDP [1] addresses stormwater reuse as capturing and reusing surface water runoff from storm events. Stormwater reclamation can potentially provide water for non-potable water demands such as irrigation and toilets. There are a variety of stormwater technologies as illustrated in **Table 3** (from Table 8.25 from the MDWS Maui Island WUDP [1]) below ranging from small rainwater catchment systems to reservoir storage systems. The entire MMP lies makai of the DOH's Underground Injection Control (UIC) Line; therefore, dry wells may be used to capture stormwater runoff and inject it into the brackish portions of the aquifer.

Due to contaminants picked up by stormwater runoff, various levels of treatment may be necessary. Stormwater reclamation methods that employ capture and storage technologies must be planned, constructed, and operated to ensure minimal impact to streams, riparian environments, conservation lands, water rights, cultural practices, and community lifestyles. Reduced reliance on ground water and surface water for landscape irrigation may be appropriate, especially when incorporated into the design of development projects to maximize water retention and minimize infrastructure costs. However, there is no code requirement for development projects to incorporate water retention or reclamation design features for the purpose of supplementing non-potable water supplies.

Table 4. Table 8-25 Stormwater Reclamation Technologies

Technology	Description
Source Reuse	Use rain barrels or cisterns to collect precipitation or stormwater runoff at the source to provide water for a variety of non-potable purposes or, with treatment, potable water.
Small Lot Reuse	Manage precipitation or runoff as close to source as feasible. Examples: infiltration planter boxes, vegetated infiltration basins, eco roofs (vegetated roofs), porous pavements, depressed parking lot planter strips for biofiltration, narrowed street sections with parallel or pocket bioswales.
Stormwater Capture	Employ ditches, storm drainage system interception, dry wells, infiltration galleries, and injection wells to capture stormwater.
Stormwater Storage	Use aquifer storage and recovery, stream-bank storage, detention basins, and surface reservoirs to store stormwater.
Stormwater Distribution	Distribute stormwater via gravity ditch or pipe networks, operated/regulated ditch systems, pressure pipe networks, onsite wells.

4.6.6. New Private Brackish Wells

As described in Section 4.3.3 of this report, one new brackish well could be drilled within the MMP to develop approximately 350 gpm or 0.5 Mgd and stay within the SY limits established by the CWRM assuming uniform spacing coastal discharge. This new well is the ATC Mākena 8 (3925-004) which has been recently constructed and tested to show a yield of 350 gpm [5] [44]. To further minimize impacts on the water levels, chloride concentrations, and coastal leakage along the MMP shoreline, other new brackish irrigation wells could also be drilled north and south of the MMP area to meet the same demands and spread pumpage stress over a greater area to lessen localized ground water impacts. However, this would incur additional costs of drilling, transmission, operation, and maintenance.

5. CUMULATIVE/SECONDARY IMPACTS TO WATER RESOURCES & NEARBY DEVELOPMENT

This section seeks to understand the hydrological impacts MMP will have on these developments and the hydrological impacts these planned developments (MMP included) will cumulatively have on the Kama'ole ASA and the MDWS CMS.

Appendix P shows excerpts from the 2019 Maui County Water Use Development Plan (MWUDP) with the state's projected demands in the relevant aquifer sectors. Section 15.6.6 states that the Kama'ole ASA irrigation demands--the majority use in the ASA--will be expected to increase from 3.68 Mgd to 5.59 Mgd (an increase of 1.91 Mgd) in the 2015-2035 planning period, still well below the 11 Mgd SY. Tables 14-30 and 14-33, along with figure 14-28 of the MWDUP, illustrate the projected future demands served by MDWS CMS. The projected 34.673 Mgd by 2035 is nearing the 36 Mgd SY of the Wailuku aquifer sector, but the Haiku ASA is also viable to pump from due to its relatively low pumping compared to its SY. Table 16-31 of the Maui Island WUDP shows the projected local demands of the Ko'olau aquifer sector, which Haiku ASA is in. The 1 Mgd expected demand by 2035 is far below the 24 Mgd SY of Haiku ASA. In summary, the groundwater sources are capable of sustainably supplying the future projected demands of the Kama'ole ASA and CMS based on the MWUDP projections [1].

However, the Maui Island WDUP projections were made in 2014 with information that does not include the expected development details in **Exhibit 23** below. **Appendix Q** is a summary of Akinanka estimates of additional water demands of known planned development near the MMP area within the Kama'ole ASA. **Exhibit 23** details the locations of the ongoing and potential future projects listed in **Appendix Q.** Most of the projects are in progress and have either taken steps towards approval or have already undergone construction. A few projects shown are ideas of future projects and not currently in the planning stage.

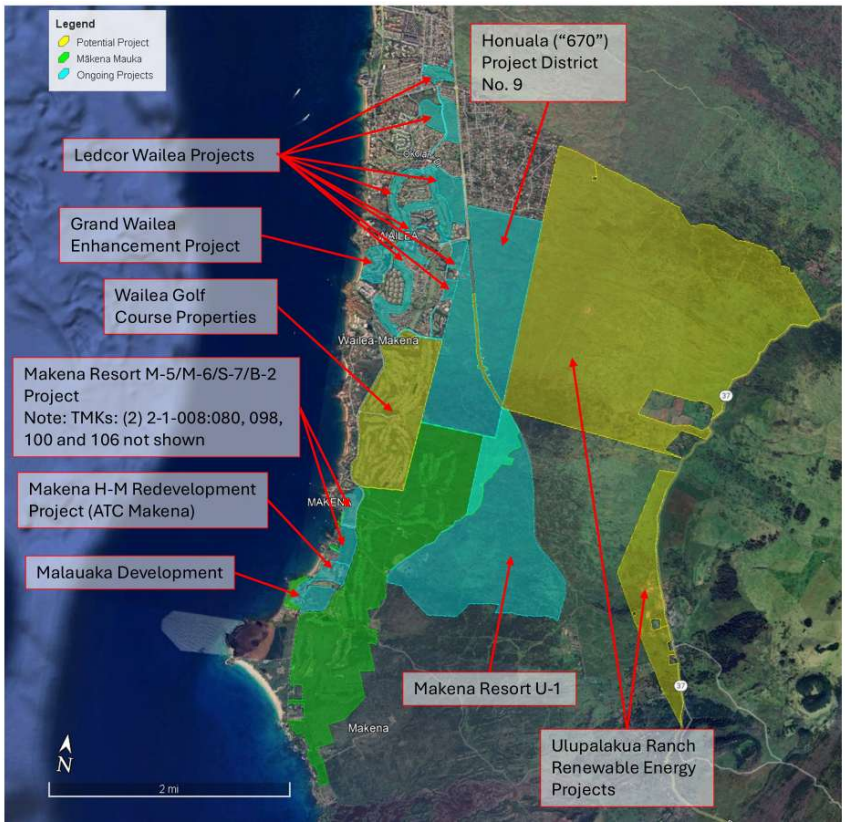

Exhibit 23. Map of Planned and Potential Projects Nearby

Combining MMP demands with other projects and DHHL reservations within the Kama'ole ASA, the total demands are summarized in Table 5 below. Both the average and maximum/peak day operational pumpage will remain below the 11 Mgd SY of the Kama'ole ASA.

Table 5. Total Demands on Kama'ole Aquifer (Including MMP)

	Total Average	Maximum/Peak Day
Current 12-Mav Use[1]	3,660,000	3,660,000
Planned Developments	3,019,728	4,529,593
DHHL Reservations	2,547,000	2,547,000
Total	9,226,728	10,736,593

[1] As of January 2025

.

Though these projected demands are both below the conservative Kama'ole ASA sustainable yield of 11 Mgd, they are near enough to warrant attention from the CWRM. The projected average use is 84% of SY and may trigger informational public hearings by the CWRM to assess the ground water situation to devise mitigative measures[20], such as those described in Section 6 of this report. Though more relevant to operational hydraulic, backup, and fire flow considerations rather than impacts to the aquifer, the projected maximum/peak day use is 98% of the SY and may trigger designation proceedings whereby regulation of pumpage will be increased through water use permits.

From the MDWS CMS, it is estimated that an additional average demand of 0.792 Mgd and a maximum demand of 1.188 Mgd will be needed for the cumulative proposed future projects in the Kama'ole ASA. This would may require MDWS to develop new groundwater well sources for the CMS. As described in section 4.3.3, the Waiheʻe (**Exhibit 11/Appendix H**) and Haiku (**Exhibit 12/Appendix I**) ASAs are not being pumped to their SY and are viable sources to supply all the projected new development in the area.

As previously discussed in Section 4.3.3 of this report, the other cause for concern would be localized saltwater intrusion caused by concentrated pumping in one area. Pumping groundwater reduces the freshwater zone that floats above a saltwater zone in the aquifer, allowing the saltwater to encroach further inland and cause thinning of the basal lens. The immediate adverse effect would be that wells spaced too close together would cause chloride levels to increase due to well interference. Ideally, a adequately calibrated numerical model would help to answer these concerns but one does not exist for the Kama'ole ASA like it does for Waiheʻe, ʻĪao, and Waikapū ASAs (MDWS/USGS, [26]).

In lieu of a numerical model, observational data over time can be just as effective. Closely spaced wells would need to be closely monitored to adjust pumpages

[20] HRS §174C-44

to ensure chloride levels do not reach undesirable levels that reduce the utility of the pumped water. The twelve (12) Mākena-Seibu golf course irrigation wells constructed between 1977 to 1988 average approximately 670-feet apart from each other along a 7,250-ft long line at the average ground elevation of +216-ft msl have been operating for decades. As discussed in Section 4.3.3, the coastal discharge range should be limited to between 1.446 to 2.229 Mgd/mile and the current total 12-MAV pumpage from the ATC Mākena wells is 0.844 Mgd (see **Appendix R**), which is within the estimated 1.79 pumpage for the MMP coastline discharge limitations within the estimate SY for the ASA. Pumpage for ATC Mākena has decreased over time and managing pumpage such that current chlorides have remained below 1,000 ppm chlorides over the past 20 years except between 2012-2014. Original chlorides encountered and reported were only gathered for three wells and are shown by hashed lines for Seibu 4 (1000 mg/L in 1978), Seibu 6 (668 in 1984), and Seibu 12 (1,900 in 1989). Seibu 12 is not pumped. The important take away from **Exhibit 24** is that the chloride trends have been relatively stable with Seibu 4 seemingly improving with pumpage over time. In short, the pumpage at the Mākena wells has been managed well to keep chlorides stable in the area since 2016.

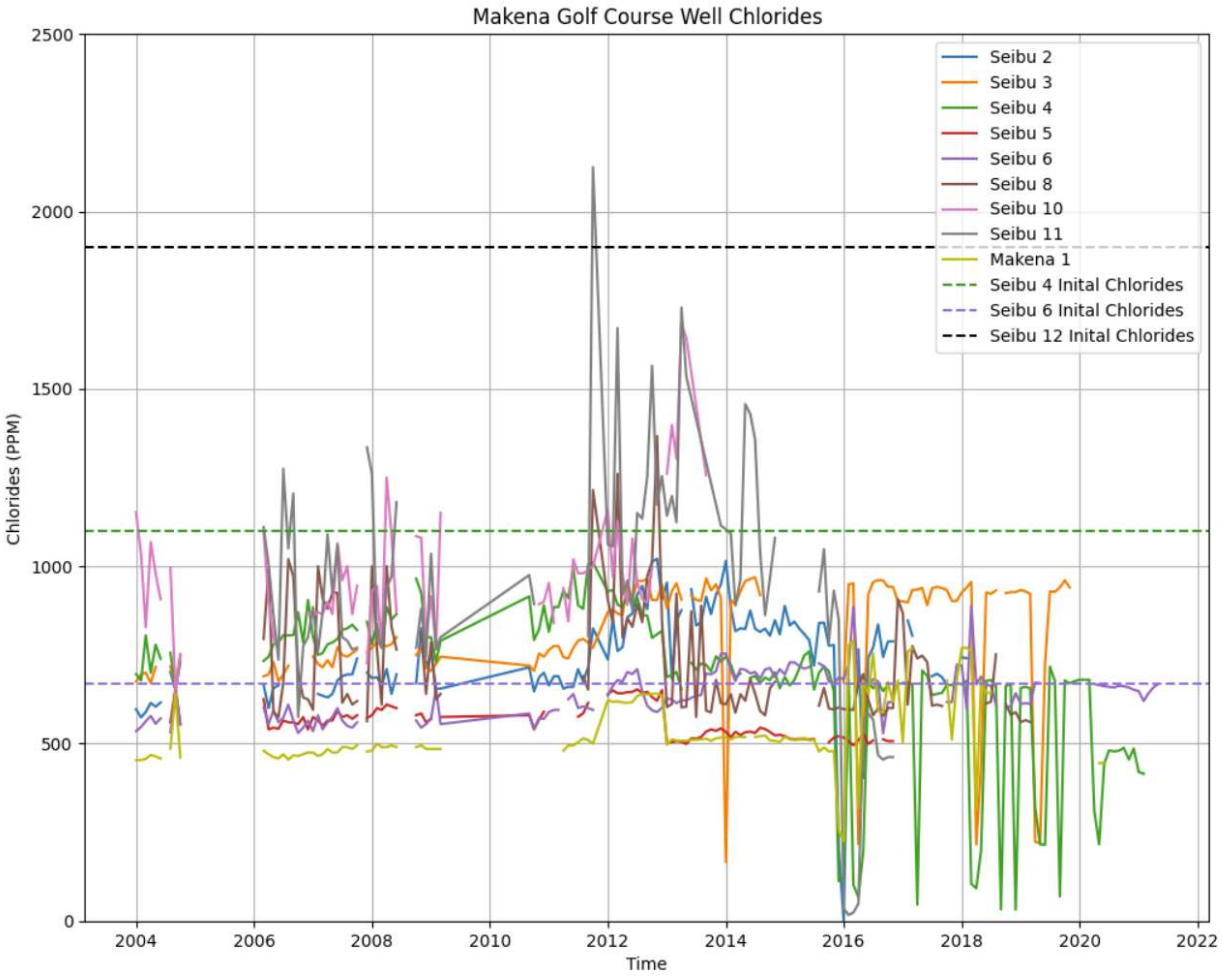

Exhibit 24. ATC Mākena Well Chlorides (as reported to CWRM March 2025)

6. MITIGATION MEASURES

To minimize the adverse effects on the MDWS CMS and Kama'ole ASA, we will primarily be focusing on water conservation strategies to reduce the water demands. 5This involves implementing strategies such as:

1. Installation of Low-Flow Fixtures: Utilizing low-flow faucets, showerheads, and toilets can significantly reduce indoor water consumption and lead to substantial water savings over time.

2. Pool Evaporation Covers: Pool evaporation covers will be used to minimize water loss due to evaporation. These covers can reduce evaporation by up to 95% according to the EPA [45].

3. Use of Non-Potable Water for Landscaping: Non-potable groundwater well sources and collected rainwater will be prioritized for landscape irrigation. This approach decreases the demand for RO treated potable water.

4. Efficient Irrigation Systems: The implementation of advanced irrigation systems, including drip lines and moisture sensors, will optimize water use. These systems deliver water directly to plant roots, reducing water loss due to runoff or evaporation.

5. Irrigation Scheduling: Irrigation will be scheduled during early morning and late evening hours to minimize evaporation losses. Midday watering will be avoided because that is when evaporation rates are the highest.

6. Xeriscaping and Drought-Tolerant Landscaping: Landscaping will incorporate xeriscaping principles and drought-tolerant, native plant species that require minimal watering. This practice not only reduces water demand but also promotes local biodiversity.

7. Rainwater and Stormwater Harvesting: Systems for rainwater and stormwater collection and reuse will be installed to capture runoff for non-potable uses, such as irrigation and exterior cleaning. This practice reduces reliance on groundwater and potable water sources.

7. CONCLUSION

MMP plans to minimize the use of MDWS water by developing their own water system with RO treatment to supply about 94% of their maximum water demands. This requires them to pump a maximum of 1.464 Mgd of water from the Kama'ole ASA, still very much below the 11 Mgd SY of the ASA when added to the current 3.660 Mgd pumping (33% of SY).

The remaining 6% of MMP's water demand (0.092 Mgd) will be supplied by the Maui MDWS CMS, sourced by the ʻĪao and Waihe'e ASA. As of January 2025, the actual reported non-caprock use is 13.157 Mgd, which is 2.694 Mgd below the current total allocations that count against SY. The Waihe'e ASA is pumping 5.518 Mgd, 69% of the 8 Mgd SY. Also, this is within the recent MDWS maximum reliable capacity and recent 3-

year forecast projections[21]. MDWS can also expand into the nearby Haiku and Waikapū ASAs, which have very low pumpage relative to their SYs. Given the current water availability in both the aquifer source and CMS, MMP's water demands will not overstress the groundwater resources of the CMS.

Considering the cumulative impact from future projects of developments in the area to the Kama'ole ASA, pumpage would rise to a maximum of 8.190 Mgd. If DHHL reservations of 2.547 Mgd were to be implemented, this would put the maximum future pumpage at 10.737 Mgd if the full amount of the reservations were to be pumped from the Kama'ole ASA. Although this would be below the SY of 11 Mgd, this would raise the pumpage to greater than 90% of the SY, which is something that could initiate designation of a GWMA under the CWRM.

To mitigate the impacts, MMP will be implementing conservation strategies to reduce their water demands. They will be ensuring LEED certified construction for buildings greater than 500 square feet.

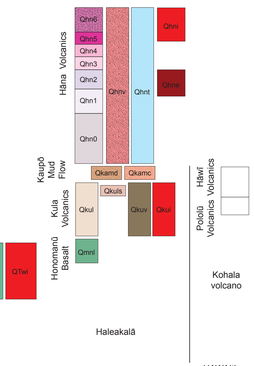
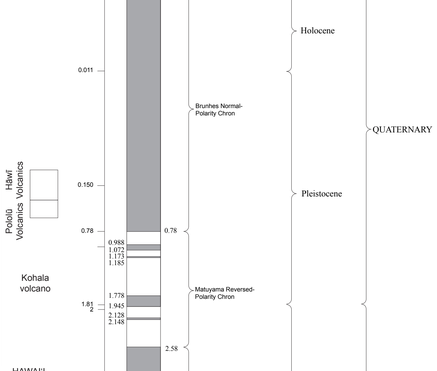
APPENDIX E



OPEN-FILE REPORT 2007-1089
SHEET 7 of 8
Pamphlet accompanies map



SURFICIAL DEPOSITS COMMON TO SEVERAL OF THE ISLANDS

VOLCANIC AND INTRUSIVE ROCKS AND SPARSE INTERBEDDED SEDIMENTARY BEDS

Geologic linework in Universal Transverse Mercator projection, North American datum 1983, zone 4

Topographic base and bounding latitude-longitude ticks from Defense Mapping Agency, Kipahulu Valley, Makawao, Waiakoa, and Wailuku (1989), 1:50,000

Transverse Mercator projection based on GRS 1980 spheroid, North American datum 1983

Grid on map from UTM zone 4, North American datum 1983

Base, intended for visual reference only, is fitted to GIS-based coastline by inspection

Geology from Stearns and Macdonald (1942), Macdonald (1978), and D.R. Sherrod, 1997-2003. Compiled by D.R. Sherrod, 2004

INDEX FOR 1:50,000-SCALE DEFENSE MAPPING AGENCY SHEETS

LIST OF MAP UNIT ON SHEET 7 (THIS MAP)

See explanatory pamphlet for complete descriptions

SURFICIAL DEPOSITS COMMON TO SEVERAL OF THE ISLANDS

Qf **Fill (Holocene)**
Qa **Alluvium (Holocene)**
Qbd **Beach deposits (Holocene)**
Qdy **Younger dune deposits (Holocene)**
Qls **Landslide deposits (Holocene)**
Qtc **Talus and colluvium (Holocene)**
Qdo **Older dune deposits (Holocene and Pleistocene)**
Qcbc **Calcareous breccia and conglomerate (Pleistocene)**
QTao **Older alluvium (Pleistocene and Pliocene)**

VOLCANIC AND INTRUSIVE ROCKS ON THE ISLAND OF MAUI

Hāna Volcanics (Holocene and Pleistocene)—Divided into:

Lava flows (Holocene and Pleistocene)—Divided into:

	Lava flows	Age, years
Qhn6	Qhn6	0 - 1500
Qhn5	Qhn5	1500 - 3000
Qhn4	Qhn4	3000 - 5000
Qhn3	Qhn3	5000 - 13,000
Qhn2	Qhn2	13,000 - 30,000
Qhn1	Qhn1	30,000 - 50,000
Qhn0	Qhn0	50,000 - 140,000

Qhnv **Vent deposits (Holocene and Pleistocene)**
Qhnt **Tephra deposits (Holocene and Pleistocene)**
Qhni **Intrusive rocks (Holocene and Pleistocene)**
Qhne **Explosion crater deposits (Pleistocene)**
Qkamd **Kaupō Mud Flow (Pleistocene)**—Mapped separately is:
Qkamc **Conglomerate**

Kula Volcanics (Pleistocene)—Divided into:

Qkul **Lava flows**—Mapped separately is:
Qkuls **Summit ankaramite**
Qkuv **Vent deposits**
Qkui **Intrusive rocks**
Qmnl **Honomanū Basalt (Pleistocene)**

Lahaina Volcanics (Pleistocene)—Divided into:

Qlhl **Lava flows**
Qlhv **Vent deposits**

Honolua Volcanics (Pleistocene)—Divided into:

Qul **Lava flows**
Qud **Domes**
Quv **Vent deposits**
Qui **Intrusive rocks**

Wailuku Basalt (Pleistocene and Pliocene(?))—Divided into:

QTwl **Lava flows**
QTwv **Vent deposits**
QTwt **Tuff**
QTwpc **Pit crater deposits**
QTwlc **Lava cone**
QTwp **Phreatic explosion debris**
QTwdc **Dike complex**
QTwcc **Caldera complex**
QTwi **Intrusive rocks**

—— **Contact—Approximately located**
Fault—Approximately located; dotted where concealed

Geologic Map of the State of Hawai'i, Sheet 7—Island of Maui

APPENDIX F

Monthly Pumpage Chart

12 Month Moving Average

Report Parameters

Date:	01/01/1988 - 01/13/2025
Island:	Maui
Well Owner:	All
Well Reporter:	All
Well # Prefix:	All
Aquifer Sector:	Central
Aquifer:	60304 Kamaole
Water Quality:	Fresh (0-250 ppm), Brackish (251-16,999 ppm), Not Specified
Potable/Non-Potable:	All
TMK:	All
PWS:	All
Aquifer Type:	Alluvial, Basal, Caprock, Deep Fresh Water, Dike, Perched, Not
Pump Capacity:	Specified
Well Use:	All

APPENDIX G

Monthly Pumpage Chart

12 Month Moving Average

Report Parameters

Date:	01/01/1948 - 01/13/2025
Island:	Maui
Well Owner:	All
Well Reporter:	All
Well # Prefix:	All
Aquifer Sector:	Wailuku
Aquifer:	60102 Iao
Water Quality:	Fresh (0-250 ppm), Brackish (251-16,999 ppm), Not Specified
Potable/Non-Potable:	All
TMK:	All
PWS:	All
Aquifer Type:	Alluvial, Basal, Caprock, Deep Fresh Water, Dike, Perched, Not
Pump Capacity:	Specified
Well Use:	All

APPENDIX K

STATE OF HAWAI'I
DEPARTMENT OF HEALTH
July 2002 (Version 6)

GUIDELINES APPLICABLE TO GOLF COURSES IN HAWAI'I

The State Department of Health recommends the following guidelines for all golf courses in Hawai`i to promote, protect, and enhance environmental quality and public health. These recommendations cover measures that could prevent groundwater and surface water pollution, soil contamination, chemical spills, noise and solid waste nuisances, and unsafe exposure to applied chemicals. Under certain situations, a state or county regulation may be necessarily applicable to a given activity, and such a regulation would require mandatory compliance. However, the intent of these guidelines is to voluntarily foster environmental protection and safety. Thank you for supporting these guidelines and caring about Hawai`i.

1. A groundwater or soil water monitoring plan for the purpose of preventing or minimizing groundwater contamination should be established with the following components:

    a. Baseline groundwater quality;

    b. Monitoring locations consisting of monitoring wells or lysimeters, or combination of both;

    c. Routine groundwater and/or soil water monitoring at frequencies such as quarterly, semiannually, or annually depending on the use of chemicals and the detection of contaminants;

    d. A list of chemicals and fertilizers that will be or have been used that may affect soil or groundwater adversely, and the analyses for such contaminants;

    e. Recordkeeping of monitoring results and a system of tracking trends in order to prevent, minimize, or mitigate occurrences of contamination;

    f. A procedure to notify all affected parties and the Department of Health of occurrences of contamination that pose, or may pose, a threat to public health or the environment.

    g. Availability of monitoring data to any interested person.

2. A surface water monitoring plan, if applicable, for the purpose of preventing or minimizing surface water contamination should be established using the principles of item No. 1.

3. If the golf course uses recycled water (treated wastewater) for irrigation, please refer to the Department of Health's Guidelines for the Treatment and Use of Recycled Water, May 15, 2002, for recycled water requirements. Information about this subject may be obtained from the Department's Wastewater Branch at 586-4294 (Honolulu).

4. The use of an above-ground storage tank with applicable safety considerations for petroleum products, used for fueling golf carts, maintenance vehicles, or emergency generators, should be preferred over an underground storage tank in order to easily detect leaks and minimize the risk of soil and groundwater contamination resulting from a leaking storage tank. Information about underground storage tanks may be obtained from the Department's Solid and Hazardous Waste Branch at 586-4226 (Honolulu).

5. Buildings used to store fertilizers, pesticides, algicides, fungicides, herbicides, and other chemicals especially in liquid form should be designed purposely for the containment and recovery of a catastrophic spill or leak of contents. An early warning system for spill or leak detection is advantageous.

6. Noise and dust from maintenance or construction activities should not disturb neighbors. Maintenance or construction activities should be scheduled and conducted accordingly.

7. Solid wastes should be managed without creating a nuisance. Furthermore, all green waste generated by the golf course should be reused on-site. Shredding and composting are activities that precede the reuse of green waste as a soil conditioner or a ground cover for weed control. Space and equipment should be provided to accomplish these activities. Additionally, where practicable, locally produced compost and soil amendments should be used whenever available.

8. Chemicals should be handled and applied according to instructions, and offsite drift during application should not occur. Methods of application and weather conditions should be chosen to optimize success.

9. A Best Management Practices (BMP) plan should be made for the golf course. The BMP plan functions as a hands-on environmental and worker safety maintenance manual that describes in plain English the elements and procedures for irrigation, chemical use, processing and reuse of green wastes, minimizing or preventing runoff, soil erosion and nuisance conditions, and sustaining worker safety. Use of the BMP should prevent the occurrence or recurrence of environmental or safety problems. The BMP should be available to any interested person.

10. Agencies or organizations such as the State Department of Agriculture, the Federal National Resource Conservation Service, and the Golf Course Superintendents Association of America may provide ideas or practices that would help to achieve the intent of these guidelines. Inquiries to these sources of information are advantageous.

The Department of Health appreciates your cooperation to preserve and protect environmental quality in Hawai`i. Questions about these guidelines may be directed to the Groundwater Pollution Control Section of the Safe Drinking Water Branch at 586-4258 (Honolulu). Direct toll free calls can be made from Kaua`i: 274-3141, ext. 64258; Maui: 984-2400, ext. 64258; Big Island: 974-4000, ext. 64258; Molokai and Lana`i: 1-800-468-4644, ext. 64258.

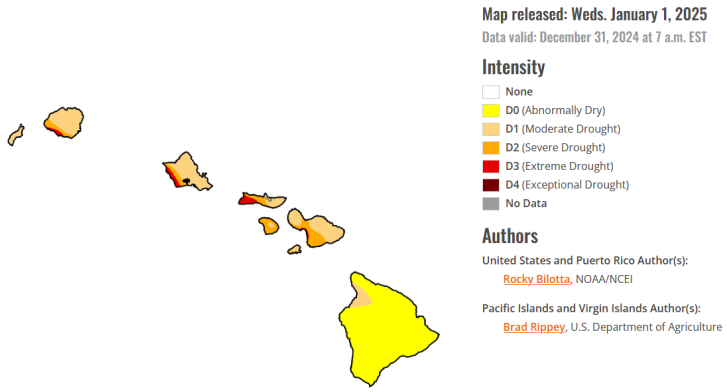
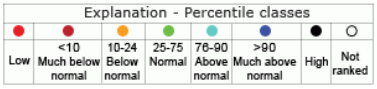
Effective August 1, 2009, the monthly bulletin will only be available on our website at http://dlnr.hawaii.gov/cwrm/.
To receive an email notice when the bulletin is posted on the Commission website please notify the Commission at 808.587.0234 or dlnr.cwrm@hawaii.gov. To continue to receive the bulletin by postal mail, please submit a request in writing to the Commission at P.O. Box 621, Honolulu, HI 96809.

A. New Notices/Announcements

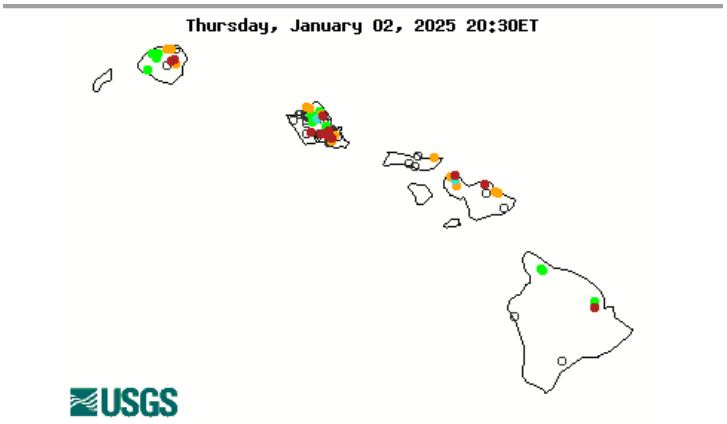


Drought Updates
The Wildfire & Drought LOOKOUT! campaign kicked off June 4, 2024 on Maui (https://dlnr.hawaii.gov/blog/2024/06/04/nr-66/). This comprehensive public information campaign to raise awareness about wildfire, drought, and water conservation, For more information please visit the Hawaii Wildfire Management Organization website: https://www.hwmo.org/lookout. Also check out water conservation and fire prevention tips in DLNR's social media posts https://www.instagram.com/hawaiidlnr/ and https://www.facebook.com/HawaiiDLNR/

See the NOAA Drought Information Statement for the Hawaiian Islands, valid November 15, 2024, here: https://www.weather.gov/media/hfo/DGT/DGT_HFO_11152024.pdf



The NWS issued its Hawaiian Islands 2024-2025 Wet Season Outlook. http://weather.gov/media/hfo/MediaAdvisory-2024-2025HawaiiWetSeasonOutlook.pdf



County of Maui: The County of Maui Department of Water Supply Water Shortage declaration: Stage 1 Water Shortage for Central Maui. The Central Maui service area includes Waiheʻe, Waiehu, Wailuku, Kahului, Spreckelsville, Pāʻia, Kūʻau, Māʻalaea, Kīhei, Wailea and Mākena. https://www.mauicounty.gov/CivicAlerts.aspx?AID=15800. Stage 1 Water Shortage is still in effect for West Maui. The West Maui service area includes Lahaina, Kaanapali, Kahana, Mahinahina, Napili-Honokowai, and Honokohau. https://www.mauicounty.gov/CivicAlerts.aspx?AID=15799 The Department is asking all customers throughout West, Central and South Maui to follow all water use restrictions to conserve water supply and protect our water resources. Stage 1 Water Shortage in Upcountry ended September 3, 2024. https://www.mauicounty.gov/CivicAlerts.aspx?AID=15798

The **U.S. Drought Monitor (USDM)** is a map released every Thursday, showing drought intensity across the U.S. and its territories. The map uses six classifications: normal conditions, abnormally dry (D0), showing areas that may be going into or are coming out of drought, and four levels of drought: moderate (D1), severe (D2), extreme (D3) and exceptional (D4). The weekly map for Hawai'i can be viewed online at: https://droughtmonitor.unl.edu/CurrentMap/StateDroughtMonitor.aspx?HI

The **U.S. Geological Survey (USGS)** maintains a summary map of daily mean streamflow conditions at its network of real-time gaging stations statewide. The current map, along with station-specific information on all streamflow, precipitation (rainfall), reservoir, and groundwater stations monitored by the USGS, can be viewed at: https://waterdata.usgs.gov/hi/nwis/rt.

The colored dots on this map depict streamflow conditions as a percentile, which is computed from the period of record for the current day of the year. Only stations with at least 30 years of record are used. The gray circles indicate other stations that were not ranked in percentiles either because they have fewer than 30 years of record or because they report parameters other than streamflow. Some stations, for example, measure stage only.

Streams across Hawai'i are experiencing record low-flows as normally wet conditions observed in December have eluded the islands. Streams that support traditional kalo cultivation, habitat for native freshwater species, and instream hydropower production are experiencing critically low-flows. Conditions are affecting the availability of water for drinking water supply on Hawai'i and Maui as well as irrigation water supply on Hawai'i, Maui, Moloka'i, O'ahu, and Kaua'i.

B. Upcoming Meetings and Hearings*

The Commission on Water Resource Management's monthly meeting agenda and staff submittals are available on our website at http://dlnr.hawaii.gov/cwrm/.

Subscribe to the Commission's YouTube Channel to follow livestream events including monthly Commission meetings and public hearings. https://www.youtube.com/user/dlnrcwrm/

Follow the Commission's Vimeo Channel to view videos including online Commission meetings, public hearings, limited meetings, and more. https://vimeo.com/cwrm

Date	Time	Location	Type
January 28, 2025	9:00 am	Online Meeting: Live Stream via YouTube and DLNR Boardroom, 1st Floor 1151 Punchbowl Street Honolulu, HI 96813	Regular Meeting
February 18, 2025	9:00 am	Online Meeting: Live Stream via YouTube and DLNR Boardroom, 1st Floor 1151 Punchbowl Street Honolulu, HI 96813	Regular Meeting

Commission meetings can be viewed via live stream at https://www.youtube.com/user/dlnrcwrm/

***Meeting dates, times, & locations should be confirmed with staff.**

C. Petitions for Reservation of Water

- **CWRM.5641.6** – The State Department of Hawaiian Home Lands has filed a petition for reservation of 11,177,500 gallons per day originating from the watershed of, and tributaries to, the East Maui streams diverted by the East Maui Irrigation system for non-potable water use in Pūlehunui and Kēōkea-Waiohuli Hawaiian Home Lands.

D. Designation of Water Management Areas

- **Lahaina Aquifer Sector Area:** The Chair of the Commission on Water Resource Management has recommended to designate the Lahaina Aquifer Sector Area (ASA), Maui, as a Surface and Ground Water Management Area under Section 174C-41. The proposed Lahaina ASA Surface Water Management Areas include the Honokōhau (6014), Honolua (6013), Honokahua (6012), Kahana (6011), Honokōwai (6010), Wahikuli (6009), Kahoma (6008), Kaua'ula (6007), Launiupoko (6006), Olowalu (6005), and Ukumehame (6004) surface water hydrologic units. The

proposed Lahaina ASA Ground Water Management Areas include the Honokōhau (60201), Honolua (60202), Honokōwai (60203), Launiupoko (60204), Olowalu (60205), Ukumehame (60206) ground water hydrologic units. On June 14, 2022, the Commission accepted the Findings of Fact and Chairperson's Recommendation to designate the Lahaina Aquifer Sector Area as both a Surface Water and Ground Water Management Area. A public notice was issued on July 29, 2022, and published in The Maui News issue of August 6, 2022.

