AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EB sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai’i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylot” of confined dairy operations where animals walk over dirt and dryened manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential dust emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua’i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy herifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.
The DEIS evaluates alternatives that could attain the objectives of the project’s proposed action, including those that would not be detectable by 50 percent of the sensitive population once per 200 hours, or 44 reasonable alternative against those of the proposed action. Additionally, potential Alternative Future Actions (AFA’s) are evaluated. The project’s scope is defined by a series of alternatives that could be reasonably considered against those of the proposed action. Additionally, AFA’s are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

Four possible uses that would not meet the project’s purpose are considered: (1) the development of the Pasture-Based Dairy at an Alternative Location on Kauai; (2) conversion of the Pasture-Based Dairy to a Different Use; (3) no development of the Pasture-Based Dairy; and (4) no development of the Pasture-Based Dairy. Each of these alternatives is evaluated against the project’s proposed action using the eight Project Objectives and the four established Evaluation Criteria. These alternatives are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

The alternatives analysis provides a comprehensive evaluation of the range of uses that could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include agricultural uses, non-agricultural uses, and no development. The alternatives are evaluated against the project’s proposed action using the eight Project Objectives and the four established Evaluation Criteria. The alternatives that do not meet the project’s purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules (HRS 11-200) require a discussion of alternatives that could be reasonably considered against those of the proposed action.

Rigorously exploring and evaluating the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid or reduce the impacts of the proposed action, is a key component of the alternatives analysis. This analysis is performed to ensure that the project’s purpose is achieved while minimizing environmental impacts.

ALTERNATIVES:

As a part of the DEIS, alternatives were evaluated to attain the objectives of the action’s purpose and need, and were compared with proposed action to determine those alternatives that could be reasonably considered against those of the proposed action. Additionally, potential Alternative Future Actions (AFA’s) are evaluated. The project’s scope is defined by a series of alternatives that could be reasonably considered against those of the proposed action. Additionally, AFA’s are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

Four possible uses that would not meet the project’s purpose are considered: (1) the development of the Pasture-Based Dairy at an Alternative Location on Kauai; (2) conversion of the Pasture-Based Dairy to a Different Use; (3) no development of the Pasture-Based Dairy; and (4) no development of the Pasture-Based Dairy. Each of these alternatives is evaluated against the project’s proposed action using the eight Project Objectives and the four established Evaluation Criteria. These alternatives are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

The alternatives analysis provides a comprehensive evaluation of the range of uses that could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include agricultural uses, non-agricultural uses, and no development. The alternatives are evaluated against the project’s proposed action using the eight Project Objectives and the four established Evaluation Criteria. The alternatives that do not meet the project’s purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules (HRS 11-200) require a discussion of alternatives that could be reasonably considered against those of the proposed action.

Rigorously exploring and evaluating the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid or reduce the impacts of the proposed action, is a key component of the alternatives analysis. This analysis is performed to ensure that the project’s purpose is achieved while minimizing environmental impacts.

GREENHOUSE GASSES:

These options would not be reasonably viable given the existing private land tenure and 4.26 address the potential for greenhouse gas emissions by Hawai'i Dairy Farms (HDF). Estimates of GHG emission rates from a pasture-based dairy, including feedlots, as reported in the Second National Communication to the United Nations Framework Convention on Climate Change (UNFCCC) in 2014. Power generation does not include vehicle emissions and other GHG emitters on the island.

Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project’s requirements and established Evaluation Criteria. The alternatives that do not meet the project’s purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules (HRS 11-200) require a discussion of alternatives that could be reasonably considered against those of the proposed action. Additionally, potential Alternative Future Actions (AFA’s) are evaluated. The project’s scope is defined by a series of alternatives that could be reasonably considered against those of the proposed action. Additionally, AFA’s are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

Four possible uses that would not meet the project’s purpose are considered: (1) the development of the Pasture-Based Dairy at an Alternative Location on Kauai; (2) conversion of the Pasture-Based Dairy to a Different Use; (3) no development of the Pasture-Based Dairy; and (4) no development of the Pasture-Based Dairy. Each of these alternatives is evaluated against the project’s proposed action using the eight Project Objectives and the four established Evaluation Criteria. These alternatives are evaluated against the project’s proposed action in the context of existing development, land use, and land ownership.

The Environmental Impact Statement Rules (HRS 11-200) require a discussion of alternatives that could be reasonably considered against those of the proposed action.

Rigorously exploring and evaluating the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid or reduce the impacts of the proposed action, is a key component of the alternatives analysis. This analysis is performed to ensure that the project’s purpose is achieved while minimizing environmental impacts.
None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).

The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

However, after years of trying, it appears there was limited interest in such a venture.

Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria:

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawai‘i Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i

TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001: 001 portion

Dear Sara DeZerega:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP)N, published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy." The term "zero-discharge" under the U.S.
management practices and pasture model applied by HDF maximize grass as the cows' primary nutrition source and minimize stress to the animals. Cows tend to be fed "grass-fed," which is defined by the USDA as what animals can and cannot be fed. The Food and Agriculture Organization (FAO) of the United Nations defines "grass-fed" as the raising of animals on grass or pasture for more than 70 percent of their diet. Therefore, HDF is using the term "grass-fed" to describe their pasture model, which is not necessarily "zero discharge," as it is being used for the constituent components that provide benefit.

The term "grass-fed" was used in the HF EISPN. This term was used to identify the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil nutrient concentrations, and agricultural practices. The timing and application of nutrients will correspond with plant uptake, soil nutrient concentrations, and agricultural practices.

The timing and application of nutrients will correspond with plant uptake, soil nutrient concentrations, and agricultural practices. The timing and application of nutrients will correspond with plant uptake, soil nutrient concentrations, and agricultural practices. The timing and application of nutrients will correspond with plant uptake, soil nutrient concentrations, and agricultural practices.
The NRCS soil classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalahi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Luaukī Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.
ARCHAEOLOGICAL AND CULTURAL: The Hawai’i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-298. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The six historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites may not be adversely affected by the proposed dairy project. No site is related to burials, and no bone was found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā‘ulepū Valley has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerus traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plant species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā‘ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specific areas, marking tall structures and fencing with white visibility polystyrene, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.
It is likely that Hawaiian hoary bats overfly the project area on a seasonal basis. Herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow operations.

The potential impacts of Hawaiian hoary bats on the project area are evaluated in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 5.2, and 4.23. The technical consultants identified potential habitat that could affect the species within the study area. No suitable roost trees are present in the area, and the location and connectivity of the quality of the water and surface water were documented.

While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

GROUNDED WATER

The HDF project would create short-term benefits through jobs for local contractors, suppliers, and material suppliers. Such jobs would include field supervisors, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average approximately 36 jobs, of which 28 would be expected to average 36 jobs per year during the construction period.

Therefore, water movement through soils under the proposed dairy site would be predominantly from the alluvium, which generally extends about 60 feet under the surface and is underlain by bedrock, to the groundwater bodies with the valley. Two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is estimated to have a hydraulic conductivity of 100 feet per day, and (2) groundwater located in a soft, thoroughly decomposed rock. The hydraulic conductivity of the alluvium that underlies the area is less permeable than the unweathered volcanic material. The hydraulic conductivity of the alluvium material is 100 feet per day.

The groundwater and surface water analyses conducted for the Draft EIS show no impacts on the environment resulting from the proposed actions. The groundwater and water resources in the area were evaluated in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 5.2, and 4.23.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. The dairy is expected to generate a net additional contribution to the County of approximately $560,000 annually. The dairy farm and related dairy operations would provide approximately 9 jobs, of which the majority would be full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to ongoing dairy operations would be created.

Therefore, water movement through soils under the proposed dairy site would be predominantly from the alluvium, which generally extends about 60 feet under the surface and is underlain by bedrock, to the groundwater bodies with the valley. Two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is estimated to have a hydraulic conductivity of 100 feet per day, and (2) groundwater located in a soft, thoroughly decomposed rock. The hydraulic conductivity of the alluvium that underlies the area is less permeable than the unweathered volcanic material. The hydraulic conductivity of the alluvium material is 100 feet per day.

The groundwater and surface water analyses conducted for the Draft EIS show no impacts on the environment resulting from the proposed actions. The groundwater and water resources in the area were evaluated in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 5.2, and 4.23.
conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further details.

**Potable Water**: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring**: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand**: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction**: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and reporting structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality**: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waipio Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococci to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waipio Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Complaints from the public citing the high levels of enterococci in Waipio Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waipio Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has...
completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dune canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (https://health.hawaii.gov/cwb).

**Long-term Operations: Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageway; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 669 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of the time, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po‘ipu region were also calculated. Nitrogen input to the marine environment in the Po‘ipu region is calculated to be 36,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 14 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment:** An assessment of groundwater and surface water interaction with the marine water downstream from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment, which actively dispenses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditch downstream to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWPL, dairy neighbors and the local Kaua‘i community.
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: http://tinyurl.com/OEQCKAUAI.

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
facts were much different than what we were presented earlier. I am very concerned about the impacts.

Specific points that I believe need to be addressed in the draft EIS are as follows:

1. I am very concerned about the potential for water quality contamination of our drinking water and run off. This carries concerns also about the public health of Kolow/Poiupu residents and our tap water and beaches and aquatic life.

2. I am concerned about the location of the milking area and waste ponds. They are very, very close to the aquifer. I would like to see the data examined for the harmful impacts of the waste ponds in regards to leaching into the aquifer and overall cleanliness of holding waste in this manner.

3. The amount of water consumed for operation is enormous. The dairy may feel they own the self-replenishing aquifers and all the water they want from the Waitea Reservoir, but they don't. I question why we would use such a large amount of our water resources on yet another type of agriculture that leaves our island and gives us nothing to eat. Please include in the EIS a water usage analysis.

4. The EIS must include the consideration of other reasonable locations both on Kauai and perhaps also on the other islands, including the island it will be ultimately processed and packaged on.

5. The EIS must include detailed and accurate soil and hydrological data of the entire ahupua'a of Maha'ulepu. It must address the complete watershed, including the lava tube system, and show that no run off will occur under any circumstance.

6. We must include study and disclosure about what integrated pest management plan for fly control, and if this would require the potential for pesticide application.

7. The importance of Maha'ulepu to the south shore for the residents, fishermen, geologists, archeologists, the students and the visitors, should require that bonding mitigation measures are in place, such as an environmental remediation bond and continual monitoring protocols. Such monitoring and sampling must include community involvement and disclosure.

8. The EIS must include environmental indicators and metrics to determine what size of a herd the land and resources can support without damaging the ecology of the valley and the surrounding towns.

9. The EIS must include plans for site remediation for when the lease ends. Site remediation must include a guarantee from HDF that Maha'ulepu will be fully restored to its current condition. A remediation fund should be required to cover the costs of damage or impact to its natural state.