Applications for water use permits to continue an existing use of surface or ground water had to be filed with the Commission within a period of one year from the effective date of designation, that is between August 6, 2022 (the date this Public Notice is published) and no later than August 7, 2023 (as August 5, 2023 fell on a Saturday).

The Commission is currently reviewing filed water use permit applications for both existing and new uses. Applications for new uses of both ground or surface water may continue to be filed with the Commission. More information is available online at: https://dlnr.hawaii.gov/cwrm/groundwater/gwma/lahaina/.

E. Contested Case Hearings Pending at the Commission:

- **CCH-MA15-01** – Surface Water Use Permit Applications, Nā Wai ʻEhā Surface Water Management Area, Waiheʻe, Waiehu, ʻĪao, Waikapū Streams, Maui, Hawaiʻi. On January 28, 2015, the Commission determined that a contested case hearing is required to hear and determine all surface water use permits applications in the Nā Wai ʻEhā Surface Water Management Areas, Maui, and delegated authority to the Chairperson to appoint a Hearings Officer. The Hearings Officer issued his Proposed Findings of Fact, Conclusions of Law and Decision and Order on November 1, 2017. The Commission issued its Findings of Fact, Conclusions of Law, and Decision and Order on June 28, 2021, along with an Executive Summary. On June 30, 2021, the Commission issued an Errata to the Findings of Fact, Conclusions of Law, and Decision and Order. On October 22 and 25, 2021, MMK Maui, LP, Hui O Na Wai Eha and Maui Tomorrow Foundation, Inc. and Office of Hawaiian Affairs filed an Appeal to the Commission's Decision. On October 25 and 28, 2021, Mahi Pono, LLC and Wailuku Water Company, LLC filed a Cross-Appeal. The deadline to file the Record on Appeal with the Supreme Court of the State of Hawaii is March 21, 2022. On March 14, 2022 the Supreme Court granted the Commission's request for an extension of time to transmit the Record on Appeal to April 20, 2022. Oral arguments in the State Supreme Court for SCOT-21-0000581 (Case Number CCH-MA 15-01) were heard on December 5, 2023. The Supreme Court issued its Opinion on June 20, 2024. The Opinion and contested case information are available online at http://dlnr.hawaii.gov/cwrm/newsevents/cch/cch-ma15-01/. The contested case has been remanded back to the Commission for further proceedings.

- **CCH-MA20-01** – On June 16, 2020, the Commission granted a petition for a contested case hearing filed by Wailuku Water Company, LLC to enter into a contested case hearing on the Issuance of Written Notice of Violation for Enforcement Against Waste, and Recommendation to Impose Fines Against Wailuku Water Company, LLC, Owner/Operator of Waiheʻe Ditch, in Response to HRS §174C-13, Citizen Complaint filed by Hui o Nā Wai ʻEhā Alleging Waste by Wailuku Water Company at Paleʻaʻahu Gulch, Nā Wai ʻEhā Surface Water Management Area, Maui, TMK No. (2) 3-6-004:003.

- **CCH-OA20-04** – On November 17, 2020, the Commission granted a petition for contested case hearing from Protect Mokulēʻia Hui to enter into contested case for GWUPA 1088 for Dillingham Ranch for modified withdrawals of ground water from the Mokulēʻia Aquifer System Area. The Contested Case Hearing is currently held in abeyance and a new water use permit application quantity will be considered.

APPENDIX N

Summary of New Water Demands for the Mākena Mauka Project

Required Supply for the Mākena Mauka Project (Exclusive of Workforce Housing in M-2 and M-3 Lots) to be Supplied by Private Water System

Use	No. of Units	Potable GPD/Unit	Irrigation GPD/Unit	Potable GPD	Irrigation GPD
Single Family	180	300	500	54,000	90,000
Multi-Family	363	300	300	108,900	108,900
Golf Course Amenity Building	- -	- -	- -	42,900	31,400
Other Water Use	- -	- -	- -	19,000	- -
Park	6.7 (Acres)	- -	1,700 / Acre	- -	11,390
South Golf Course	65 (Acres)	- -	- -	- -	388,500
Total Average Demand				**224,800**	**630,190**
Total Maximum Demand (1.5x Average)				**337,200**	**945,285**

This table was modified from Table 2 Tom Nance's Water Resources Assessment for the Makena Mauka Project dated November 2025 to include the South Golf Course using data provided by SSFM.

Required Supply for Workforce Housing in Lots M-2 and M-3 at Mākena Mauka Project to be Supplied by MDWS

Use	No. of Units	Potable GPD/Unit	Potable GPD
Single Family	15	600	9,000
Multi-Family	94	560[1]	52,640
Total Average Demand			**61,640**
Total Maximum Demand (1.5x Average)			**92,460**

[1] Estimated consumption demand taken from table 100-18 of MDWS Standards.

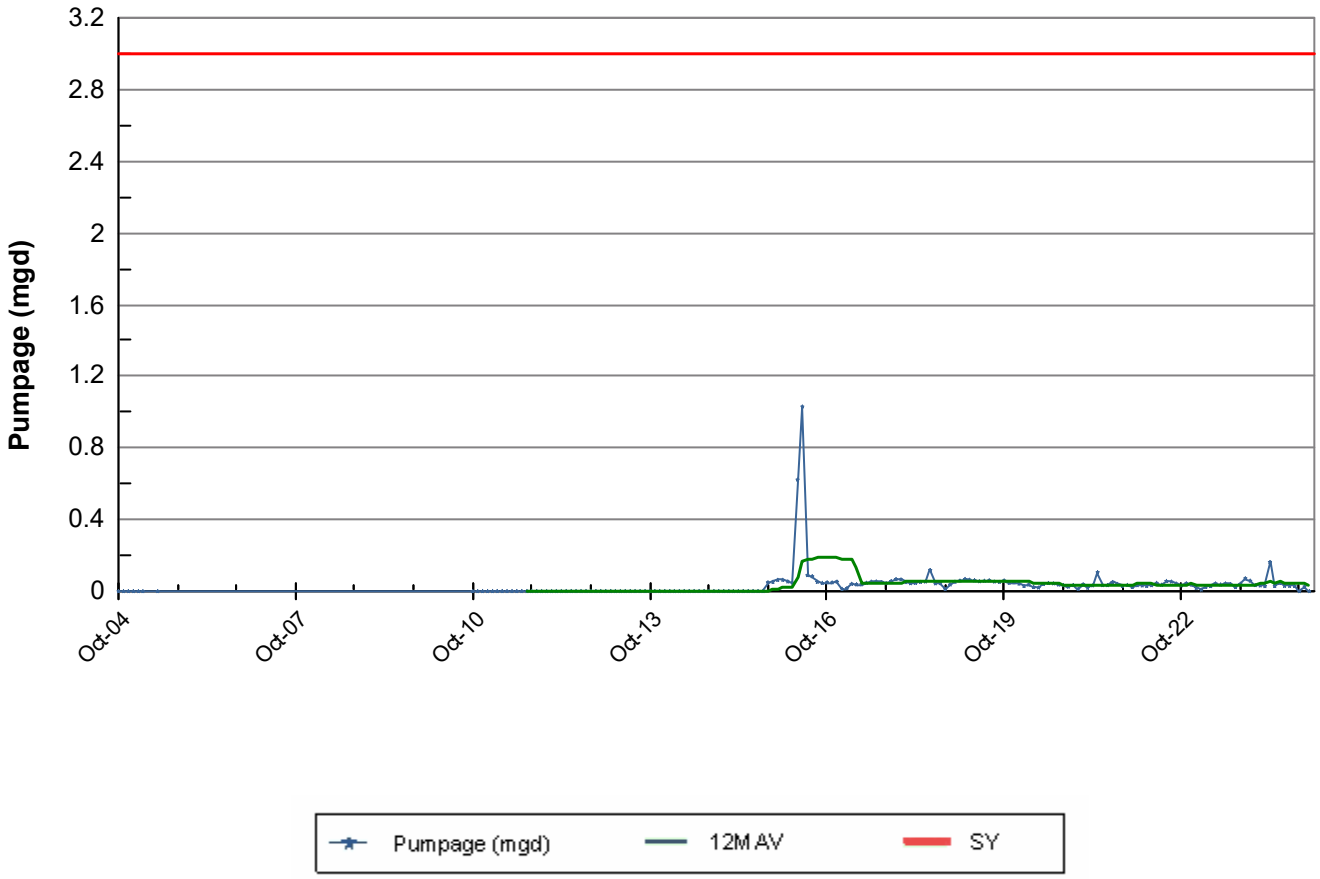
Demand Summary for the Mākena Mauka Project without RO recovery

Item	Potable GPD	Irrigation GPD	Total GPD
Average Demand to MDWS	61,640	N/A	**61,640**
Maximum Demand to MDWS CMS	92,460	N/A	**92,460**
Average Demand for Private System	224,800	630,190	**854,990**
Maximum Demand for Private System	337,200	945,285	**1,282,485**
Total Average Demand	**286,440**	**630,190**	**916,630**
Total Maximum Demand	**429,660**	**945,285**	**1,374,945**

This table totals demands from the above two tables.

Demand Summary for the Mākena Mauka Project with RO Recovery by Category

Category	Total Average Demand GPD (with RO Recovery)	Total Maximum Demand GPD (with RO Recovery)
Potable (supplied by private water system)	**345,846**	**518,769**
Potable Affordable Housing (supplied by MDWS CMS)	**61,640**	**92,460**
Non-Potable Irrigation (supplied by private water system)	**630,190**	**945,285**
Total Demand	**1,037,676**	**1,556,514**



Total Required Supply Needed to be Pumped from Private Well with 65% RO Recovery

Item	Potable GPD	Irrigation GPD
Average Consumption Demand	224,800	630,190
Average Well Demand	345,846	630,190
	Total Average Well Demand	976,036
Maximum Consumption Demand	337,200	945,285
Maximum Well Demand	518,769 (RO Treatment Required with 65% Recovery)	945,285 (no RO treatment needed)
	Total Maximum Well Demand	**1,464,054**

APPENDIX P

15.6.6 Irrigation Demand Projections

Reported irrigation use of 3.68 mgd within the aquifer sector includes brackish water used for golf course, resort and landscaping irrigation purposes. Over 75 percent of irrigation withdrawals are from the Kamaʻole Aquifer but the data is likely under-reported. This is in addition to irrigation uses served by the MDWS Central and Upcountry Systems. Although irrigation needs may not correspond directly to population growth, it's prudent to project an increase in demand based on population growth, which is at a higher rate than the de facto population growth ("de facto" includes visitors). Demand would increase from 3.68 mgd to 5.59 mgd over the planning period.

In addition to groundwater withdrawals for irrigation, recycled water from the Kīhei Wastewater Reclamation Facility provides up to 1.75 mgd during peak summer months. Reclaimed water is distributed to 24 commercial properties in South Maui for landscape and agricultural irrigation, cooling, fire control, erosion and dust control, drinking water for cattle and other uses.[63] The volume of R-1 water reused varies seasonally. It is estimated that about 1 mgd is reused on average for irrigation purposes. An additional 0.08 mgd of reclaimed water is generated and used at the Mākena Resort, primarily for golf course irrigation. The reclamation facility is undergoing an upgrade to further integrate on-site reclaimed water generation and use.

Table 14-30 Planned Growth Wailuku ASEA and MDWS Central Maui System Service Area

Planned Growth Area	# Units	# Acres	Projected Demand (mgd)
Waiʻale	300+2,254	50+495	1.40 – 1.52

Source: MDWS. Based on Calendar Year 2014 consumption billing data within the Koʻolau ASEA for MDWS Water Use Zone (WUZ) Subdistricts: Kokomo-Kaupakalua (311), Kuiaha (312), Haʻikū-Paʻuwela (313), Pukalani (316), Upper Kula (331), Lower Kula (333), Nahikū (913), Keʻanae (915).

*Includes water exported to Central ASEA and then supplied to MDWS Upcountry System customers located within Koʻolau ASEA.

APPENDIX Q

Summary of Proposed New Water Demands in the Makena Area

Ongoing and Potential Impact Projects Map

MALUAKA DEVELOPMENT

Estimated Supply for Maluaka Development

Use	No. of Units	Potable GPD/Unit	Potable GPD
Single-family	13	600	7,800
Multi-Family	6	560	3,360
Total Average Demand			**11,160**
Total Maximum Demand (1.5x Average)			**16,740**

Number of single and multi family units provided by MMP.

Estimated consumption demand taken from table 100-18 of MDWS Standards.

All demands assumed to be supplied by MDWS.

MAKENA REDEVELOPMENT PROJECT

Based on information provided to us by MMP, this redevelopment plans to convert a former hotel 310-room hotel at the Makena Beach & Golf Club Resort into a combination of hotel, condominium, beach cottage units, together with a spa hale. A total of 65 units are proposed.

Since this project is a conversion, we will assume that there will be no additional water demands that comes with this redevelopment.

MAKENA RESORT

Estimated Required Supply for Makena Resort

Use	No. of Units	Potable GPD/Unit	Potable GPD
Multi-family	30	560	16,800
Single-family cottages	18	600	10,800
Single-family Custom Lot	32	600	19,200
Transient Vacation Rental (TVR) Units	9	600	5,400
Condos	14	560	7,840
Commercial Space	0.627 acres	600 gal/acre	376.2
Total Average Demand			**60,416**
Total Maximum Demand (1.5x Average)			**90,624**

Number of units and planned use provided by MMP.

Supplied by MDWS CMS

[1] Assume same demands as Single Family

[2] Assume same demands as Multi-Family

WAILEA 670/ Honua'ula

In the Honua'ula FEIS, they state that they will not rely upon on MDWS, and instead will develop their own private water system. Their EIS estimates that a total average of 1.7 Mgd will be withdrawn from brackish wells in the Kama'ole ASA.

LEDCOR

Estimated Supply for Ledcor Wailea Projects

Average Demand (gpd)	Maximum Demand (gpd)
558,000	837,000

Demands taken from the Ledcor South Maui Properties and Improvements EIS.
To be supplied by MDWS per the Ledcor South Maui Properties and Improvements EIS.

GRAND WAILEA ENHANCEMENT PROJECT

Estimated Required Supply for Grand Wailea Enhancement Project

Use	No. of Units	Potable GPD/Unit	Potable GPD
Resort	151	350	52,850
		Total Average Demand	**52,850**
		Total Maximum Demand (1.5x Average)	**79,275**

Number of resort units provided by MMP.
Assumed to be supplied by MDWS.
Estimated consumption demand taken from table 100-18 of MDWS Standards.

PROPOSED H-2 RESIDENTIAL PROJECT

Estimated Required Supply for Proposed H-2 Residential Project

Use	Average Demand (gpd)	Maximum Demand (1.5x average) (gpd)
Domestic (potable)	47,700	71,550
Irrigation (non-potable)	66,400	99,600

Domestic demands to be supplied by MDWS per the Proposed H-2 Residential Project EA.
Non-potable water demands to be supplied by Makena Golf Course System per the Proposed H-2 Residential Project EA.
Estimated demands per the Proposed H-2 Residential Project EA .

MAKENA RESORT U-1 PROJECT

Estimated Required Supply for Makena Resort U-1 Project

Use	No. of Units	Potable GPD/Acre	Irrigation GPD/Unit	Potable GPD	Irrigation GPD
Main residences	36	1,000	4,000	36,000	144,000
Accessory Dwelling Unit (ADU)	36	600	600	21,600	21,600
Cattle Troughs	- -	15,000	- -	15,000	- -
Total Average Demand				**72,600**	**165,600**
Total Maximum Demand (1.5x Average)				**108,900**	**248,700**
Total average demand required to be pumped and treated with RO				**277,292**	
Total maximum demand required to be pumped and treated with RO				**415,938**	

Demands taken from TNWRE Water Resources Assessment for the MMP.
Assumed to be supplied from private wells.

WAILEA GOLF COURSE PROPERTIES

Based on information provided to us by MMP, Wailea Golf LLC proposes a planned, mix-use development among 214 acres, to include a resort hotel and between 856 and 1,070 housing units. This proposal has been included for possible land use designations in the South Maui Community Plan, awaiting review and approval by the Maui County Council in 2025. However, this information is too preliminary, and the demands are not taken into the total demands on Kama'ole Aquifer.

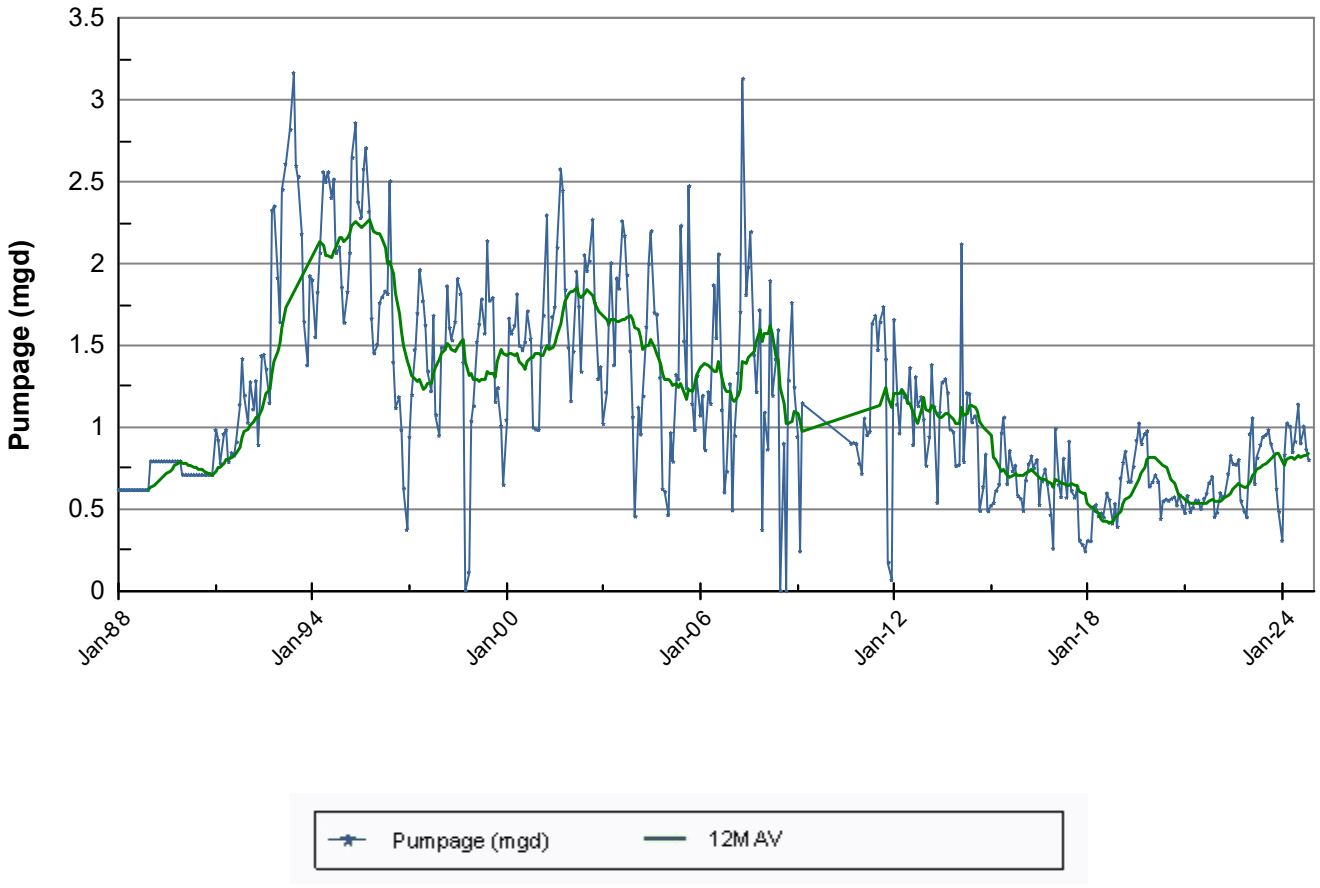
Ulupalakua Ranch Renewable Energy Projects

Based on information provided to us by MMP, the Paeahu Solar Project, a 15 MW solar array with 60 MWh battery storage, was proposed for Ulupalakua Ranch land. However, it is not currently proceeding. The Hawaii State Energy Office has announced plans for conducting a geothermal survey, so the potential exists for renewable energy projects at Ulupalakua Ranch.

DHHL Reservations

CWRM has established water reservations for DHHL of 2.547 Mgd in the Kama'ole ASA .

Demands to MDWS CMS		
Development	Total Average Demands to MDWS	Maximum Demands to MDWS
MMP Workforce Housing	61,640	92,460
Maluaka Development	11,160	16,740
Makena Resort	60,416	90,624
Ledcor	558,000	837,000
Grand Wailea Enhancement Project	52,850	79,725
H-2 Domestic Potable	47,700	71,550
Total	791,766	1,187,649



Total Demands on Kama'ole Aquifer		
Development	Total Average Demands on Aquifer	Maximum Average Demands on Aquifer
Current 12-MAV Use	3,660,000	3,660,000
MMP	976,036	1,464,054
U-1 Makena Ranch	277,292	415,938
Wailea 670/Honua'ula	1,700,000	2,550,000
H-2 Irrigation Non-Potable	66,400	99,600
Total Additional Pumpage (Excluding 12-MAV)	3,019,728	4,529,593
Total Pumpage (Including 12-MAV)	6,679,728	8,189,593
DHHL Reservations	2,547,000	2,547,000
Total Including DHHL Reservations	9,226,728	10,736,593

Introduction

Mākena Mauka Project is a low-density master-planned residential community that will offer market rate housing together with residential workforce housing, with a mixture of rural and single-family lots and multi-family residential units, within an area that has largely been planned for such uses for decades. The Project will incorporate the existing 18-hole Mākena North Golf Course and the 18-hole Mākena South Golf Course (to be renovated as part of the land plan), together with a community gathering place, hiking trails, programs to support connectivity, walking, bicycling, and golf cart paths, beach parking for the public, areas reserved for conservation/open space, and areas reserved for public beach access. The Applicant's current vision for the Mākena Mauka Project land plan includes 652 housing units, including 109 onsite residential workforce housing units, and approximately 135,000 sf of operational support buildings, which include golf maintenance, staff offices, restaurants, back of house, golf operations and other uses; within the approximately 1,043.71-acre total Project area which includes approximately 473 acres of parcels proposed for residential development. Figure 1 shows the location of the Mākena Mauka Project and its various land uses.

Mākena Mauka Project

Table 1 summarizes the proposed residential uses within the Mākena Mauka Project, which include 195 single-family units and 457 multi-family units. Within the 195 single-family units will be 15 workforce housing units and within the 457 multi-family units will be 94 workforce housing units. All of the workforce housing will be supplied by Maui Department of Water Supply (MDWS). Also noted within Table 1 is the adjacent U1 Mākena Ranch Agricultural Subdivision which includes 72 single-family units that will be utilizing the privately owned and operated water system. There are other relatively minor water uses listed in Table 2

Mākena Ranch Agricultural Subdivision

This Project consists of 36 lots and it will be supplied by the same wells as for the Mākena Mauka Project. In calculating its required water supply, it is assumed that a second residence would ultimately be constructed on all 36 Lots. It is also assumed that landscape irrigation would be limited to one acre per lot. Its water system, using reverse osmosis (RO) filtration to produce the potable supply and untreated well water for irrigation has been designed and is currently under construction (Figure 2). The two wells identified as ATC Mākena 3 Well (State No. 3925-002) known as ATC-3 and ATC Mākena 7 Well (State No. 3925-003) known as ATC-7 would provide the supply. Each well was pump tested at a little over 350 GPM (Figures 3 and 4) and produced stable chlorides of 260 and 368 MG/L, respectively. Their permanent pumps will be 350 GPM. A third well, identified as ATC-8 (State No. 3925-004) has also been constructed and pump tested. Its yield is equivalent to the ATC-3 and ATC-7 Wells (Figure 5).

The three wells identified above will be the sources of supply for the Mākena Mauka Project and the Mākena Ranch Agricultural Subdivision. To quantify their combined safe yield, it is assumed that one well would be down and the two other two wells with 350 GPM pumps would provide the safe yield.

Required Water Supply

Table 2 presents the calculation of the required supply for both Projects. Use rates for the calculations are greater than MDWS standards. As stated previously, the 15 single-family and 94 multi-

family workforce housing units in the M-2 and M-3 lots of the Mākena Mauka Project will be supplied by MDWS. The required maximum day potable supply for both Projects, excluding the workforce housing and assuming a 65 percent recovery rate in the RO treatment process amounts to 686,308 GPD, equivalent to 477 GPM if pumped 24 hours a day. This is less than the safe yield from two of the three 350 GPM supply wells. In addition to the required new supply tabulated in Table 2, the Project will include approximately 65 additional acres of South Golf Course irrigated area in addition to the existing 100 acres of the operational North Golf Course.

At the Project's full build out and occupancy, wastewater generation would be treated to R-1 quality and made available for irrigation use. Also at full build out, the RO treatment process is expected to produce 182,000 GPD of concentrate. On a long-term basis, and in line with the sustainability objectives for the project, these two sources of supply would be blended with brackish well water and used for golf course irrigation. This use of blended R-1 and RO concentrate will reduce use of brackish well water for golf course irrigation needs.

On an interim basis, the additional golf course irrigation would be provided by brackish well water from the 12 existing irrigation wells at Makena. A number of these are not currently operational and would need to be made operational. At full capacity, these 12 wells provide 4.97 million gpd of potential supply, which is more than enough to cover the additional demand from the South Golf Course [in decades past, the wells irrigated two 18-hole golf courses.]

Notably, at full build out there would be a substantial volume of RO concentrate (about 182,000 GPD) for reuse or disposal. The State of Hawaii Department of Health's (DOH) current position is that the RO concentrate cannot be reused for irrigation. The reality is that it is likely to be too saline for irrigation in the two Projects but may be appropriate for golf course irrigation. If DOH's position on the RO reuse is not changed, then a method of disposal would be required. A disposal well or pit would ultimately need to be installed.

Summary Conclusions

The three, slightly brackish Wells (ATC-3, ATC-7, and ATC-8), with RO treatment for potable supply, will have sufficient capacity for the Mākena Mauka Project and the Mākena Ranch Agricultural Subdivision for a dual water system. Irrigation would be by untreated well water and may require a modest supplement from an existing golf course irrigation well. The three ATC Wells do not have sufficient capacity for a single potable and irrigation water system due to the requirement to RO treat the well water for irrigation.

The RO treatment will produce a concentrate for possible reuse or disposal. The State Department of Health's current position does not allow reuse of the concentrate. If that position is not changed, the concentrate would have to be disposed of in a disposal well or pit.

I. INTRODUCTION

I. INTRODUCTION

A. PROJECT BACKGROUND

The Kihei-Makena region contains an array of land uses, ranging from rural residential communities to commercial centers and master-planned resorts, each interlaced with public parks and other recreational facilities. The area specific to Makena is comprised of open mountainsides, a string of beaches, high-end residences, a world-class resort, and scenic vistas. These characteristics have established this region of Maui as a highly desirable vacation destination.

As this region of South Maui flourished, a resort community master plan better known as Makena Resort Master Plan was developed for approximately 1,860 acres. See **Figure 1**. In November 1998, a request for a Change in Zoning (CIZ) was filed with the County of Maui, Department of Planning. The CIZ request sought to reclassify approximately 603 acres of the 1,860 acres of land encompassed by Makena Resort. In 2007, the lands owned by Makena Resort Corp. were purchased by various entities and affiliated companies, and referred to hereinafter as "Makena Resort". Makena Resort pursued the County entitlements, and after careful review and deliberation by the Maui County Council, the CIZ was approved in December 2008, and was signed into law January 7, 2009. The CIZ approval was subject to a list of 44 conditions pertaining to cultural resources, environmental protection, recreation, affordable housing, and traffic, among others.

1. CIZ Conditions

One of the 44 conditions, Condition No. 27, required a water conservation plan for Keaka LLC, Makena Golf, LLC, Makena Hotel, LLC, Makena Resort Services LLC, and Makena MF-2&3, LLC, its successors and permitted assigns, referred to hereinafter as "Makena Resort". The condition reads as follows:

Condition No. 27:

> *The developer shall provide a water conservation plan for the Makena Resort Area, approved by the Department of Water Supply, prior to the issuance of any SMA permits. For each project, the developer shall construct a dual waterline system to accommodate*

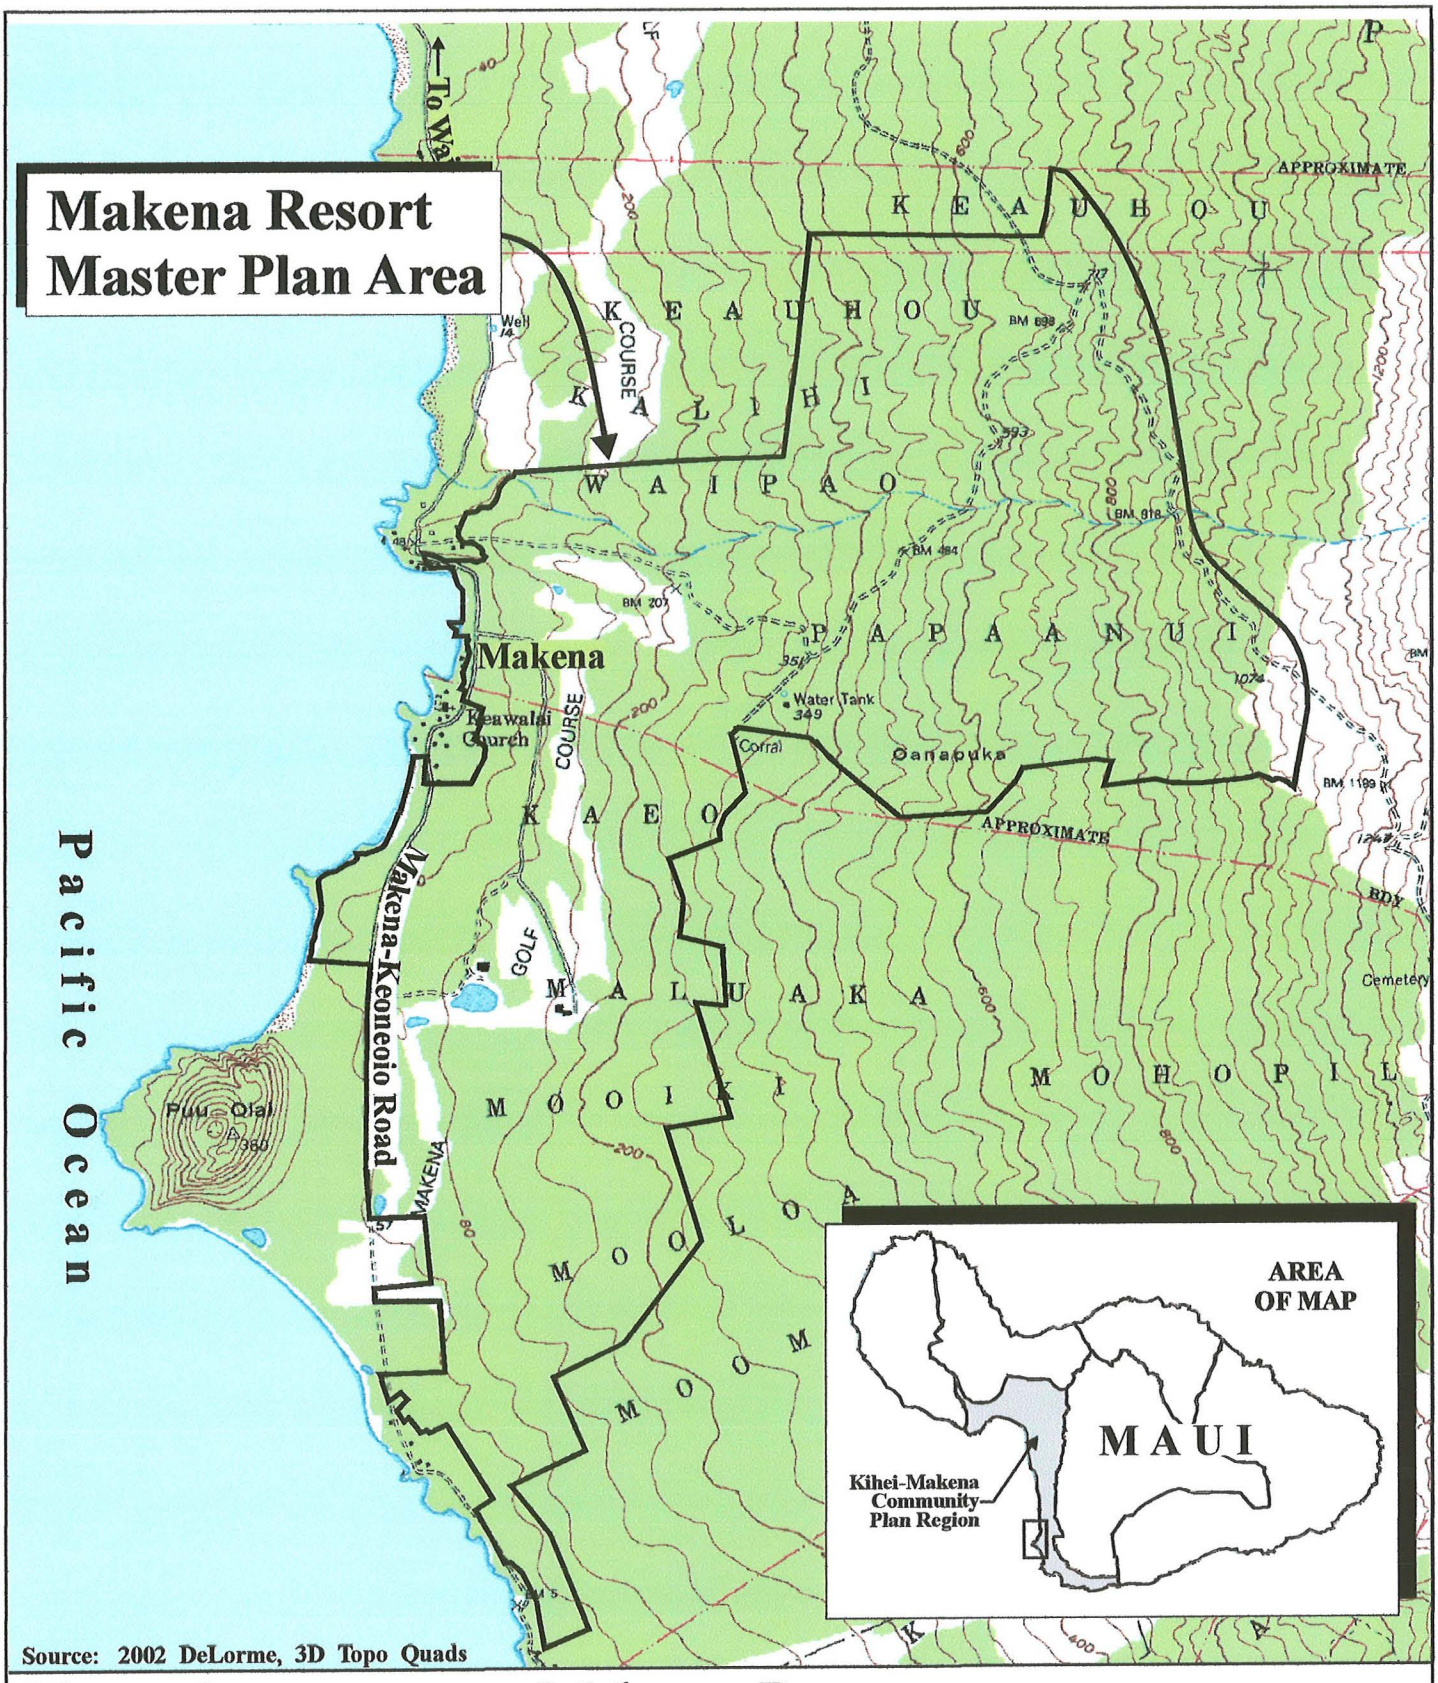

Figure 1

MUNEKIYO & HIRAGA, INC.

Dowling\MakenaConditions\WaterPlan\REGIONAL

non-potable water for landscaping and irrigation purposes prior to the issuance of any building permits.

B. WATER CONSERVATION PLANNING OBJECTIVES

Pursuant to Condition No. 27 set forth by the CIZ approval, the Water Conservation Plan (WCP) seeks to manage water resources at Makena Resort. The primary objective of this WCP is to encourage water conservation practices through planned improvements and conservation measures that reduce water use. The WCP's goal is to reduce indoor demand for water through water-efficient fixtures and fittings; and reduce landscaping irrigation through the use of non-potable water sources. This WCP will be submitted for review and approval by the County of Maui, Department of Water Supply.

Water is a vital resource and the future residences and businesses of Makena Resort will employ high efficiency water systems to meet the objectives of the WCP through reduction of water consumption throughout Makena Resort.

II. COMMUNITY CONTEXT

II. COMMUNITY CONTEXT

While the Makena Resort Master Plan encompasses resort residences, a world class hotel, and resort-oriented shopping and recreational facilities, the surrounding region contains a varied array of land uses as well. In this context, South Maui attracts a significant number of visitors while accommodating a sizeable population of local residents.

A. SURROUNDING LAND USES

1. Residential

According to the 2006 Socio-Economic Forecast for the County of Maui, the 2005 resident population of the Kihei-Makena region was estimated at 25,609 people, a 67 percent increase from the 1990 population of 15,365 people (Department of Planning, 2006). In concert with this documented population growth, the housing stock of the Kihei-Makena region has also expanded in recent years. Together, the towns of South Maui, namely Kihei, Wailea, and Makena, provide a spectrum of residential neighborhoods, ranging from affordable, single- and multi-family developments to upscale resort-residential and gated communities. Whereas housing in Kihei Town ranges from affordable to market-priced, subdivisions in Wailea and Makena cater to luxury housing markets.

2. Hotels and Resort

Since its early beginnings, the Kihei-Makena region has welcomed a robust visitor population. In 1990, on average, approximately 16,079 tourists stayed in the South Maui area, outnumbering the resident population. Estimates for 2005 show an increase in visitor arrivals, with approximately 19,447 tourists vacationing in the region (Department of Planning, 2006). While Kihei is characterized by a variety of apartment rentals, cottages, and beachfront condominiums, both Wailea and Makena have been developed as master planned resort communities, boasting award-winning spas and world class resorts.

3. Public Services and Facilities

In order to support the ever-growing resident and visitor communities, a number of public services and amenities have been established throughout the region.

a. Police and Fire Protection

Operating out of a substation located at the Kihei Town Center, the Kihei Patrol squad of the County of Maui Police Department covers the Kihei-Makena Community Plan region. Planning has been initiated for a new South Maui Police Station mauka of Pi`ilani Highway in the vicinity of Kanani Road. The project is currently undergoing environmental review and land entitlement amendments.

Fire prevention, protection, and suppression services for the island of Maui are provided by the County of Maui, Department of Fire and Public Safety, which has two (2) stations serving this region: the Kihei Fire Station, which serves Kihei Town, south to Kama`ole Beach Park II; and the Wailea Fire Station, which serves the remainder of South Kihei, south to Makena.

b. Medical Facilities

The only major medical facility on the island is Maui Memorial Medical Center, which is located in Wailuku, approximately 20 miles from the project area. However, a number of medical clinics and doctors' offices offering select medical services are located throughout Kihei and Wailea. These facilities include Kihei Clinic, Wailea Medical Services, Kihei Pediatric Clinic, Kihei Physicians, the Kihei-Wailea Medical Center, Maui Medical Group, and Kaiser Permanente. Meanwhile, planning and design phases of the proposed South Maui Ambulance station have commenced. With an anticipated completion date in 2011, the ambulance station is proposed to be located on Kilohana Drive, adjacent to the Wailea Fire Station.

c. Educational Facilities

The State of Hawai`i, Department of Education (DOE) operates three (3) public schools in the Kihei-Makena region. Kihei Elementary School and Kamali`i Elementary School, each covering grades Kindergarten through 5, are located approximately 2.1 miles apart, both on the makai (west) side of Pi`ilani Highway. Lokelani Intermediate School, which covers grades 6 through 8, is located adjacent to Kihei Elementary School. Of note, the DOE has initiated preliminary planning and design for a new Kihei High School.

Pursuant to site acquisition and land use entitlements, build-out of Kihei High School is anticipated in the next five (5) to ten (10) years.

The Kihei Public Charter High School, offering grades 9 through 12, is located near the northern terminus of Pi`ilani Highway, within the Kihei industrial area.

d. Recreational Facilities

The climate of the South Maui region is decidedly warm and dry, creating optimal conditions for the pursuit of outdoor activities, such as fishing, surfing, jogging, camping, snorkeling, swimming, and windsurfing. In following, the County of Maui has established a variety of public parks along the coast, including Waipu`ilani Park, Kalama Park, and Kama`ole Beach Parks I, II, and III, among others. Other recreational resources include the Kihei Community Center and Aquatic Center, and world-class golf courses and tennis facilities. Meanwhile, Makena State Park, a 165-acre coastal area which includes the popular Big Beach and Little Beach, is well-frequented by both residents and visitors alike.

4. Attractions

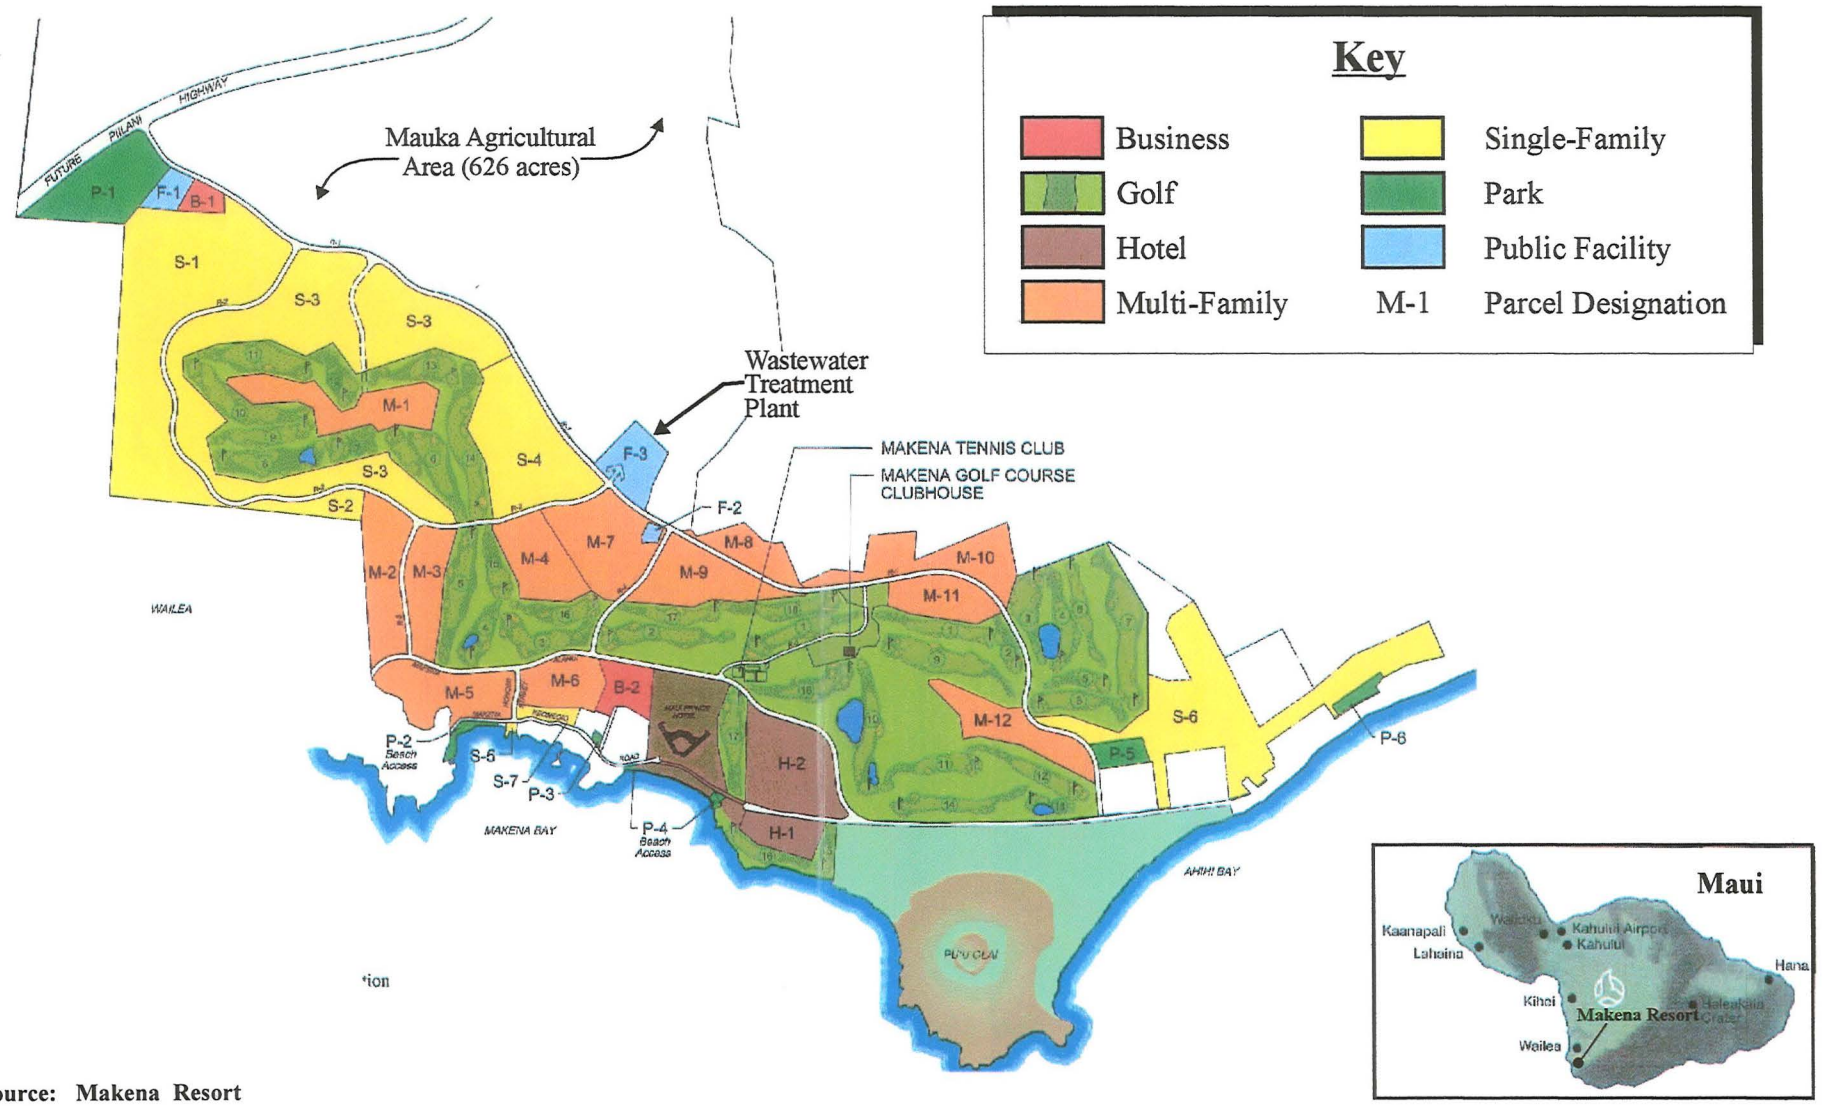
An array of natural features and landscapes may be observed in the South Maui region. A prominent physical landmark located within the immediate vicinity of the master plan area is Pu`u Ola`i, a volcanic cinder cone. Further to the south of Pu`u Ola`i lies the `Ahihi-Kina`u Natural Area Reserve, an area home to a number of rare and endangered native species which is maintained by the State of Hawai`i, Department of Land and Natural Resources. The bays skirting this reserve offer prime snorkeling locations, and a string of beach parks line the entire coastline. Due to their pristine condition, these scenic sites are popular attractions for both residents and visitors.

III. PROJECT OVERVIEW AND DEVELOPMENT PARAMETERS

III. PROJECT OVERVIEW AND DEVELOPMENT PARAMETERS

A. MASTER LAND USE PLAN

Encompassing approximately 1,860 acres of South Maui, the Makena Resort Master Plan includes multi-family and single-family resort residential components, a hotel site, business, retail and commercial areas; and outdoor recreational facilities such as parks and golf courses. Aside from the existing 310 guestrooms and 19 luxury units at Maui Prince Hotel, the Master Plan proposes approximately 849 units, consisting of new hotel rooms, and multi-family and single-family homes. The project area affected by Condition No. 27 is limited to the parcels which were subject to the Change in Zoning (CIZ) action; the 603 acres encompassed by the CIZ project area have approximately 414 units. **Figure 2** exhibits the Master Land Use Plan for Makena Resort.



Current plans for each component of Makena Resort are described below. It is emphasized, however, that these are preliminary plans, subject to change over time.

1. Multi-Family Residential

In total, the master plan dedicates approximately 226 acres to multi-family residential developments, accommodating approximately 475 units. Distributed across the resort property in twelve (12) distinct pockets, these acreages will front stretches of the Makena North and South Golf Courses.

2. Single-Family Residential

Approximately 349 acres of land have been devoted to the development of approximately 217 single-family residential units. Similar to the multi-family lands, these 349 acres are divided amongst seven (7) parcels, distributed throughout the resort property.

3. Hotel

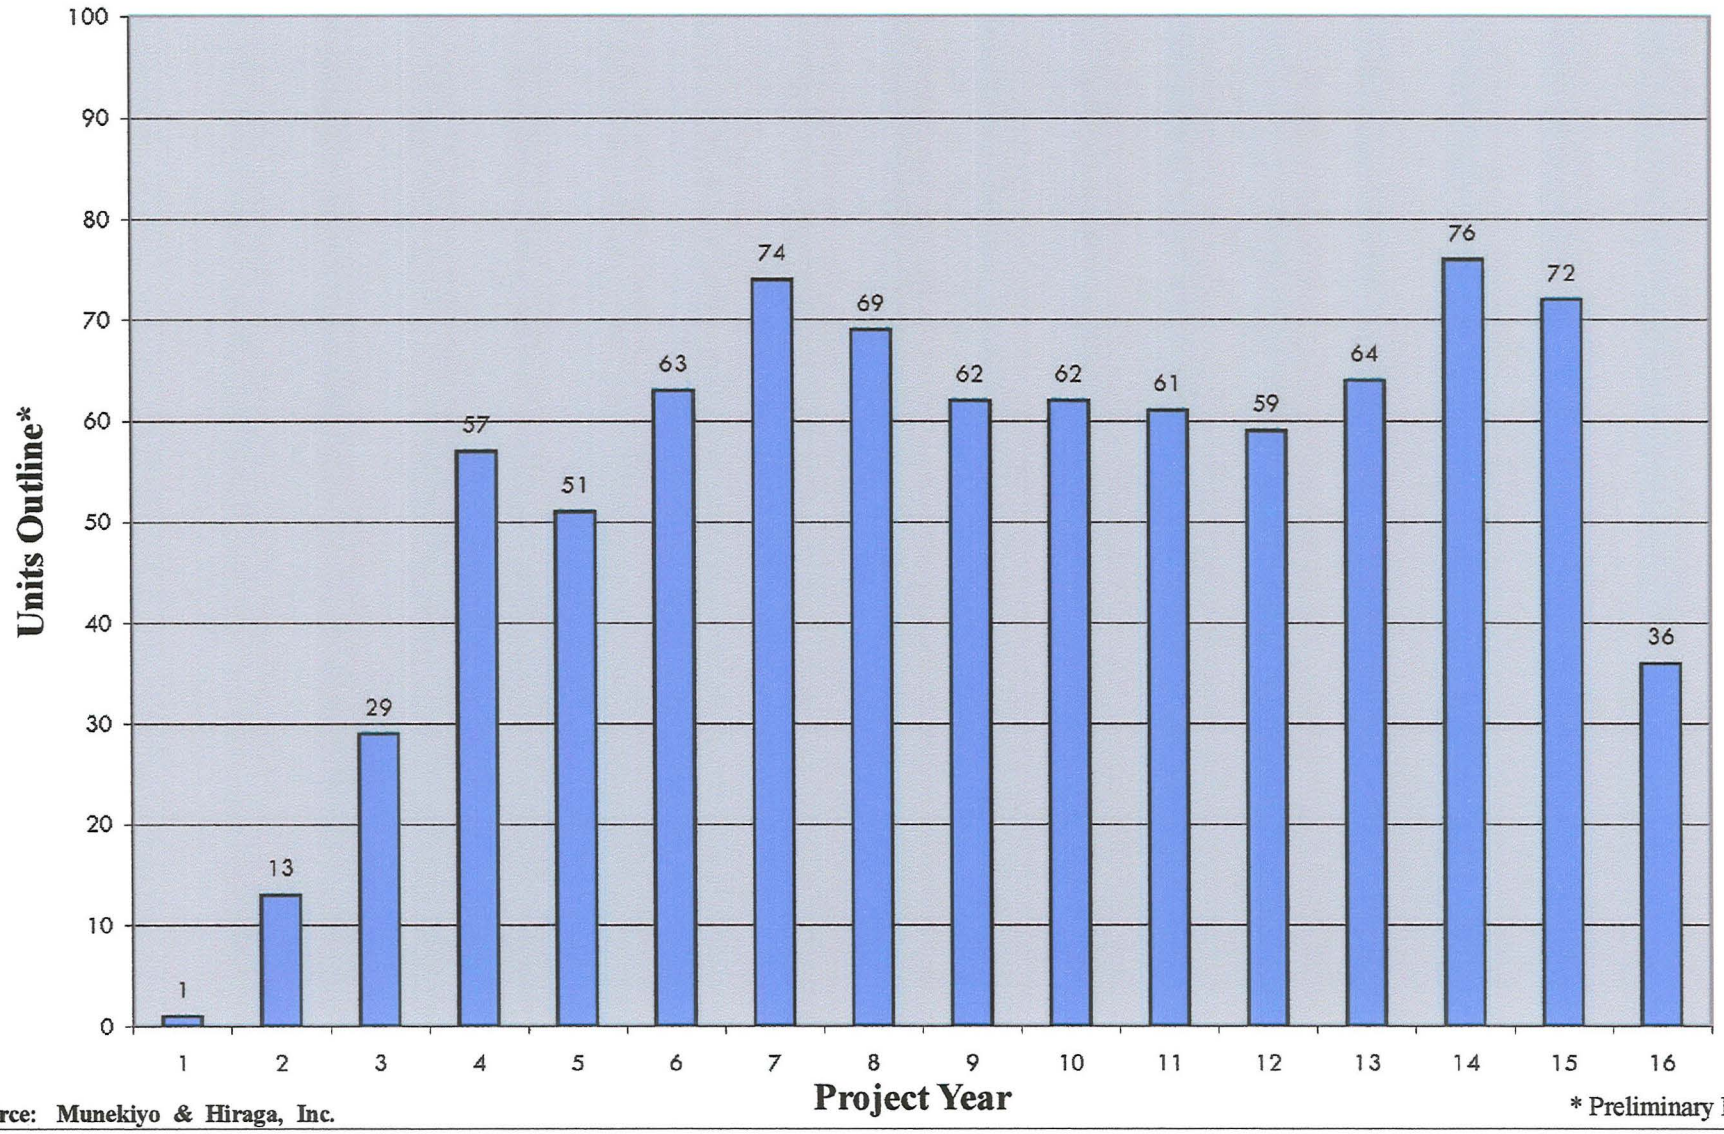
Situated makai of Makena Alanui Road, the Maui Prince Hotel includes 310 guest rooms and 19 luxury units, set atop approximately 38 acres of land fronting the shoreline. In time, however, this facility will be demolished and replaced with a smaller hotel or closed for renovation and subsequent re-opening with less hotel rooms.

4. Village Center

Near the heart of Makena Resort will be a Village Center which will provide for day-to-day needs of residents and guests. Incorporated within this area will be a general store and post office accompanied by a restaurant, cultural center, lecture theater, and other such facilities. This site will be used to support the hotel, golf, and real estate operations of the resort.

5. Parks and Golf Courses

Currently existing within the Makena Resort grounds are the Makena North and South Golf Courses and the Makena Tennis Club, which together, cover an area of approximately 431 acres. In addition to these amenities, the master plan also provides for approximately 35 acres of park lands, scattered in six (6) locations across the resort property.



6. Mauka Agricultural Area

In addition to the multi-family and single-family neighborhoods surrounding the golf courses and *makai* landholdings, the Makena Resort Master Plan also includes an agricultural subdivision located on 626 acres of land in the *mauka* portion of Makena Resort. The 113 units planned for this area will be the last units constructed in Makena Resort.

B. DEVELOPMENT PHASING

At this time, the development of Makena Resort is programmed over a 16-year time span. In sum, the completed development will include approximately 849 resort-residential units. The developer will construct a portion of these 849 units; however, the majority will be custom-built by individual lot owners, with construction operations of the developer limited to site work and related infrastructure and utilities improvements. In effect, although unit

absorption is scheduled over the 16-year duration, construction and sitework activity conducted by the developer will only occur from Project Year 1 through Project Year 11. Construction initiated by individual lot owners will be ongoing through Project Year 16. See **Figure 3**.

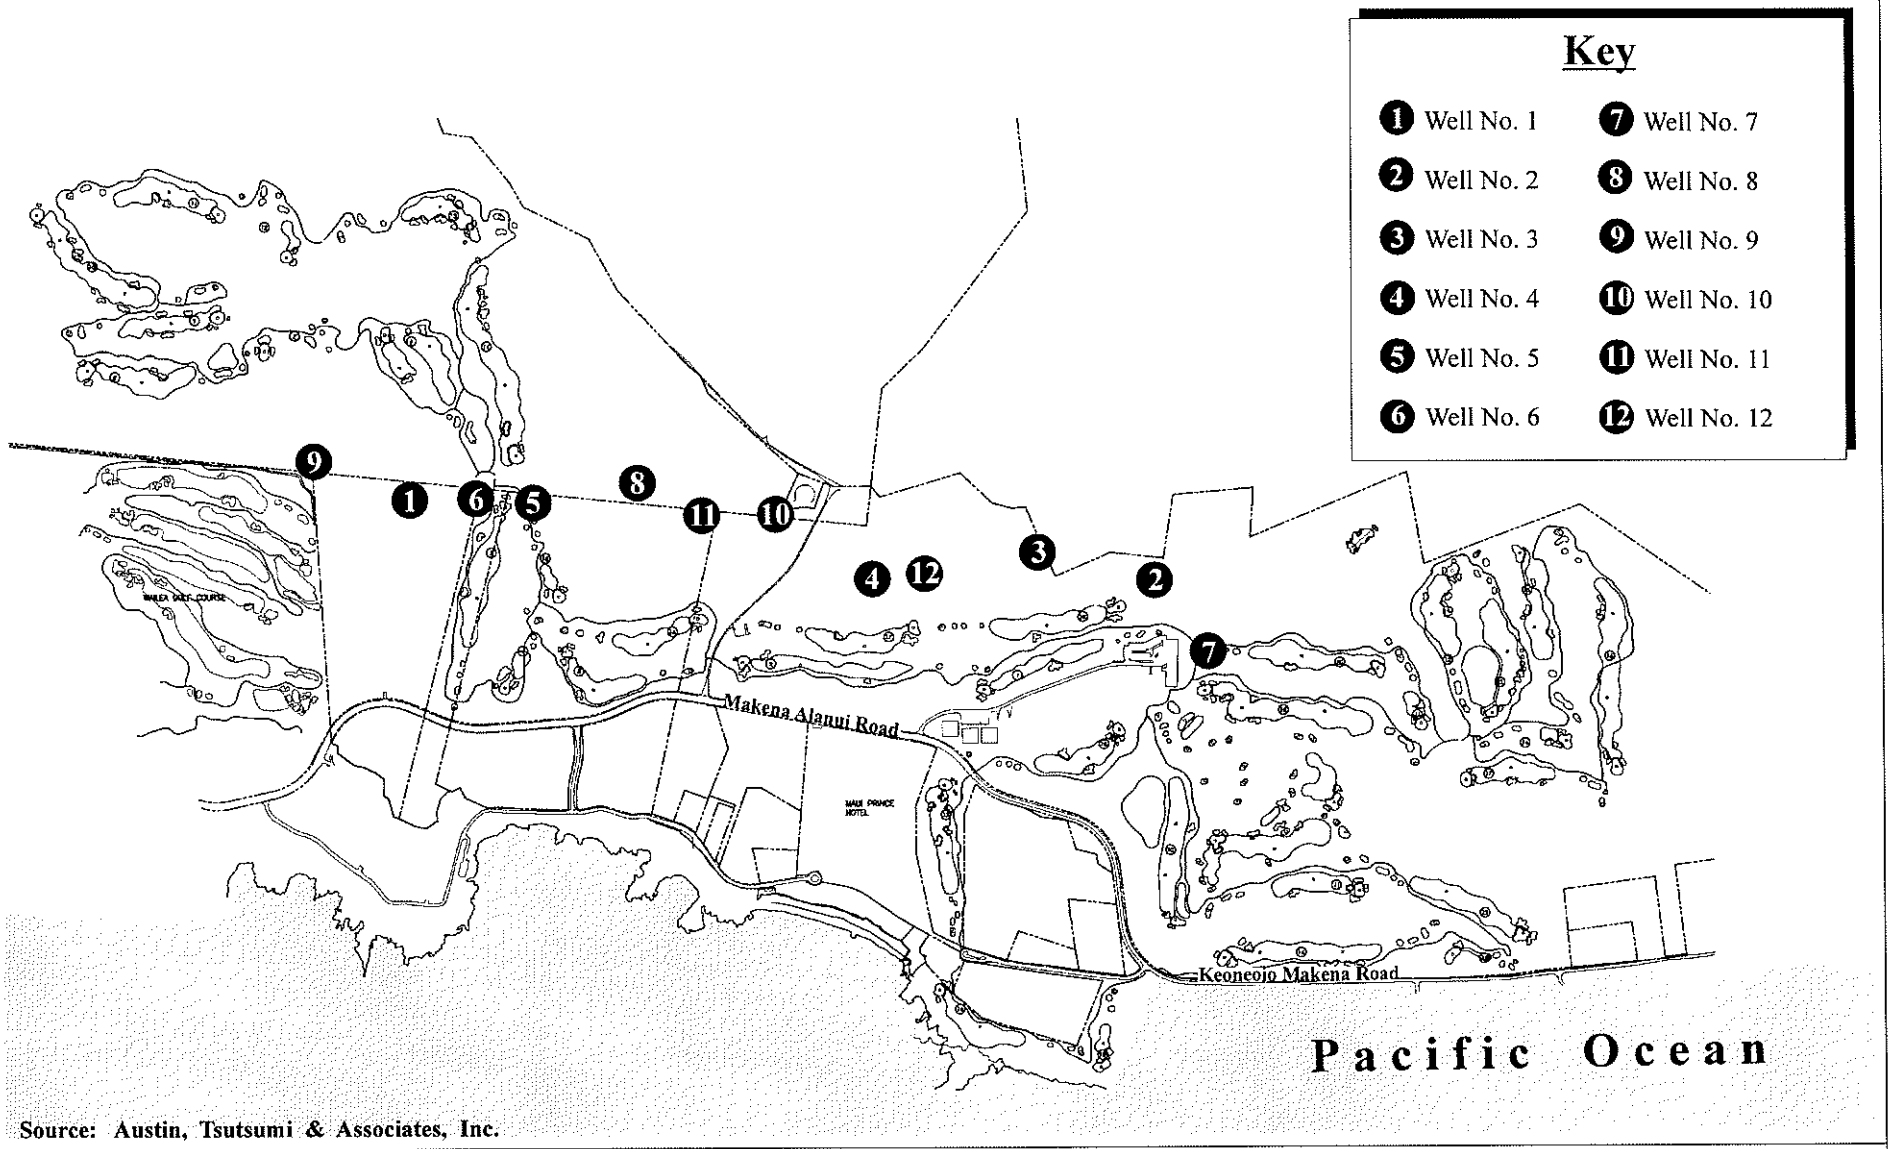
IV. EXISTING WATER SYSTEMS

IV. EXISTING WATER SYSTEMS



Makena Resort has three (3) existing water sources: (1) potable water from the County of Maui, Department of Water Supply; (2) non-potable water from wells; and (3) existing non-potable water from treated effluent from Makena Resort Wastewater Treatment Plant. The following is a discussion on the existing water systems at Makena Resort.

A. POTABLE WATER

The County of Maui, Department of Water Supply provides potable water service to Makena Resort. This system consists of a network of transmission and distribution lines and reservoirs. Existing 12-inch and 20-inch ductile iron waterlines are located within Makena Alanui Road and a 1.5 million gallon watertank is located approximately 265 feet above sea level. Built by Makena Resort Corp. and turned over to the County of Maui, Department of Water Supply, the water tank serves the Makena area.

B. NON-POTABLE WELLS

Makena Resort owns and operates nine (9) wells that provide approximately 2.4 million gallons per day (MGD) of non-potable water, mainly for irrigation purposes. This non-potable water provides water service for the golf courses and landscaping along Makena Alanui Road within Makena Resort. See **Figure 4** for the location of the wells. The capacities of the wells are illustrated in **Table 1**.

Table 1. Makena Non-Potable Well Capacities

Well Number	Capacity (GPD)
#1	336,000
#2	288,000
#3	288,000
#4	192,000
#5	384,000
#6	384,000
#8	192,000
#10	192,000
#11	192,000
TOTAL	**2,448,000**

C. TREATED EFFLUENT FROM WASTEWATER TREATMENT PLAN

A private wastewater treatment plant and reclamation facility is owned and operated by Makena Resort. Refer to **Figure 2** for location. The Makena Resort Wastewater Treatment Plant has a design capacity of 720,000 gallons per day (gpd). As of June 2009, the monthly average daily flow was approximately 80,700 gpd with a maximum daily flow was of 105,000 gpd. The Makena Resort Wastewater Treatment Plant provides a monthly average daily flow of approximately 76,000 gpd of treated effluent for the golf courses, common area landscaping, and construction watering.

V. DESCRIPTION OF WATER CONSERVATION MEASURES

V. DESCRIPTION OF WATER CONSERVATION MEASURES

The objective of Makena Resort Water Conservation Plan is to encourage water conservation practices and measures that reduce water use by specifically reducing indoor demand for water through water-efficient fixtures and fittings; and reduce landscaping irrigation through the use of non-potable water sources. To this end, the following conservation measures will be implemented.

A. UNIVERSAL METERING FOR IRRIGATION WATER

1. Source-Water Metering

Each entity along the irrigation water line benefits from metering. Source metering is essential for water accounting purposes to determine the quantity of water supply. Makena Resort will use metering data to accurately track water usage.

2. Service-Connection Metering

Service-connection metering is needed to inform the end-user of irrigation water use. Meters will be read on a fixed interval once a month. Metering will provide accurate comparisons and analysis. For example, it helps to detect leaks when there is a spike in usage. It also allows for future rate-demand pricing methods where peak usage times are charged a higher rate.

3. Public-Use Water Metering

All irrigation water provided free of charge for public, such as fire hydrant maintenance, use will be metered and read at regular intervals. This will allow Makena Resort to accurately account for water usage for the entire system.

4. Meter Maintenance

Inaccurate meter readings will give misleading information on irrigation water usage, make leak detection difficult, and result in non-potable water waste. Irrigation water meters can be damaged and deteriorate with age, thus all meters should be tested for accuracy and recalibrated on a regular basis. During this process, the Makena Resort will also determine if the meter is appropriately sized. Meters that are too large for an end-user's usage will tend to under-register water usage.

B. IRRIGATION WATER ACCOUNTING AND LOSS CONTROL

Once the irrigation water system is universally metered, Makena Resort's irrigation water accounting systems will track water throughout the system. The system will identify areas that may need attention, particularly large volumes of non-accounted water which includes water for utility purposes (i.e. construction water trucks) and for certain public uses (fire hydrant maintenance). Non-accounted water also includes unauthorized uses, including losses from accounting errors, malfunctioning distribution system controls, thefts, or leaks. This measure will provide valuable data to manage irrigation water properly.

C. WATER AUDITS

Makena Resort currently audits the resort's domestic water use every two (2) months by detailed review of its water bill from the County of Maui, Department of Water Supply. Any spike in water usage is investigated to ensure that water is being used conservatively and leaks are immediately repaired.

In addition, Makena Resort will complete random water audits of its users of irrigation water to ensure minimal water waste.

D. INFORMATION AND EDUCATION

Information and education are critical to the success of any water conservation program. Information and education measures can directly produce water savings when end-users change their water-use habits. These types of water savings are difficult to estimate, however, these measures can enhance the effectiveness of other conservation measures. In

general, end-users that are informed and involved are more likely to support the water conservation planning goals.

Makena Resort will provide irrigation water bills that are both understandable and informative. End-users will be able to identify volume of usage, corresponding rates and quickly identify spikes in usage in comparison to other months. Beyond the basic information, Makena Resort will provide tips on water conservation that help end-users make informed decisions on water use.

Makena Resort will initiate a water conservation advisory committee that will involve the Makena Resort community in the conservation process. The committee's objective will be to provide feedback and help implement its water conservation plan. The committee will consist of a Makena Resort representative, Homeowners Association Presidents, and Building Managers (i.e. Hotel Director of Engineering). The committee will meet quarterly to discuss, among other topics, implementation of water conservation measures.

E. WATER USE STANDARDS

1. Indoor Water Use

The Makena Resort's Design Guidelines will impose standards on new homes with regard to water conserving plumbing fixtures and irrigation equipment. These include flow restrictors at all shower heads and faucets, low-flow toilets and low-flow irrigation heads. Plumbing fixtures specification shall be included in the construction drawings. For example, M-2 and M-3 Design Guidelines for the proposed project require that high-efficiency fixtures and fittings must meet the following requirements:

- The average flow rate of all lavatory faucets must be less than or equal to 2.0 gpm.
- The average flow rate of all shower heads must be less than or equal to 2.0 gpm.
- The average flow rate of all toilets must be less than or equal to 1.3 gallons per flush or toilets must be dual-flush.

In addition, Makena Resort Design Guidelines will impose Energy Star® standards on new homes for dishwashers and clothes washers. Energy Star® qualified

appliances incorporate advanced technologies that use 10 to 50 percent less water than standard models.

Furthermore, future residences will be Leadership in Energy and Environmental Design (LEED) Certified under the U.S. Green Building Council's LEED for Homes Green Building Rating System as required by Makena Resort Design Guidelines. LEED is a nationally recognized standard for design and construction of high-performance green buildings. LEED includes a section for indoor water use that minimizes indoor demand for water through water-efficient fixtures and fittings.

2. Landscaping Water Use

Makena Resort will provide non-potable water from their existing non-potable water wells and treated effluent from the Makena Resort Wastewater Treatment Facility. Each project will consist of a dual waterline system that will provide non-potable water for common area landscaping irrigation use. In addition, each single-family residence will have a dual-line system that users can utilize to reduce potable water use through non-potable water sources.

Additionally, the Makena Resort's Design Guidelines will provide a Plant Palette that requires both water conserving plants and sense of place. The majority of the Plant Palette lists Moderate to High drought tolerant plants. The Design Guidelines also encourage carefully designed irrigation systems that could include drip irrigation, high-efficiency nozzles, and moisture sensors to reduce common area landscape irrigation needs.