10. We must study the impacts on cultural practices, cultural sites, hunting, and hiking. The ahupua'a of Maha'ulepu as the last remaining, easily accessible, undeveloped coastline deserves our highest stewardship. It is a natural and living museum. It is an important example of how things used to be. It provides unparalleled beauty and outdoor classroom for our local children.

11. I would like for the EIS to include encouragement for the HDF plan to avoid the importation and feeding of genetically engineered corn for cow feed. Consumers are seeing out truly grass fed dairy milk and they avoid milk from GE grains. Alternatives exist. If the milk produced did not include GE grains, there could be a local use for the milk fat to remain on island and become a value added product like yogurt.

Please keep in mind that we would know the importance of food security and ecological soundness and historical conservation. I feel that this plan from HDF provides none of these measures. It is the wrong location for a model that takes from important resources and leaves the community with only negative impacts. I can see no community benefit.

Thank you for incorporating these comments into the draft EIS scoping project. Please remember, or visit, this special site. I am sure you understand the significance of this area, not only our community, but to future generations.

Mahalo and aloha 'ina

Dear Jeri Di Pietro:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will continue the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agriculutural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yield essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways
and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

The NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai’i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, application method, and timing of plant nutrient and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 600 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 600-cow dairy. Throughout the less than 30-day storage period, effluent is planned for the cattle and the effluent application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua’i to be raised off-site. The committed herd size of 600 mature dairy cows at the Māhāʻulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and insure the beef market in Hawai’i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as HST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during drier periods, to filter and buffer potential pollutants from leaching fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yont and Nicholas Krueger of the University of Hawai’i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua’i Soil & Water Conservation District in December, 2012.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua’i, Hawai’i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data...
the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kā'ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai’i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbon in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical regions, partly due to long pasture-growing season. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**ARCHAEOLOGICAL AND CULTURAL**

The Hawai’i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on land owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bonework was found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāulepū Ahupua’a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the...
exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kāloa area was built by Napali formation lavas of the Waimānalo volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprilithe, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kāloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kāloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kāloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kāloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and surface water in the alluvial material were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kāloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kāloa - Po‘ipū - Kalibhea districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 projects the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**
The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'uōpili Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'uōpili watershed.

The HDF site is located on the bottom land of the upper Māhā'uōpili Valley, which is fed by several intermittent streams coming off of the south slope of the Ha'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'uōpili Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'uōpili and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'uōpili Valley. The deme canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The

This groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'uōpili will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, the runoff contributions would be limited to periods of the major rainfall over 0.8
reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. Those options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kau‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4). The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient
contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

- However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).
To Whom It May Concern-

It should be obvious that a dairy will have significant impact on the environment and human health, unless many, many safeguards are put in place in advance and protocols for monitoring. Of note, what happens to all the bovine excrement? How is it treated or is it treated so as not to contaminate ground water and our oceans? How does a dairy alter the environment and what can be done to insure that the environment is not altered? Who monitors this? And lastly, what is the effect on humans? A dairy will attract flies and other insects, which can carry disease. What safeguards will be put in place to help guarantee that the impact on humans is non-existent?

CAFO is a system designed to discharge pollutants into waters of the United States. CAFOs must be large livestock operations, and the term is used to identify farms with more than 1,000 animal units or 1,000 animal units of livestock by species. CAFOs are subject to permitting requirements under the Clean Water Act (CWA) and the National Pollutant Discharge Elimination System (NPDES) program. The term is used for farms that discharge pollutants to waters of the United States and are not subject to NPDES permits due to their small size. CAFOs are regulated under the Federal Agriculture Improvement and Risk Management Act of 1996 (FAIRMA).

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent from the dairy facility. The irrigation system is designed to distribute water uniformly across the pasture, minimizing runoff and ensuring adequate moisture for the grass. The irrigation system will be controlled using computer software and GPS receivers, allowing for precise application of water and nutrient management. The irrigation system will be designed to accommodate future expansion of the pasture area.

The pasture-based model provides a local feedstock – grass – as the cows' primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass and suitable sites to support sufficient production. NRCS provides technical guidance on applying agricultural waste depending on the actual use of the waste. Reflected in the title of the livestock waste guidance for Hawaii is the parthenial inclusion of the word “nutrients.” Where possible, nutrients are returned to the pasture to enhance productivity and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent from the dairy facility. The irrigation system is designed to distribute water uniformly across the pasture, minimizing runoff and ensuring adequate moisture for the grass. The irrigation system will be controlled using computer software and GPS receivers, allowing for precise application of water and nutrient management. The irrigation system will be designed to accommodate future expansion of the pasture area.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total project area.

Agricultural infrastructure and utilities required for the dairy operations will be located at the western end of the site, and access to the new buildings will be provided from the existing access road. Additional building information can be found in Draft EIS Section 3.3.1.

other partner ranches as needed for animal health and dairy productivity. This will help expand the dairy and infuse the beef market in Hawaii with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16.1, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waiman volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black alluvial clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that overlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poʻipiʻi region is on the order of 201 – 500 feet per day.

Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Poʻipiʻi region shows large and increasing demand for potable water for community and resort development.
The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua’i will increase county-wide by 17,300 residents by 2030. The South Kaua’i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua’i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a stream from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery.

Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data; however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for nearly nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopied along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface water. Vegetated buffers will be established between the fences and drainage ditches, to control erosive strips that could capture particulates during storm events. Another setback restricts application of effluent within 50 feet of the drainages; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the
current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement (EIS) is based on the potential for nutrients and bacteriological constituents to not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the Department of Conservation and local residents.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL:

http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Dear Sir or Madam,

I personally feel like the proposed planned dairy for Maha'ulepu is an unsafe, overreaching plan that should be put on hold at this time until an independently contracted EIS can be done. I believe that the concentrated rotational dairy proposed by HDF is far too much waste to add safely to the area in question. Soil testing needs to be taken seriously, with the long-term effects of grazing management systems and their impacts on soil quality and water quality in local wells preeminent.

A Voluntary "EIS" is a travesty to those concerned with the long-term viability of Kauai’s Tourism in the Poipu area. A large, high-density dairy is not what was likely envisioned for Mahalepu’s agricultural zoning and is also extremely close to residential zoning.

Kauai can support good neighbor business when care for local resources and not just a profits first mentality is part of the mission statement.

Kauai has supported small dairies in the past with the largest herd of less than 500. These dairies were located in more rural locations with herds rotated to different pastures. The proposed dairy in Mahalepu is a completely different practice and will have much more concentrated effect on the pasture land in question.

Kauai will change with the times however it is all our concern as people of Kauai to steward a future that balances new opportunities without losing others or perhaps creating insolvable problems.

I am disappointed that our Department of Health is not taking part in this EIS.

Jay Dorrance
Kapaa, Kauai
planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawaii Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS sequencing process involves Group 70’s experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawaii Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

**Dairy Operations:** Hawaii Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawaii families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhāulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mocks”, mimicking the natural social order of herds. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and roads minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow roads are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waihau Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.
NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawaii is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 5.5.5, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā‘ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā‘ulepū site applies to mature pasture application. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy production goals. This will benefit both the dairy and infuse the market in Hawaii with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the herd or sold as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe the use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dry periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawaii at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kāhilani Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015 and focused on evaluation of soils characterized as “poorly drained,” and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.
Poorly drained is not an indication of low or poor infiltration. Infiltration refers to
the ability of water to enter the soil surface, whereas “drainage” refers to
the movement of water within or from the soil profile. Poorly drained soils typically
have low hydraulic conductivity, or a slow rate of groundwater movement through
the soil. This slow movement can create anaerobic conditions, which typically result
in higher rates of denitrification. This is the conversion of potentially nitrites and
nitrates to gaseous forms, which reduces the potential for impacts on waterbodies.
In this way, “poorly drained” soils may represent less risk of nitrate and nitrite
leading to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of
nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF
site are known to adsorb and retain large amounts of phosphorus. Under the NRCS
phosphorus leaching index for Hawai’i soils, HDF soils show low risk for leaching.
With low risk, phosphorus can be applied at rates greater than crop requirements if
manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in
soils through use of manure as a natural fertilizer. Soil can incorporate carbon from
the atmosphere, which benefits soil health. According to recent studies in the Soil
Science Society of America Journal, the conversion of formerly tilled cropland to
grazed pasture can drive substantial accumulation of organic carbons in soil, with a
potential to offset up to one-third of the annual increase in atmospheric carbon
dioxide. The potential soil organic matter and carbon dioxide sequestration benefits
are likely greatest in highly degraded soils in warm subtropical climates, partly due
to long pasture-growing seasons. Long-term soil impacts are anticipated to result in
improvement to the physical, chemical, and biological condition of the soil.

This response letter accompanies your copy of the Draft Environmental Impact
Statement (EIS). The Draft EIS is available on the OEQC website at the following
URL: search “Hawai’i Dairy Farms”: http://tinyurl.com/OEQCKK4UA

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

February 20, 2015

Mr. Jeff Overton
Group 70 International, Inc.
925 Bishop Street, 5th Floor
Honolulu, HI 96813

Dear Mr. Overton,

My family has lived in Koloa, Hawaii for decades. We swim at Poipu beaches and
often frequent the area to dine or for recreation. It’s home, a bastion of peace,
safety and comfort. The proposed dairy in Maha’ulepu, as we see it, will completely
destroy life on the South Side and beyond as we now know it.

Four wells that serve as sources of public drinking water for Koloa and Poipu are
close to the area of the dairy designated to receive pumped manure sludge when
drainage the effluent ponds. Scientists specializing in agricultural operations have
issued a dire warning: The risk of water CONTAMINATION from migrating bacteria
and nitrites would be great. This translates into not only exposing South Side
residents to contaminated drinking water but also the thousands of visitors who
arrive annually and infuse the economy with millions of dollars.

A herd of 2,000 dairy cows (Phase II) will produce millions of pounds of manure
monthly. HDF’s plans claim zero waste elimination but the NRCS’s June 2014
study, “Custom Soil Resource Report”, concludes that the soil on this site is
“very limited” in its ability to absorb animal waste and risk of runoff is “high” or
“very high”. Millions of pounds of runoff flowing into the ocean waters of the
South Shore - a monumental environmental and economic disaster in the making
for the entire South Shore. HDF’s plan calls for the creation of 10-15 new jobs.
And what of the thousands who will lose jobs as we watch the demise of the hotel
and visitor industry and other related businesses - restaurants, those engaged in
water sports, sightseeing, etc.?

Entomologists have stated that the dairy will swarm billions of flies within months -
the biting variety with serrated mouths that live on blood - and they will inhabit a
radius of five miles. What plans does HDF have in place to address this serious
health threatening situation?