VI. SUMMARY

VI. SUMMARY

In summary, Makena Resort's WCP outlines a list of water conservation measures that include water accountability, education, audits and design standards that will reduce indoor demand for water through water-efficient fixtures and fittings. Additionally, the resort will reduce potable water demand for landscaping irrigation through the use of non-potable water sources for common areas, as well as individual single-family residences.

Flora and Fauna Surveys Report Proposed Makena Ma Uka Project

Date: March 26, 2025
Survey Period: September - December 2024
Survey Area: Makena, Maui (Approximately 1,043.71 acres surveyed)
Surveyor: Rick Barboza

Executive Summary:

This report details the findings of a biological survey conducted at the project site of Mākena Mauka between September and December 2024. Survey results revealed severely impacted native plant communities and a landscape dominated by invasive species, with native flora struggling to survive due to pressure from axis deer, competition from non-native plants, and a high fire risk. A total of 170 different plant species were observed, only 26 of them native; Three highly destructive alien mammal species and one endemic bat; 22 bird species (4 of them native, 2 annual visitors); as well as 20 alien insect species and two native species.

The proposed project area itself, Mākena Mauka, is a low-density master-planned residential community that will offer market rate housing together with residential workforce housing, with a mixture of rural and single-family lots and multi-family residential units, within an area that has largely been planned for such uses for decades. The project will incorporate the existing 18-hole Mākena North Golf Course and the 18-hole Mākena South Golf Course (to be renovated as part of the land plan), together with a community gathering place, hiking trails, programs to support connectivity, walking, bicycling, and golf cart paths, beach parking for the public, areas reserved for conservation/open space, and areas reserved for public beach access.

The intended use for the Mākena Mauka land plan is for 652 housing units, including 109 onsite residential workforce housing units, within the approximately 1,043.71-acre total project area which includes approximately 473 acres of parcels proposed for residential development.

A project of this scale can greatly impact what few native species remain in a positive way by creating a unique opportunity to rebuild a functional and interactive dry forest ecosystem or in a negative way if managed poorly. This report outlines the survey findings, identifies key threats, and proposes a

comprehensive restoration strategy. The restoration of this area, even prior to development, will significantly improve its ecological function and aesthetic value.

Mix of alien kiawe and koa haole trees, lion's ear and buffel grass

'Ilie'e struggling in severe drought and alien weed competition

1. Introduction:

Lowland dry forests in Hawai'i were once biologically diverse hotspots. This survey aimed to assess the current condition of the native plant communities in the proposed project areas of Mākena Mauka, Maui; document the presence and health of native species, identify the primary threats to their survival, and utilize this information to develop a workable restoration plan with ultimate goal of enhancing the population sizes of existing native species as well as reestablishing other native species from neighboring populations to compliment the Sustainability, Conservation and overall Landscape Management Plans of this project.

2. Regulatory Environment:

This chapter describes the laws and regulations applicable to terrestrial flora and fauna in the context of the project.

2.1 ENDANGERED SPECIES ACT

The federal Endangered Species Act of 1973, as amended (ESA), is regulated by the U.S. Fish and Wildlife Service (USFWS) and National Oceanic and Atmospheric Administration National Marine Fisheries Service and protects wildlife and plant species that have been listed as threatened or endangered. It is designed to conserve the ecosystem on which species depend. Candidate species, i.e., species that may be listed in the near future, are not afforded protection under the ESA until they are formally listed as endangered or threatened. Section 9 of the ESA and rules promulgated under Section 4(d) of the ESA prohibit the unauthorized take of any endangered or threatened species of wildlife listed under the ESA. Under the ESA, the term "take" means "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect species listed as endangered or threatened, or to attempt to engage in any such

conduct. (ESA16 US Code 1532(19) At the time of this report, defined in regulations, the term "harm" means "an act that actually kills or injures wildlife; it may include significant habitat modification or degradation, which actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering" (50 Code of Federal Regulations [CFR] 17.3). The rules define "harass" to mean "an intentional or negligent act or omission that creates the likelihood of injury to wildlife by annoying it to such an extent, as to significantly disrupt normal behavior patterns, which include, but are not limited to, breeding, feeding,
or sheltering" (50 CFR 17.3). However there is a proposal by the US Fish and Wildlife Service and the National Marine Fisheries Service to rescind the regulatory definition of "harm" in the Endangered Species Act regulations. [Published Document:2025-06746 (90FR16102)] This proposal is still under review so until official changes have been made the ESA affords maximum legal protections to species listed as threatened or endangered under the law and also provides authorization for incidental take permits for take that occurs incidental to otherwise legal operations. To comply with federal laws, additional measures must be taken to ensure that take of ESA-listed species does not occur. Any fatality of a listed species should be reported to the USFWS and the Hawai'i Division of Forestry and Wildlife as soon as possible, and an incident report should be filed within 24 hours of detection of the fatality.

2.2 MIGRATORY BIRD TREATY ACT

The Migratory Bird Treaty Act of 1918, as amended (MBTA), is regulated by the USFWS and prohibits the take of migratory birds. A list of birds protected under MBTA-implementing regulations is published under 50 CFR 10.13. Unless permitted by regulations, under the MBTA, "it is unlawful to pursue, hunt, take, capture or kill; attempt to take, capture or kill; possess, offer to sell, barter, purchase, deliver or cause to be shipped, exported, imported, transported, carried or received any migratory bird, part, nest, egg or product" (16 United States Code 703–712). The MBTA provides no process for authorizing incidental take of MBTA-protected birds. As a result, birds that are not covered under the ESA that may be adversely affected by the proposed projects cannot be covered by take authorizations. However, the direction of Executive Order 13112 allows for the take of cattle egret (Bubulcus ibis) and barn owl (Tyto alba) by agencies that have functional and/or jurisdictional responsibility for controlling invasive species and protecting native species in Hawai'i (USFWS 2017). Regardless, potential incidental take of MBTA-protected species should be considered during evaluation of the environmental impacts of any proposed project.

3. Project Site and Vegetation Description:

The vegetation on this large property is quite diverse. Several distinctly different habitats are represented, each of which has a different complement of plant species. These habitats fall into five categories, each of which is described separately.

Clubhouse Complex - This approximately 10-acre area contains the clubhouse, office, tennis courts and parking area. These facilities are surrounded by intensively maintained landscaping including shade trees, lawns, hedges and a variety of ornamental plant species. Approximately 40% of the plants on the species inventory fall in this category. Ten common native species were incorporated into this landscape.

Golf Course - The fairways and greens of the approximately 150 acres Makena Golf Course are also an intensively managed landscape. The vast majority of this area consists of a monoculture of Paspalum

grass (*Paspalum vaginatum*) and its varieties that are mowed fertilized, weeded and irrigated to maintain ideal playing surfaces. Planted along the edges of the fairways are a selection of trees, shrubs and ground covers that frame and accent the course. A few native species that have been used include naupaka kahakai (*Scaevola taccada*), hala (*Pandanus tectorius*) and wiliwili (*Erythrina sandwicensis*). Polynesian introductions include niu (*Cocos nucifera*), milo (*Thespesia populnea*) and noni (*Morinda citrifolia*). All of these are common and widespread species in Hawaii.

Coastline - This approximately 4 acre strip of coastal vegetation at Maluaka is mostly naturally occurring and consists of plant species that can withstand salty sea breezes. This rocky coastline is mostly dominated by naupaka kahakai and a variety of non-native shrubs, grasses and weeds. Small amounts of two other native plants, *kīpūkai* (*Heliotropium curassavicum*) and *ʻākulikuli* (*Sesuvium portulacastrum*) were also found here. All of these native plants are common and widespread.

Dry Forests - The dry forest makes up the largest portion of the project area, roughly 370 acres, that surround the golf course and most of the southern part of the area. This forest is dominated by *kiawe* trees (*Prosopis pallida*), sourgrass (*Digitaria insularis*), koa haole (*Leucaena leucocephala*) and wild basil (*Ocimum gratissimum*). Also common are wiliwili (*Erythrina sandwicensis*), Guinea grass (*Megathyrsus maximus*), golden crown-beard (*Verbesina encelioides*), coffee senna (*Senna occidentalis*), lantana (*Lantana camara*), hairy abutilon (*Abutilon grandifolium*), Santa Maria (*Parthenium hysterophorus*), *'ilima* (*Sida fallax*) and keeled wormseed (*Dysphania carinata*). Besides *wiliwili* and *'ilima*, six other native plant species were frequently surveyed in this habitat: *maia pilo* (*Capparis sandwichiana*), *ma'o* (*Abutilon incanum*), *koali kuahulu* (*Merremia aegyptia*), *'uhaloa* (*Waltheria indica*) and *pōpolo* (*Solanum americanum*).

Kumuniu habitat and types of terrain that more time was spent looking for native plants

Aquatic Habitats - This habitat includes about 4 acres of manmade water features within the golf course landscape. Water features support a distinctively different array of vegetation and wildlife that do not occur in drier habitats. Common plant species here included the native *'ae'ae* (*Bacopa monnieri*), *naupaka kahakai*, (*Cyperus polystachyos*) and *hala* (*Pandanus tectorius*) as well as the non-native wedelia (*Sphagneticola trilobatus*), Indian fleabane (*Pluchea indica*), umbrella sedge (*Cyperus involucratus*) and Mexican washingtonia palm (*Washingtonia robusta*).

4. Survey Methodology:

The survey, conducted between September and December 2024, encompassed 1043-acres and involved a combination of survey methods. Perimeter surveys were conducted using an all-terrain vehicle (ATV) to

establish the boundaries of the study area and identify access points. Within the perimeter, transects were surveyed on foot by a team walking side-by-side within view of each other or roughly 10 meters apart. Any questionable species not one hundred percent identifiable by any team member was photographed and sent to the lead botanist to determine immediately what it was or if it needed further investigating. These transect surveys allowed for detailed visual reconnaissance, photographic documentation, and species identification. Emphasis was placed on locating and assessing the health of native plant species, documenting the extent of alien plant species dominance, and observing the impacts of axis deer activity. Extended time was spent in areas that had a higher concentration of *wiliwili* trees, or other natives like *ʻilima* (*Sida fallax*) and *maiapilo* (*Capparis sandwichiana*) as well as in areas where drastic elevation changes occurred from either a ravine or any sort of large hill, mound or rock piles since these areas held a greater possibility of finding other native plant species. Every floral and fauna species observed was then grouped together and listed out in a Table 1 by family and each item, when applicable included the botanical, Hawaiian and common name for each species, their biological status of either being Alien, Polynesian introduced, indigenous or endemic as being noted as Endangered if that was the case. The table also approximates their abundance relative to the rest of the species documented.

5. Flora Survey Findings:
The resulting checklist for the entire project area included 170 plant species. The native and Polynesian introduced species are itemized as follows:

Endemic Hawaiian plants:
wiliwili (*Erythrina sandwicensis*)
maiʻa pilo (*Capparis sandwichiana*)
puakala (*Argemone glauca*)
kumuniu (*Doryopteris decipens*)

Indigenous Hawaiian plants:
kupukupu (*Nephrolepis cordifolia*)
ʻukiʻuki (*Dianella sandwicensis*)
kiolohia (*Cyperus polystachyos*)
hala (*Pandanus tectorius*)
ʻākulikuli (*Sesuvium portulacastrum*)
kīpūkai (*Heliotropium curassavicum*)
koali kuahulu (*Merremia aegyptia*)
naupaka kahakai (*Scaevola taccada*)
ʻilima (*Sida fallax*)
ʻilieʻe (*Plumbago zeylanica*)
ʻuhaloa (*Waltheria indica*)
naio (*Myoporum sandwicense*)
ʻaeʻae (*Bacopa monnieri*)
ʻaʻalii (*Dodonaea viscosa*)
pili (*Heteropogon contortus*)
pōpolo (*Solanum americanum*)
pōhinahina, manawanawa (*Vitex rotundifolia*)

ma′o (*Abutilon incanum*)
niu, coconut (*Cocos nucifera*)
moa (*Psilotum nidum*)
′ala′alawainui (*Peperomia blanda*)
alena (*Boerhavia repens*)

Polynesian introduction:
hau (*Hibiscus tiliaceus*)
milo (*Thespesia populnea*)
kī, ti leaf (*Cordyline fruticosa*)
′ape (*Alocasia macrorrhiza*)
noni (*Morinda citrifolia*)
kukui (*Aleurites mollucana*)

The remaining 139 species are non-native, ornamental plants or naturalized trees, shrubs, vines or herbaceous plants and can be seen on the attached Table 1. Flora and Fauna Species List

- **Dominant Tree Species:** The native *wiliwili* tree (*Erythrina sandwicensis*) was present throughout the site and shared a sizable amount of canopy space, with visual observation suggesting approximately 20 percent of the overall coverage. The rest of the canopy coverage is heavily dominated by introduced trees, most notably *kiawe* (*Prosopis pallida*) and *koa haole* (*Leucaena leucocephala*).
- **Wiliwili Regeneration Crisis:** Existing mature *wiliwili* trees produce a large amount of seeds annually, although no precise count was made. Observations noted multiple average sized trees between 15 to 20 ft tall had over a 1,000 seed pods totaling over 2,500 seeds on each tree. However, seedling recruitment is virtually non-existent due to axis deer predation and competition for water resources and suitable germinating substrate from invasive grasses and shrubs. Within the entire restoration site, only one seedling was documented yet over 100 mature *wiliwili* trees were observed to be dead or in grave decline as a result of prolonged and severely dry soil from surrounding invasive plant competition as well as scarring and root trampling from Axis deer. There were also three trees observed to be hollowed out and subsequently occupied by barn owls (*Tyto alba*) or honey bees (*Apis mellifera*)
- **Understory Composition:** The understory is almost entirely composed of non-native grasses and shrubs, creating a dense, dry fuel load and significantly increasing the risk of wildfires.
- **Axis Deer Impact:** *Axis deer* (*Axis axis*) are a major ecological driver of degradation. Their browsing pressure on seedlings and saplings prevents native plant regeneration, contributes to soil erosion, and facilitates the spread of invasive plants. Deer scat and tracks were observed throughout the survey area.
- **Remaining Native Species:** *ʻUhaloa* (*Waltheria indica*), ma'o (*Abutilon incanum*) and *ʻilima* (*Sida fallax*) were observed relatively frequently. *Maiapilo* (*Capparis sandwichiana*) was present but in much lower numbers than expected compared to parallel elevations on properties adjacent to this site. Only one endemic prickly poppy (Puakala) was seen as well as only one patch of *ʻAlaʻalawainui* (*Peperomia blanda*) and one small area of *ʻilieʻe* (*Plumbago zeylanica*).

6. Threats to Native Flora:

- **Axis Deer:** Direct browsing, erosion, and invasive species dispersal. Increased spread of less desirable foraging
- **Invasive Plant Species:** Competition for resources, altered fire regimes, and habitat degradation.
- **Fire:** The high fuel load of non-native grasses in this extremely dry environment creates favorable conditions for fast spreading fire potential.
- **Habitat Loss and Fragmentation:** Past land use practices, dominant alien plant communities and future development plans could further contribute to habitat loss and increase distances between healthier native plant populations.

7. Restoration Recommendations:

We recommend using native plant species for landscaping that are appropriate for the area, i.e., plants for which climate conditions are suitable for them to thrive, plants that historically occurred there, etc. For guidance, please refer to www.plantpono.org on the selection and evaluation of landscaping plants and to determine the potential invasiveness of plants proposed for use in the project.

We recommend minimizing the movement of plant or soil material between worksites. Soil and plant material may contain detrimental fungal pathogens (e.g., Rapid 'Ohi'a Death), vertebrate and invertebrate pests (e.g., Coqui Frogs, Little Fire Ants, etc.), or invasive plant parts (e.g., Miconia, Mullein, etc.) that could harm our native species and ecosystems. We recommend consulting the Maui Invasive Species Committee (MISC) at (808) 573-6472 to help plan, design, and construct the project, learn of any high-risk invasive species in the area, and ways to mitigate their spread. All equipment, materials, and personnel should be cleaned of excess soil and debris to minimize the risk of spreading invasive species.

The invasive Coconut Rhinoceros Beetle (CRB) or Oryctes rhinoceros is found on the islands of O'ahu, Hawai'i Island, Maui and Kaua'i. On July 1, 2022, the Hawai'i Department of Agriculture (HDOA) approved Plant Quarantine Interim Rule 22-1. This rule restricts the movement of CRB-host material within or to and from the island of O'ahu, which is defined as the Quarantine Area. Regulated material (host material or host plants) is considered a risk for potential CRB infestation. Host material for the beetle specifically includes (a) entire dead trees, (b) mulch, compost, trimmings, fruit and vegetative scraps, and (c) decaying stumps. CRB host plants include the live palm plants in the following genera: Washingtonia, Livistona, and Pritchardia (all commonly known as fan palms), Cocos (coconut palms), Phoenix (date palms), and Roystonea (royal palms). When such material or these specific plants are moved there is a risk of spreading CRB because they may contain CRB in any life stage. For more information regarding CRB, please visit https://dlnr.hawaii.gov/hisc/info/invasive-species profiles/coconut-rhinoceros-beetle/.

Avoid importing soil or other plant material from off-island. Soil and plant material may contain fungi (e.g., Rapid 'Ohi'a Death) and other pathogens that could harm our native species and ecosystems. We recommend consulting the Hawai'i Interagency Biosecurity Plan at http://dlnr.hawaii.gov/hisc/plans/hibp/ in planning, design, and construction of the project.

We recommend that Best Management Practices are employed during and after construction to contain any soils and sediment with the purpose of preventing damage to near-shore waters and marine ecosystems.

8. Conclusion:

The Makena area, despite its current degraded condition, holds significant potential for ecological restoration. The remnant *wiliwili* forest and the presence of rare endemic species provide a foundation and blueprint upon which to rebuild a healthy native ecosystem. By implementing the comprehensive restoration strategy outlined in this report, it is possible to mitigate the threats posed by invasive species and axis deer, promote the recovery of native plant communities, and enhance the ecological integrity and aesthetic value of this unique landscape. Restoring this area throughout the progression of construction offers a rare opportunity to showcase the potential for ecological restoration and create a lasting legacy of conservation enhanced development.

Bark of a healthy wiliwili tree

Peeled off translucent outer bark of mature wiliwili tree with the sun shining through

Large bee hive in hollowed out trunk of a dying wiliwili tree

Only wiliwili seedling seen in entire survey

Large healthy wiliwili tree

New leaf growth on wiliwili

Wiliwili seed pod with ripe seeds

FAUNA SURVEY REPORT

Survey Methods

A walk-through fauna survey method was conducted in conjunction with the botanical survey. All parts of the project area were covered, including the clubhouse, complex, golf course, coastline and aquatic habitat. Field observations were made with the aid of binoculars and by listening to vocalizations. Notes were made on species, abundance, activities and location as well as observations of trails, tracks, scat and signs of feeding. In addition, an evening visit was made to record crepuscular activities and vocalizations and to see if there was any evidence of occurrence of the Hawaiian hoary bat (*Lasiurus cinereus semotus*) in the area.

RESULTS

MAMMALS

Four mammal species were observed during five visits to this large property.

Axis deer (Axis axis) – Signs of deer were observed in all parts of this project area in the form of trails, tracks, feeding sign, antler rubbings and droppings. These animals are active nocturnally, mobilizing at dusk to feed in the forests, fairways and lush landscaped areas under the cover of darkness.

Domestic cattle (Bos Taurus) – Signs of the presence of cattle was seen in the upper north corner of the property above the fence.

Mongoose (Herpestes auropunctata) – A few individuals were seen near the fairways and in the forest.

'Ōpe'ape'a, Hawaiian hoary bat (*Lasiurus cinereus semotus*)* Endangered Species – A special effort was made to look for these endemic and Endangered bats at four locations during an evening survey. A bat detector device (Batbox IIID) was utilized, set to a frequency of 27,000 Hertz which is the frequency at which these bats emit pulses of sound to home in on nocturnal flying insect prey. Bats were detected at two of the four sampling sites. These bats are strong fliers that cover a lot of ground during a night of hunting and are known to range widely during the seasons as they follow insect activities.

Although none were observed during this survey other non-native mammals that are likely to be found in this habitat are feral pigs (*Sus scrofa*), feral cats (*Felis catus*), rats (*Rattus spp*.), mice (*Mus domesticus*) and occasionally domestic dogs (*Canis familiaris*).

BIRDS

Birdlife was diverse because of the size of the property and the wide range of habitats present. Twenty-two species were recorded during five site visits. Taxonomy and nomenclature follow the American Ornithologists' Union (2020). Three endemic wetland bird species were seen swimming around the water hazards within the golf course: the Endangered *'alae ke'oke'o* or Hawaiian coot (*Fulica alai*), the Endangered *ae'o* or Hawaiian stilt (*Himantopus mexicanus knudseni*), and the Endangered koloa duck (*Anas wyvilliana*). It should be noted that outside of Kaua'i all other populations of koloa duck are considered hybridized with Mallard ducks (Gorresen, et al. 2024).

The endemic *pueo* or Hawaiian short-eared owl (*Asio flammeus sandwichensis*) was observed flying in the early evening and morning along the upper perimeter of golf course and also perched on a fence on the upper perimeter of the property. No nests were observed of any of these species.

Three migratory bird species were seen: the *kōlea* or Pacific golden-plover (*Pluvialis fulva*) were most observed with the fairways of the golf course, a large flock of *'iwa* or great frigate birds (*Fregata minor palmerstoni*) were regularly seen flying in a cluster between the farm and Pu'u 'Ola'i, and the *'ūlili* or wandering tattler (*Tringa incana*) were seen along the exposed 'a'a lava.

The indigenous *'auku'u* or black-crowned night-heron (*Nycticorax nicticorax hoactli*) were also present around the water features.

Fourteen non-native bird species were also present. Four species were common within the project area: the common myna (*Acridotheres tristis*), the zebra dove (*Geopelia striata*), the spotted dove (*Streptopelia chinensis*), the gray francolin (*Francolinus pondicerianus*). An additional four species were uncommon here: the cattle egret (*Bubulbus ibis*), the northern cardinal (*Cardinalis cardinalis*), the barn owl (*Tyto alba*) and the African silverbill (*Lonchura cantans*). The remaining six non-native species were sighted but of rare occurrence and can be seen in Table 1. FLORA AND FAUNA SPECIES LIST

INSECTS

Insect life was moderate in diversity and in total numbers. Twenty-two species were recorded, representing six insect orders. Three species were common throughout the project area: the kiawe moth (*Anacamptodes fragilaria*), the dung fly (*Musca sorbens*) and the sleepy orange butterfly (*Eurema niccipe*). Six species were uncommon: the bluebottle fly (*Calliphora vicina*), the passion flower butterly (*Agraulis vanillae*), the Cuban koa haole psyllid (*Heteropsylla cubana*), the Sonoran carpenter bee (*Xylocopa sonorina*), the big-headed ant (*Pheidole megacephala*) and the globe skimmer dragonfly (*Pantala flavescens*). Thirteen other insect species were of rare occurrence.

Two indigenous dragonflies, the *pinao* or green darner and the globe skimmer (also called *pinao*), were the only two native insects observed during the survey. Both are widespread and common in Hawaii.

REPTILES

One non-native mourning gecko (*Lepidodactylus lugubris*) was heard calling in the forest during the evening survey.

MOLLUSKS

One non-native terrestrial giant African snail (Achatina fulica) was found to be common throughout the project area. There were also a few deposits of stream and ocean mollusks found in or around archaeological sites.

One of several Axis deer carcass seen throughout survey area

Archaeological cache containing native freshwater mollusks and ocean echinoderms fragments

‘ilima shrubs amongst other alien grasses
Luhe e cowrie shell lure at potential archaeological site

‘Ae’o and ‘Alae ke’oke’o forage along
End of Summer. Iwa Bird Congregation
retention pond margin

Mitigation Recommendations:

1. The ʻŌpeʻapeʻa or Hawaiian Hoary Bat could potentially occur at or in the vicinity of the project and may roost in nearby trees. Ay required site clearing should be timed to avoid disturbance to bats during their birthing and pup rearing season (June 1 through September 15). During this period woody plants greater than 15 feet (4.6 meters) tall should not be disturbed, removed, or trimmed. Barbed wire should also be avoided for any construction because bats can become ensnared and killed by such gencing material during flight.

2. Artificial lighting can adversely impact seabirds that may pass through the area at night by causing them to become disoriented. This disorientation can result in their collision with manmade structures or the grounding of birds. Nighttime work that requires outdoor lighting should be avoided during the seabird fledging season, from September 15 through December 15, when young seabirds make their maiden voyage to sea. If nighttime construction is required during the seabird fledgling season (September 15 to December 15), we recommend lights used be fully shielded to minimize the attraction of seabirds and a qualified biologist be present at the project site to monitor and assess the risk of seabirds being attracted or grounded due to the lighting. If seabirds are seen circling around the area, lights should then be turned off. If a downed seabird is detected, please follow DOFAW's recommended response protocol by visiting https://dlnr.hawaii.gov/wildlife/seabird-fallout-season/.

3. Permanent lighting also poses a risk of seabird attraction and as such should be minimized or eliminated to protect seabird flyways and preserve the night sky. For illustrations and guidance related to seabird-friendly light styles that also protect seabirds and the dark starry skies of Hawai'i please visit https://dlnr.hawaii.qov/wildlife/files/2016/03/DOC439.pdf.

4. The State endangered 'ilio holo i ka uaua or Hawaiian Monk Seal, honu 'ea or Hawksbill Sea Turtle, and threatened honu or Green Sea Turtle could potentially occur or haul out onshore within the vicinity of the proposed project site. Nesting season is April through December for honu and May through December for honu 'ea. 'Ilio holo i ka uaua can give birth to pups all year round. If either species is detected within 100 feet (30 meters) of the project area, all nearby construction operations should cease and not continue until the focal animal has departed the area on its own accord.

5. State-listed waterbirds such as ae'o or Hawaiian stilt, 'alae ke'oke'o or Hawaiian coot, koloa maoli or Hawaiian Duck, and nene or Hawaiian Goose could potentially occur at or in the vicinity of the proposed project site. It is against State law to harm or harass these species. If any of these species are present during construction, all activities within 100 feet (30 meters) should cease and the bird or birds should not be approached. Work may continue after the bird or birds leave the area of their own accord. If a nest is discovered at any point, please contact the Maui Branch DOFAW Office at (808) 984-8100 and establish a buffer zone around the nest.

6. The endemic pueo or Hawaiian short-eared owl could potentially nest in the project area. Pueo nest on the ground and active nests have been found year-round. Before any potential vegetative alteration, especially ground-based disturbance, we recommend that line transect surveys are conducted during

crepuscular hours through the project area. If a pueo nest is discovered, a minimum buffer distance of 100 meters from the nest should be established until chicks are capable of flight.

7. The project area is within the range of the State listed Blackburn's Sphinx Moth (BSM). Larvae of BSM feed on many nonnative host plants, which includes tree tobacco, that grow in disturbed soil. We recommend contacting the Maui Branch DOFAW Office at (808) 984-8100 for further information about where BSM may be present and whether a vegetation survey should be conducted to determine the presence of plants preferred by BSM. We recommend removing plants less than one meter in height or during the dry season to avoid harm to BSM. If you intend to either remove tree tobacco over one meter in height or to disturb the ground around or within several meters of these plants, they must be thoroughly inspected by a qualified entomologist for the presence of BSM eggs and larvae.

8. There could potentially be impacts to vulnerable birds from nonnative predators such as cats, rodents, and mongooses. We recommend taking action to minimize predator presence; remove cats, place bait stations for rodents and mongoose, and provide covered trash receptacles. Cats prey on native birds, including State-listed endangered waterbirds, seabirds, and forest birds.

Project Code: 2025-0098083
Project Name: Mākena Mauka

Subject: List of threatened and endangered species that may occur in your proposed project location or may be affected by your proposed project

To Whom It May Concern:

The enclosed species list identifies threatened and endangered species, as well as designated critical habitat that may occur within the boundary of your proposed project and that may be affected by project related actions. The species list fulfills the requirements of the U.S. Fish and Wildlife Service (Service) under section 7(c) of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 *et seq.*). Please contact the Service's Pacific Islands Fish and Wildlife Office (PIFWO) at 808-792-9400 if you have any questions regarding your IPaC species list.

The purpose of the Act is to provide a means whereby threatened and endangered species and the ecosystems upon which they depend may be conserved. Under sections 7(a)(1) and 7(a)(2) of the Act and its implementing regulations (50 CFR 402 *et seq.*), Federal agencies are required to utilize their authorities to carry out programs for the conservation of threatened and endangered species and to determine whether projects may adversely affect threatened and endangered species and/or designated critical habitat.

Please note that under 50 CFR 402.12(e) of the regulations implementing section 7 of the Act, the accuracy of this species list should be verified after 90 days. New information based on updated surveys, changes in the abundance and distribution of species, changed habitat conditions, or other factors could change this list. This verification can be completed formally or informally as desired. The Service recommends that verification be completed by visiting the IPaC website at regular intervals during project planning and implementation for updates to species lists and information. An updated list may be requested through the IPaC system by completing the same process used to receive the enclosed list.

A Biological Assessment is required for construction projects (or other undertakings having similar physical impacts) that are major Federal actions significantly affecting the quality of the human environment as defined in the National Environmental Policy Act (42 U.S.C. 4332(2)(c)). For projects other than major construction activities, the Service suggests that a Biological

Evaluation, similar to a Biological Assessment, be prepared to determine whether the project may affect listed or proposed species and/or designated or proposed critical habitat. Recommended contents of a Biological Assessment or Biological Evaluation are described at 50 CFR 402.12.

Due to the significant number of listed species found on each island within PIFWO's regulatory jurisdiction, and the difficulty in accurately mapping ranges for species that we have limited information about, your species list may include more species than if you obtained the list directly from a Service biologist. We recommend you use the species links in IPaC to view the life history, habitat descriptions, and recommended avoidance and minimization measures to assist with your initial determination of whether the species or its habitat may occur within your project area. If appropriate habitat is present for a listed species, we recommend surveys be conducted to determine whether the species is also present. If no surveys are conducted, we err on the side of the species, by regulation, and assume the habitat is occupied. Updated avoidance and minimization measures for plants and animals, best management practices for work in or near aquatic environments, and invasive species biosecurity protocols can be found on the PIFWO website at: https://www.fws.gov/office/pacific-islands-fish-and-wildlife/library.

If a Federal agency determines, based on the Biological Assessment or Biological Evaluation, that a listed species and/or designated critical habitat may be affected by the proposed project, the agency is required to consult with the Service pursuant to 50 CFR 402. More information on the regulations and procedures for section 7 consultation, including the role of permit or license applicants, can be found in the "Endangered Species Consultation Handbook" at: http://www.fws.gov/endangered/esa-library/index.

Non-federal entities can also use the IPaC generated species list to develop Habitat Conservation Plans (HCP) in accordance with section 10(a)(1)(B) of the Act. We recommend HCP applicants coordinate with the Service early during the HCP development process. For additional information on HCPs, the Habitat Conservation Planning handbook can be found at https://www.fws.gov/sites/default/files/documents/habitat-conservation-planning-handbook-entire.pdf.

Please be aware that wind energy projects should follow the Service’s wind energy guidelines (http://www.fws.gov/windenergy) for minimizing impacts to migratory birds. Listed birds and the Hawaiian hoary bat may also be affected by wind energy development and we recommend development of a Habitat Conservation Plan for those species, as described above. Guidance for minimizing impacts to migratory birds for projects including communications towers can be found at:

- http://www.fws.gov/migratorybirds/CurrentBirdIssues/Hazards/towers/towers
- http://www.towerkill.com
- http://www.fws.gov/migratorybirds/CurrentBirdIssues/Hazards/towers/comtow

We appreciate your concern for threatened and endangered species. The Service encourages Federal agencies to include conservation actions that benefit threatened and endangered species into their project planning to further the purposes of the Act in accordance with section 7(a)(1). Please include the Consultation Tracking Number associated with your IPaC species list in any

request for consultation or correspondence about your project that you submit to our office. Please feel free to contact us at PIFWO_admin@fws.gov or 808-792-9400 if you need more current information or assistance regarding the potential impacts to federally listed species and federally designated critical habitat.

OFFICIAL SPECIES LIST

This list is provided pursuant to Section 7 of the Endangered Species Act, and fulfills the requirement for Federal agencies to "request of the Secretary of the Interior information whether any species which is listed or proposed to be listed may be present in the area of a proposed action".

This species list is provided by:

Pacific Islands Fish And Wildlife Office
300 Ala Moana Boulevard, Box 50088
Honolulu, HI 96850-5000
(808) 792-9400

PROJECT SUMMARY

Project Code: 2025-0098083
Project Name: Mākena Mauka
Project Type: Residential Construction
Project Description: The Applicant proposes the development of Mākena Mauka, a low-density master planned residential community within the Makena area of South Maui. Mākena Mauka will offer market rate housing/lots and residential workforce housing as well as related amenities – including renovation of the South Golf Course.

Project Location:

The approximate location of the project can be viewed in Google Maps: https://www.google.com/maps/@20.6446725,-156.43628113632994,14z

Counties: Maui County, Hawaii

ENDANGERED SPECIES ACT SPECIES

There is a total of 34 threatened, endangered, or candidate species on this species list.

Species on this list should be considered in an effects analysis for your project and could include species that exist in another geographic area. For example, certain fish may appear on the species list because a project could affect downstream species.

IPaC does not display listed species or critical habitats under the sole jurisdiction of NOAA Fisheries[1], as USFWS does not have the authority to speak on behalf of NOAA and the Department of Commerce.

See the "Critical habitats" section below for those critical habitats that lie wholly or partially within your project area under this office's jurisdiction. Please contact the designated FWS office if you have questions.

---

1. NOAA Fisheries, also known as the National Marine Fisheries Service (NMFS), is an office of the National Oceanic and Atmospheric Administration within the Department of Commerce.

MAMMALS

NAME	STATUS
Hawaiian Hoary Bat *Lasiurus cinereus semotus*	Endangered

No critical habitat has been designated for this species.
Species profile: https://ecos.fws.gov/ecp/species/770
General project design guidelines:

REPTILES

NAME STATUS

Green Sea Turtle *Chelonia mydas* Threatened
Population: Central North Pacific DPS
There is **proposed** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/6199
General project design guidelines:
https://ipac.ecosphere.fws.gov/project/WP3XP3BWPZHNJCDXEAPSVTIM5I/documents/generated/6929.pdf

Hawksbill Sea Turtle *Eretmochelys imbricata* Endangered
There is **final** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/3656

INSECTS

NAME STATUS

Blackburn's Sphinx Moth *Manduca blackburni* Endangered
There is **final** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/4528
General project design guidelines:
https://ipac.ecosphere.fws.gov/project/WP3XP3BWPZHNJCDXEAPSVTIM5I/documents/generated/6926.pdf

FLOWERING PLANTS

NAME STATUS

(=native Yellow Hibiscus) Ma`o Hau Hele *Hibiscus brackenridgei* Endangered
There is **final** critical habitat for this species. Your location overlaps the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/4075

`aiea *Nothocestrum latifolium* Endangered
No critical habitat has been designated for this species.
Species profile: https://ecos.fws.gov/ecp/species/1061

NAME	STATUS
`awikiwiki *Canavalia pubescens* There is **final** critical habitat for this species. Your location overlaps the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/7908	Endangered
`ena`ena *Pseudognaphalium sandwicensium var. molokaiense* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/5993	Endangered
Awiwi *Schenkia sebaeoides* There is **final** critical habitat for this species. Your location does not overlap the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/7103	Endangered
Bonamia menziesii There is **final** critical habitat for this species. Your location overlaps the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/2503	Endangered
Carter's Panicgrass *Panicum fauriei var. carteri* There is **final** critical habitat for this species. Your location does not overlap the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/5578	Endangered
Dwarf Naupaka *Scaevola coriacea* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/4669	Endangered
Gouania hillebrandii There is **final** critical habitat for this species. Your location does not overlap the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/3464	Endangered
Honohono *Haplostachys haplostachya* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/5815	Endangered
Ihi *Portulaca villosa* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/4886	Endangered
Ko`oko`olau *Bidens micrantha ssp. kalealaha* There is **final** critical habitat for this species. Your location overlaps the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/7697	Endangered
Ko`oloa`ula *Abutilon menziesii* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/3268	Endangered
Kulu`i *Nototrichium humile* There is **final** critical habitat for this species. Your location overlaps the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/1001	Endangered
Lanai Sandalwood (=`iliahi) *Santalum haleakalae var. lanaiense* There is **final** critical habitat for this species. Your location overlaps the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/3282	Endangered
Nehe *Melanthera kamolensis*	Endangered

NAME STATUS

There is **final** critical habitat for this species. Your location overlaps the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/3476

Ohai *Sesbania tomentosa* Endangered
There is **final** critical habitat for this species. Your location overlaps the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/8453
General project design guidelines:
https://ipac.ecosphere.fws.gov/project/WP3XP3BWPZHNJCDXEAPSVTIM5I/documents/generated/7050.pdf

Popolo *Solanum nelsonii* Endangered
No critical habitat has been designated for this species.
Species profile: https://ecos.fws.gov/ecp/species/2281
General project design guidelines:
https://ipac.ecosphere.fws.gov/project/WP3XP3BWPZHNJCDXEAPSVTIM5I/documents/generated/7050.pdf

Round-leaved Chaff-flower *Achyranthes splendens var. rotundata* Endangered
There is **final** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/4709

Spermolepis hawaiiensis Endangered
There is **final** critical habitat for this species. Your location overlaps the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/1670

Tetramolopium arenarium Endangered
There is **proposed** critical habitat for this species.
Species profile: https://ecos.fws.gov/ecp/species/1655

Uhiuhi *Mezoneuron kavaiense* Endangered
There is **final** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/7129

Vigna o-wahuensis Endangered
There is **final** critical habitat for this species. Your location does not overlap the critical habitat.
Species profile: https://ecos.fws.gov/ecp/species/8445

CRITICAL HABITATS

There are 17 critical habitats wholly or partially within your project area under this office's jurisdiction.

NAME STATUS

(=native Yellow Hibiscus) Ma`o Hau Hele *Hibiscus brackenridgei* Final
https://ecos.fws.gov/ecp/species/4075#crithab

`awikiwiki *Canavalia pubescens* Final
https://ecos.fws.gov/ecp/species/7908#crithab

A`e *Zanthoxylum hawaiiense* Final

NAME STATUS

For information on why this critical habitat appears for your project, even though A`e is not on the list of potentially affected species at this location, contact the local field office.
https://ecos.fws.gov/ecp/species/4645#crithab

Alani *Melicope mucronulata* Final
For information on why this critical habitat appears for your project, even though Alani is not on the list of potentially affected species at this location, contact the local field office.
https://ecos.fws.gov/ecp/species/706#crithab

Bonamia menziesii Final
https://ecos.fws.gov/ecp/species/2503#crithab

Kamanomano *Cenchrus agrimonioides* Final
For information on why this critical habitat appears for your project, even though Kamanomano is not on the list of potentially affected species at this location, contact the local field office.
https://ecos.fws.gov/ecp/species/2928#crithab

Kauila *Colubrina oppositifolia* Final
For information on why this critical habitat appears for your project, even though Kauila is not on the list of potentially affected species at this location, contact the local field office.
https://ecos.fws.gov/ecp/species/850#crithab

Ko`oko`olau *Bidens micrantha ssp. kalealaha* Final

USFWS NATIONAL WILDLIFE REFUGE LANDS AND FISH HATCHERIES

Any activity proposed on lands managed by the National Wildlife Refuge system must undergo a 'Compatibility Determination' conducted by the Refuge. Please contact the individual Refuges to discuss any questions or concerns.

THERE ARE NO REFUGE LANDS OR FISH HATCHERIES WITHIN YOUR PROJECT AREA.

BALD & GOLDEN EAGLES

Bald and Golden Eagles are protected under the Bald and Golden Eagle Protection Act [2] and the Migratory Bird Treaty Act (MBTA) [1]. Any person or organization who plans or conducts activities that may result in impacts to Bald or Golden Eagles, or their habitats, should follow appropriate regulations and consider implementing appropriate avoidance and minimization measures, as described in the various links on this page.

---

1. The Bald and Golden Eagle Protection Act of 1940.
2. The Migratory Birds Treaty Act of 1918.
3. 50 C.F.R. Sec. 10.12 and 16 U.S.C. Sec. 668(a)

BALD & GOLDEN EAGLES INFORMATION WAS NOT AVAILABLE WHEN THIS SPECIES LIST WAS GENERATED. PLEASE CONTACT THE FIELD OFFICE FOR FURTHER INFORMATION.

MIGRATORY BIRDS

The Migratory Bird Treaty Act (MBTA) [1] prohibits the take (including killing, capturing, selling, trading, and transport) of protected migratory bird species without prior authorization by the Department of Interior U.S. Fish and Wildlife Service (Service). The incidental take of migratory birds is the injury or death of birds that results from, but is not the purpose, of an activity. The Service interprets the MBTA to prohibit incidental take.

---

1. The Migratory Birds Treaty Act of 1918.
2. The Bald and Golden Eagle Protection Act of 1940.

3. 50 C.F.R. Sec. 10.12 and 16 U.S.C. Sec. 668(a)

MIGRATORY BIRD INFORMATION WAS NOT AVAILABLE WHEN THIS SPECIES LIST WAS GENERATED. PLEASE CONTACT THE FIELD OFFICE FOR FURTHER INFORMATION.

WETLANDS

Impacts to NWI wetlands and other aquatic habitats may be subject to regulation under Section 404 of the Clean Water Act, or other State/Federal statutes.

For more information please contact the Regulatory Program of the local U.S. Army Corps of Engineers District.

Please note that the NWI data being shown may be out of date. We are currently working to update our NWI data set. We recommend you verify these results with a site visit to determine the actual extent of wetlands on site.

U.S. Fish & Wildlife Service

Hawaiian hoary bat

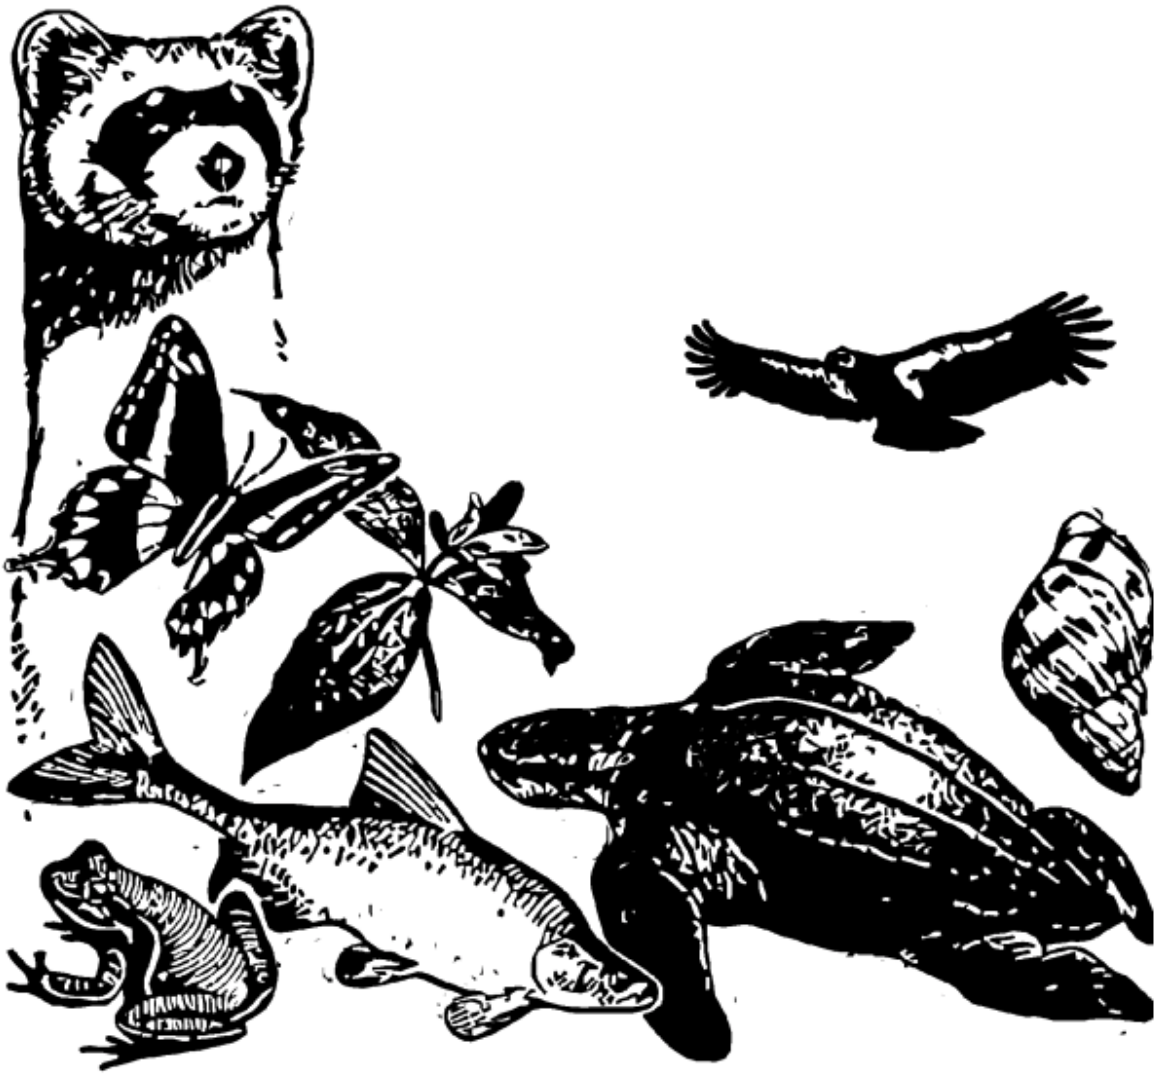
Hawaiian Hoary Bat

Generated September 12, 2025 12:27 AM UTC, IPaC v6.128.15-rc1

IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

Hawaiian hoary bat (*Lasiurus cinereus semotus*): The Hawaiian hoary bat roosts in both exotic and native woody vegetation across all islands and will leave young unattended in trees and shrubs when they forage. If trees or shrubs 15 feet or taller are cleared during the pupping season, there is a risk that young bats could inadvertently be harmed or killed since they are too young to fly or may not move away. Additionally, Hawaiian hoary bats forage for insects from as low as 3 feet to higher than 500 feet above the ground and can become entangled in barbed wire used for fencing.

To avoid and minimize impacts to the endangered Hawaiian hoary bat we recommend you incorporate the following applicable measures into your project description:



- Do not disturb, remove, or trim woody plants greater than 15 feet tall during the bat birthing and pup rearing season (June 1 through September 15).
- Do not use barbed wire for fencing.

U.S. Fish & Wildlife Service

Hawaiian seabirds

Hawaiian Petrel and 2 more species

Generated September 05, 2025 10:29 PM UTC, IPaC v6.128.15-rc1

IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

General Project Design Guidelines - Hawaiian Petrel and 2 more species

Published by Pacific Islands Fish And Wildlife Office - Publication Date: February 1, 2022 for the following species included in your project

- Hawaiian Petrel *Pterodroma sandwichensis*
- Newell"s Shearwater *Puffinus newelli*
- Band-rumped Storm-petrel *Hydrobates castro*

Endangered Hawaiian petrel (*Pterodroma sandwichensis*), Threatened Newell's shearwater (*Puffinus auricularis newelli*), and Endangered Hawaii Distinct Population Segment of the band-rumped storm-petrel (*Oceanodroma castro*):
Hawaiian seabirds may traverse the project area at night during the breeding, nesting and fledging seasons (March 1 to December 15). Outdoor lighting could result in seabird disorientation, fallout, and injury or mortality. Seabirds are attracted to lights and after circling the lights they may become exhausted and collide with nearby wires, buildings, or other structures or they may land on the ground. Downed seabirds are subject to increased mortality due to collision with automobiles, starvation, and predation by dogs, cats, and other predators. Young birds (fledglings) traversing the project area between September 15 and December 15, in their first flights from their mountain nests to the sea, are particularly vulnerable to light attraction.

To avoid and minimize potential project impacts to seabirds we recommend you incorporate the following measures into your project description:

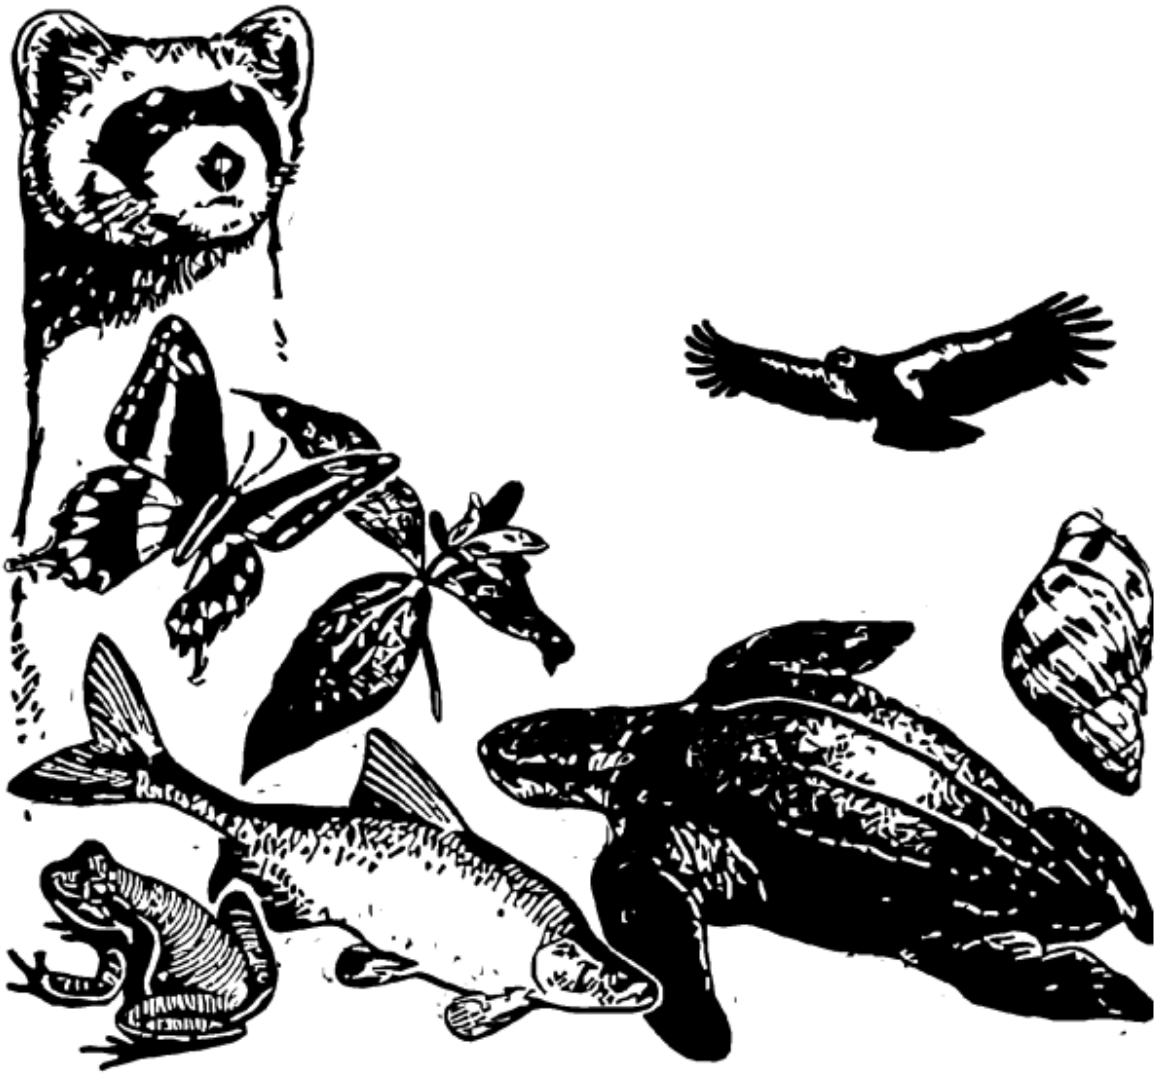
- Fully shield all outdoor lights so the bulb can only be seen from below.
- Install automatic motion sensor switches and controls on all outdoor lights or turn off lights when human activity is not occurring in the lighted area.
- Avoid nighttime construction during the seabird fledging period, September 15 through December 15.

Listed seabirds have been documented colliding with communication towers, particularly in areas of high seabird passage rate. In general, self-supporting monopoles are the least likely to result in collisions, whereas lattice towers, particularly those that rely on guy-wires, have a greater risk.

To avoid and minimize the likelihood that towers will result in collisions by listed seabirds we recommend you incorporate the following measures into your project description:

- The profile of the tower should be as small as possible, minimize the extent of the tower that protrudes above the surrounding vegetation layer, and avoid the use of guywires.
- If the top of the tower must be lit to comply with Federal Aviation Administration regulations, use a flashing red light verses a steady-beam red or white light.
- If possible, co-locate with existing towers or facilities.

Seabirds have been known to collide with fences, powerlines, and other structures near nesting colonies. To avoid and minimize the likelihood of collision we recommend you incorporate the following measures into your project description:



- Where fences extend above vegetation, integrate three strands of polytape into the fence to increase visibility.
- For powerlines, guywires and other cables, minimize exposure above vegetation height and vertical profile.

U.S. Fish & Wildlife Service

Hawaiian waterbirds

Hawaiian Duck and 3 more species

Generated September 05, 2025 10:28 PM UTC, IPaC v6.128.15-rc1

IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

General Project Design Guidelines - Hawaiian Duck and 3 more species

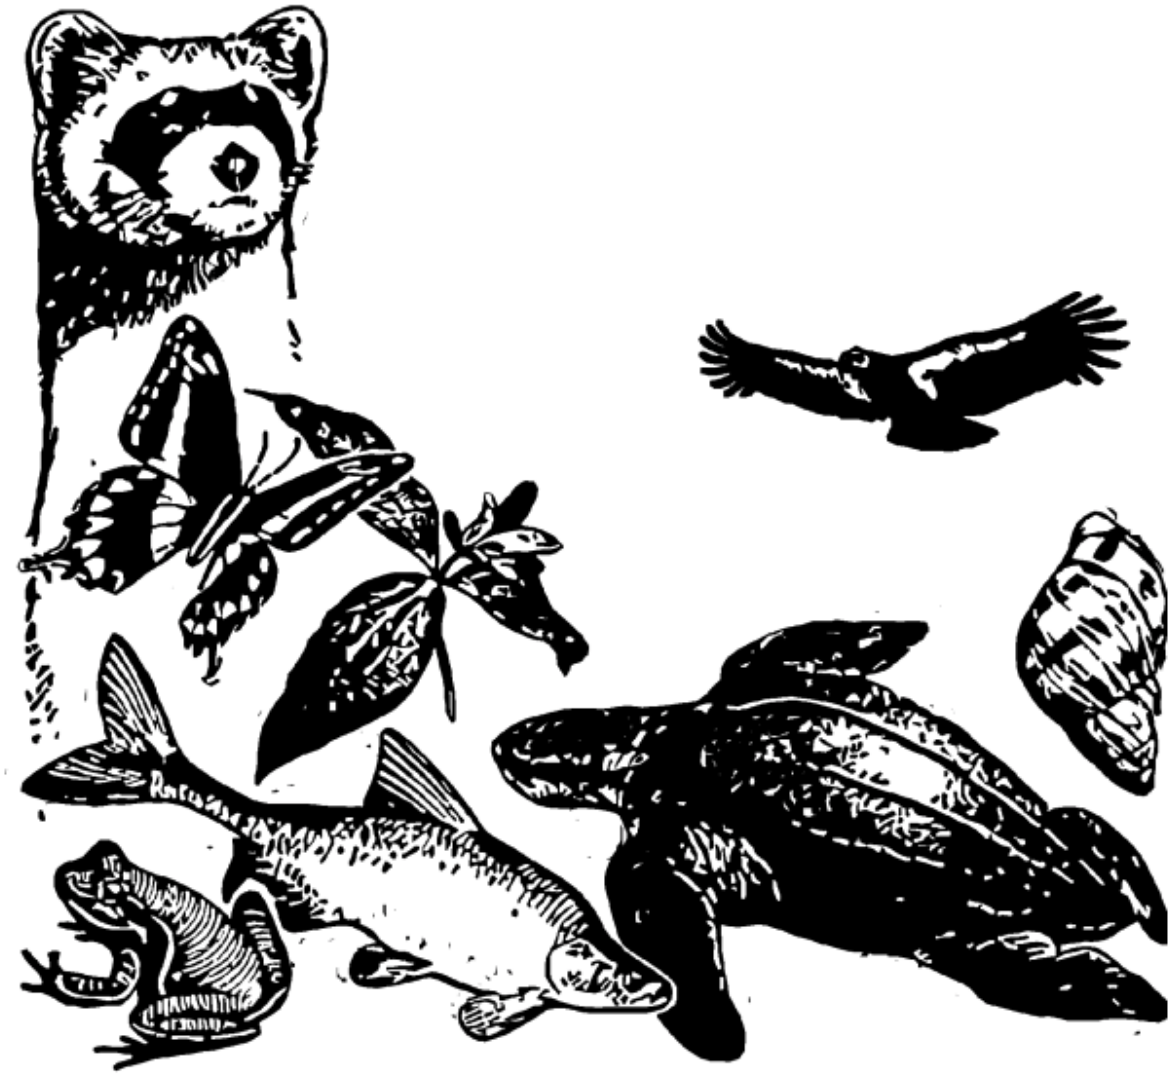
Published by Pacific Islands Fish And Wildlife Office - Publication Date: February 1, 2022 for the following species included in your project

- Hawaiian Duck *Anas wyvilliana*
- Hawaiian Common Gallinule *Gallinula galeata sandvicensis*
- Hawaiian Stilt *Himantopus mexicanus knudseni*
- Hawaiian Coot (alae Ke`oke`o) *Fulica alai*

Hawaiian waterbirds (Hawaiian stilt, *Himantopus mexicanus knudseni*; Hawaiian coot, *Fulica alai*; Hawaiian common gallinule, *Gallinula galeata sandvicensis*; Hawaiian duck, *Anas wyvilliana*):
Listed Hawaiian waterbirds are found in fresh and brackish-water marshes and natural or man-made ponds. Hawaiian stilts may also be found wherever ephemeral or persistent standing water may occur. Threats to these species include non-native predators, habitat loss, and habitat degradation. Hawaiian ducks are also subject to threats from hybridization with introduced mallards.

The creation of standing or open water may result in the attraction of Hawaiian waterbirds to a site (creative nuisance or habitat sink). In particular, the Hawaiian stilt is known to nest in sub-optimal locations (e.g. any ponding water), if water is present. Hawaiian waterbirds attracted to sub-optimal habitat may suffer adverse impacts, such as predation and reduced reproductive success, and thus the project may create an attractive nuisance. Therefore, we recommend you work with our office during project planning so that we may assist you in developing measures to avoid impacts to listed species (e.g., fencing, vegetation control, predator management).

To avoid and minimize potential project impacts to Hawaiian waterbirds we recommend you incorporate the following applicable measures into your project description:



- In areas where waterbirds are known to be present, post and enforce reduced speed limits, and inform project personnel and contractors about the presence of endangered species on-site.
- Incorporate the Service's Best Management Practices for Work in Aquatic Environments into the project design.
- Have a biological monitor that is familiar with the species' biology conduct Hawaiian waterbird nest surveys, where appropriate habitat occurs within the vicinity of the proposed project site, prior to project initiation. Repeat surveys again within 3 days of project initiation and after any subsequent delay of work of 3 or more days (during which the birds may attempt to nest). If a nest or active brood is found:
    - Contact the Service within 48 hours for further guidance.
    - Establish and maintain a 100-foot buffer around all active nests and/or broods until the chicks/ducklings have fledged. Do not conduct potentially disruptive activities or habitat alteration within this buffer.
    - Have a biological monitor that is familiar with the species' biology present on the project site during all construction or earth moving activities until the chicks/ducklings fledge to ensure that Hawaiian waterbirds and nests are not adversely impacted.

U.S. Fish & Wildlife Service

Hawaiian goose

Hawaiian Goose

Generated September 05, 2025 10:31 PM UTC, IPaC v6.128.15-rc1

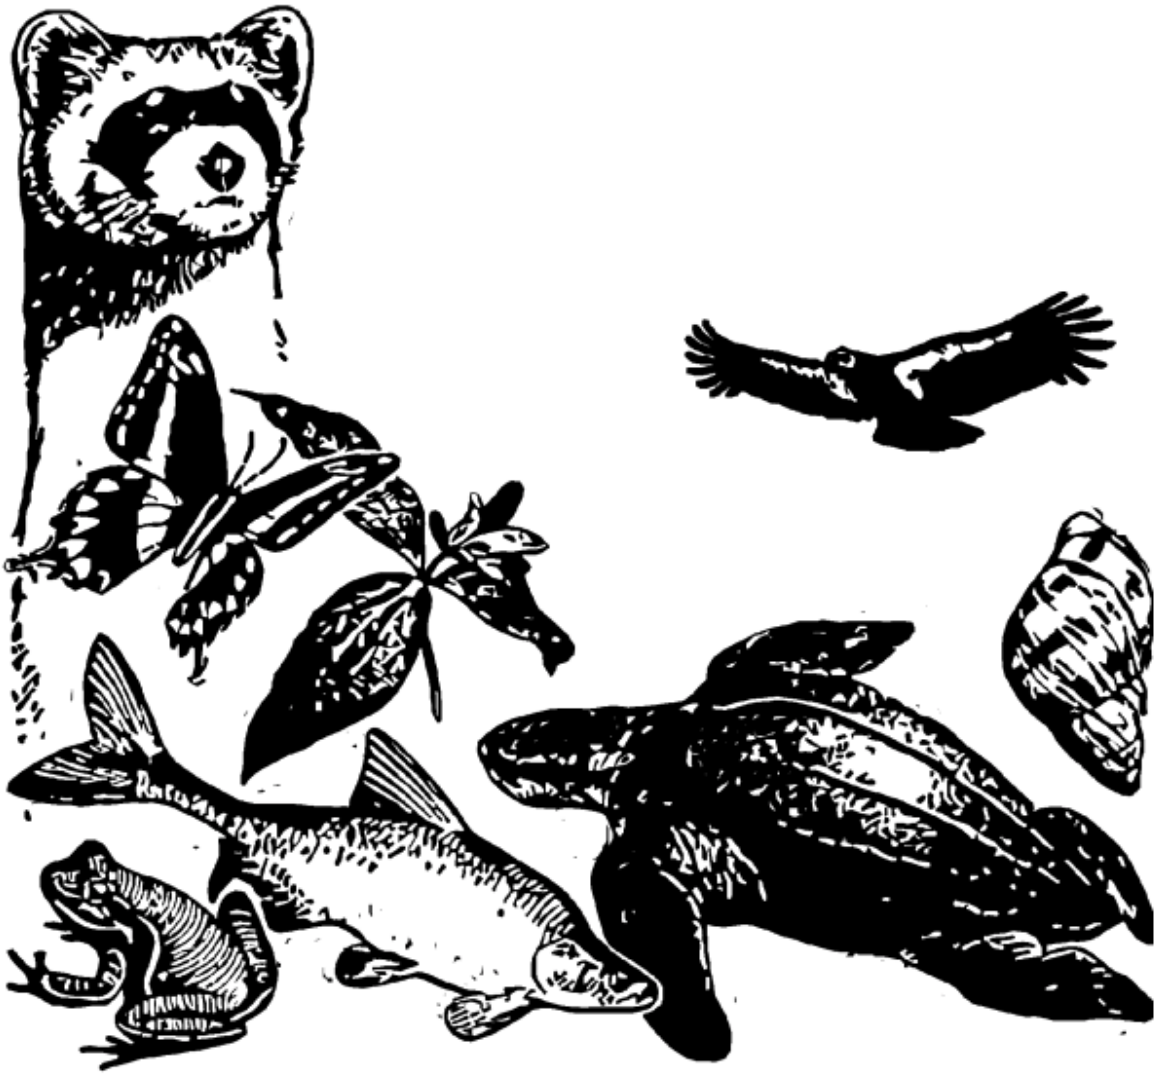
IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

Hawaiian goose (nene), (*Branta (Nesochen) sandvicensis*): Nene are found on the islands of Hawaii, Maui, Molokai, and Kauai. They are observed in a variety of habitats, but prefer open areas, such as pastures, golf courses, wetlands, natural grasslands and shrublands, and lava flows. Threats to the species include introduced mammalian and avian predators, wind facilities, and vehicle strikes.

To avoid and minimize potential project impacts to nene we recommend you incorporate the following measures into your project description:

- Do not approach, feed, or disturb nene.
- If nene are observed loafing or foraging within the project area during the breeding season (September through April), have a biologist familiar with nene nesting behavior survey for nests in and around the project area prior to the resumption of any work. Repeat surveys after any subsequent delay of work of 3 or more days (during which the birds may attempt to nest).
- Cease all work immediately and contact the Service for further guidance if a nest is discovered within a radius of 150 feet of proposed project, or a previously undiscovered nest is found within the 150-foot radius after work begins.
- In areas where nene are known to be present, post and implement reduced speed limits, and inform project personnel and contractors about the presence of endangered species on-site.

nene 4(d) rule: A 4(d) rule was established at the time the nene was downlisted to threatened status. Under the 4(d) rule, the following actions are not prohibited under the Act, provided the additional measures described in the downlisting rule are adhered to:



- Take by landowners, or their agents, conducting intentional harassment in the form of hazing or other deterrent measures not likely to cause direct injury or mortality, or nene surveys.
- Take that is incidental to conducting lawful control of introduced predators or habitat management activities for nene.
- Take by authorized law enforcement officers for the purpose of aiding or euthanizing sick, injured, or orphaned nene; disposing of dead specimens; and salvaging a dead specimen that may be used for scientific study.

U.S. Fish & Wildlife Service

Sea turtles

Green Sea Turtle and 2 more species

Generated September 05, 2025 10:23 PM UTC, IPaC v6.128.15-rc1

IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

General Project Design Guidelines - Green Sea Turtle and 2 more species

Published by Pacific Islands Fish And Wildlife Office - Publication Date: February 1, 2022 for the following species included in your project

- Green Sea Turtle *Chelonia mydas*
- Green Sea Turtle *Chelonia mydas*
- Green Sea Turtle *Chelonia mydas*

Pacific sea turtles: Green sea turtles (*Chelonia mydas*) (Central North Pacific DPS - Hawaii and Johnston Atoll), (Central West Pacific DPS - Mariana Archipelago and Wake NWR) and (Central South Pacific DPS - American Samoa, Palmyra, Kingman, Howland, Baker and Jarvis NWR), and Hawksbill sea turtle (*Eretmochelys imbricata*):
The Service consults on sea turtles and their use of terrestrial habitats (beaches where nesting and/or basking is known to occur), whereas the National Marine Fisheries Service (NMFS) consults on sea turtles and their use of off-shore and open ocean habitats. We recommend that you consult with NMFS regarding the potential impacts from the proposed project to sea turtles in off-shore and open ocean habitats.

Green sea turtles may nest on any sandy beach area in the Pacific Islands. Hawksbill sea turtles exhibit a wide tolerance for nesting substrate (ranging from sandy beach to crushed coral) with nests typically placed under vegetation. Both species exhibit strong nesting site fidelity. Nesting occurs on Hawaiian beaches from May through September, peaking in June and July, with hatchlings emerging through November and December. Sea turtle nesting in the Western Pacific, Marianas, and South Pacific Islands can occur year-round; peaking in April and July. Nesting in American Samoa is from October to March).

Construction on, or in the vicinity of, beaches can result in sand and sediment compaction, sea turtle nest destruction, beach erosion, contaminant and nutrient runoff, and an increase in direct and ambient light pollution which may disorient hatchlings or deter nesting females. Off-road vehicle traffic may result in direct impacts to sea turtles and nests, and also contributes to habitat degradation through erosion and compaction.

Projects that alter the natural beach profile, such as nourishment and hardening, including the placement of seawalls, jetties, sandbags, and other structures, are known to reduce the suitability of on-shore habitat for sea turtles. These types of projects often result in sand compaction, erosion, and additional sedimentation in nearshore habitats, resulting in adverse effects to the ecological community and future sea turtle nests. The hardening of a shoreline increases the potential for erosion in adjacent areas, resulting in subsequent requests to install stabilization structures or conduct beach nourishment in adjacent areas. Given projected sea level rise estimates, the likelihood of increase in storm surge intensity, and other factors associated with climate change, we anticipate that beach erosion will continue and likely increase.

Whenever possible, projects should consider alternatives that avoid the modification or hardening of coastlines. Beach nourishment or beach hardening projects should evaluate the long-term effect to sea turtle nesting habitat and consider the cumulative effects.

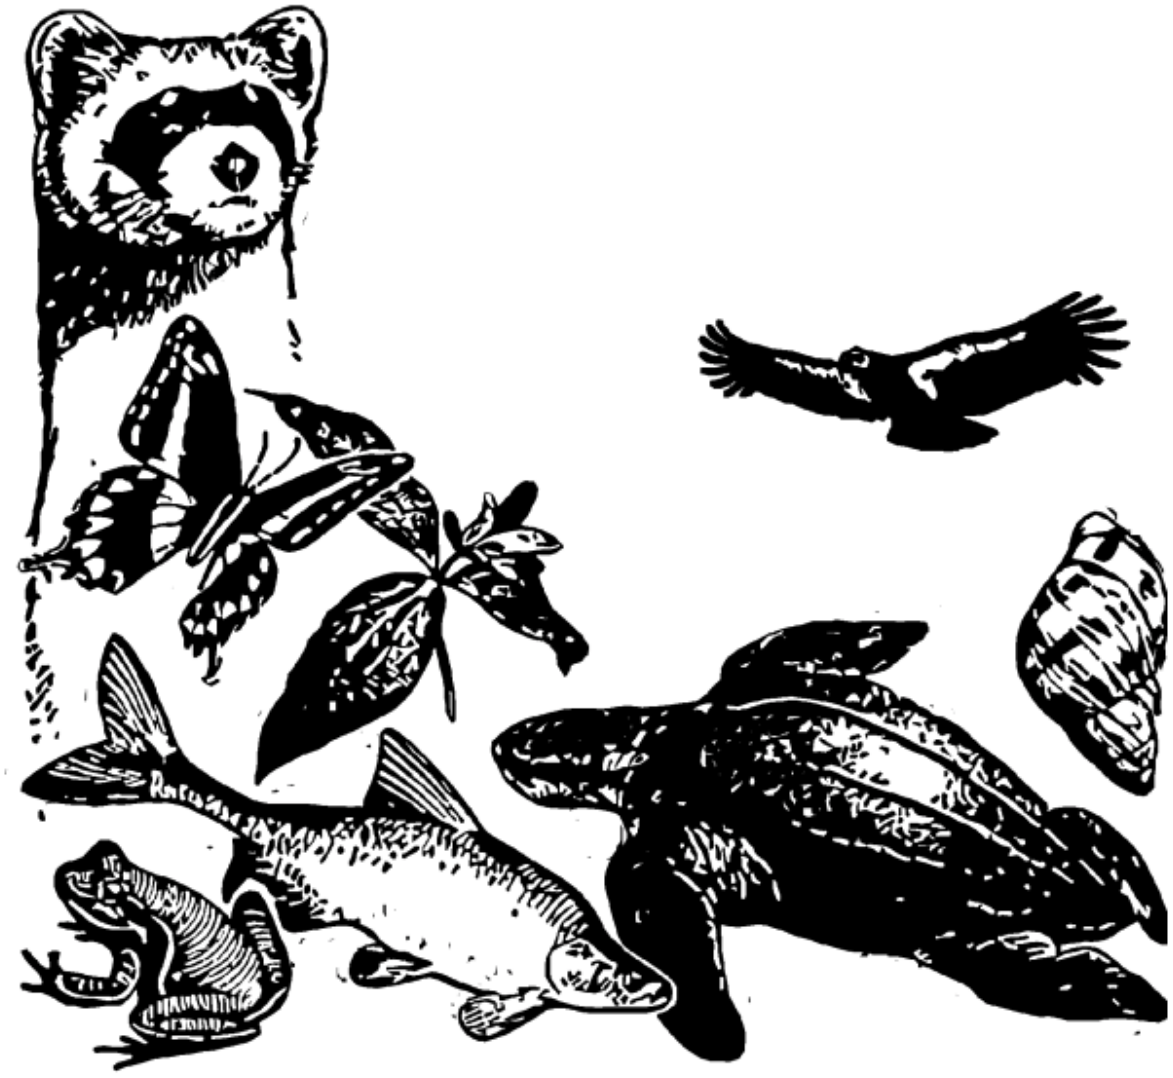
To avoid and minimize project impacts to sea turtles and their nests we recommend you incorporate the following applicable measures into your project description:

- No vehicle use on, or modification of, the beach/dune environment during the sea turtle nesting or hatching season, or on beaches where sea turtles are known to bask.
- Do not remove or destroy native dune vegetation.
- Incorporate applicable Best Management Practices for Work in Aquatic Environments into the project design.