Maha’ulepu’s spectacular landscape is home to endangered species, irreplaceable
natural, cultural, historic, agricultural and scientific resources - petroglyphs, a heiau
and unexcavated sites are amongst the treasures to be found in the area. Surely
we owe it to the Native Hawaiians to honor all that is sacred to them. In honoring
them, we preserve for ourselves the sites that is irreplaceable. Endangering or
destroying these sites would be an unconscionable act.

OF COUNSEL

Ralph E. Portmore

Hitoshi Hida

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPAN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy.” The term “zero-discharge” under the U.S.

Sincerely,

Ellen T. Ebata
Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISP N. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the daily herds’ diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture or a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhāʻulepū site on Kauaʻi have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting out in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, padlock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pond effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

The NCRC provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflect on the title of the livestock waste guidance for Hawaiʻi is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NCRC Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and DRA EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauaʻi to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepū site applies to mature dairy cows.
Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in water, soil, and natural resources management. These practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon what data the user would like to display. These user-generated reports are not evaluated by NRCS.
NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawaiʻi Dairy Farms (HDF) lies between the 60 and 150 foot elevation, outside the tsunami evacuation zone. The Kauaʻi and Niʻihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kauaʻi has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāʻulepū region during and following the hurricanes that affected Kauaʻi in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāʻulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events received on Kauaʻi over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

ARCHEOLOGICAL AND CULTURAL: The Hawaiʻi Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-208. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugar cane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugar cane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāʻulepū Ahupuaʻa, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are confined within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the
A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The survey summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāʻulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and musaphilia. Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhāʻulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pads in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Poipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Alaka‘i Forest Road between Kōloa and Poipū, and it is likely that the livestock-related flies identified at the HDF site occur in this region as well. Localized control to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.
DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kau‘ai, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct plus indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kau‘ai.

The HDF project would contribute to diversification of Kau‘ai’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. Ongoing dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kau‘ai, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,700 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kau‘ai, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kau‘ai and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kūloa area was built by Nāpali formation lavas of the Waimāna volcanic series. Surface lavas of the Nāpali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā’ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā’ulepū Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kūloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two water bodies within Māhā’ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered...

EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evaportranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōlōa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōlōa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōlōa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōlōa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waipoi Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Management Plan has been completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kaua‘i, Part I.* The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs...
from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pastures growing with the committed herd size of 669 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kūkoʻa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 36,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR dairy neighbors and the local Kauaʻi Water Quality Branch.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawaiʻi Dairy Farms”: http://tinyurl.com/OEQCkaual
Thank you for your participation in the environmental review process.

Sincerely,

Honolulu, HI 96813

RE: COMMENT ON HAWAII DAIRY FARM’S ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE, DATED JANUARY 2015.

Dear Ms. McIntyre,

My husband and I have many concerns regarding this proposed Hawai‘i Dairy Farm (HDF) in Maha‘ulepu on Kaua‘i. We have lived in our home in the Bay View House Lots of Poipu Kai, just adjacent to the Grand Hyatt Resort and Spa, for over 17 years. It had long been a dream of ours to live here and enjoy the beauty and peace that this area offered. Now that we are about to retire and realize that dream, along comes HDF. Even without HDF completed we are suffering financial loss on our property investment. As much as $500,000.00 already and not a single cow in place yet. Just that fact that this project could come to fruition we have lost THAT much value. We have been told that if completed our total value would go down by at least 50%. That’s one heck of a hit! These are our selfish reasons for not wanting HDF in our area, following are all the other reasons this just does not make any sense.

The environment in Maha‘ulepu cannot handle the dairy. The resources, our wells, cannot handle the contamination that will come with that much waste. The airborne fumes from the waste (urine and solid), the flies will be horrible and we are down wind most of the time. The soil will not handle this and will then go on to contaminate not just the land but the ocean and marine environment. We fish out there and feed our families, we enjoy the beach and marine life, Hawaiian Monk Seals frequent the beaches of Maha‘ulepu, and of give birth and raise their pups there. Hawaiian Monk Seals are on the Endangered List and are the most endangered marine mammal in the United States. As an endemic species of the Hawaiian Islands they feed and breed in the waters. Sleep on our beaches. Maha‘ulepu is one of their habitat and would be forever ruined.

Our drinking water wells are located adjacent to these effluent ponds and stand to become contaminated forever. Where will we get our drinking water? And speaking of water, where will this 3 million gallons of water they need per day come from? The water from the mountains that collects in Waiau Reservoir belongs to all of us and is not for sale to HDF by their landlord. What about flooding, such as happened in 2006? The whole valley out there was under water and they were spilling overflow from Waiau that ran to Maha‘ulepu. What will happen to their containment ponds where we have rains like that?

We could go on and on why all this does not make sense to place a dairy in such a sensitive area, we have to consider the cultural significance of this area also before it’s too late!

Subject: Hawai’i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhūʻulepū Road
Kauaʻi, Hawaiʻi
TMK: (4) 2-9-003:001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Ronalee and Eric Eckberg:

Thank you for your letter concerning the Environmental Impact Statement
Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to
demonstrate the pasture-based system as an economically and environmentally
sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’
health, grass productivity, and effluent management will be used to ensure
environmental health and safety, as well as best management practices, and help
determine the ultimate carrying capacity of the land. With proven success at a herd
size of 699, HDF will contemplate the possibility of expanding the herd in the future.
For dairy operations with 700 or more mature dairy cows, additional regulatory
review and permitting by the State Department of Health is required. At the
discretion of HDF, management may choose to expand operations up to the carrying
capacity of the land, which is estimated to be up to 2,000 productive milking dairy
cows. Permit process compliance would be followed at such time HDF may decide to
pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS**: Hawai‘i Dairy Farms (HDF) will establish and operate a
sustainable, pastoral rotational-grazing dairy farm in Māhūʻulepū Valley on the
island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i
families. The rotational-grazing method utilizes 100 percent of the cows’ manure as
natural fertilizer to grow pasture grass as a primary source of nutrition for dairy
cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of
the Draft Environmental Impact Statement (EIS), the proposed facilities and
operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPNI) published
January 21, 2015, described the proposed pasture-based rotational grazing system
as a “zero-discharge, grass-fed dairy.” The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISP/N. This term was used to identify HDF’s intent to utilize a locally-produced feedstock—grass—for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed,” the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastural rotational-grazing dairy provides a local feedstock—grass—as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā’ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs,” mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices related to pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Wai‘ā Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste management plan is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 390, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā’ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of
SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer pollutant pollutants from leaching fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil qualities, and anticipated impacts from efficient and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in a watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kāena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients; which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium. Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrate and nitrite gases to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NCES phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbon in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due

699 mature dairy cows at the Māhāulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rGH.
to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**NATURAL HAZARDS**: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Niihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāʻulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāʻulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

**FLORA AND FAUNA**: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhāʻulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kaua‘i may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specifed areas, marking tall structures and fencing with white visibility polypile, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.
It is highly likely that Hawaiian hoary bats overfly the project area on a seasonal basis. Results of technical studies and the findings values in the area, and evaluated conditions project are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23. The technical reports were determined, and the quality of groundwater and surface water was documented.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of the project on the local economy were evaluated in the Draft Environmental Impact Statement (EIS) Section 4.15. The EIS Section 4.15 completed in April, 2016 by consultant Pacific Environmental Consultants, provided for the construction personnel and local economy. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average approximately 36 jobs, of which 28 would be on Kauai.

WATER QUALITY: The groundwater and surface water resources in the area were evaluated in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23. The technical reports were determined, and the quality of groundwater and surface water was documented.

Hydrology: The HDF project would contribute to diversification of Kauai’s economy, which is highly based on the tourism industry. Only two dairies remain in the State of Hawaii and the dairies on the Island of Kauai would provide an additional 699 cows and 11.2 million gallons of milk annually, a 50 percent increase in statewide milk production. Ongoing dairy operations are expected to average about 12 jobs per year during the construction period. Thus direct-plus-indirect employment associated with construction would be expected to average approximately 36 jobs, of which 28 would be on Kauai.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is saturated beneath thick alluvium, which generally extends about 60 feet beneath the surface. The groundwater within this aquifer is highly productive. The alluvium material underlying the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvial material underlying the valley floor is less than the hydraulic conductivity of the unweathered volcanics by orders of magnitude.

The alluvial material consists of fine to coarse sand and silt, with occasional gravel and cobble. The alluvial material is generally brown to black clay and clayey silt. The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is saturated beneath thick alluvium, which generally extends about 60 feet beneath the surface. The alluvium material consists of fine to coarse sand and silt, with occasional gravel and cobble. The alluvium material is generally brown to black clay and clayey silt.
conduct to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable drinking water quality) water from groundwaters provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Kōloa F well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,500 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed. The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels the Railroad to the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Structures to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Complainants from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has...
completed Part I of its report: *Waiopili Ditch Sanitary Survey, Kauai, Part I*. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (https:// health.hawaii.gov/cwb).

Long-term Operations: Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageways (totaling 75-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analyses conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Pō’ipū region were also calculated. Nitrogen input to the marine environment in the Pō’ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Pō’ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be initiated in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWP, dairy neighbors and the local Kaua’i community.
**AIR QUALITY:** As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. ER sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dry manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₀.₅ and PM₁₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₀.₅ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₁₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF; so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual odors in the area are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search “Hawaii’s Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

RE: Hawaii Dairy Farm Environmental Impact Study for operations on Kauai.

My husband and I own a small condo in the Poipu Area and we will be retiring to the beautiful island of Kauai within the next 3 years.

We were very surprised to hear that Hawaii Dairy Farms, LLC is proposing an Industrial Dairy Farm at Maha‘ulepu on Kauai with a herd of up to 2000 cows.

We are very happy that there is an Environmental Impact Study being completed but we have many concerns and questions.

My mother was raised in a dairy farming family. My grandparents were dairy farmers and a number of generations before them were as well. They all used “sustainable” and “grass fed” farming practices. My cousins continued the family dairy farming up until just recently.

My family’s farm consisted of 100 acres with a total of 25-30 humanely treated adult purebred Holstein cows. They grazed daily in the summer, spring and fall on 10 – 20 acre pastures in a rotational manner to preserve the soil. The land was also used to grow all of the feed required for the animals. They ate only food grown on the land within the 100 acres. Crops (no corn) were grown and stored for winterfeed and to augment feed when they arrived in the barn for milking twice a day. This was and is sustainable grass-fed dairy farming.

HDF is proposing a “Grass Fed” Dairy with cows grazing on 500 acres of land that is within 4/5th of a mile of the Pacific Ocean at Maha‘ulepu. They plan to start production with 699 cows and then move to 2000 cows over time. In HDF’s proposal at start-up they will have 115 cows in each 4 acres of paddock area per day and at full production 330 cows on each of these paddocks.