- Have a biologist familiar with sea turtles conduct a visual survey of the project site to ensure no basking sea turtles are present.
    - If a basking sea turtle is found within the project area, cease all mechanical or construction activities within 100 feet until the animal voluntarily leaves the area.
    - Cease all activities between the basking turtle and the ocean.
- Remove any project-related debris, trash, or equipment from the beach or dune if not actively being used.
- Do not stockpile project-related materials in the intertidal zone, reef flats, or stream channels.

Lighting: Optimal nesting habitat is a dark beach free of barriers that restrict sea turtle movement. Nesting turtles may be deterred from approaching or laying successful nests on lighted or disturbed beaches. They may become disoriented by artificial lighting, leading to exhaustion and placement of a nest in an inappropriate location (such as at or below the high tide line). Hatchlings that emerge from nests may also be disoriented by artificial lighting. Inland areas visible from the beach should be sufficiently dark to allow for successful navigation to the ocean.

To avoid and minimize project impacts to sea turtles from lighting we recommend incorporating the following applicable measures into your project description:



- Avoid nighttime work during the nesting and hatching season.
- Minimize the use of lighting and shield all project-related lights so the light is not visible from any beach.
    - If lights can’t be fully shielded or if headlights must be used, fully enclose the light source with light filtering tape or filters.
- Incorporate design measures into the construction or operation of buildings adjacent to the beach to reduce ambient outdoor lighting such as:
    - tinting or using automatic window shades for exterior windows that face the beach;
    - reducing the height of exterior lighting to below 3 feet and pointed downward or away from the beach; and
    - minimize light intensity to the lowest level feasible and, when possible, include timers and motion sensors.

U.S. Fish & Wildlife Service

Blackburn sphinx moth

Blackburn's Sphinx Moth

Generated September 05, 2025 10:26 PM UTC, IPaC v6.128.15-rc1

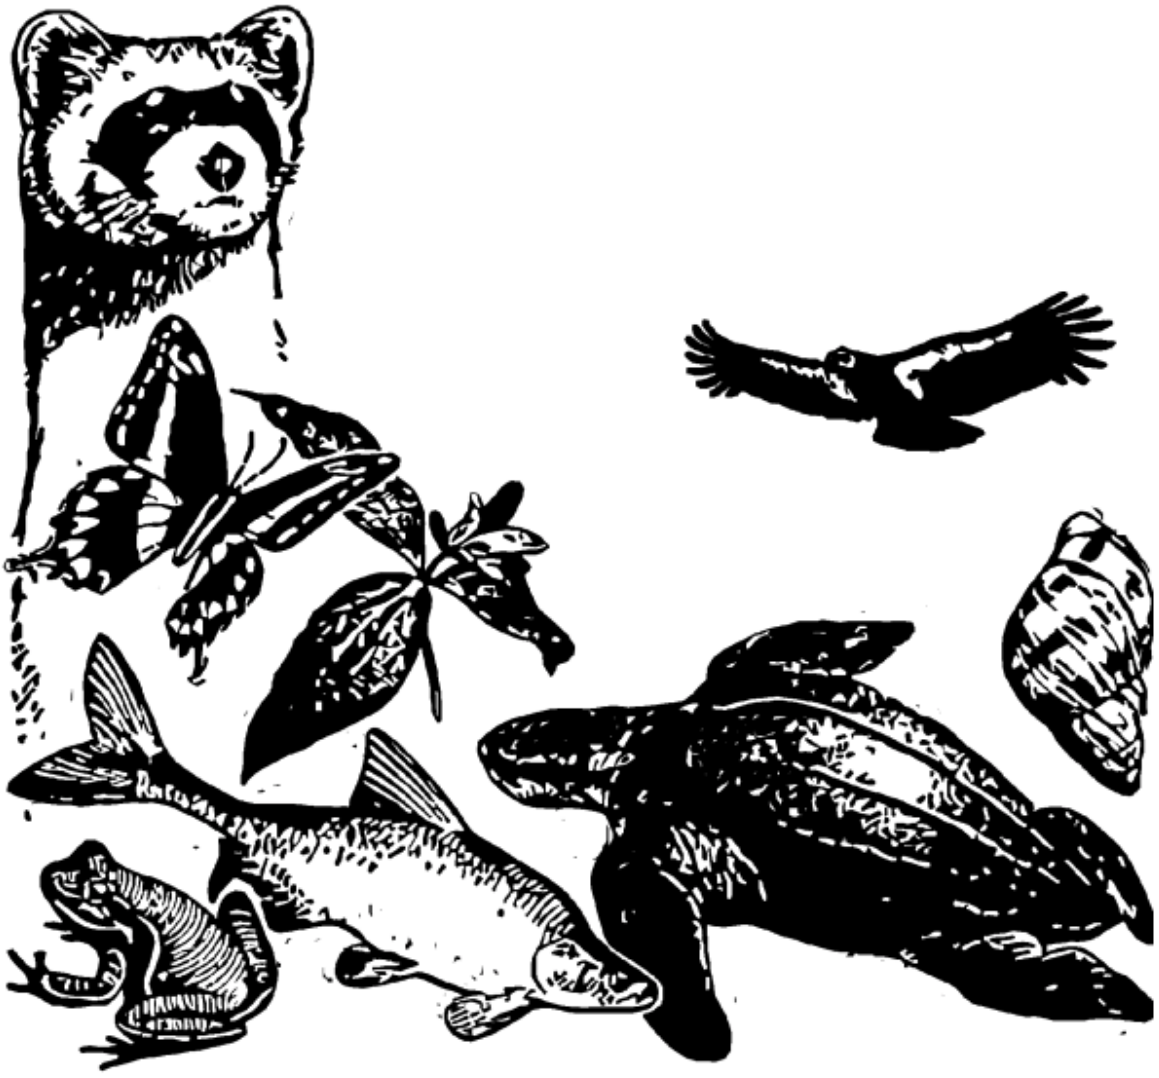
IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

Blackburn’s sphinx moth (*Manduca blackburni*):
Adult Blackburn’s sphinx moths feed on nectar from native plants, including beach morning glory (*Ipomoea pes-caprae*), iliee (*Plumbago zeylanica*), and maiapilo (*Capparis sandwichiana*); larvae feed upon non-native tree tobacco (*Nicotiana glauca*) and native aiea (*Nothocestrum* sp.). To pupate, the larvae burrow into the soil and can remain in a state of torpor for a year or more before emerging from the soil. Soil disturbance can result in death of the pupae.

We offer the following survey recommendations to assess whether the Blackburn’s sphinx moth is within the project area:

- A biologist familiar with the species should survey areas of proposed activities for Blackburn’s sphinx moth and its larval host plants prior to work initiation.
    - Surveys should be conducted during the wettest portion of the year (usually November-April or several weeks after a significant rain) and within 4-6 weeks prior to construction.
    - Surveys should include searches for eggs, larvae, and signs of larval feeding (chewed stems, frass, or leaf damage).
    - If native aiea or tree tobacco over 3 feet tall, or adult Blackburn’s sphinx moths are found during surveys, do not disturb them and contact the Service for additional guidance to avoid take.

If no Blackburn’s sphinx moth, aiea, or tree tobacco are found during surveys, it is imperative that measures be taken to avoid attraction of Blackburn’s sphinx moth to the project location and prohibit tree tobacco from entering the site. Tree tobacco can grow greater than 3 feet tall in approximately 6 weeks. If it grows over 3 feet after surveys have been completed, the plants may become a host plant for Blackburn’s sphinx moth larvae. We therefore recommend that you:



- Remove any tree tobacco less than 3 feet tall.
- Monitor the site every 4-6 weeks for new tree tobacco growth before, during, and after the proposed ground-disturbing activity. This monitoring for can be completed by any staff, such as groundskeeper or regular maintenance crew, if they are provided with picture placards of tree tobacco at different life stages.

U.S. Fish & Wildlife Service

Avoidance, Minimization, and Conservation Measures for listed plants in the Pacific Islands

Ohai and 1 more species

Generated September 05, 2025 10:33 PM UTC, IPaC v6.128.15-rc1

IPaC - Information for Planning and Consultation (https://ipac.ecosphere.fws.gov/): A project planning tool to help streamline the U.S. Fish and Wildlife Service environmental review process.

General Project Design Guidelines - Ohai and 1 more species

Published by Pacific Islands Fish And Wildlife Office - Publication Date: April 1, 2022 for the following species included in your project

- Ohai *Sesbania tomentosa*
- Popolo *Solanum nelsonii*

Avoidance, Minimization, and Conservation Measures for listed plants in the Pacific Islands

Project activities may affect listed plant species by causing physical damage to plant parts (roots, stems, flowers, fruits, seeds, etc.) as well as impacts to other life requisite features of their habitat which may result in reduction of germination, growth and/or reproduction. Cutting and removal of vegetation surrounding listed plants has the potential to alter microsite conditions (e.g., light, moisture, temperature), damaging or destroying the listed plants and also increasing the risk of invasion by nonnative plants which can result in higher incidence or intensity of fire. Activities such as grazing, use of construction equipment and vehicles, and increased human traffic (i.e. trails, visitation, monitoring), can cause ground disturbance, erosion, and/or soil compaction which decrease absorption of water and nutrients and damage plant root systems and may result in reduced growth and/or mortality of listed plants. Soil disturbance or removal has the potential to negatively impact the soil seed bank of listed plant species if such species are present or historically occurred in the project area.

In order to avoid or minimize potential adverse effects to listed plants that may occur on the proposed project site, we recommend minimizing disturbance outside of existing developed or otherwise modified areas. When disturbance outside existing developed or modified sites is proposed, conduct a botanical survey for listed plant species within the project action area, defined as the area where direct and indirect effects are likely to occur. Surveys should be conducted by a knowledgeable botanist with documented experience in identifying native Hawaiian and Pacific Islands plants, including listed plant species. Botanical surveys should optimally be conducted during the wettest part of the year (typically October to April) when plants and identifying features are more likely to be visible, especially in drier areas. If surveys are conducted outside of the wet season, the Service may assume plant presence.

The boundary of the area occupied by listed plants should be marked with flagging by the surveyor. To avoid or minimize potential adverse effects to listed plants, we recommend adherence to buffer distances for the activities in the **Table below**. Where disturbed areas do not need to be maintained as an open area, restore disturbed areas using native plants as appropriate for the location. Whenever possible we recommend using native plants for landscaping purposes. The following websites are good resources to use when choosing landscaping plants: Landscape Industry Council of Hawai‘i Native Plant Poster (http://hawaiiscape.wpengine.com/publications/), Native Hawaiian Plants for Landscaping, Conservation, and Reforestation (https://www.ctahr.hawaii.edu/oc/freepubs/pdf/of-30.pdf), and Best Native Plants for Landscapes (https://www.ctahr.hawaii.edu/oc/freepubs/pdf/OF-40.pdf).

If listed plants occur in a project area, the avoidance buffers are recommended to reduce direct and indirect impacts to listed plants from project activities. However, where project activities will occur within the recommended buffer distances, additional consultation is required. The impacts to the plants of concern within the buffer area may be reduced by placing temporary fencing or other barriers at the boundary of the disturbance, as far from the affected plants as practicable.

The above guidelines apply to areas outside of designated critical habitat. If project activities occur within designated critical habitat unit boundaries, additional consultation is required.

All activities, including site surveys, risk introducing nonnative species into project areas. Specific attention needs to be made to ensure that all equipment, personnel and supplies are properly checked and are free of contamination (weed seeds, organic matter, or other contaminants) before entering project areas. Quarantines and or management activities occurring on specific priority invasive species proximal to project areas need to be considered or adequately addressed. This information can be acquired by contacting local experts such as those on local invasive species committees (Kauai: https://www.kauaiisc.org/; Oahu: https://www.oahuisc.org/; Maui Nui: https://mauiinvasive.org/; and Hawaii: https://www.biisc.org/

Table 1. Recommended buffer distances to minimize and avoid potential adverse impacts to listed plants from activities listed below.

Action	Buffer Distance (feet (meters)) - Keep Project Activity This Far Away from Listed Plant	
	Grasses/Herbs/Shrubs and Terrestrial Orchids	Trees and Arboreal Orchids
Walking, hiking, surveys	3 ft (1 m)	3 ft (1 m)
Cutting and Removing Vegetation By Hand or Hand Tools (e.g., weeding)	3 ft (1 m)	3 ft (1 m)
Mechanical Removal of Individual Plants or Woody Vegetation (e.g., chainsaw, weed eater)	3 ft up to height of removed vegetation (whichever greater)	3 ft up to height of removed vegetation (whichever greater)
Removal of Vegetation with Heavy Equipment (e.g., bulldozer, tractor, "bush hog")	2x width equipment + height of vegetation	820 ft (250 m)

Use of Approved Herbicides (following label)	**Ground-based Spray Application; hand application (no wand applicator; spot treatment)**	10 ft (3 m)	Crown diameter
	Ground-based Spray Application; manual pump with wand, backpack	50 ft (15 m)	Crown diameter
	Ground-based Spray Application; vehicle-mounted tank sprayer	50 ft (15 m)	Crown diameter
	Aerial Spray (ball applicator)	250 ft (76 m)	250 ft (76 m)
	Aerial Application – herbicide ballistic technology (individual plant treatment)	100 ft (30 m)	Crown diameter
	Aerial Spray (boom)	Further consultation required	Further consultation required
Use of Insecticides (pollinators, seed dispersers)		Further consultation required	Further consultation required
Ground/Soil Disturbance/Outplanting/Fencing (Hand tools, e.g. shovel, `ō`ō; Small mechanized tools, e.g., auger)		20 ft (6 m)	2x crown diameter
Ground/Soil Disturbance (Heavy Equipment)		328 ft (100 m)	820 ft (250 m)
Surface Hardening/Soil compaction	**Trails (e.g., human, ungulates)**	20 ft (6 m)	2x crown diameter
	Roads/Utility Corridors, Buildings/Structures	328 ft (100 m)	820 ft (250 m)
Prescribed Burns		Further consultation required	Further consultation required
Farming/Ranching/Silviculture		820 ft (250 m)	820 ft (250 m)

Definitions (Wagner *et al*. 1999)

Crown: The leafy top of a tree.
Herb: A plant, either annual, biennial, or perennial, with the non-woody stems dying back to the ground at the end of the growing season.
Shrub: A perennial woody plant with usually several to numerous primary stems arising from or relatively near the ground.
Tree: A woody perennial that usually has a single trunk

1.0 SUMMARY OF FINDINGS

Terry A. Hayes Associates Inc. (TAHA) has completed an Air Quality and Climate Change Study (Study) for the Mākena Mauka Project (proposed project). Key findings are listed below.

- The proposed project would generate temporary (e.g., construction equipment exhaust) and permanent (e.g., residential vehicle exhaust, utility use) greenhouse gas (GHG) emissions. Construction-related GHG emissions, which are quantified and disclosed below, would be temporary and not significant. The proposed project would implement the Leadership in Energy and Environmental Design (LEED) certification on all lands pursuant to the 2008 Change in Zoning (CIZ) conditions of approval, which would reduce the environmental footprint associated with potential impacts, enhance the local ecosystem, and better community well-being. Cumulatively, permanent emissions would be unavoidable but not significant because the proposed project would not interfere with the development of clean energy supply in Hawaii.

- The State of Hawaii is committed to renewable energy production, which does not generate GHG emissions. Hawaii has enacted a law that mandates that all of the State's electricity comes from renewable sources no later than 2045. The proposed project is anticipated to be fully built out by 2058. Project-related indirect emissions would decline as the State moves toward a fully renewable supply of energy.

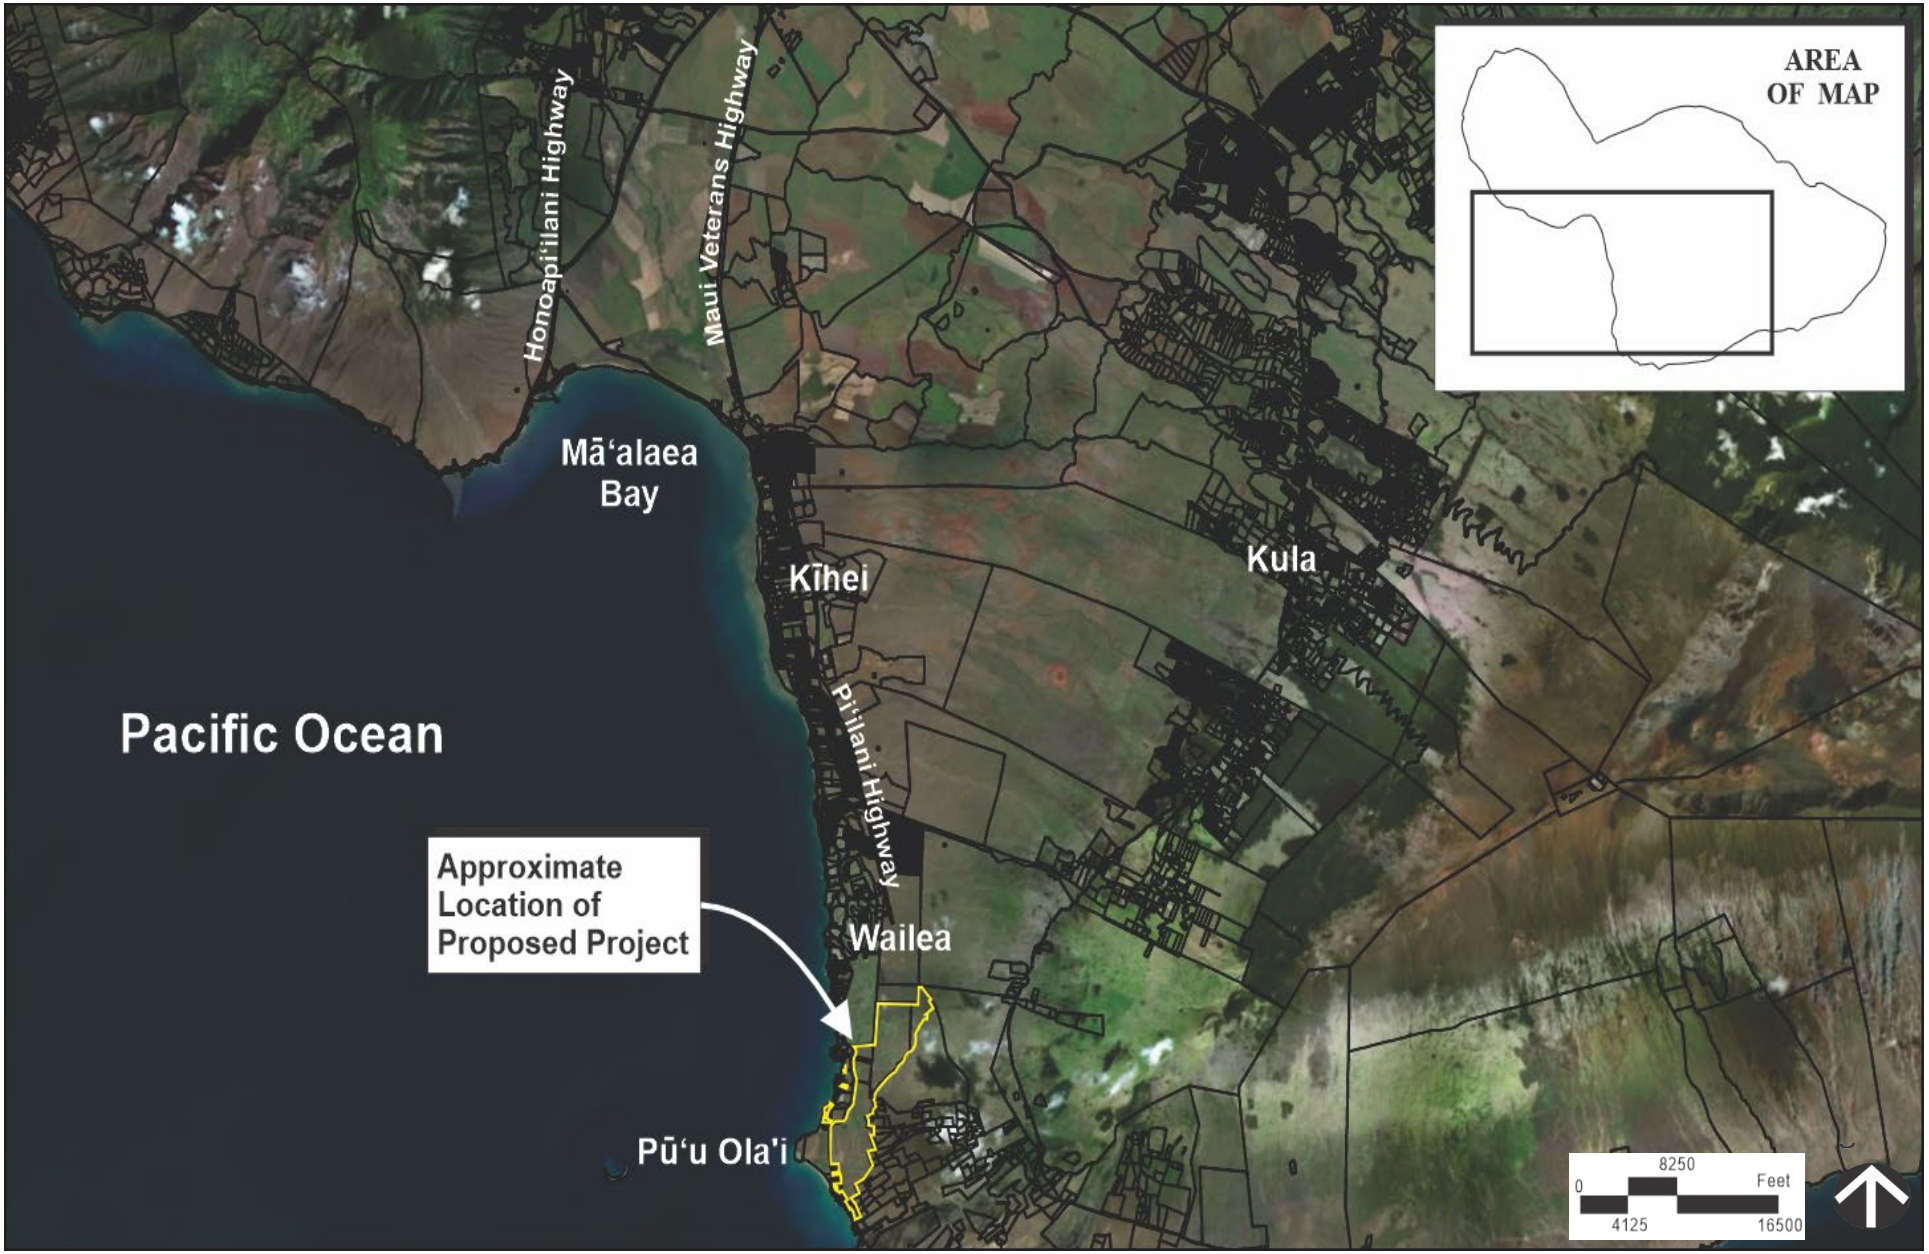
- The proposed project would generate GHGs from shipping most construction materials to Maui. The global nature of present-day manufacturing makes calculating emissions associated with that process incredibly difficult. Additionally, the sources of materials needed for construction are unknown at this stage of the planning process and environmental approvals. Furthermore, the effects from the transport of construction materials to Maui are best evaluated in the context of port-related emissions and not on a project-by-project basis due to the fact the ships importing construction materials benefit numerous construction projects. Material shipping emissions are not included in this Study but are acknowledged as a necessary part of construction in Hawaii.

- The proposed project would generate temporary construction emissions of criteria air pollutants. The primary sources of pollutant emissions during construction activities would be exhaust from diesel-powered equipment and trucks. Construction emissions would be temporary and would cease upon completion of activities.

- Construction activities could generate fugitive dust, although it would be minimized by utilizing control measures. The proposed project will follow reasonable control measures included in the Hawaii Department of Health (DOH) Clean Air Branch Fugitive Dust Fact Sheet (April 2019) to reduce fugitive dust. Control measures include, but are not limited to, fugitive dust control plans, watering as necessary to maintain soils in a damp condition, limiting the amount of exposed areas through planning and timing of project phases, and covering temporarily exposed areas with mulch. Which control measures to implement is/are the responsibility of the owner, project manager, or operator of the site in response to the County of Maui's grading permit and National Pollutant Discharge Elimination System (NPDES) permit requirements from the Hawaii DOH. The site topography and surroundings, soil conditions, meteorological conditions, site activities, site equipment, and types of material processed must be considered. Generally, dry and windy conditions will require more control measures than rainy and calm periods.

- The proposed project would not result in adverse effects related to regional operational emissions. Vehicle exhaust associated with residential trips would be the primary source of direct emissions. The entirety of Maui is designated as attainment of the ambient air quality standards, and mobile source emissions from the proposed project vehicle trips would not have the potential to compromise the attainment designations by deteriorating air quality.

2.0 INTRODUCTION



2.1 PURPOSE

The use of state or county lands or state or county funds, the use within a shoreline area, and any amendment to existing county general plans where the amendment would result in designations other than agriculture, conservation, or preservation requires preparation of an Environmental Impact Statement (EIS) pursuant to the Hawaii Administrative Rules (HAR) §343-5(a)(1); (e). This Study is intended to inform the EIS being prepared in accordance with the Hawaii Environmental Policy Act (HEPA). The purpose of the Study is to evaluate the potential for adverse air quality and GHG emission effects associated with implementation of the proposed project.

2.2 PROJECT DESCRIPTION

The proposed project is a low-density master planned residential community within the Makena area of South Maui. The regional location is shown in **Figure 2-1** and a conceptual land use plan is shown in **Figure 2-2**. The proposed project would offer market rate housing together with residential workforce housing with a mixture of single- and multi-family residential units all located mauka (mountain side, in this region this would be east side) of Makena Alanui Road (TMK (2)2-1-005:108, (2)2-1-006:036 and 057, (2)2-1-007:068, 092 and 093, (2)2-1-008:078, 079, 081, and 090, and (2)2-1-031:036(Por.)). A total of 652 residential units, inclusive of 195 single-family units and 457 multi-family units, are planned for phased development to be completed by the year 2057. Of the 652 residential units, 543 would be offered at market rate and 109 would qualify as residential workforce housing under Maui County Code Chapter 2.96.

The affordable housing is expected to be completed within the first 10 years of construction, with the remaining single- and multi-family homes being constructed equally over three 10-year periods (10, 20, and 30 years into the future). A total of 3,000 square feet of retail and 46,000 square feet of office space would also be developed in phases over the 30 years. The proposed project would incorporate the existing 18-hole Makena North Golf Course and the existing (to-be-renovated) 18-hole Makena South Golf Course, with improvements including a new clubhouse and practice range. The proposed project would include a community gathering place, hiking trails, programs to support connectivity, walking, bicycling, golf cart paths, beach parking areas for the public, areas reserved for conservation/open space, and areas reserved for public beach access. Improvements to existing roadways and intersections within the project area are anticipated as part of the proposed project. Additionally, all proposed buildings over 500 square feet would be LEED certified.

3.0 TOPICAL BACKGROUND & REGULATORY FRAMEWORK

This section provides an overview of how ambient air quality is characterized and the applicable regulations that have been established to protect public health and the environment, as well as a discussion of GHG emissions, how they contribute to climate change, and the regulatory framework developed to reduce GHG emissions. According to the DOH, air pollution is a general term that refers to the presence in the outdoor air of substances in quantities and for durations which may endanger human health or welfare, plant or animal life, or property, or may reasonably interfere with the comfortable enjoyment of life and property.

Through extensive scientific research, specific chemical substances have been identified as air pollutants that are known to cause adverse health effects and degradation of environmental quality. Concentrations of the following pollutants in ambient air are regulated at the federal and state level to protect public health and the environment. A separate discussion of GHG emissions and climate change is provided subsequently.

3.1 AIR POLLUTANTS

This Study discusses pollutants from two perspectives: daily emissions and pollutant concentrations. “Emissions” refer to the quantity of pollutant released into the air, measured in pounds per day (ppd) or tons per year (tpy) in this Study. “Concentrations” refer to a way to describe how much of a pollutant is in the air. Concentration is usually shown as an amount, or mass, of pollutant per certain volume of air, measured in parts per million (ppm) for gaseous pollutants and micrograms per cubic meter ($\mu g/m^3$) for pollutants in the particulate phase in this Study.[1] Air pollutants are presented as criteria pollutants, GHGs, hazardous air pollutants (HAPs), and nuisance pollutants such as odors and dust.

Criteria Pollutants

Ozone (O_3). O_3 is the main constituent in photochemical air pollution. It is formed in the atmosphere by a chemical reaction of nitrogen oxides (NOx) and volatile organic compounds (VOCs) in the presence of sunlight. In the upper atmosphere, O_3 shields the earth from harmful ultraviolet radiation; however, at ground level, it can cause harmful effects in humans and plants.[2]

Nitrogen Dioxide (NO_2). NO_2 is a brownish, highly corrosive gas with a pungent odor. It is formed in the atmosphere from emissions of nitrogen oxides (NO_X). Sources of NO_X include electric utilities, industrial boilers, motor vehicle exhaust, and combustion of fossil fuels. NO_2 is also a component in the atmospheric reaction that produces ground-level ozone.[3]

Carbon Monoxide (CO). CO is a colorless, odorless, tasteless gas under atmospheric conditions. It is produced by the incomplete combustion of carbon fuels with the majority of emissions coming from transportation sources.[4] CO can be emitted by volcanoes. However, it is rarely abundant enough in volcanic gases to cause serious problems. Volcanic gases contain between 0.01 and two percent CO.[5]

Sulfur Dioxide (SO_2). SO_2 is a colorless gas that easily combines with water vapor forming sulfuric acid. Emissions of SO_2 are largely from sources that burn fossil fuels such as coal and oil. In Hawaii, another possible major source of SO_2 emissions is from any active eruption of Kilauea Volcano on the Big Island.[6]

Particulate Matter. Particulate matter refers to a wide range of solid or liquid particles in the atmosphere, including smoke, dust, aerosols, and metallic oxides. Respirable particulate matter with an aerodynamic diameter of 10 micrometers or less is referred to as PM_{10}. $PM_{2.5}$ includes a subgroup of finer particles that have an aerodynamic diameter of 2.5 micrometers or less. Some particulate matter, such as pollen, is naturally occurring. Particulate matter emissions in the Hawaiian Islands are typically caused by volcanic eruptions, combustion, factories, construction, grading, demolition, agricultural activities, and motor vehicles. Volcanic sources of particulate matter can be substantial in Hawaii depending on the activity and wind direction.[7] The United States Environmental Protection Agency (USEPA) Particulate Matter standards apply only to these fine particles.

Lead (Pb). Sources of lead emissions vary from one area to another. At the national level, major sources of lead in the air are ore and metals processing and piston-engine aircraft operating on leaded aviation fuel. Other sources are waste incinerators, utilities, and lead-acid battery manufacturers. The highest air concentrations of lead are usually found near lead smelters. As a result of USEPA's regulatory efforts including the removal of lead from motor vehicle gasoline, levels of lead in the air decreased by 98 percent between 1980 and 2014.[8]

Hazardous Air Pollutants (HAPs)

HAPs, also known as toxic air pollutants or air toxics, are those pollutants that are known or suspected to cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental effects. Examples of toxic air pollutants include benzene, which is found in gasoline; perchloroethylene, which is emitted from some dry-cleaning facilities; and methylene chloride, which is used as a solvent and paint stripper by a number of industries. Examples of other listed air toxics include dioxin, asbestos, toluene, and metals such as cadmium, mercury, chromium, and lead compounds.[9]

Nuisance Pollutants (Odors and Dust)

Other air quality issues of concern include nuisance impacts of odors and dust. Objectionable odors may be associated with a variety of pollutants. Common sources of odors include wastewater treatment plants, landfills, composting facilities, refineries, and chemical plants. Similarly, nuisance dust may be generated by a variety of sources including quarries, agriculture, grading, and construction. Odors rarely have direct health impacts, but they can be very unpleasant and can lead to anger and concern over possible health effects among the public.

3.2 AIR QUALITY REGULATORY FRAMEWORK

Federal Regulations

United States Environmental Protection Agency (USEPA). At the federal level, the USEPA has been charged with implementing national air quality programs. The USEPA's authority over air quality is drawn primarily from the Federal Clean Air Act (FCAA), which was enacted in 1963. The FCAA was amended in 1970, 1977, and most recently in 1990. The FCAA required the USEPA to establish primary and secondary National Ambient Air Quality Standards (NAAQS) — concentrations of pollutants with the goal that they are not to be exceeded—shown below in **Table 3-1**. If concentrations exceed the NAAQS threshold, the area is considered to be in nonattainment. The NAAQS were devised to protect public health, reduce smog, and prevent degradation of environmental quality. Attainment of the NAAQS is achieved by demonstrating that measured concentrations of criteria pollutants for a region remained below the designated thresholds over a period of three years. The attainment status for Hawaii for each criteria air pollutant is shown in **Table 3-1**.

The FCAA also required each state to prepare an air quality control plan referred to as a State Implementation Plan (SIP). The FCAA Amendments of 1990 (FCAAA) added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIP is periodically modified to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins as reported by their jurisdictional agencies. USEPA has responsibility to review all state SIPs to determine conformation to the mandates of the FCAAA and determine if implementation will achieve air quality goals. Hawaii does not have a SIP because, as shown in **Table 3-1**, the State is in attainment with all NAAQS.