500 acres sounds like a lot of land to graze 699-2000 cows on, but basically it means that during the start-up phase 7 cows would be grazing and defecating on 10,000 square feet of “pasture”, the size of a standard house lot. At full production it would mean that at least 17 cows would graze and defecate on the same area.

According to the EPA a dairy cow defecates at least 120 pounds of wet manure every day. In their Waste Management Plan, page 42, HDF reports that they anticipate their dairy cows will each weigh 1,200 pounds and produce 143 pounds of wet manure per cow daily. Using HDF’s own waste expectations, at full production HDF’s 2,000 cows would produce 2,648 pounds of wet manure on a 10,000 square foot area every day! Imagine having more than one ton of manure added to your lot daily. My husband and I live in a standard house lot of about 10,000 square feet. As I write this and look out my window and try to understand the impact of the concentrated rotational dairy proposed by HDF, I can’t imagine anything left of my yard after 17 cows graze, defecate and urinate for even one day. How is HDF going to handle all this manure? How will they keep it from run-off into the wells, streams and ocean? This must be addressed in the EIS.

This manure is not just manure, it is filled with the drugs that the modern farming practices give to these animals such as growth hormones and antibiotics - these will be part of the run-off so how will this affect humans, animals, birds and fish both on land and in the ocean? This too much be addressed in the EIS.

According to HDF, the cows rotate through the grazing paddocks, returning to the pasture paddocks first grazed every 18 days. Not only will the grass be unlikely to re-generate in that short an interval but the manure will still be wet and likely contribute to hoof rot when trampled by the returning herd. This needs to be addressed in the EIS.

The dense grazing will not only sicken the cows, there is also a very real risk to the public’s health. There were cases of E.coli in 2006 that were caused by spinach contaminated by feces from cattle nearby. There were 3 deaths and many were sickened. With all the rain on Kauai won’t there be a risk of contamination just by run-off? Will the flies carry disease to our food or any containers we eat from? These need to be addressed in the EIS.

What about the chemicals that will be in use to clean the cows and the milking structure and other facilities on-site? This needs to be addressed in the EIS.

I know they use iodine to wash cow udders. When that gets into the run-off who or what does that harm? This too needs to be addressed in the EIS.

What about large animal vets? Are there enough on the island to make
sure these animals are healthy as they need to be examined on a regular basis? This needs to be addressed in the EIS.

In Industrial Farming a cow has only a 5 year life expectancy. Where will all the deceased animals be disposed if they cannot be used for hamburger meat? Could this be another possible contaminant? This needs to be addressed in the EIS.

HDF will have to bring in additional feed for these animals. From where will this additional feed come? I know that there will be an opportunity for farmers on-island to grow crops but what if that does not happen. When additional feed is brought in from other areas what pests, or other contaminates will be introduced to the environment that could cause disease to the plant, animal and human life on the island? This also needs to be addressed in the EIS.

In the Poipu area, we have wildlife that is already protected like the Monk Seal and the Sea Turtle. We also have a tremendous number of fish species living on the reefs on the island. Will these animals and fish or the reefs be harmed from the run-off? This needs to be addressed in the EIS.

My husband and I rent our home at this time and are responsible for collecting over $13K into the GET and TAT per year. If you multiply that by the number of other vacation rentals in the area it represents a large amount of lost revenue to the State of Hawaii if the tourists stop coming due to odor and flies. Will this possible impact to the state taxes be addressed in the EIS?

Please ensure that the EIS for this project is being done fairly and based on facts that will ensure that the Poipu Coastline will not be negatively impacted.

Thank you for your consideration.

Sincerely,

Attention: Ms. Laura McIntyre:

RE: Hawaii Dairy Farm Environmental Impact Study for operations on Kauai.

My husband and I own a small condo in the Poipu Area and we will be retiring to the beautiful island of Kauai within the next 3 years.

We were very surprised to hear that Hawaii Dairy Farms, LLC is proposing an Industrial Dairy Farm at Maha'ulepu on Kauai with a herd of up to 2000 cows.

We are very happy that there is an Environmental Impact Study being completed but however were very disappointed of the very close relationship of HDF and Group 70 International that is compiling the study. We have many concerns and questions.

My mother was raised in a dairy farming family. My grandparents were dairy farmers and a number of generations before them were as well. They all used “sustainable” and “grass fed” farming practices. My cousins continued the family dairy farming up until just recently.

My family’s farm consisted of 100 acres with a total of 25-30 humanely treated adult purebred Holstein cows. They grazed daily in the summer, spring and fall on 10 – 20 acre pastures in a rotational manner to preserve the soil. The land was also used to grow all of the feed required for the animals. They ate only food grown on the land within the 100 acres. Crops (no corn) were grown and stored for winter feed and to augment feed when they arrived in the barn for milking twice a day. This was and is sustainable grass-fed dairy farming.

HDF is proposing a “Grass Fed” Dairy with cows grazing on 500 acres of land that is within 4/5 of a mile of the Pacific Ocean at Maha’ulepu. They plan to start production with 699 cows and then move to 2000 cows over time. In HDF’s proposal at start-up they will have 115 cows in each 4 acres of paddock area per day and at full production 330 cows on each of these paddocks.

500 acres sounds like a lot of land to graze 699-2000 cows on, but basically it means that during the start-up phase 7 cows would be grazing and defecating on 10,000 square feet of “pasture”, the size of a standard house lot. At full production it would mean that at least 17 cows would graze and defecate on the same area.

According to the EPA a dairy cow defecates at least 120 pounds of wet manure every day. In their Waste Management Plan, page 42, HDF reports that they anticipate their dairy cows will each weigh 1,200 pounds and produce 143 pounds of wet manure per cow daily. Using HDF’s own waste expectations, at full production HDF’s 2,000 cows would produce 2,648 pounds of wet manure on a 10,000 square foot area every day! Imagine having more than one ton of manure added to your lot daily. My husband and I live in a standard house lot of about 10,000 square feet. As I write this and look out my window and try to understand the impact of the concentrated rotational dairy proposed by HDF, I can’t imagine anything left of my yard after 17 cows graze, defecate and urinate for even one day. How is HDF going to handle all this manure? How will they keep it from run-off into the wells, streams and ocean? This must be addressed in the EIS.

This manure is not just manure, it is filled with the drugs that the modern farming practices give to these animals such as growth hormones and antibiotics - these will be part of the run-off so how will these affect humans, animals, birds and fish both on land and in the ocean? This too much be addressed in the EIS.

According to HDF, the cows rotate through the grazing paddocks, returning to the pasture paddocks first grazed every 18 days. Not only will the grass be unlikely to re-generate in that short an interval but the manure will still be wet and likely contribute to hoof rot when trampled by the returning herd. This needs to be addressed in the EIS.

The dense grazing will not only sicken the cows, there is also a very real risk to the public’s health. There were cases of E.coli in 2006 that were caused by spinach contaminated by feces from cattle nearby. There were 3 deaths and many were sickened. With all the rain on Kauai won’t there be a risk of contamination just by run-off? Will the flies carry disease to our food or any containers we eat from? These need to be addressed in the EIS.

What about the chemicals that will be in use to clean the cows and the milking structure and other facilities on-site? This needs to be addressed in the EIS.

I know they use iodine to wash cow udders. When that gets into the run-off who or what does that harm? This too needs to be addressed in the EIS.
What about large animal vets? Are there enough on the island to make sure these animals are healthy as they need to be examined on a regular basis? This needs to be addressed in the EIS.

In Industrial Farming a cow has only a 5 year life expectancy. Where will all the deceased animals be disposed if they cannot be used for hamburger meat? Could this be another possible contaminate? This needs to be addressed in the EIS.

HDF will have to bring in additional feed for these animals. From where will this additional feed come? I know that there will be an opportunity for farmers on-island to grow crops but what if that does not happen. When additional feed is brought in from other areas what pests, or other contamimates will be introduced to the environment that could cause disease to the plant, animal and human life on the island? This also needs to be addressed in the EIS.

In the Poipu area, we have wildlife that is already protected like the Monk Seal and the Sea Turtle. We also have a tremendous number of fish species living on the reefs on the island. Will these animals and fish or the reefs be harmed from the run-off? This needs to be addressed in the EIS.

My husband and I rent our home at this time and are responsible for collecting over $13K into the GET and TAT per year. If you multiply that by the number of other vacation rentals in the area it represents a large amount of lost revenue to the State of Hawaii if the tourists stop coming due to odor and flies. Will this possible impact to the state taxes be addressed in the EIS?

Please ensure that the EIS for this project is being done fairly and based on facts that will ensure that the Poipu Coastline will not be negatively impacted.

Thank you for your consideration.

Sincerely,

Beverley Ellul

Attention: Ms. Laura McIntyre:

RE: Hawaii Dairy Farm Environmental Impact Study for operations on Kauai.

My husband and I own a small condo in the Poipu Area and we will be retiring to the beautiful island of Kauai within the next 3 years.

We were very surprised to hear that Hawaii Dairy Farms, LLC is proposing an Industrial Dairy Farm at Maha'ulepu on Kauai with a herd of up to 2000 cows.

We are very happy that there is an Environmental Impact Study being completed but however were very disappointed of the very close relationship of HDF and Group 70 International that is compiling the study. We have many concerns and questions.

My mother was raised in a dairy farming family. My grandparents were dairy farmers and a number of generations before them were as well. They all used “sustainable” and “grass fed” farming practices. My cousins continued the family dairy farming up until just recently.

My family’s farm consisted of 100 acres with a total of 25-30 humanely treated adult purebred Holstein cows. They grazed daily in the summer, spring and fall on 10 – 20 acre pastures in a rotational manner to preserve the soil. The land was also used to grow all of the feed required for the animals. They ate only food grown on the land within the 100 acres. Crops (no corn) were grown and stored for winterfeed and to augment feed when they arrived in the barn for milking twice a day. This was and is sustainable grass-fed dairy farming.

HDF is proposing a “Grass Fed” Dairy with cows grazing on 500 acres of land that is within 4/5 of a mile of the Pacific Ocean at Maha'ulepu. They plan to start production with 699 cows and then move to 2000 cows over time. In HDF’s proposal at start-up they will have 115 cows in each 4 acres of paddock area per day and at full production 330 cows on each of these paddocks.

500 acres sounds like a lot of land to graze 699-2000 cows on, but basically it means that during the start-up phase 7 cows would be grazing and defecating on 10,000 square feet of “pasture”, the size of a standard house lot. At full production it would mean that at least 17 cows would graze and defecate on the same area.