State Regulations

Hawaii Department of Health (DOH). The DOH Clean Air Branch is responsible for air pollution control in the State. The primary services of the branch are provided by its three sections: Engineering, Monitoring, and Enforcement. These sections conduct engineering analysis and permitting, perform monitoring and investigations, and enforce the federal and State air pollution control laws and regulations. The DOH HAR includes two chapters representing the Clean Air Branch. HAR §59 identifies State ambient air quality standards (**Table 3-1**), and HAR §60 discusses air pollution control methodology. HAR §60 includes air permitting, sampling, modeling, and fugitive dust and motor vehicle provisions.

TABLE 3-1: STATE AND NATIONAL AMBIENT AIR QUALITY STANDARDS AND ATTAINMENT STATUS

Pollutant	Averaging Period	State		Federal	
		Standard	Attainment Status	Standard	Attainment Status
Ozone (O_3)	8-hour Average	0.08 ppm	Attainment	0.07 ppm (137 µg/m^3)	Attainment
Respirable Particulate Matter (PM_{10})	24-hour Average	150 µg/m^3	Attainment	150 µg/m^3	Attainment
	Annual Arithmetic Mean	50 µg/m^3	Attainment	--	--
Fine Particulate Matter ($PM_{2.5}$)	24-hour Average	--	--	35 µg/m^3	Attainment
	Annual Arithmetic Mean	--	--	9 µg/m^3	Attainment
Carbon Monoxide (CO)	8-hour Average	4.4 ppm	Attainment	9 ppm (10 mg/m^3)	Attainment
	1-hour Average	9 ppm	Attainment	35 ppm (40 mg/m^3)	Attainment
Nitrogen Dioxide (NO_2)	Annual Arithmetic Mean	0.04 ppm	Attainment	53 ppb (100 µg/m^3)	Attainment
	1-hour Average	--	--	100 ppb (188 µg/m^3)	Attainment
Sulfur Dioxide (SO_2)	24-hour Average	0.14 ppm	Attainment	--	--
	3-hour Average	0.5 ppm	Attainment	0.5 ppm (1,300 µg/m^3)	Attainment
	1-hour Average	--	--	75 ppb (196 µg/m^3)	Attainment
	Annual Arithmetic Mean	0.03 ppm	Attainment	--	--
Lead (Pb)	Calendar Quarter	1.5 µg/m^3	--	--	--
	Rolling 3-Month Average	--	--	0.15 µg/m^3	--
Hydrogen Sulfide (H_2S)	1-hour Average	0.025 ppm	Attainment	--	--

SOURCE: State of Hawaii Department of Health, *Federal and State Ambient Air Quality Standards*, November 19, 2015; State of Hawaii Department of Health, *State of Hawaii Annual Summary 2022 Air Quality Data,* September 2023.

HAR §11-60.1-33 includes the following fugitive dust prohibitions:

- No person shall cause or permit visible fugitive dust to become airborne without taking reasonable precautions. Examples of reasonable precautions are:
  - Use of water or suitable chemicals for control of fugitive dust in the demolition of any buildings or structures, construction operations, the grading of roads, or the clearing of land;
  - Application of asphalt, water, or suitable chemicals on roads, material stockpiles, and other surfaces which may result in fugitive dust;

  - Installation and use of hoods, fans, and fabric filters to enclose and vent the handling of dusty materials. Reasonable containment methods shall be employed during sandblasting or other similar operations;
  - Covering all moving, open-bodied trucks transporting materials which may result in fugitive dust;
  - Conducting agricultural operations, such as tilling of land and the application of fertilizers, in such manner as to reasonably minimize fugitive dust;
  - Maintenance of roadways in a clean manner; and
  - Prompt removal of earth or other materials from paved streets which have been transported there by trucking, earth-moving equipment, erosion, or other means.
- Except for persons engaged in agricultural operations or persons who can demonstrate to the director that the best practical operation or treatment is being implemented, no person shall cause or permit the discharge of visible fugitive dust beyond the property lot line on which the fugitive dust originates.

In regard to motor vehicles, HAR §11-60.1-34 includes the following:

- No person shall operate a gasoline-powered motor vehicle which emits visible smoke while upon streets, roads, or highways.
- No person shall operate a diesel-powered motor vehicle which emits visible smoke for a period of more than five consecutive seconds while upon streets, roads, or highways.
- No person shall cause, suffer, or allow any engine to be in operation while the motor vehicle is stationary at a loading zone, parking or servicing area, route terminal, or other off-street areas, except:
  - During adjustment or repair of the engine at a garage or similar place of repair;
  - During operation of ready-mix trucks, cranes, hoists, and certain bulk carriers, or other auxiliary equipment built onto the vehicle or equipment that require power take-off from the engine, provided that there is no visible discharge of smoke and the equipment is being used and operated for the purposes as originally designed and intended. This exception shall not apply to operations of air conditioning equipment or systems;
  - During the loading or unloading of passengers, not to exceed three minutes; and
  - During the buildup of pressure at the startup and cooling down at the closing down of the engine for a period of not more than three minutes.
- No person shall remove, dismantle, fail to maintain, or otherwise cause to be inoperative any equipment or feature constituting an operational element of the air pollution control system or mechanism of a motor vehicle as required by the provisions of the Act except as permitted or authorized by law.

3.3 GREENHOUSE GAS EMISSIONS AND CLIMATE CHANGE

Cumulative GHG emissions contribute to an increased greenhouse effect and global climate change, which results in sea level rise, changes in precipitation, habitat, temperature, wildfires, air pollution levels, and changes in the frequency and intensity of weather-related-events. This Study focuses on carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) because these

are the primary GHGs emitted by land use development projects.[10] The individual pollutant's ability to retain infrared radiation represents its "global warming potential" and is expressed in terms of CO_2 equivalents (denoted CO_2e); therefore, CO_2 is the benchmark having a global warming potential of one. CH_4 has a global warming potential of 28 and thus has a 28 times greater global warming effect per metric ton of CH_4 than CO_2. N_2O has a global warming potential of 265. GHG emissions are generally expressed in units of annual metric tons of CO_2 equivalents (i.e., $MTCO_2e$/year).

3.4 CLIMATE CHANGE REGULATORY FRAMEWORK

Federal Laws

The United States Supreme Court has ruled that CO_2 and other GHGs are pollutants under the FCAA, which the USEPA may regulate. On December 7, 2009, the USEPA made two distinct findings: 1) that the current and projected concentrations of the six key GHGs (CO_2, CH_4, N_2O, hydrofluorocarbons, perfluorocarbons and sulfur hexafluoride) in the atmosphere threaten the public health and welfare of current and future generations; and 2) that the combined emissions of these GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution which threatens public health and welfare.[11]

The United States Supreme Court has ruled that the USEPA exceeded its statutory authority under the FCAA when it determined that stationary source emissions of GHGs would trigger permitting obligations under the Prevention of Significant Deterioration (PSD) program and Title V of the FCAA.[12] The Court, however, upheld those portions of USEPA's rulemaking that require a source to apply best available control technology (BACT) to GHG emissions where the source would otherwise trigger PSD permitting on account of its emissions of other pollutants. The Supreme Court's decision was limited to USEPA's regulation of GHG emissions under the PSD and Title V provisions of the FCAA, and it left unanswered other questions regarding USEPA's permitting and BACT authority under the PSD program, and the USEPA's efforts to regulate GHG emissions from stationary sources.

The Federal Greenhouse Gas Reporting Program (40 Code of Federal Regulations Part 98) requires mandatory reporting of GHG emissions from sources that emit 25,000 metric tons or more of carbon dioxide equivalent per year in the United States. Uses that are generally associated with this level of reporting include power plants, petroleum and natural gas refineries and other heavy manufacturing processes.

State Regulations

In 2007, Hawaii became the second State in the nation to set a binding cap on GHG emissions through Act 234: Hawaii's Climate Change Law, which declared a policy to reduce GHG emissions statewide to 1990 levels by the year 2020. Act 234 served as the foundation for the Hawaii Greenhouse Gas Program, which was established by the DOH to combat the threat of climate change and sea level rise. This Program utilizes the Air Pollution Control Permit process of DOH's Clean Air Branch to regulate GHG emissions statewide, in conjunction with other federal

[10]California Air Pollution Control Officers Association, *California Emissions Estimator Model Users Guide (Version 2022.1)*, April 2022.

[11]Supreme Court of the United States, *Massachusetts et al. v. Environmental Protection Agency et al.*, April 2, 2007.

[12]Supreme Court of the United States, *Utility Air Regulatory Group v. Environmental Protection Agency et al.*, June 23, 2014.

and State programs to mitigate GHGs. Parts of Act 234 are codified in HAR §342B (Air Pollution Control).

Senate Bill (SB) 559, which was signed into law on June 8, 2017, expands strategies and mechanisms to reduce GHG emissions in alignment with the principles and goals adopted in the Paris Agreement, discussed above. SB 559 documents the State's commitment to combat climate change by systematically reducing GHG emissions and improving resiliency to climate change aligned with the principles and goals set by the Paris Agreement. It expands on strategies and mechanisms to reduce GHG emissions through the reduction of energy use, adoption of renewable energy, and control of air pollution among all agencies, departments, industries, and sectors, including transportation. SB 559 states that, "Such strategies and mechanisms shall utilize the best available science, technologies, and policies to reduce GHG emissions and shall be closely aligned with the climate change principles and goals adopted in the Paris Agreement and Hawaii's share of obligations within the expectations apportioned to the United States in the Paris Agreement, regardless of federal action." In addition, "The State shall strive to formulate and communicate long-term low greenhouse gas emission development strategies and shall take actions to conserve and enhance long-term sinks and reservoirs of greenhouse gases, by prioritizing the development of parks, greenways, and restoration of native upland and coastal forests and wetlands."

In 2018, the State Legislature passed Act 15, to establish a permanent Greenhouse Gas Sequestration Task Force within the Office of Planning (now the Office of Planning and Sustainable Development). This task force will work to establish a baseline for GHG and short- and long-term benchmarks for increasing GHG sequestration in the agricultural and natural environment. The Act also establishes a statewide carbon net-negative goal by 2045.

In 2022, the State Legislature passed Act 238, which tasks the Hawaii State Energy Office to "analyze pathways and develop recommendations for achieving the State's economy-wide decarbonization goals." Additionally, the study will evaluate emission reduction pathways from all emitting sectors economy wide. Act 238 establishes a goal for the level of statewide GHG emissions to be at least 50 percent below 2005 levels by 2030 (including aviation emissions).

The DOH established the Hawaii GHG Program to combat the threat of climate change and sea level rise. The program utilizes the Air Pollution Control Permit process of the Clean Air Branch to regulate GHG emissions statewide. The Hawaii GHG program works in conjunction with other federal and State programs to mitigate GHG emissions. This includes the Priority Climate Action Plan (PCAP), which, when completed in 2024, will identify the most pressing areas in need of GHG reduction, and determine fitting implementation-ready measures. The PCAP will use the most recent statewide GHG inventory, which was completed in 2019, to produce an updated, more accurate inventory. The PCAP will be developed based on community engagement, and collaboration between the commission and community members throughout the planning process. The commission will host workshops to support community and stakeholder engagement and plan them in conjunction with neighborhood boards and councils. Information from these meetings will be pivotal in both gathering information to be used for the plan, developing the plan, and revising existing plans.

The Comprehensive Climate Action Plan (CCAP), when completed in 2025, would build upon the PCAP and identify all major sources and sinks of GHGs, establish short- and long-term reduction goals, and fitting strategies and measures. The CCAP will examine current GHG emissions and projected emissions without any changes to status quo activities and compare these to projected emissions with economy wide GHG reduction activities fully carried out.

The State settled the *Navahine v. Hawai'i Department of Transportation (HDOT)* constitutional climate case in 2024. The settlement acknowledges the constitutional rights of Hawai'i's youth to a life-sustaining climate and confirms the commitment by HDOT to plan and implement transformative changes of Hawai'i's transportation system to achieve the State's goal of net-negative emissions by 2045. The agreement includes numerous provisions for immediate and ongoing action steps by HDOT. These include, for example:

- Establishing a GHG Reduction Plan within one year of the agreement, laying the foundation and roadmap to decarbonize Hawai'i's transportation system within the next 20 years.

- Creating a lead unit and responsible positions within HDOT to coordinate the mission of GHG reduction throughout the agency; oversee climate change mitigation and adaptation for the highways program; and ensure implementation of the Complete Streets policy of building and upgrading public highways for all users, ages, and abilities.

- Establishing a volunteer youth council to advise on HDOT mitigation and adaptation commitments in the years to come.

- Improving the state transportation infrastructure budgeting process to prioritize reduction of GHG and vehicles miles traveled (VMT) and transparently analyze and disclose the GHG and VMT impacts of each project and the overall program.

- Making immediate, ambitious investments in clean transportation infrastructure, including completing the pedestrian, bicycle, and transit networks in five years, and dedicating a minimum of $40 million to expanding the public electric vehicle charging network by 2030.

4.0 EXISTING ENVIRONMENTAL SETTING

4.1 CLIMATOLOGY

Maui is characterized by a semi-tropical climate containing a multitude of individual microclimates. The mean annual temperature of the island at all locations near sea level is approximately 75 degrees Fahrenheit. A high proportion of the rainfall that Maui receives each year falls on the northeast facing shores leaving the south and southwest coastal areas relatively dry.

The project area is located within one of these drier areas of the southwest coast. The Kīhei-Makena coast is generally sunny, warm, and dry throughout the entire year. Annual temperatures in the region average in the mid 70's. July through September are historically the warmer months of the year, while the cooler months are December through February. During the summer months, average daily temperatures in Kīhei typically range from the low 70's to the high 80's.[13]

Average rainfall distribution in the Kīhei-Makena region varies from under 10 inches per year along the coastline to more than 20 inches per year in the higher elevations. Rainfall in the Kīhei-Makena region is highly seasonal, with most of the precipitation occurring in the winter months.[14]

Northeast tradewinds prevail approximately 80 to 85 percent of the time. Tradewinds originating from the northeast average 10 to 15 miles per hour during afternoons, with slightly lighter winds during mornings and nights. Between October and April, the southerly winds of Kona storms may be experienced.[15]

4.2 AIR MONITORING DATA

There are no substantial permanent sources of airborne emissions in the immediate vicinity of the project site and the project area in general does not experience adverse air quality conditions. The closest DOH air monitoring site is located at the Hale Piʻilani Park in Kihei, which is approximately nine miles to the north of the proposed project. This station monitors $PM_{2.5}$ concentrations. **Table 4-1** shows that pollutant levels are significantly below the applicable state and federal standards from 2020 to 2023. The primary and contributors to the measured pollutant levels are automobile exhaust from the region's roadways, periodic volcanic eruptions, and the recent fires.

TABLE 4-1: AIR MONITORING DATA SUMMARY

Pollutant	Averaging Period	Federal Standard	Maximum 2021	Maximum 2022	Maximum 2023
$PM_{2.5}$	24-hour	35 $\mu g/m^3$	15.4	8.2	6.1
	Annual	9 $\mu g/m^3$	2.5	2.5	2.3

SOURCE: State of Hawaii Department of Health, *2021 Hawaii Air Quality Data*, December 2022; State of Hawaii Department of Health, *2022 Hawaii Air Quality Data*, September 2023; State of Hawaii Department of Health, *2023 Hawaii Air Quality Data*, September 2024.

4.3 AIR QUALITY SENSITIVE RECEPTORS

Sensitive receptors include, but are not limited to, hospitals, schools, daycare facilities, elderly housing, and convalescent facilities. These are areas where the occupants are more susceptible to the adverse effects of exposure to toxic chemicals, pesticides, and other pollutants. Extra care

[13] County of Maui, Office of Economic Development, *Maui County Data Book 2019*, 2019.
[14] I*bid*.
[15] I*bid*.

must be taken when dealing with contaminants and pollutants in close proximity to areas recognized as sensitive receptors.[16] Sensitive receptors within the project area include single- and multi-family residences located to the west of the project site. Schools or other sensitive institutional facilities have not been identified near the project site.

4.4 STATEWIDE GREENHOUSE GAS EMISSIONS

The State published the Hawaii GHG Emissions Report for 2020 and 2021 in May 2024. The purpose of the report is to track progress toward achieving the State's 2020, 2030, and 2045 GHG reduction goals. Based on the analysis presented in the report for emissions through 2020, net GHG emissions (excluding aviation) in 2020 were lower than net GHG emissions estimated for 1990. Statewide GHG projections for 2025, 2035, and 2045 indicate Hawaii is on target to continue to meet its statewide GHG emissions limit after 2020. Act 15 (2018) and Act 238 (2022) emissions limits were not projected to be met in goal years 2045 and 2030, respectively. These findings will be reassessed and updated in the forthcoming emissions report for 2022.

In 2021, total GHG emissions in Hawaii were 20.18 million metric tons of CO_2 equivalents per year (MTCO2e/year). Emissions from the energy sector accounted for the largest portion (86.7 percent) of total emissions in Hawaii followed by the agriculture, forestry, and other land use sectors (7.2 percent), the industrial processes and product use sector (4.0 percent), and the waste sector (2.0 percent).

Total GHG emissions in Hawaii grew by 17.7 percent between 1990 and 2007 before decreasing by 25.5 percent between 2007 and 2021. Compared to 1990, total emissions in Hawaii in 2021 were roughly 12.3 percent lower, while net emissions were lower by 13.6 percent. As the largest source of emissions in Hawaii, the Energy sector is a major driver of the overall emissions trends. Transportation emissions accounted for the largest share of Energy sector emissions in all inventory years. The trend in transportation emissions increased significantly from 1990 to 2007, decreased from 2007 to 2015, and increased between 2016 and 2019. Then, transportation emissions dropped significantly in 2020 before increasing again in 2021. Transportation emissions are largely driven by domestic aviation and ground transportation emissions, which together account for roughly 84.3 percent of transportation emissions. The trend in stationary combustion emissions increased between 1990 and 2005, decreased between 2005 and 2016 and increased between 2016 and 2019. Then, stationary combustion emissions dropped in 2020 before increasing again in 2021. Stationary combustion emissions are largely driven by emissions from energy industries (electric power plants and petroleum refineries) as well as industrial and commercial emissions. The general decline in emissions from 2019 to 2020 is largely due to the impacts that the coronavirus (COVID-19) pandemic had on travel and economic activities; the increase in emissions in from 2020 to 2021 is due to economic activity rebounding following the height of the pandemic.

Hawaii GHG emissions are projected to be 19.93 million $MTCO_2e$/year in 2025, 18.32 million $MTCO_2e$/year in 2030, and 13.12 million $MTCO_2e$/year in 2045. Net emissions, which take into account carbon sinks, are projected to be 17.55 million $MTCO_2e$/year in 2025, 15.95 million $MTCO_2e$/year in 2030, and 10.57 million $MTCO_2e$/year in 2045. Relative to 2021, total emissions under the baseline scenario are projected to decrease by one percent by 2025, nine percent by 2030, and 35 percent by 2045. Over the same period, net emissions are projected to decrease by one percent, 10 percent, and 41 percent, respectively, and net emissions excluding aviation

[16]USEPA, *Environmental Issues of Concern for Urban Communities: Resources*. https://www.epa.gov/newenglandhc/environmental-issues-concern-urban-communities-resources. Accessed October 7, 2024.

are projected to decrease by four percent, 18 percent, and 63 percent, respectively. This trend is driven by the projected decrease in emissions from energy industries, which includes fuel combustion emissions from electric power plants and petroleum refineries.

5.0 SIGNIFICANCE CRITERIA

The HEPA has not established quantitative significance criteria related to air quality. According to the Council on Environmental Quality (CEQ) Regulations (40 Code of Federal Regulations §§ 1500-1508), the determination of a significant impact is a function of both context and intensity. Context means that the significance of an action must be analyzed in several contexts such as society as a whole (human, national), the affected region, the affected interests, and the locality. Both short- and long-term effects are relevant. Intensity refers to the severity of impact. To determine significance, the severity of the impact must be examined in terms of the type, quality and sensitivity of the resource involved; the location of the project; the duration of the effect (short- or long-term) and other considerations of context. Adverse effects will vary with the setting of the proposed action and the surrounding area.

Similarly, the HEPA has not established quantitative significance criteria related to GHG emissions. Accordingly, GHG emissions are quantified for disclosure. The potential for an adverse effect is based on consistency with regional GHG reduction plans.

6.0 ENVIRONMENTAL EFFECTS

6.1 CONSTRUCTION EMISSIONS OF CRITERIA AIR POLLUTANTS AND OZONE PRECURSORS

Common sources of construction-related air pollution include equipment engine exhaust, as well as mobile source vehicle trips, all of which are temporary in nature and do not represent permanent sources of air pollutants. Hawaii does not have guidance or limitations related to exhaust emissions generated by heavy-duty equipment. Building and road construction are two examples of construction activities with high emissions potential. Emissions during the construction of a building or road can be associated with land clearing, ground excavation, cut and fill operations (i.e., earth moving), and construction of a particular facility itself. Emissions often vary substantially from day to day, depending on the level of activity, the specific operations, and the prevailing meteorological conditions.

Neither Hawaii nor the USEPA have created a model for efficiently estimating construction emissions. Equipment inventories for each phase of construction were populated in the California Emissions Estimator Model (CalEEMod, Version 2022.1.1.29), and the model was used to produce estimated emissions of VOC, NO_X, CO, SO_X, PM_{10}, and $PM_{2.5}$ during each year of construction activities. This model provides a reasonable estimation of construction emissions in Hawaii for planning only purposes as the equipment fleet in the model includes varying levels of engine emission controls.

Specific construction details, such as a detailed schedule and equipment list, were not available when this analysis was prepared. Construction was assumed to occur in three ten-year phases beginning in 2028 with completion in the years 2038, 2048, and 2058. Single- and multi-family residences as well as golf course improvements were assumed to be constructed equally over the three phases. Workforce housing units, retail units, and office spaces were assumed to be completed during Phase 1, which is consistent with the *Mākena Mauka Traffic Impact Analysis Report* (TIAR). Additional buildings, including restaurant, clubhouse, kitchen, locker rooms, fitness, back-of-house, were assumed to be built in Phase 3 and were analyzed together as “High Turnover (Sit Down Restaurant)” due to lack of project-specific details. Anticipated construction activities for all phases include site preparation, grading, building construction, paving, and architectural coating. All construction activities were assumed to occur daily within each ten-year construction period. CalEEMod estimates emissions up to the year 2050. Phase 3 and full build-out scenarios were estimated using the emissions estimates up to the year 2050. The 2050 emissions estimates would provide a conservative analysis as emissions are estimated to decrease in the years following. Detailed modeling output files containing schedule and equipment information can be found in the **Appendix**.

Table 6-1 discloses the estimated annual criteria pollutant and ozone precursor emissions that would be generated during each year of proposed project construction. The emissions analysis was conservative in nature as it assumed that all equipment would operate continuously throughout an eight-hour workday for the entirety of the schedule. Construction emissions generated by the proposed project would be temporary and would cease upon completion of activities.

TABLE 6-1: CONSTRUCTION EMISSIONS FOR CRITERIA POLLUTANTS AND OZONE PRECURSORS

Phase	Maximum Annual Emissions (Tons per Year)					
	VOC	NO_X	CO	SO_2	PM_{10}	$PM_{2.5}$
Phase 1	2.9	14.6	20.9	<0.1	4.7	2.1
Phase 2	2.2	10.7	17.3	<0.1	4.2	1.9
Phase 3	2.1	9.3	16.3	<0.1	4.1	1.8
Maximum Annual	2.9	14.6	20.9	<0.1	4.7	2.1

SOURCE: TAHA, 2025.

Additionally, during the construction period, proactive transportation management would be implemented to reduce VMT by workers and equipment. Strategies considered include centralized carpool coordination from contractor base yards, establishment of an on-site centralized parking facility, and the use of remote parking lots with shuttle service for construction crews. A reduction in VMT would result in lower emissions of VOC, NO_X, CO, and PM.

Earthwork activities typically generate fugitive dust emissions. The proposed project would implement best management practices, such as periodic application of water onto exposed or disturbed ground areas and material stockpiles, dust and silt fencing for erosion control, maintaining equipment in accordance with manufacturer specifications, sweeping of dust track-out on surrounding roadways, and prompt revegetation of graded areas.

The DOH Clean Air Branch published a Fugitive Dust Fact Sheet, which was last revised in April 2019. The following are examples of reasonable precautions to reduce fugitive dust that could be implemented by the construction contractor. The examples are noted as not being requirements and are solely intended to aid in complying with the fugitive dust rules. The examples are common precautions used for various activities that may generate visible fugitive dust and are not meant to be exclusive nor comprehensive.

- General Measures
  - Design, develop, and implement a dust control plan.
  - Use water or suitable chemical compounds in the demolition of existing structures, construction operations, and grading or clearing of land.
  - Apply water, dust suppressants, or suitable compounds on roads and material stockpiles.
  - Pave ingress and egress points to the site.
  - Establish and monitor speed limits for on-site vehicles.
  - Cover all moving, open-bodied trucks transporting dusty materials.
  - Install and use enclosures, screens, hoods, vacuums, and filters to control the handling, sanding, or finishing of dusty materials.
  - Use trash chutes to direct waste downwards to the ground from upper levels.
  - Clean up material spills as soon as possible.
  - Promptly remove soil or other “carry out” materials from roads adjacent to the site.
  - Install dust screens or wind barriers around construction site.

  - Where practical, provide a buffer zone between fugitive dust activities and residential areas.
- Earth-moving Activities
  - Pre-apply and re-apply water as necessary to maintain soils in a damp condition.
  - Limit the amount of exposed areas through planning and timing of project phases.
  - Cover temporarily exposed areas with mulch.
- Stockpiles
  - Stabilize stockpile materials.
  - Keep stockpiles wet or damp as needed.
  - Keep drop or pile height as low as possible.
  - Install wind barriers.
  - Add or remove material from downwind portion of stockpile.
  - Maintain storage piles to avoid steep sides or faces.
- Trucking
  - Provide water while loading and unloading to prevent fugitive dust.
  - Maintain at least six inches of freeboard on haul vehicles.
  - Level the height of load.
  - Limit vehicular speed while traveling onsite.
  - Cover loads during transport.
  - Install a gravel pad at exit.
  - Reduce carry out with a tire wash or spray system.

The Clean Air Branch does not require specific precautions. Which precaution(s) to implement is/are the responsibility of the owner, project manager or operator of the site. Reasonable precautions to control fugitive dust are determined on a case-by-case basis. The site topography and surroundings, soil conditions, meteorological conditions, site activities, site equipment, and types of material processed must be considered. The use of any or all of the example measures does not directly correlate to compliance of the fugitive dust requirements. The owner, project manager, or operator should assess the project activities and conditions daily and make adjustments so that reasonable precautions are taken to prevent fugitive dust from becoming airborne and crossing the property lines. Generally, dry and windy conditions will require more control measures than rainy and calm periods.

6.2 OPERATIONAL EMISSIONS OF CRITERIA AIR POLLUTANTS AND OZONE PRECURSORS

CalEEMod was also used to estimate operational emissions of criteria air pollutants and ozone precursors. Direct sources of operational emissions would include mobile source vehicle trips and area source emissions, such as consumer product use (i.e., household cleaners) and landscaping activities. Tailpipe emissions from on-road vehicle trips would be distributed along the surrounding roadway network and would not be heavily concentrated in one location. Regarding regional mobile source emissions, the transportation analysis concluded that the proposed project at full

build-out would generate 294 AM peak hour trips and 368 PM peak hour trips.[17] **Table 6-2** shows a summary of the peak hour trips generated by the proposed project. The peak hour trips for each phase were generated based on the developments that would occur in each respective phase and do not include the trips generated from the developments in the other phases. The 2048 Cumulative trips include trips generated from developments completed in 2038 and 2048. The total peak hour trips generated included all trips generated by all developments at full build-out.

TABLE 6-2: PROPOSED PROJECT WEEKDAY TRIP GENERATION

Year	Peak Hour Trips	
	AM	PM
2038	158	192
2048	68	88
2048 Cumulative	226	280
2058	68	88
Total	294	368

SOURCE: SSFM International, *Mākena Mauka Traffic Impact Analysis Report*, March 2025.

Trip rates were taken from the TIAR, which analyzed project generated trips based on the development of 100 affordable housing units, 162 single-family units, and 390 multi-family units. Refinements to the site plan included modifications to the residential unit counts to 109 affordable housing units, 180 single-family units, and 363 multi-family units, and specifics were provided for what had been previously identified as operational support buildings. The TIAR found that the increase in trips generated as a result of the changes was not significant (less than seven total trips in full buildout) and would have no appreciable effect on the operational results. Thus, no changes were made to the project generated trip calculation after the project refinement.

The emissions model requires daily trips to generate emissions. PM peak hour trips were assumed to be ten percent of the total daily trips, resulting in a total of approximately 3,680 trips per day. Area source emissions also include golf course maintenance activities. The emissions analysis accounts for 16 hours per day of riding mower operations and 16 hours per day of other equipment such as green rollers and trimmers.

Indirect source emissions during operations would include energy consumption such as electricity for ventilation and air conditioning, water heating, stoves, lighting, and appliances. To more accurately represent emissions from water in the project area, the water-energy intensity for Maui from the *2016 Hawaii Energy Nexus Report* was used. Water-energy intensity is the amount of energy required to collect, treat, and distribute 1,000 gallons of water (kWh/kgal). The average water-energy intensity in Maui in 2015 was 4.3 kWh/kgal.[18] Detailed operational emissions data can be found in the **Appendix**. **Table 6-3** presents the results of the operational emissions modeling after construction of each phase in 2038, 2048, and 2058. The operational emissions calculated for each phase were based on the developments that would occur in each respective phase and do not include emissions generated from the developments in the other phases. The 2048 Cumulative emissions show the operational emissions in 2048 that would be generated from developments completed in 2038 and 2048. The total annual operational emissions show emissions in 2058 that would be generated from all developments at full build-out.

TABLE 6-3: OPERATIONAL EMISSIONS FOR CRITERIA POLLUTANTS AND OZONE PRECURSORS

Year	Annual Emissions (Tons per Year)					
	VOC	NO_X	CO	SO_2	PM_{10}	$PM_{2.5}$
2038	2.7	1.0	7.8	<0.1	1.8	0.5
2048	1.4	0.5	3.5	<0.1	0.8	0.2
2048 Cumulative	4.1	1.5	11.3	<0.1	2.6	0.7
2058	2.7	1.0	41.6	<0.1	0.9	0.2
TOTAL	**6.6**	**2.3**	**52.2**	**<0.1**	**3.5**	**0.9**

SOURCE: TAHA, 2025.

Additionally, the proposed project would include transportation strategies, which focus on reducing private vehicle dependence and offering convenient, comfortable, and low-emission alternatives for residents, guests, and employees. Planned features include an integrated bicycle network, an extensive pedestrian trial, and on-demand shuttles. These features would result in lowered VMT and a decrease in VOC, NO_X, CO, and PM emissions.

Regarding localized mobile source emissions, CO concentrations are often used as one indicator of pollutant exposure to sensitive receptors. The USEPA has published guidance on prevention of CO "hot spots" at congested traffic intersections resulting from idling and slow-moving vehicles. The guidance focuses on the avoidance of localized spikes in CO concentrations causing violations of the ambient air quality standards that may occur at heavily trafficked and highly congested intersections. In response to the guidance promulgated by the USEPA, numerous regulatory agencies throughout the country undertook research to determine the types of intersections that may pose air quality concerns with regards to CO hot spots. Since the island of Maui has always been in attainment of the ambient air quality standards, local regulatory agencies did not have a need to conduct research to satisfy the air quality plan requirements. However, mobile source emissions of CO are of particular concern in California, where the South Coast Air Quality Management (SCAQMD) engaged in extensive research to demonstrate how the CO NAAQS could be attained for the region.

Research published in 2003 by the SCAQMD to support SIP documentation involved air dispersion modeling of mobile CO emissions at some of the busiest intersections in Southern California, where regional mobile source emissions are substantially higher than the project area on a per-square-mile basis. Results of the CO dispersion modeling exercise determined that an intersection experiencing a peak hour volume of approximately 10,000 vehicles per hour would generate a maximum 1-hour CO concentration approximately 77 percent below the ambient air quality standard.[19] The traffic analysis prepared for the proposed project demonstrates that local intersection volumes are nowhere near 10,000 vehicles per hour.[20] There is no potential for the proposed project to result in a CO hotspot and, therefore, no potential for the proposed project to result in substantial concentrations of related exhaust pollutants.

6.3 CONSTRUCTION GREENHOUSE GAS EMISSIONS

The State, through Act 234 and SB 559, has acknowledged that GHG emissions are a statewide impact. The proposed project would generate temporary GHG emissions through construction activities.

GHG emissions related to construction activities were estimated in a similar manner as the criteria pollutant emissions analysis presented above. The primary source of construction related GHG emissions would be exhaust from heavy-duty equipment. **Table 6-4** shows construction related GHG emissions.

TABLE 6-4: CONSTRUCTION-RELATED GHG EMISSIONS

	Annual Emissions (Tons per Year)			
Year	CO_2	CH_4	NO_2	$MTCO_2e$
2028	4,320	0.2	0.2	4,374
2029	4,300	0.2	0.2	4,353
2030	4,269	0.2	0.2	4,321
2031	4,239	0.2	0.2	4,290
2032	4,222	0.2	0.1	4,266
2033	4,184	0.2	0.1	4,227
2034	4,160	0.2	0.1	4,201
2035	4,137	0.1	0.1	4,179
2036	4,129	0.1	0.1	4,170
2037	3,998	0.1	0.1	4,038
2038	3,662	0.1	0.1	3,696
2039	3,672	0.1	0.1	3,707

2054	3,621	0.1	0.1	3,654
2055	3,621	0.1	0.1	3,654
2056	3,621	0.1	0.1	3,654
2057	3,621	0.1	0.1	3,654

SOURCE: TAHA, 2025.

As previously discussed, total statewide GHG emissions are projected to be 19.93 million $MTCO_2e$/year in 2025. Construction-related GHG emissions associated with the proposed project would generate an annual maximum of approximately 4,374 $MTCO_2e$, which represents 0.02 percent of the statewide annual emissions inventory. Additionally, proactive transportation management would be implemented to reduce VMT by workers and equipment. A reduction in VMT would result in lower CO_2 emissions.

6.4 OPERATIONAL GREENHOUSE GAS EMISSIONS

GHG emissions related to operational activities were estimated in a similar manner as the criteria pollutant emissions analysis presented above. The proposed project would generate permanent GHG emissions through energy consumption, landscaping equipment, residential vehicular travel, water use, and waste generation. Hawaii is committed to renewable energy production, which does not generate GHG emissions. In 2023, approximately 31 percent of electricity in Hawaii was from renewable sources.[21] Hawaii has enacted a law that mandates that all of the State's electricity comes from renewable sources no later than 2045.

Table 6-5 shows the estimated annual operational GHG emissions after construction of each phase in 2038, 2048, and 2058. The operational emissions calculated for each phase were based on the developments that would occur in each respective phase and do not include emissions generated from the developments in the other phases. The 2048 Cumulative emissions show the operational emissions in 2048 that would be generated from developments completed in 2038 and 2048. The total annual operational emissions show emissions in 2058 that would be generated from all developments at full build-out. The proposed project would generate approximately 3,734 metric tons of CO_2e at full build out in 2058.

TABLE 6-5: ESTIMATED ANNUAL GREENHOUSE GAS EMISSIONS

Scenario and Emission Source	Carbon Dioxide Equivalent (Metric Tons per Year)				
	2038	**2048**	**2048 Cumulative**	**2058**	**Total**
Mobile Source Emissions (Direct)	1,620	713	2,333	712	2,966
Area Source Emissions (Direct)	4	2	6	76	83
Energy Source Emissions (Indirect)	782	--	--	--	--
Water Distribution Emissions (Indirect)	99	59	158	157	340
Waste Disposal Emissions (Indirect)	82	42	124	222	346
TOTAL	**2,587**	**818**	**2,621**	**1,167**	**3,734**

SOURCE: TAHA, 2025.