According to the EPA a dairy cow defecates at least 120 pounds of wet manure every day. In their Waste Management Plan, page 42, HDF reports that they anticipate their dairy cows will each weigh 1,200 pounds and produce 143 pounds of wet manure per cow daily. Using HDF’s own waste expectations, at full production HDF’s 2,000 cows would produce 2,648 pounds of wet manure on a 10,000 square foot area every day! Imagine having more than one ton of manure added to your lot daily. My husband and I live in a standard house lot of about 10,000 square feet. As I write this and look out my window and try to understand the impact of the concentrated rotational dairy proposed by HDF, I can’t imagine anything left of my yard after 17 cows graze, defecate and urinate for even one day. How is HDF going to handle all this manure? How will they keep it from run-off into the wells, streams and ocean? This must be addressed in the EIS.

This manure is not just manure, it is filled with the drugs that the modern farming practices give to these animals such as growth hormones and antibiotics - these will be part of the run-off so how will this affect humans, animals, birds and fish both on land and in the ocean? This too much be addressed in the EIS.

According to HDF, the cows rotate through the grazing paddocks, returning to the pasture paddocks first grazed every 18 days. Not only will the grass be unlikely to re-generate in that short an interval but the manure will still be wet and likely contribute to hoof rot when trampled by the returning herd. This needs to be addressed in the EIS.

The dense grazing will not only sicken the cows, there is also a very real risk to the public’s health. There were cases of E.coli in 2006 that were caused by spinach contaminated by feces from cattle nearby. There were 3 deaths and many were sickened. With all the rain on Kauai won’t there be a risk of contamination just by run-off? Will the flies carry disease to our food or any containers we eat from? These need to be addressed in the EIS.

What about the chemicals that will be in use to clean the cows and the milking structure and other facilities on-site? This needs to be addressed in the EIS.

I know they use Iodine to wash cow udders. When that gets into the run-off who or what does that harm? This too needs to be addressed in the EIS.
What about large animal vets? Are there enough on the island to make sure these animals are healthy as they need to be examined on a regular basis? This needs to be addressed in the EIS.

In Industrial Farming a cow has only a 5 year life expectancy. Where will all the deceased animals be disposed if they cannot be used for hamburger meat? Could this be another possible contaminate? This needs to be addressed in the EIS.

HDF will have to bring in additional feed for these animals. From where will this additional feed come? I know that there will be an opportunity for farmers on-island to grow crops but what if that does not happen. When additional feed is brought in from other areas what pests, or other contaminates will be introduced to the environment that could cause disease to the plant, animal and human life on the island? This also needs to be addressed in the EIS.

In the Poipu area, we have wildlife that is already protected like the Monk Seal and the Sea Turtle. We also have a tremendous number of fish species living on the reefs on the island. Will these animals and fish or the reefs be harmed from the run-off? This needs to be addressed in the EIS.

My husband and I rent our home at this time and are responsible for collecting over $13K into the GET and TAT per year. If you multiply that by the number of other vacation rentals in the area it represents a large amount of lost revenue to the State of Hawaii if the tourists stop coming due to odor and flies. Will this possible impact to the state taxes be addressed in the EIS?

Please ensure that the EIS for this project is being done fairly and based on facts that will ensure that the Poipu Coastline will not be negatively impacted.

Thank you for your consideration.

Sincerely,
Beverley Ellul

experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai‘i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy." The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was constructed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify livestock manure management practices. The HDF EISPN stated that "grass-fed" refers to grazing that will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastural rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob,” mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer; productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Watta Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivot can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and...
irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**FLORA AND FAUNA:**

Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under federal or state of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammal species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhāulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kaua‘i may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōkua area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specific areas, marking tall structures and fencing with white visibility polytype, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

**DEMOGRAPHIC AND ECONOMIC**

The potential impacts of Hawai‘i’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plachy Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix 1.
The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk would be produced. This would double local milk production currently supplied by operational dairy farms on O'ahu.

The dairy is expected to generate a net income of $8,000 to $360,000 annually in the County of Kaua'i, depending on the actual herd size. Additional employment generated by a possible expansion to accommodate the committed herd size of 699 cows is estimated to be approximately 3 full-time equivalent jobs. The dairy's production will be sold primarily to the local market, with some milk being delivered to processing facilities for conversion into products such as cheese and butter.

The HDF project's environmental impact will be limited to the immediate vicinity of the dairy site. The operation will not cause any significant adverse effects on the environment, water quality, or air quality. The proposed dairy is expected to have a negligible impact on the ecological and socio-economic environment of the area.

The HDF project is subject to the approval of the County of Kaua'i, and any changes in the proposed plan will be evaluated through an updated draft environmental impact statement (EIS). The project is expected to commence in the near future.
Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction. The dairy facility and associated infrastructure operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County’s Kōkoʻa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōkoʻa-Poʻipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōkoʻa - Poʻipū - Kalāheo districts), water use in 2035 is projected to be 3,24 GPD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Surface Water

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface
Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching

To provide perspective, nutrient inputs from the adjacent Kūloa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Resource Consultants, Inc. (MRCI). Surface water from the Waipōlī Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team and the environmental agencies. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua’i community.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūle‘epā will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūle‘epā will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawaii\'s Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawai‘i Dairy Farms Environmental Impact Statement Preparation Notice

Kaua‘i, Hawai‘i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-09:001:001 portion

Dear Russell Faraldi:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhūulepu‘e Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 21, 2015, described the proposed pasture-based rotational grazing system
as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency is designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd's diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastural rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow's diet. Additional project-specific trials at the Måhāʻulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided from the farm from Wa‘ia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Måhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of...
699 mature dairy cows at the Māhā'ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian is available to prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Ni‘ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua‘i in 1992 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class B under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in theDraft EIS Section 4.6.2.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs or national property. EIS Sections 49 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated the presence of plants currently listed as endangered, threatened, or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plant species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat seabirds that nest in upland areas of Kaua‘i overfly the site. The endangered Hawaiian goose, nēnē, was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject.
property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project specified areas, marking tall structures and fencing with white visibility polytype, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 410.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators on site that control these species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kaua‘i Cave Wolf Spider and the Kaua‘i Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all cases in the Kōloa area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawai‘i Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Pest insects such as flies can negatively impact livestock health and production, and are therefore actively managed to prevent stress and loss of productivity at dairy operations.

At the HDF site, two common flies were identified: the stable fly and the horn fly. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kaua‘i but not seen at the HDF site during the survey were identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

In response to cattle-related insect pests, numerous species known to compete with the pests were introduced to Hawai‘i between 1898 and 1982. Twenty species of predators and competitors to the horn fly were successfully established during that period. Cattle egrets break up dung patties while searching for prey, and were introduced to Hawai‘i in the late 1950s to control cattle-associated insects. Extensive introduction of dung beetle species resulted in 16 dung beetle species becoming established on Kaua‘i.

A healthy population of dung beetles can bury a dung patty in one to three days, which disrupts reproduction of flies such as the stable fly and horn fly. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive; the horn fly takes 10 to 20 days from egg to adult. Incorporation of the manure into the soil profile by dung beetles removes the habitat these flies require to complete their lifecycle. Research shows that 95 percent fewer horn flies emerged from dung patties containing a dung beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure.

Among the invertebrates previously introduced to Hawai‘i to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnats. Using an ovipositor – described by lay people as a “stinger” – the female lays eggs in the larva or pupa of flies. The male wasp has no such “stinger”. See Draft EIS Section 4.11 for a photo providing scale for these tiny, non-stinging wasps.

To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site. Short-term controls, including mechanical methods (e.g. sticky tapes or ribbons in the milking parlor, or traps with or without attractants) and chemical methods may be used to prevent short-term spikes in pest populations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Should chemical control be needed for short-term spikes in pest populations, application would be by those qualified, and in accordance with regulatory labeling requirements. HDF will implement long-term...
integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua‘i may choose to engage with the State Department of Agriculture to translocation dung beetle species already introduced on Kaua‘i to Māhūʻulepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment associated with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 12 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to ongoing dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,219,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total) versus $68,000 for the committed herd size. The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Nāpali formation lavas of the Waimea volcanic series. Surface lavas of the Nāpali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprohite, a soft, thoroughly decomposed rock. The Māhūʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa...
The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water**: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring**: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium and in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand**: The adjacent, developed Kōloa-Poipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i region (the Kōloa-Poipū-Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāulepū Road. This ditch, named Waiopōlō Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction**: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and
prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makuawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāulepū Valley. The deme canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and that it is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, US Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fenceline and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 1.62 tons DM per acre to 20 tons DM per acre. Section 423 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kāhā-Mi’ipu‘u region were also calculated. Nitrogen input to the marine environment in the Po‘ipu region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 14 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.
The minor contributions of nutrients from episodic rainfall anticipated to occur just
10 days annually from dairy operations will not adversely affect ocean water quality
and the marine environment. The nearshore area is a highly mixed environment
which actively disperses inputs within several meters from shore. Comparing
nutrient constituents in surface water samples taken from the HDF site and the
agricultural ditches down gradient to nutrients sampled in the nearshore ocean
water revealed that indicator bacteria were substantially lower in the ocean than in
the ditch. The rapid decrease is likely a result of both physical mixing of water
masses and toxicity from saline water. In any event, the elevated levels of indicator
bacteria do not extend beyond the shoreline. Baseline water quality data and the
surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality
monitoring will be instituted in conjunction with the surface water quality
monitoring to regularly sample and analyze the nearshore ocean waters. The
ongoing testing program will provide feedback to the dairy management team to
help ensure that nutrients and bacteriological constituents are not being released at
levels of environmental concern. Data from the nearshore water monitoring
program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i
community.

This response letter accompanies your copy of the Draft Environmental Impact
Statement (EIS). The Draft EIS is available on the OEQC website at the following
URL search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC

RE: EIS – Hawaii Dairy Farm

I am writing to ask about several concerns to be evaluated as part of the EIS to the Hawaii Farms Dairy.

My first concern is the lack of objectivity of Group 70 International conducting an EIS – specifically on waste management since Group 70 International created the waste management process. An independent environmental engineering firm should be evaluating the plan and any mitigations. There is certainly a conflict of interest having the developer critique its own plan.

Second, there will a substantial degradation to the entire Mauka area with a high density board. For years, local families have been allowed to hike to what is commonly known as “Hidden Beach.” This has a spectacular view along the coast line and leads to a secluded beach where many visitors and locals enjoy a quiet day.

Additionally, there are many family traditions of camping at Mauka area beach during holidays. All of these activities and way-of-life will be impacted by gated, fenced areas as well as impose odor, biting flies, and potential run-off. The dairy insists the fed lot will be zero waste. I am not convinced. The plan to liquify and spray adjacent fields as a “nutrient fertilizer” will either run off during heavy rain or seep into the ground. Such seepage is likely to reach the water table. These “sprayed” fields are at close as 750 yards from the Kolos water well and nitrate pollution to the water via contamination to the water table is a highly likely scenario as evidenced in other states recently.