The proposed project would include transportation features, which focuses on reducing private vehicle dependence and offering convenient, comfortable, and low-emission alternatives for residents, guests, and employees. These transportation features would result in lower mobile-source emissions. Furthermore, all buildings over 500 square feet within the project area would be LEED certified, which would include design features that encourage energy and water efficiency. Project-related indirect emissions would decline as the State moves toward a fully renewable supply of energy. In addition, the proposed project would not interfere with the development of clean energy supplies. Thus, the proposed project would not contribute to a

[21]U.S. Energy Information Administration, *Hawaii State Energy Profile*, April 18, 2024.

significant increase in GHG emissions. Part time residents typically travel to and from Maui via public or private aircraft. Because Maui residents also travel and tourism is Maui's largest industry, it would be very difficult if not impossible to determine and distinguish the specific impacts from new part time residents of the project from impacts from others that travel to and from Maui. It would not be possible to discern the air travel effects of new potential residences and impacts from others that travel to Maui. Furthermore, none of the applicable climate change and/or GHG emission reduction plans include the reduction of flights to/from Maui as a method for reducing GHG emissions. As the majority of aviation emissions would be generated outside of the State jurisdiction, there is no potential for project-related air travel to interfere with State GHG reduction goals.

6.5 CLIMATE CHANGE

The Mākena Mauka Sustainability Report (Sustainability Report), commissioned by AREG AC Makena Propco, LLC, serves as a guide to understanding and implementing regenerative development practices within the context of Mākena Mauka, setting a precedent for harmonizing development with nature.[22] While sustainability emphasizes meeting present needs without jeopardizing the future, the focus of this initiative extends beyond mere sustainability; it aims to cultivate a restorative long-term relationship between the community and the ecosystems of Makena through regenerative design. Regenerative design is an innovative approach that seeks to create systems and environments capable of restoring and revitalizing their ecosystems. This design philosophy goes beyond sustainability by not only aiming to minimize negative impacts on the environment but also to enhance and regenerate the natural world and improve overall human well-being. It emphasizes the interconnectedness of all systems and aims to create positive ecological, social, and economic outcomes by integrating nature and human activity in a harmonious way. The Sustainability Report was built on the foundation of State, County, and local initiatives, leaning heavily on the Hawaii 2050 Sustainability Plan, the Maui Island Plan and the proposed South Maui Community Plan for policies and applications that could inform the Mākena Mauka plans. It also includes sustainability plans and practices currently being implemented by Mākena Golf and Beach Club. In alignment with LEED standards, the proposed project emphasizes systemic thinking, stakeholder engagement, performance feedback, and innovation, paving the way for new benchmarks for development in Maui.

Regarding climate change, the Sustainability Report focuses on integrating design elements that enhance resilience against climate-related effects, ensuring structures and landscapes are equipped to withstand environmental stresses.

Although the proposed project will generate temporary construction-related GHG emissions, these emissions will not significantly interfere with Hawaii's clean energy development goals. The permanent emissions, primarily from vehicle exhaust and utility use, are also noted to be relatively small in context and will not impede the state's climate objectives. The proposed project will emphasize energy independence by incorporating renewable energy sources that align closely with Hawaii's clean energy objectives. The proposed project will assist with Hawaii's goal of achieving 100% renewable energy by 2045. The anticipated transition to renewable energy sources will help reduce GHG emissions associated with energy consumption once the proposed project is operational. Within the project site, solar installations have already been installed on the Wastewater Treatment Plant, HM residential garages, and the golf maintenance building. Electric charging stations will be present throughout the site. LEED certification also inherently focuses

[22] Amanda Cording, *Mākena Mauka Sustainability Report*, 2025.

on reducing energy use and enhancing environmental performance during construction and operation.

The proposed project would be guided by the U.S. Green Building Council's LEED rigorous criteria. The certification process requires diligent adherence to a set of sustainability metrics. All buildings over 500 square feet within the proposed project will be LEED certified. The criteria are as follows:

- *Sustainable Site Development*: Focuses on site selection, construction practices, and habitat protection.
- *Water Efficiency*: Emphasizes water conservation and efficiency in irrigation and indoor water use.
- *Energy Efficiency & Renewable Energy Sources*: Promotes reduced energy consumption, minimum energy performance standards, and advanced metering. Renewable energy generation on-site from sources like solar or wind is highly recommended.
- *Materials and Resources*: Encourages the use of sustainable materials, recycling, and efficient resource management.
- *Indoor Environmental Quality*: Aims to improve indoor air quality, lighting, and thermal comfort for occupants.

Transportation is the largest source of energy use and GHG emissions in Hawai‘i. Within the project boundary, the opportunity to reduce site-based transportation emissions through master-planning design and operational strategies is significant. The proposed project's transportation plan focuses on reducing private vehicle dependence and offering convenient, comfortable, and low-emission alternatives for residents, guests, and employees. This strategy will have the greatest impact when implemented in coordination with the broader Mākena Golf & Beach Club and potentially connected to regional mobility networks. Components of the transportation plan include:

Benefits of Expanding Mobility Options. Offering diverse and accessible transportation choices enhances sustainability while delivering a wide range of user benefits:

For Employees:

- Reduces commuting costs, increasing take-home pay;
- Enables more productive or restful commute options (e.g., via shuttle or carpool);
- Supports shorter travel times during off-peak hours; and
- Encourages walking and biking for physical and mental health.

For Residents:

- Reduces or eliminates the need for car ownership or rental;
- Enhances connectivity across the site and to the broader community;
- Provides opportunities for informal outdoor recreation and engagement with nature; and
- Contributes to personal wellness and ease of movement.

Design Strategies to Promote Walkability and Alternative Modes. The proposed project site plan is intentionally designed to support walkability and reduce reliance on private vehicles, incorporating principles of compact development and Complete Streets. Planned features include:

- Compact, pedestrian-friendly site layout to encourage walking as a primary mode of movement;
- Complete Street design for all internal roadways, prioritizing pedestrian safety, interest, and comfort Integrated bicycle network using shared lanes, striped paths, or protected bikeways for connectivity and safety; and
- Extensive pedestrian trail system, offering varied lengths and surfacing to connect to beaches, recreational amenities, and gathering spaces;

Ongoing Operations & Mobility Programming. Post-construction, a range of operational programs would be implemented to encourage long-term transportation sustainability, including:

- A Resort Transportation Concierge Program offering on-demand shuttles and offsite transportation coordination from the public parking areas within the project to the nearby beach parks.

Construction Phase Mobility Measures. Even during the construction period, proactive transportation management will be implemented to reduce VMT by workers and equipment. Strategies under evaluation include:

- Centralized carpool coordination from contractor base yards;
- Establishment of an on-site centralized parking facility; and
- Use of remote parking lots with shuttle service for construction crews.

The proposed project is committed to operating under the overarching principles of low impact development. Low impact development is an approach to new or re-development that aims to reduce the impact of the project on the environment by mimicking pre-development hydrology, observing landforms and minimizing grading, mimicking nature in architectural components (biophilia), incorporating micro-catchments to increase infiltration (keyline design), thinking carefully about existing site conditions like sun, wind, and rain in planting design (permaculture) and filtering stormwater with nature-based solutions like Green Stormwater Infrastructure.

Through smart design, coordinated programming, and intentional investment in low-emission mobility, the proposed project is working to create a community that is not only beautiful and connected, but also forward-thinking in how people move—honoring the land and reducing the project's long-term carbon impact.

As global climate conditions continue to evolve, sea level rise and coastal storm surge are increasingly critical considerations in long-term land use planning and development, especially for shoreline properties such as portions of the proposed project. For coastal communities in Hawai‘i—where the interface between land and ocean is both culturally significant and ecologically sensitive—responsible planning requires a proactive approach to climate adaptation. The proposed project acknowledges that future environmental conditions may shift dramatically over the coming decades. In alignment with best practices from State agencies, the scientific

community, and national resilience frameworks, the following guiding principles were recommended to be integrated into project planning and design to address the risks of sea level rise and storm surge:

1. *Use of Best Available Science*. Planning benchmarks are informed by leading institutions such as the University of Hawai'i's School of Ocean and Earth Science and Technology and the National Oceanic and Atmospheric Administration. These resources offer sea level rise projections that support scenario-based planning and adaptive design.
2. *Scenario-Based Risk Assessment*. Rather than relying on a single estimate, the project team will consider a range of sea level rise projections—typically from 1 foot by mid-century to up to 6.2 feet by the end of the century. This includes modeling the impacts of storm surge in combination with high tide events to understand compounding risk.
3. *Site-Sensitive Design and Elevation Awareness*. Natural topography and elevation will be evaluated carefully in project siting to avoid development in low-lying, flood-prone zones. Whenever feasible, structures and infrastructure are placed outside of areas vulnerable to projected inundation.
4. *Protection of Coastal Ecosystem*. Beaches and rocky shoreline outcroppings serve as natural buffers against storm events and sea level rise. The project seeks to avoid hard armoring and instead supports nature-based solutions that allow for coastal adaptation, such as vegetated buffers and managed retreat where necessary.

By embedding these principles into the overall sustainability framework, the proposed project demonstrates a forward-thinking, resilient approach to development that balances innovation with respect for place, people, and the ever-changing coastal environment.

7.0 CUMULATIVE EFFECTS

HAR §11-200.1-2 contains the definition of a cumulative impact. A cumulative impact is defined as the impact on the environment, which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. Ten past, present, and reasonably foreseeable future projects have been identified in the project area. They include:

- The Maluaka Development includes 13 single-family and six multi-family condominium units.
- The Makena H-M Redevelopment Project (ATC Makena) includes conversion of the former 310-room hotel at the Makena Beach & Golf Club Resort into a combination of hotel, condominium, beach cottage units, together with a spa hale. A total of 65 units are proposed.
- The Makena Resort M-5/M-6/S-7/B-2 Project (Kaeo, ATC Makena) is a mixed-use project involving single-family, multi-family, resort commercial, transient vacation rental components and related improvements. Project totals include 30 multi-family units, 18 single-family cottages, 32 single-family custom lots, 9 transient vacation rental units, 14 condominiums, and 27,300 square feet of commercial space.
- Wailea 670 is a master planned residential community with 1,150 residential units, inclusive of 288 on-site affordable housing.
- The Ledcor Wailea Projects include construction of 925 to 975 single-family and multi-family units.
- The Grand Wailea Enhancement Project includes the proposed addition of 137 guest rooms, improvements to resort pool areas, luau grounds, spa, and the main Napua Tower.
- The H-2 Residential Project includes up to 53 single-family condominium lots, beach parking, and related infrastructure improvements.
- The Makena Resort U-1 Project is a 36-lot agricultural residential subdivision project.
- Wailea Golf LLC proposes a planned, mix-use development among 214 acres, to include a resort hotel and between 856 and 1,070 housing units, with between 198 and 247 being workforce housing.
- The Ulupalakua Ranch Renewable Energy has ongoing consideration for large-scale solar or geothermal renewable energy projects on 200 acres of Ulupalakua Ranch land, however, no specific project is proposed at this time.

By its very nature, air pollution is largely a cumulative impact. Ambient air quality standards may be violated or approach nonattainment levels due to past development or by increasing emissions-generating activity in the region. The proposed site is located in an Attainment/Unclassified area for all NAAQS. The regional air quality in Hawaii is considered to be good. The nearest air quality monitoring station to the project site only records concentrations of $PM_{2.5}$. **Table 4-1** shows that pollutant levels are significantly below the State standards. The monitored concentrations account for all existing sources in the project area, including motor vehicles, agricultural activities, industrial stationary sources, and many other existing sources of emissions in the project area. The project and the ten past, present, and reasonably foreseeable future projects represent a relatively small percentage of existing development. It is reasonable

to assume that the additional land use developments would not cumulatively contribute to an exceedance of the State air quality standards due to the existing low concentrations. In addition, there is no existing cumulative air quality impact. There is no potential for the project to significantly contribute to a cumulative air quality impact.

The State, through Act 234 (June 30, 2007) and SB 559 (June 8, 2017), has acknowledged that GHG emissions are a statewide impact. Emissions generated by the proposed project in combination with past, present, and reasonably probable future related projects could contribute to this impact. Although climate change is cumulative in nature, not every individual project that emits GHGs would necessarily be found to contribute to a significant cumulative impact on the environment. Therefore, there is no potential for the proposed project to significantly contribute to a cumulative GHG impact. Furthermore, neither the proposed project nor related projects would interfere with statewide efforts to reduce GHG emissions. To the contrary, the solar energy related project will increase the regional availability of clean energy. In addition, it is reasonable to assume that, similar to the proposed project, the related projects also include sustainability plans to minimize GHG emissions.

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	Makena Mauka - Phase 1
Construction Start Date	1/3/2028
Operational Year	2038
Lead Agency	—
Land Use Scale	Plan/community
Analysis Level for Defaults	Statewide
Windspeed (m/s)	15.0
Precipitation (days)	113
Location	34.022579521235755, -118.40535118073069
County	Los Angeles-South Coast
City	Los Angeles
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	4454
EDFZ	16
Electric Utility	Statewide Average
Gas Utility	Southern California Gas
App Version	2022.1.1.29

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
Apartments Mid Rise	94.0	Dwelling Unit	2.47	90,240	0.00	—	278	affordable housing

Single Family Housing	15.0	Dwelling Unit	4.87	29,250	175,693	—	44.0	affordable housing
Apartments Mid Rise	121	Dwelling Unit	3.18	116,160	0.00	—	358	multifamily homes
Strip Mall	3.00	1000sqft	0.07	3,000	0.00	—	—	retail spaces
Office Park	46.0	1000sqft	1.06	46,000	0.00	—	—	offices
Single Family Housing	60.0	Dwelling Unit	19.5	117,000	702,771	—	178	single family housing

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-2*	Limit Heavy-Duty Diesel Vehicle Idling
Energy	E-12-A	Install Alternative Type of Water Heater in Place of Gas Storage Tank Heater in Residences
Energy	E-12-B	Install Electric Space Heater in Place of Natural Gas Heaters in Residences
Energy	E-13	Install Electric Ranges in Place of Gas Ranges

* Qualitative or supporting measure. Emission reductions not included in the mitigated emissions results.

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

Control Strategies Applied	PM10 Reduction	PM2.5 Reduction
Water unpaved roads twice daily	55%	55%
Limit vehicle speeds on unpaved roads to 25 mph	44%	44%
Sweep paved roads once per month	9%	9%

5.5. Architectural Coatings

Phase Name	Residential Interior Area Coated (sq ft)	Residential Exterior Area Coated (sq ft)	Non-Residential Interior Area Coated (sq ft)	Non-Residential Exterior Area Coated (sq ft)	Parking Area Coated (sq ft)
Architectural Coating	714,116	238,039	73,500	24,500	—

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

Phase Name	Material Imported (cy)	Material Exported (cy)	Acres Graded (acres)	Material Demolished (sq. ft.)	Acres Paved (acres)
Site Preparation	—	—	3,900	0.00	—
Grading	—	—	7,800	0.00	—
Paving	0.00	0.00	0.00	0.00	0.83

5.6.2. Construction Earthmoving Control Strategies

Control Strategies Applied	Frequency (per day)	PM10 Reduction	PM2.5 Reduction
Water Exposed Area	2	61%	61%

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
Apartments Mid Rise	—	0%
Single Family Housing	0.17	0%
Apartments Mid Rise	—	0%
Strip Mall	0.00	0%
Office Park	0.00	0%
Single Family Housing	0.66	0%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2028	0.00	453	0.03	< 0.005
2029	0.00	453	0.03	< 0.005
2030	0.00	453	0.03	< 0.005

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit

Temperature and Extreme Heat	5.68	annual days of extreme heat
Extreme Precipitation	5.50	annual days with precipitation above 20 mm
Sea Level Rise	—	meters of inundation depth
Wildfire	0.00	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (Radke et al., 2017, CEC-500-2017-008), and consider inundation location and depth for the San Francisco Bay, the Sacramento-San Joaquin River Delta and California coast resulting different increments of sea level rise coupled with extreme storm events. Users may select from four scenarios to view the range in potential inundation depth for the grid cell. The four scenarios are: No rise, 0.5 meter, 1.0 meter, 1.41 meters
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	45.0
AQ-PM	66.1
AQ-DPM	96.2
Drinking Water	52.7
Lead Risk Housing	24.4
Pesticides	0.00
Toxic Releases	79.2

Traffic	68.7
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	25.1
Haz Waste Facilities/Generators	44.7
Impaired Water Bodies	66.7
Solid Waste	42.3
Sensitive Population	—
Asthma	35.8
Cardio-vascular	47.2
Low Birth Weights	7.17
Socioeconomic Factor Indicators	—
Education	20.9
Housing	50.7
Linguistic	30.0
Poverty	42.6
Unemployment	45.8

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	66.05928397
Employed	97.78005903
Median HI	50.49403311
Education	—
Bachelor's or higher	85.98742461
High school enrollment	100

Preschool enrollment	78.71166431
Transportation	—
Auto Access	15.29577826
Active commuting	83.42101886

2016 Voting	48.9

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	39.0
Healthy Places Index Score for Project Location (b)	60.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	Yes
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Characteristics: Project Details	Updated characteristics screen to match project specific characteristics
Characteristics: Utility Information	Using statewide average electricity defaults to better estimate emissions for project area
Construction: Construction Phases	removed demolition phase and updated construction schedule to match project needs
Construction: Off-Road Equipment	updated construction equipment list to match project needs
Construction: Trips and VMT	updated construction trips to match needs of the project

Operations: Hearths	removed hearths
Operations: Water and Waste Water	updated electricity intensity factor for water for Maui
Operations: Vehicle Data	Adjusted traffic data based on TIAR

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	Makena Mauka - Phase 2
Construction Start Date	1/4/2038
Operational Year	2048
Lead Agency	—
Land Use Scale	Plan/community
Analysis Level for Defaults	Statewide
Windspeed (m/s)	15.0
Precipitation (days)	113
Location	34.022579521235755, -118.40535118073069
County	Los Angeles-South Coast
City	Los Angeles
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	4454
EDFZ	16
Electric Utility	Statewide Average
Gas Utility	Southern California Gas
App Version	2022.1.1.29

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
Single Family Housing	60.0	Dwelling Unit	19.5	117,000	702,771	—	178	single family homes

Apartments Mid Rise	121	Dwelling Unit	3.18	116,160	0.00	—	358	multifamily homes

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-2*	Limit Heavy-Duty Diesel Vehicle Idling
Energy	E-12-A	Install Alternative Type of Water Heater in Place of Gas Storage Tank Heater in Residences
Energy	E-12-B	Install Electric Space Heater in Place of Natural Gas Heaters in Residences
Energy	E-13	Install Electric Ranges in Place of Gas Ranges

* Qualitative or supporting measure. Emission reductions not included in the mitigated emissions results.

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	5.68	annual days of extreme heat
Extreme Precipitation	5.50	annual days with precipitation above 20 mm
Sea Level Rise	—	meters of inundation depth
Wildfire	0.00	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (Radke et al., 2017, CEC-500-2017-008), and consider inundation location and depth for the San Francisco Bay, the Sacramento-San Joaquin River Delta and California coast resulting different increments of sea level rise coupled with extreme storm events. Users may select from four scenarios to view the range in potential inundation depth for the grid cell. The four scenarios are: No rise, 0.5 meter, 1.0 meter, 1.41 meters
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.

The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	45.0
AQ-PM	66.1
AQ-DPM	96.2
Drinking Water	52.7
Lead Risk Housing	24.4
Pesticides	0.00
Toxic Releases	79.2
Traffic	68.7
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	25.1
Haz Waste Facilities/Generators	44.7
Impaired Water Bodies	66.7
Solid Waste	42.3
Sensitive Population	—
Asthma	35.8
Cardio-vascular	47.2
Low Birth Weights	7.17
Socioeconomic Factor Indicators	—

Education	20.9
Housing	50.7
Linguistic	30.0
Poverty	42.6
Unemployment	45.8

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	66.05928397
Employed	97.78005903
Median HI	50.49403311
Education	—
Bachelor's or higher	85.98742461
High school enrollment	100
Preschool enrollment	78.71166431
Transportation	—
Auto Access	15.29577826

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	39.0
Healthy Places Index Score for Project Location (b)	60.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	Yes
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Characteristics: Project Details	Updated characteristics screen to match project specific characteristics
Characteristics: Utility Information	Using statewide average electricity defaults to better estimate emissions for project area
Construction: Construction Phases	Adjusted construction schedule to match project needs
Construction: Off-Road Equipment	Adjust construction equipment mix for project needs
Construction: Trips and VMT	updated construction trip to match project needs
Operations: Hearths	removed hearths
Operations: Water and Waste Water	Adjusted electric intensity factor for Maui
Operations: Vehicle Data	Adjusted traffic data based on TIAR

Makena Mauka - Phase 3 Detailed Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.3. Construction Emissions by Year, Mitigated

2.4. Operations Emissions Compared Against Thresholds

2.5. Operations Emissions by Sector, Unmitigated

2.6. Operations Emissions by Sector, Mitigated

3. Construction Emissions Details

3.1. Site Preparation (2048) - Unmitigated

3.2. Site Preparation (2048) - Mitigated

3.3. Site Preparation (2049) - Unmitigated

3.4. Site Preparation (2049) - Mitigated

3.5. Site Preparation (2050) - Unmitigated

3.6. Site Preparation (2050) - Mitigated

3.7. Site Preparation (2051) - Unmitigated

3.8. Site Preparation (2051) - Mitigated

3.9. Site Preparation (2052) - Unmitigated

3.10. Site Preparation (2052) - Mitigated

3.11. Site Preparation (2053) - Unmitigated

3.12. Site Preparation (2053) - Mitigated

3.13. Site Preparation (2054) - Unmitigated

3.14. Site Preparation (2054) - Mitigated

3.15. Site Preparation (2055) - Unmitigated

3.16. Site Preparation (2055) - Mitigated

3.17. Site Preparation (2056) - Unmitigated

3.18. Site Preparation (2056) - Mitigated

3.19. Site Preparation (2057) - Unmitigated

3.20. Site Preparation (2057) - Mitigated

3.21. Grading (2048) - Unmitigated

3.22. Grading (2048) - Mitigated

3.23. Grading (2049) - Unmitigated

3.24. Grading (2049) - Mitigated

3.25. Grading (2050) - Unmitigated

3.26. Grading (2050) - Mitigated

3.27. Grading (2051) - Unmitigated

3.28. Grading (2051) - Mitigated

3.29. Grading (2052) - Unmitigated

3.30. Grading (2052) - Mitigated

3.31. Grading (2053) - Unmitigated

3.32. Grading (2053) - Mitigated

3.33. Grading (2054) - Unmitigated

3.34. Grading (2054) - Mitigated

3.35. Grading (2055) - Unmitigated

3.36. Grading (2055) - Mitigated

3.37. Grading (2056) - Unmitigated

3.38. Grading (2056) - Mitigated

3.39. Grading (2057) - Unmitigated

3.40. Grading (2057) - Mitigated

3.41. Building Construction (2048) - Unmitigated

3.42. Building Construction (2048) - Mitigated

3.43. Building Construction (2049) - Unmitigated

3.44. Building Construction (2049) - Mitigated

3.45. Building Construction (2050) - Unmitigated

3.46. Building Construction (2050) - Mitigated

3.47. Building Construction (2051) - Unmitigated

3.48. Building Construction (2051) - Mitigated

3.49. Building Construction (2052) - Unmitigated

3.50. Building Construction (2052) - Mitigated

3.51. Building Construction (2053) - Unmitigated

3.52. Building Construction (2053) - Mitigated

3.53. Building Construction (2054) - Unmitigated

3.54. Building Construction (2054) - Mitigated

3.55. Building Construction (2055) - Unmitigated

3.56. Building Construction (2055) - Mitigated

3.57. Building Construction (2056) - Unmitigated

3.58. Building Construction (2056) - Mitigated

3.59. Building Construction (2057) - Unmitigated

3.60. Building Construction (2057) - Mitigated

3.61. Paving (2048) - Unmitigated

3.62. Paving (2048) - Mitigated

3.63. Paving (2049) - Unmitigated

3.64. Paving (2049) - Mitigated

3.65. Paving (2050) - Unmitigated

3.66. Paving (2050) - Mitigated

3.67. Paving (2051) - Unmitigated

3.68. Paving (2051) - Mitigated

3.69. Paving (2052) - Unmitigated

3.70. Paving (2052) - Mitigated

3.71. Paving (2053) - Unmitigated

3.72. Paving (2053) - Mitigated

3.73. Paving (2054) - Unmitigated

3.74. Paving (2054) - Mitigated

3.75. Paving (2055) - Unmitigated

3.76. Paving (2055) - Mitigated

3.77. Paving (2056) - Unmitigated

3.78. Paving (2056) - Mitigated

3.79. Paving (2057) - Unmitigated

3.80. Paving (2057) - Mitigated

3.81. Architectural Coating (2048) - Unmitigated

3.82. Architectural Coating (2048) - Mitigated

3.83. Architectural Coating (2049) - Unmitigated

3.84. Architectural Coating (2049) - Mitigated

3.85. Architectural Coating (2050) - Unmitigated

3.86. Architectural Coating (2050) - Mitigated

3.87. Architectural Coating (2051) - Unmitigated

3.88. Architectural Coating (2051) - Mitigated

3.89. Architectural Coating (2052) - Unmitigated

3.90. Architectural Coating (2052) - Mitigated

3.91. Architectural Coating (2053) - Unmitigated

3.92. Architectural Coating (2053) - Mitigated

3.93. Architectural Coating (2054) - Unmitigated

3.94. Architectural Coating (2054) - Mitigated

3.95. Architectural Coating (2055) - Unmitigated

3.96. Architectural Coating (2055) - Mitigated

3.97. Architectural Coating (2056) - Unmitigated

3.98. Architectural Coating (2056) - Mitigated

3.99. Architectural Coating (2057) - Unmitigated

3.100. Architectural Coating (2057) - Mitigated

4. Operations Emissions Details

4.1. Mobile Emissions by Land Use

4.1.1. Unmitigated

4.1.2. Mitigated

4.2. Energy

4.2.1. Electricity Emissions By Land Use - Unmitigated

4.2.2. Electricity Emissions By Land Use - Mitigated

4.2.3. Natural Gas Emissions By Land Use - Unmitigated

4.2.4. Natural Gas Emissions By Land Use - Mitigated

4.3. Area Emissions by Source

4.3.1. Unmitigated

4.3.2. Mitigated

4.4. Water Emissions by Land Use

4.4.1. Unmitigated

4.4.2. Mitigated

4.5. Waste Emissions by Land Use

4.5.1. Unmitigated

4.5.2. Mitigated

4.6. Refrigerant Emissions by Land Use

4.6.1. Unmitigated

4.6.2. Mitigated

4.7. Offroad Emissions By Equipment Type

4.7.1. Unmitigated

4.7.2. Mitigated

4.8. Stationary Emissions By Equipment Type

4.8.1. Unmitigated

4.8.2. Mitigated

4.9. User Defined Emissions By Equipment Type

4.9.1. Unmitigated

4.9.2. Mitigated
4.10. Soil Carbon Accumulation By Vegetation Type
4.10.1. Soil Carbon Accumulation By Vegetation Type - Unmitigated
4.10.2. Above and Belowground Carbon Accumulation by Land Use Type - Unmitigated
4.10.3. Avoided and Sequestered Emissions by Species - Unmitigated
4.10.4. Soil Carbon Accumulation By Vegetation Type - Mitigated
4.10.5. Above and Belowground Carbon Accumulation by Land Use Type - Mitigated
4.10.6. Avoided and Sequestered Emissions by Species - Mitigated
5. Activity Data
5.1. Construction Schedule
5.2. Off-Road Equipment
5.2.1. Unmitigated
5.2.2. Mitigated
5.3. Construction Vehicles
5.3.1. Unmitigated
5.3.2. Mitigated
5.4. Vehicles
5.4.1. Construction Vehicle Control Strategies

5.5. Architectural Coatings
5.6. Dust Mitigation
5.6.1. Construction Earthmoving Activities
5.6.2. Construction Earthmoving Control Strategies
5.7. Construction Paving
5.8. Construction Electricity Consumption and Emissions Factors
5.9. Operational Mobile Sources
5.9.1. Unmitigated
5.9.2. Mitigated
5.10. Operational Area Sources
5.10.1. Hearths
5.10.1.1. Unmitigated
5.10.1.2. Mitigated
5.10.2. Architectural Coatings
5.10.3. Landscape Equipment
5.10.4. Landscape Equipment - Mitigated
5.11. Operational Energy Consumption
5.11.1. Unmitigated

5.11.2. Mitigated
5.12. Operational Water and Wastewater Consumption
5.12.1. Unmitigated
5.12.2. Mitigated
5.13. Operational Waste Generation
5.13.1. Unmitigated
5.13.2. Mitigated
5.14. Operational Refrigeration and Air Conditioning Equipment
5.14.1. Unmitigated
5.14.2. Mitigated
5.15. Operational Off-Road Equipment
5.15.1. Unmitigated
5.15.2. Mitigated
5.16. Stationary Sources
5.16.1. Emergency Generators and Fire Pumps
5.16.2. Process Boilers
5.17. User Defined
5.18. Vegetation

5.18.1. Land Use Change
5.18.1.1. Unmitigated
5.18.1.2. Mitigated
5.18.1. Biomass Cover Type
5.18.1.1. Unmitigated
5.18.1.2. Mitigated
5.18.2. Sequestration
5.18.2.1. Unmitigated
5.18.2.2. Mitigated
6. Climate Risk Detailed Report
6.1. Climate Risk Summary
6.2. Initial Climate Risk Scores
6.3. Adjusted Climate Risk Scores
6.4. Climate Risk Reduction Measures
7. Health and Equity Details
7.1. CalEnviroScreen 4.0 Scores
7.2. Healthy Places Index Scores
7.3. Overall Health & Equity Scores

7.4. Health & Equity Measures

7.5. Evaluation Scorecard

7.6. Health & Equity Custom Measures

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	Makena Mauka - Phase 3
Construction Start Date	1/6/2048
Operational Year	2050
Lead Agency	—
Land Use Scale	Plan/community
Analysis Level for Defaults	Statewide
Windspeed (m/s)	15.0
Precipitation (days)	113
Location	34.022579521235755, -118.40535118073069
County	Los Angeles-South Coast
City	Los Angeles
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	4454
EDFZ	16
Electric Utility	Statewide Average
Gas Utility	Southern California Gas
App Version	2022.1.1.29

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
Single Family Housing	60.0	Dwelling Unit	19.5	117,000	702,771	—	178	single family homes

Apartments Mid Rise	121	Dwelling Unit	3.18	116,160	0.00	—	358	multifamily homes
High Turnover (Sit Down Restaurant)	48.0	1000sqft	1.10	48,000	0.00	—	—	a. Restaurant, Clubhouse, Kitchen, Locker Rooms, Fitness, Back of House

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-2*	Limit Heavy-Duty Diesel Vehicle Idling
Energy	E-12-A	Install Alternative Type of Water Heater in Place of Gas Storage Tank Heater in Residences
Energy	E-12-B	Install Electric Space Heater in Place of Natural Gas Heaters in Residences
Energy	E-13	Install Electric Ranges in Place of Gas Ranges

* Qualitative or supporting measure. Emission reductions not included in the mitigated emissions results.

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

Un/Mit.	TOG	ROG	NOx	CO	SO2	PM10E	PM10D	PM10T	PM2.5E	PM2.5D	PM2.5T	BCO2	NBCO2	CO2T	CH4	N2O	R	CO2e
Daily, Summer (Max)	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	5.68	annual days of extreme heat
Extreme Precipitation	5.50	annual days with precipitation above 20 mm
Sea Level Rise	—	meters of inundation depth
Wildfire	0.00	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (Radke et al., 2017, CEC-500-2017-008), and consider inundation location and depth for the San Francisco Bay, the Sacramento-San Joaquin River Delta and California coast resulting different increments of sea level rise coupled with extreme storm events. Users may select from four scenarios to view the range in potential inundation depth for the grid cell. The four scenarios are: No rise, 0.5 meter, 1.0 meter, 1.41 meters
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A

Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	N/A	N/A	N/A	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	N/A	N/A	N/A	N/A
Wildfire	N/A	N/A	N/A	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	N/A	N/A	N/A	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	45.0
AQ-PM	66.1
AQ-DPM	96.2
Drinking Water	52.7
Lead Risk Housing	24.4
Pesticides	0.00
Toxic Releases	79.2
Traffic	68.7
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	25.1
Haz Waste Facilities/Generators	44.7
Impaired Water Bodies	66.7
Solid Waste	42.3
Sensitive Population	—
Asthma	35.8
Cardio-vascular	47.2
Low Birth Weights	7.17
Socioeconomic Factor Indicators	—
Education	20.9
Housing	50.7
Linguistic	30.0
Poverty	42.6
Unemployment	45.8

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	66.05928397
Employed	97.78005903
Median HI	50.49403311
Education	—

Diagnosed Diabetes	95.7
Life Expectancy at Birth	81.8
Cognitively Disabled	93.6
Physically Disabled	98.1
Heart Attack ER Admissions	34.3
Mental Health Not Good	76.1
Chronic Kidney Disease	95.6
Obesity	77.3
Pedestrian Injuries	94.6
Physical Health Not Good	92.3
Stroke	96.9
Health Risk Behaviors	—
Binge Drinking	6.6
Current Smoker	70.9
No Leisure Time for Physical Activity	88.3
Climate Change Exposures	—
Wildfire Risk	0.0
SLR Inundation Area	0.0
Children	19.0
Elderly	98.6

English Speaking	73.8
Foreign-born	76.3
Outdoor Workers	35.3
Climate Change Adaptive Capacity	—
Impervious Surface Cover	0.9
Traffic Density	60.1
Traffic Access	87.4
Other Indices	—
Hardship	35.5
Other Decision Support	—
2016 Voting	48.9

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	39.0
Healthy Places Index Score for Project Location (b)	60.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	Yes
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Characteristics: Project Details	Updated characteristics screen to match project specific characteristics
Characteristics: Utility Information	Using statewide average electricity defaults to better estimate emissions for project area
Construction: Construction Phases	Adjusted construction schedule to match project needs
Construction: Off-Road Equipment	Adjust construction equipment mix for project needs
Construction: Trips and VMT	updated construction trip to match project needs
Operations: Hearths	removed hearths
Operations: Water and Waste Water	Adjusted electric intensity factor for Maui
Operations: Vehicle Data	Adjusted traffic data based on TIAR

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	Makena Mauka - Golf
Construction Start Date	1/4/2028
Operational Year	2050
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	Statewide
Windspeed (m/s)	15.0
Precipitation (days)	113
Location	34.022579521235755, -118.40535118073069
County	Los Angeles-South Coast
City	Los Angeles
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	4454
EDFZ	16
Electric Utility	Statewide Average
Gas Utility	Southern California Gas
App Version	2022.1.1.29

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description
Golf Course	18.0	Hole	126	0.00	2,500,000	2,500,000	—	—

Health Club	63.0	1000sqft	1.45	63,000	0.00	—	—	Golf Maintenance, Staff Center, Golf Operations, Receiving Area

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Construction	C-2*	Limit Heavy-Duty Diesel Vehicle Idling
Construction	C-9	Use Dust Suppressants
Construction	C-10-A	Water Exposed Surfaces

* Qualitative or supporting measure. Emission reductions not included in the mitigated emissions results.

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

Un/Mit.	TOG	ROG	NOx	CO	SO2	PM10E	PM10D	PM10T	PM2.5E	PM2.5D	PM2.5T	BCO2	NBCO2	CO2T	CH4	N2O	R	CO2e
Daily, Summer (Max)	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