Third, there have been no reports on how to mitigate biting flies. An entomologist sent Mayor Carvalho an open letter about the typical 5-mile range of such biting flies and how the flight pattern is likely in swarms. Anyone with a pond or pool will have to contend with swarms of flies which can migrate as far as five miles. This would likely impact all outdoor activities as far as Spouting Horn. All resorts such as the Hyatt, Sheraton, Kolos Laundry and shopping at Poipu Village, Kekaha‘ukai, and Spouting Horn would be affected. The National Tropical Botanical Gardens are also within the 5-mile zone of migrating flies. Quality of life would be adversely affected; the economy would also be adversely affected as the shopping areas are also outdoors. This entire issue has not been addressed.

A fourth issue is that of irrigation. Recently the State District Court ruled that a private enterprise Kaua‘i Springs did not have rights to the spring water for commercial purposes. Grove Farm has entered into an
agreement to supply water from the Waiake reservoir which reverted water rights back to Hawaiian rights after the closure of the Kolos Sugar Mill. Access to the water for use to liquify all the solid waste is using a water
source for commercial purposes. Should the legal defense through Office of Hawaiian Affairs retain rights to
the water, what source of water is proposed for the dairy?

Lastly, I personally own a home in Poipu. I am less than a mile from the Grand Hyatt. I have a fish pond
in my yard. My neighborhood is only about 2 miles downwind from the proposed site. Having grown up in
Colorado and having been around many cattle operations, I am all too familiar with both the odor and fly
problem affiliated with such large scale operations. The proposed site for the dairy operation is too close to
some of the most coveted real estate in the country. It is certainly too close to my home.

The concept for the dairy is a theory. The only other example, which HDF points to, is the New Zealand effort.
The consequences of the New Zealand effort has been disastrous and well documented. Because I value living
in Poipu and consider my home and my access to clean beaches, access to pristine waters off of the Mahahulepu
coast - integral to my quality of life- I find the proposed site for this large scale dairy to be obviously deficient
in analyzing the impact it can have on our lives here.

Mahahulepu is the wrong location for this project.

Mahalo mai loa.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Mahahulepu Road
Kauai, HI
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Cheryl Ann Farrell:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to
demonstrate the pasture-based system as an economically and environmentally
sustainable model for Hawaii’s Precision agricultural technology that monitors cows’
health, grass productivity, and effluent management will be used to ensure
environmental health and safety, as well as best management practices, and help
determine the ultimate carrying capacity of the land. With proven success at a herd
size of 699, HDF will contemplate the possibility of expanding the herd in the future.
For dairy operations with 700 or more mature dairy cows, additional regulatory
review and permitting by the State Department of Health is required. At the
discretion of HDF, management may choose to expand operations up to the carrying
capacity of the land, which is estimated to be up to 2,000 productive milking dairy
cows. Permit process compliance would be followed at such time HDF may decide to
pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for
the preparation and processing of the Hawai’i Dairy Farms Environmental Impact
Statement (EIS). The EIS was prepared in accordance with the requirements of
Chapter 343 Hawai’i Revised Statutes and the “Environmental Impact Statement
Rules” (Chapter 200 of Title 11, Hawai’i Administrative Rules). The environmental
planning team at Group 70 has prepared several hundred Environmental
Assessment and EIS documents over the past 40 years, and every document has
been accepted by the responsible County, State and Federal agency. On numerous
past EIS projects, the Hawai’i Chapter of the American Planning Association has
recognized Group 70’s professional work with Chapter awards for excellence in
environmental planning. Part of the EIS scoring process involves Group 70’s

The pastoral rotational-grazing dairy provides a local feedstock - grass - as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially identified sufficient yield and nutrition to supply 70 percent of the herd's primary food source, the existing environmental conditions, probable impacts with mitigation, and identifying appropriate varieties of grass. Additional project-specific trials have identified sufficient yield and nutrition to supply 70 percent of the herd's primary food source.

The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and known as "mobs," mimic the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The cows' primary nutrition source and minimizes stress to the animals. Cows tend to be very precise application of irrigation and/or diluted effluent on the pasture. The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through the pivot irrigation systems or through gun irrigation. Irrigation water supply is provided from Wai Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The term "grass-fed" was used in the HDF EIS. This term was used to identify any cow or calf being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways through the site. Seeding of grasses begins with the establishment of the existing vegetation in the setbacks. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. HDF's intent to use a locally-applied feedstock - grass - for more than 70 percent of the dairy herd's diet is a narrow legal definition of grass-fed, and is not in the revised EIS. The term "grass-fed" is no longer used in HDF's Draft EIS for any dairy operations. Due to the evolving definition of grass-fed, the term is not used in this EIS.
irrigation water. Nutrient management is the practice of managing the amount, rate, and timing of nutrient application to ensure effective plant uptake, soil management, and environmental protection. Nutrient management involves the use of fertilizers, crop rotation, and other practices to optimize nutrient use and minimize nutrient losses.

The HDF site includes the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could contribute to the growth of pest populations, particularly in the absence of effective sanitation practices. The timing and application of nutrients will correspond with plant uptake, soil properties, and nutrient management strategies. Appropriate nutrient management practices will be implemented to prevent and control nutrient loss without compromising plant productivity. A full list of site management measures is provided in the Draft EIS.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It is estimated that the storage period will be less than 30 days, and the effluent is planned for application every 45 days, to ensure that the ponds are kept at manageable levels. During the calves' initial 90 days, they will be transitioned to pasture at the HDF site.

The potential impacts of the Hawaiian Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS) completed in April 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

Demographic and Economic: The potential economic impacts of the Hawaiian Dairy Farms (HDF) on the existing economy were evaluated in the Draft Environmental Impact Statement (EIS) completed in April 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

Flies were identified on the HDF site using manure from neighboring livestock as bait. Flies were identified as the house fly, the latter known for causing disease in livestock. Various species of flies are present at the HDF site, including the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could contribute to the growth of pest populations, particularly in the absence of effective sanitation practices. The timing and application of nutrients will correspond with plant uptake, soil properties, and nutrient management strategies. Appropriate nutrient management practices will be implemented to prevent and control nutrient loss without compromising plant productivity. A full list of site management measures is provided in the Draft EIS.

The potential impacts of the Hawaiian Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS) completed in April 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.
be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawaii Island), approximately 10 percent of Hawaii’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 12 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36.7 million pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawaii.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairies Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāulepū Valley and the HDF site ranges from 105 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD) of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii’s Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.85 MGD). These demands are a small fraction of the 3 MGD
produced by the on-site, existing Māhūulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhūulepū 14 well and the County's Kolōa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūulepū Valley, HDF established a 1,000-foot setback surrounding the Kolōa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kolōa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kolōa - Po‘ipū - Kalīheo districts), water use in 2035 is projected to be 3,244 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Surface Water: The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūulepū watershed.

The HDF site is located on the bottom-land of the upper Māhūulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure to disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makuwahine Care Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhūulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a ‘Sanitary Survey’ of the Māhūulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhūulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations: Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or
maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhō`ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on a episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po`ipū region were also calculated. Nitrogen input to the marine environment in the Po`ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po`ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipoli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua`i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai`i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the
DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4.19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to lesser than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES:

As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed project. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision.
alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to produce more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Aloha Bill and staff ~ you may use any or all of my enclosed testimony for TGI.

I’m sending the following to State of Hawaii, HDF@Group 70int.com; epo@doh.hawaii.gov, as recommended in today’s TGI.

Others too? Council? Mayor? email addresses?

Mahalo,

Alan

Comments re Hawaii Dairy Farms

Does HDF want to consider relocating their eventual 2,000 dairy cow herd NOW, before having to move it later? The history of milking cow dairy’s on Kauai is one of relocating here and there until they all moved off the Island of Kauai.

Starting back in around 1905, Mr. HP Faye started the Waiamea Dairy as a part of his Waimea Sugar Mill Co. His in-laws had a dairy in Moloa’a prior to his marriage. He suggested to the Lindsay family, that they relocate their dairy to Waimea; which they did. Over the many years, Waimea Dairy flourished through the late 1960’s when the milk was delivered by milkmen as far as Hanalei on the North Shore of Kauai. The dairy herd was about 278 milking cows.

As a young teenager, through high school, I worked many “dairy” hours. We mulched sugar cane tops and mixed this with pine-apple bran skins that were dried. We even picked keawe-tree beans, as school kids during World War II for ten cents a burlap bag! There was no “milk-flo” feed coming during the War. Keawe-tree beans kept cows cleaner, along with sugar-cane tops and pineapple bran.

Waimea Dairy was always very careful about cleanliness of the cows, pastures and pasteurizing plant. Near the end of 1969, the Faye family faced a required major expense to update the pasteurizing plant. The decision was made to accept an offer from MeadowGold Milk Co. of Honolulu. They would buy the herd, take over operations, and lease the facilities.

All went well until MeadowGold stopped control of nauseous odor and biting flies. MeadowGold Milk Co. closed operations and Kikiaola Land Co. then owned the Waimea Dairy facility. After Hurricane Iniki, Kikiaola converted the many sugar plantation homes into the Waiamea Plantation Cottages. Now came the problem of dairy causing a problem with guests at the Waiamea Plantation Cottages; a resort. Kind of like HDF being near the Hyatt Resort, hey?

As a result, Kikiaola evicted MeadowGold, who then moved their dairy to Moloa’a; not to process milk, but to produce milk from the cow herd and send to Honolulu for processing and selling. It was not very long that the local residents of Moloa’a manage to evict MeadowGold, claiming bad odors and dirty run-off that polluted Moloa’a Bay.

This begs the question: Why not relocate the HDF NOW? There are many parcels that should not result in eventual eviction. Example: Kahili Mountain area. This location is away from residential complainers and business ventures. The special New Zealand grass will flourish there. The higher the elevation, the better the growth. The soil is more porous and less likely to generate major run-offs.

Surely with Mr. Case and his 16,000 acres of former Grove Farm lands, can find a more suitable location that is still “ag” than historical Mahu‘ulepu. I rest my case.

Alan Faye, Princeville 808-826-7630  Feb 23, 2015
Dear Alan Faye:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP) published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISP. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob”, mimicking the natural social order of herds. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways, and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and grass footpaths are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the
other partner ranches as needed for animal health and dairy productivity. This will help ensure a healthier and longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

Of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers will be utilized as a resource, it is being used for the constituent components that provide the potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunamis, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 1% annual chance-floodplain. The proposed location for the farm is not known to experience flooding conditions. The area has experienced two earthquakes originating further south in the Hawaiian Islands. Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management practices in the proposed location for the farm are designed to minimize environmental impact due to agriculture and livestock waste. The area lies within the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands is located within FEMA Zone X, areas determined to be outside the 1% annual chance-floodplain.

regulatory requirements, with containment in excess of the major rainfall events recorded on Kauai over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōkua area was built by Napali formation lavas of the Waimale volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhū‘ulepi Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōkua series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhū‘ulepi Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōkua-Poi’ipi’i region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhū‘ulepi may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhū‘ulepi 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhū‘ulepi 14 well and the County’s Kōkua F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhū‘ulepi Valley, HDF established a 1,000-foot setback surrounding the Kōkua F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōkua-Poi’ipi’i region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauai will increase county-wide by 17,300 residents by 2030. The South Kauai population is estimated to reach 16,855 in 2035, when it is projected to
encompass 19.2 percent of the County population. For the South Kaua’i region (the Kōlia- Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā’upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery.

Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua’i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however; DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Graz yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three
times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Puʻipū region were also calculated. Nitrogen input to the marine environment in the Puʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Puʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment.** An assessment of groundwater and surface water interaction with the marine water downstream from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipōli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

**AIR QUALITY:** As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odors. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaiʻi has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kauaʻi and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM2.5 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM10 is
The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).

The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

However, after years of trying, it appears there was limited interest in such a venture.

Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search “Hawaii Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

Gentlemen,

I have been coming to the Poipu area of Kauai with my family for over 40 years. Sixteen years ago I purchased a house at Poipu Kai which I gave to my daughters two years ago. The house is rented when we are not in Hawaii, we pay our fair share of state and local taxes. I am very alarmed by the proposal to start an industrial dairy at Maha’ulepu.

The HDF proposal does not address the public health consequences of polluting the aquifer that we all depend on, or the expected rise in respiratory illness that accompany industrial dairies. It does not address the accidental importation of invasive species with the cattle and their food. It does not address the loss of one of the most scenic areas of the Island, the down stream consequences of a rainstorm like 2006 which caused one of the dams on the island to fail, or another storm like Iwa or Iniki.

Economically, the upside profitability of the Maha’ulepu dairy is questionable given that the owners of one of the largest dairies in Idaho, Steve Whitesides who boasts in the local Rupert paper that he has 14,000 cattle in his herd, has an industrial dairy operation on the Hanakua Coast 30 miles from Hilo where his Big Island Dairy produces 15,000 gallons of milk a day. Why not 14,000 cattle here too?
In summary, I think the proposed industrial dairy at Maha'ulepu is a bad idea.

Sincerely,

James M. Ferguson, MD

Susan J. Ferguson

Cow Country: The Rise of the CAFO in Idaho

As mega-dairies and feedlots make up more of Idaho’s dairy industry, the conflicts between people and cattle are increasing

By Scott Weaver

On a quiet June day, Dave Diment looked out from his front porch at a field of grass washing in the wind. Diment lives on and farms a patch of land in the Magic Valley just north of Jerome. A small, but significant, farm is located close to the former Japanese Internment camp where the National Park Service is building a memorial.

Diment, in any measure, an enormous man, with long, sun-soaked hands that exude power in a handshake. He makes his living growing hay and corn for the dairies that populate this area where he has lived nearly all of his life. It’s a good place for this kind of farming. Three counties in the Magic Valley—Jerome, Custer, and Twin Falls—have the highest concentration of dairies in the state.

So you wouldn’t expect Diment—a self-described staunch Republican—to side with a movement to slow and even stop the expansion of large dairies. But as he looks over the field just feet from his back door, the contradiction begins to make sense.

Over the last two decades, the vision of a dairy has morphed from an idyllic setting to an industrialized, high-tech feedlot—factory farms. This is one of the concentrated animal feeding operations. The process of economies of scale, dairies and feedlots grow into expansive operations able to hold tens of thousands of animals.

The nearest field is more than a mile away, but you could toss a rock from the porch into its stalls. It belongs to South View Dairy, which has had trouble finding a site to open its new 5,000-head feedlot on 60 acres one mile upwind of Minooka and next to Diment’s farm.

There are a lot of good dairyman out there,” said Diment. “This dairy industry has been really good for this area. There are some that try to take care of their neighbors. But these guys just want to come in and build this mega-facility.”

The fight over South View became an embattlement that Jerome Sheriff David Hinds used natural selection to search the public for a weapon for the hearing. During the hearing, a woman was led by a bull by the courtroom after refusing to yield the floor to the county commission chairman.

In many ways, South View is emblematic of what former Jerome County Commissioner Daria Orman recently called a shift in public attitudes about CAFOs in their county.

While the dairy and beef industries are revenue generators for counties and financial bettholders for the state and the 10th-leading producer of milk and dairy products in the nation, many who live and work near CAFOs diminish the physical and environmental landscape are fighting for their property rights and better regulations of operations. And to make their voices heard.

“We all have cows. We all understand them,” Diment said. “But these things need to be located out in the middle. They can’t affect your people. These guys came in and wanted to put it right on top of us.

During the 1980s, an exodus of dairies from California reshaped Idaho. By 1997, income from dairy products exceeded those from the state’s signature crop, potatoes. The next year, dairy outpaced both potatoes and beef. Dairy operations fleeing California’s regulations found in Idaho a state with space and a welcoming attitude.

But the boom didn’t translate into more dairies. Between 1990 and 2007, the number of dairies dropped from 1,952 to 648. During the same period, the amount of milk produced skyrocketed from just less than 3 billion pounds to 11 billion pounds.

What was once an industry of small farmers has become dependent on CAFOs. The average herd size increased from 20 cattle in 1990 to 763 in 2007. The decrease in dairies coupled with the increase in herd sizes puts more animals in fewer concentrated areas.

CAFO’s environmental impacts are evident. During 1,000-plus cows in a confined space produces an enormous amount of animal waste that often contains high levels of nutrients, pesticides and pharmaceuticals, if not properly handled, it can leak into surface and ground water. According to a 2008 paper in Environmental Health Perspectives, this happens all too often.

“Based on available data, generally accepted livestock waste management practices do not adequately or effectively protect water resources from contamination with excessive nutrients, microbial pathogens and pharmaceuticals present in waste.”

The Idaho Department of Environmental Quality has found increasing levels of nitrogen in areas heavily populated with CAFOs. These levels are caused by fertilizer applications—including spraying of liquid manure onto fields—and agricultural activities of confined animal feeding operations. High nitrate levels in water can cause brain damage in infants and has been associated with reproductive problems and cancer, according to researchers at Colorado State University.

According to the EQC, nitrate is a concern because more than 95 percent of Idaho’s drinking water comes from groundwater. The Magic Valley and its CAFOs sit on the Eastern Snake River Plain, the only source of drinking water for 200,000 people in Southern Idaho.

Cow Country: The Rise of the CAFD in Idaho | As mega-daileks and...hoarse people and cattle are licensoring | Features | Boise Weekly
2/17/15, 10:29 AM

STILL, residents were only able to submit a portion of the documents they wanted because of the tight deadlines and short notification.

Roughly 25 homes around the dairy are on wells or underground. Many who live them, in homes built before the dairy moved in, are fed economically to the dairies of Treasure County, whether they work for them or supply them with things like feed.

That a dairy wanted to expand in an area already concentrated with CAFDs was a concern. But that the dairy was the Ted Miller Dairy was another issue. Just one of the 243 dairy CAFDs in Idaho, the Ted Miller Dairy has a curious story.

It began in 1969/1970 in C Bar, a high-bred dairy owned by Greg Sibbett, who became Idaho’s state veterinarian in 2005—and his wife, Jane, ISDA records show five dairies or non-compliances in the past 10 years, a violation of the rules governing dairy CAFDs. In 2001 a permit was issued; and in 2003 the dairy experienced water from its fountain on a country road. These types of violations usually result in a larger problem—a much more water and not enough storage capacity.

But the most egregious dairy case came in 2008, when a C Bar M hurricane was large enough that buildings (located from one to five miles from directly to the Black River. C Bar M was sent $3,800 by the Environmental Protection Agency.

This was the only time that C Bar M had been fined for an illegal discharge, while ISDA had previously fined the dairy for failing to locate more than 100 calves against deadlocks, it has never been a fine against a dairies for the dairy’s numerous non-compliances.

After the DPA files, C Bar M changed its name to the Ted Miller Dairy.  

Multiple calls to the member listed for the Ted Miller Dairy were not answered.

At the late-morning public hearing, most of the people who live near the dairy spoke against the expansion. According to Jacob, the only people in favor of the expansion were Ted Miller employees and the dairy’s lawyers.

"There’s really nobody here who is anti-dairy, saying CAFDs should be eliminated," Jacob said. "They’re for people making money. People need to make money, but they need to do things in a manner that’s legal,” and in a manner that’s going to make a sustainable dairy.

Almost all of the people interviewed for this story agree on one thing: Idaho needs to raise its dairy. The majority make their living from agriculture and are astounded about the fact that most operate their farms to raise their families and working with neighbors.

Bernard Farms is one such operator. He tells roughly 95 cows and walks 60 to 70. Because the cows are kept in an open lot, or corral, it’s classified as a CAFD. Because of its small herd size, Bernard Farms doesn’t have a major impact on the water. Instead, it composts manure during the summer and fall.

"Everyone I talk to in the dairy industry tries to do the right things," said Steve Barrall. "We try to talk to our neighbors and make sure everything is going well with them, that we’re not a nuisance to anyone."

Barrall said that his irrigation equipment sprays the dirt road the farm shares with a neighbor, creating noise, he will come back and grade the road.

Meanwhile, many of Ted Miller Dairy’s neighbors have had to spend $1,500 to $8,000 to re-drill wells because of the growing water use, Jacob said.

He finally felt the impact of living close to so many CAFDs more personally and profoundly. But moving away from a CAFD is a complicated and money-losing proposition. CAFDs and their small-scale, dust, noise and tills are all on the list. Making matters worse, there is a huge financial cost, a huge economic cost.

Johnstone Road in Treasure County is just as rocky as the mountains that serve as its backdrop. Countless trucks and tracks have taken their toll. Half-burned county roads, built up by the constant and heavy traffic missing animals and waste, are a reality of living near CAFDs.

When I first met Helen Kettles, she’s trimming the branches of trees that line the dirt path from Johnstone to the farm. A retired DIT, Kettles’ face shows the years she’s spent under the sun, riding horses and working her farm.

"I thought I’d be farm hands," she said later as we walked out toward the property line she shares with Wilkie Fendall, a 6/100-head kitten replacement CAFD. Kettles and her then-husband bought the land in 1979 and built the house where she lives in 1985.

A barn separates Kettles property from Wilkie. Whether the dirt of size, manure and rocks constitutes a barn has been a contentious source of debate and quickening arguments for years. On top of the barn sits two parallel railings left by the CAFDs’ owner. They are not Dischmann school-adolescents.

Just across the bordered fence from the barn, hundreds of feet. Like the CAFDs from the Shit Town, manure is scattered nearly 100 feet high. The pigs—"cow condo" in the vernacular—are so large that some keepers leave on their touring, surrounding themselves.

For more than four years, Kettles tried to sell for place after a series of incidents with the Ted Miller Dairy. After Wilkie’s water and manure fouled her property in 2005, a conditional use permit issued by Treasure County required Wilkie to build an engineered fence to keep water from the property line.

The nature of the thing that situating the fence line is debatable. It’s essentially a fence line of dirt and gravel remote to keep water from running 30 feet from the cow pens onto Kettles property. Whether an engineer designed the fence is also debatable.

Then there are the toilets. They appeared after Kettles complained to Southwest District Health that Wilkie employees had been dumping the toilets and defecating on her property.

According to both Kettles and Allen Hesse, where the two were walking along the fence and taking pictures of the toilets, the owner had been told and threatened to take Hesse’s camera from him. Both women left shaken.

"You think of the worst person, the term makes you think friendly or caring about another human being," Kettles said. "This is certainly not them, and I wouldn’t call them neighbors."

When asked if e-mail the toilets, barn and relationship with the farm’s neighbors, a Wilkie representative, who repeatedly declined to be named, sent her this two-sentence statement:

"The lease is approved, meets required government specifications and has never failed, and any claims otherwise are incorrect. We adhere to, and are in compliance with, all State and Federal mandates and state environmental regulations."

The representative did not answer questions about the toilets.

After the Site 1999 disputes, Kettles, and Wilkie paid less than $1,000 for a new well pump and it’s time to plant along the property line. Wilkie was also fined $9,000 by ISDA, but only past $50 of the fine, the rest went into abeyance, to be levied in the future if necessary. Dakey said that holding the majority of fines in abeyance is "not an uncommon practice."

"An illegal tree doesn’t do anything to protect the neighbor from future discharge," said Dakey. "But if there’s $4,500 in looming penalty money, they need to get it done."

While that may be true, in Cattle’s case, there’s the issue of the barn. It needed to be installed by Dec. 31, 2005, by NRCS standards and approved by ISDA. On the day that United Kettle in early April, rather than these things had been done. Two weeks later, when inspected by ISDA officials, the barn had been approved, even though there were never any evidence of engineering documents.

Why did it take five years for ISDA to approve the barn while holding the majority of Wilke’s fine in abeyance?

"I don’t have a good answer for that," said Van Matz, the chief of the ISDA Dairy and Egg bureau. "I think there was some confusion."

Back in Treasure County, the Kettles are still waiting to see if they’ll be next to a CAFD. If South Valley is built, the Kettles aren’t sure if they’ll be able to stay in their home of 12 years.

"I just don’t think I’d want to live in this house," he said, sitting at the kitchen table, a glass pitcher of pink lemonade his wife Eden just made in front of him, unfolded. "I know it’s not huge and fancy, but it’s ours."

In the other room, a boy, maybe 3 or 4 years old, wakes up from a nap on the couch. His father’s voice is breath and was born premature. The Kettle pediatrician told them that they can’t live next to anything like a CAFD. His lungs couldn’t handle it.

"If it goes in," said Eden with a sigh, "nobody would want to buy our house. But we can’t live here."

**CORRECTION:** The C Bar M dairy began operations in 1880, not 1980, as the story previously reported. It changed its name to the Ted Miller Dairy in 2003.

Page 5 of 10
formation exhibit extensive weathering which may extend to considerable depths - as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS examined whether the two waterbodies within Māhāʻulepū Valley might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**POTABLE WATER:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the existing Māhāʻulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāʻulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of
groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well. Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kīloa Fowell in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauaʻi community.

**Regional Water Demand:** The adjacent, developed Kōkoʻa-Poʻipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauaʻi will increase county-wide by 17,300 residents by 2030. The South Kauaʻi population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauaʻi region (the Kōkoʻa-Poʻipū-Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhūʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūʻulepū Road. This ditch, named Waiopīli Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment log around drain inlets.

**Surface Water Quality:** The Kauaʻi Chapter of the Surfrider Foundation began collecting water samples in Waiopīli Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopīli Ditch, or of surface waters in the Māhūʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopīli Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhūʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopīli Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopīli Ditch Sanitary Survey, Kauaʻi, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhūʻulepū Valley. The ditch runs along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopīli Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to
create filter strips that could capture particulates during stormwater runoff events. Waioli Ditch provides the majority of freshwater input to the immediate coastal zone and marine environment. The mouth area is highly eroded, forming a meandering channel with some alluvial deposits within the Ditch itself. With the help of the USGS, the creeks drain into the Ditch and have been sampled for bacteria and nutrient levels. Nutrients from Waioli Ditch are transported to the nearshore ocean, which is protected by the coral reef. The bacteria and nutrient levels in the Ditch are monitored daily, ensuring that nutrient concentrations are not above the background levels. As a result, the EIS provides an excellent assessment of the water quality impacts of the project on the nearshore ocean. The groundwater and surface water analysis conducted for the Environmental Impact Statement (EIS) is included in the Draft EIS as Appendix F.
DUST
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylot” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM<sub>10</sub> and PM<sub>2.5</sub>) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM<sub>10</sub> is 2.01 μg/m<sup>3</sup>, well below the State standard of 150 μg/m<sup>3</sup>. The estimated concentration for PM<sub>2.5</sub> is 0.23 μg/m<sup>3</sup>, well below the Federal standard of 35 μg/m<sup>3</sup> (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR
Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Dear Collin Fleming & Kim Factor:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāʻulepū Valley on the island of Kauai to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy." The term "zero-discharge" under the U.S.
Environmental Protection Agency related to concentrated feeding operations. States. As not noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to groundwater and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow herd to operate at capacity, especially given the evolving definition of "grass-fed". The term in not used in this EIS.

Agricultural infrastructure and utilities required for the dairy operations, and drainage improvements: The irrigation system and distribution of livestock water ef fluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 dairy cows, and over 60 days of storage for the committed 699-cow herd. The effluent storage ponds are designed to accommodate 30 days of storage for up to 2,000 dairy cows, and over 60 days of storage for the committed 699-cow herd. The effluent storage ponds are designed to accommodate 30 days of storage for up to 2,000 dairy cows, and over 60 days of storage for the committed 699-cow herd. The effluent storage ponds are designed to accommodate 30 days of storage for up to 2,000 dairy cows, and over 60 days of storage for the committed 699-cow herd.
Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. Licensed veterinarians may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plachy Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawaii‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (367,198,700 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22, and 4.23; the technical reports are in Appendixes E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimānalo volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhū‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The
material. The alluvial material blanketing the valley floor is less permeable than the groundwater in the deep aquifer were documented. Future monitoring will allow unweathered volcanics by orders of magnitude. Hydraulic conductivity represents comparison between conditions prior to, and during, HDF operations. Results from the ability of soils to transport water given a hydraulic gradient, and is expressed in the monitoring program will be shared with the Department of Health Clean Water units of feet per day. It is a measure of how easily water will move within the project's growth and water demand anticipated in the region through 2055.

**SURFACE WATER**

**Regional Water Demand:**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Mānāiki Deep Surface Water Hydrologic Unit, which features relatively high precipitation with relatively slow movement through the HP site across the valley floor, and meets a concrete ditch that parallels the West Ridge. These normally dry streams converge into man-made channels running towards the north.

Replenishment from Construction: The dairy facility and associated infrastructure will be constructed on a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural and non-structural erosion control measures; minimizing dust generation; and implementing sediment collection in key locations and storage facilities.

**Surface Water Quality:** The Ka‘au Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi.
Collin Fleming & Kim Factor
May 26, 2016
Page 9 of 15

Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The deme canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb.).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35 feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageway; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The deme canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb/).

Impact to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient concentrations in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water
masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua’i community.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhāʻulepū Road, a two-way, two-lane road, which is accessible from Koloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhāʻulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua’i and rural agricultural demographics of the south Kaua’i area and Māhāʻulepū. Traffic on Māhāʻulepū Road consists of agricultural vehicles, residential and resort/visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhāʻulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Koloa Road was 8,000 and 6,500 cars daily. HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Koloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have an minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai’i’s Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai’i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy operations include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua’i and the total concentration was compared to the State ambient
air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM$_{10}$ is 0.21 μg/m$^3$, well below the State standard of 150 μg/m$^3$. The estimated concentration for PM$_{2.5}$ is 0.23 μg/m$^3$, well below the Federal standard of 35 μg/m$^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be detectable. By creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year; within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

**ALTERNATIVES**

As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. These alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawaii, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow
local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

- However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 6) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
As any entomologist will confirm, one fly lays a minimum of 300 eggs and they prefer warm wet manure. The types that develop in manure are horn flies, stable flies, deer flies and horseflies; all piercing sucking flies that exist on blood. Our frequent rains will greatly increase the proliferation and these insects can fly up to 4 miles from the HDF site. Within a few months, there will be billions of flies. The EIS must offer proof that this will not happen. Please hire the best environmental entomologist available for your study. We also need to know the facts as to how the HDF will control run off. Gravity operates at even a small pitch (especially over clay soil) and this land is only 65 feet above sea level. Although the proposed sloping the land to the ditches could encourage control of the run off, you are really just passing it to the Waipii stream which runs to the ocean. In a few years it will have polluted all the beaches along the south shore. In addition, how you will reduce the Nitrates in the water and the methane gas contribution to our fragile Ozone layer.

The overall probable long-term impact of allowing HDF to go into production is as follows:

- There will be no more eating on our lanais, thriving outdoor restaurants or picnics on the beach.
- Bankruptcy of restaurants, businesses and condos will follow.
- Unemployment will be rampant as the economy of the entire island gradually dies from loss of jobs related to the loss of our profitable Visitor Industry.

In return HDF will provide maybe a dozen "filthy jobs". Certainly that is not an acceptable trade off.

As I stated earlier, HDF is a bad idea for the proposed Mahalalepu location and I'm an objectively conducted EIS will bear that out.

Sincerely,

Karl Forer
1939 Haelekaana St.
Lihue, HI 96766
Dear Karl Forer:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhū‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" as used by the U.S. Environmental Protection Agency related to concentrated feeding operations (CARE) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero-discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd's diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhū‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mobs", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period grazing on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be...
Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of animal health protocols and monitored for treatment of illnesses. Alternative treatment of illness may precipitate use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of bovine illnesses and ensure the herd’s well-being. A pooled testing of milk from cows for laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for off-site herd management, refer to Section 3.7 of the Draft EIS.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigation systems. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The NRCS Conservation Practice Standard 590, Nutrient Management, applies to dairy. Throughout the less than 30-day storage period, effluent is planned for use at least once every three days and application is spread at least once every seven days. The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,500 mature dairy cows, and over 85 days of storage for mature dairy cows. The menus contain of 2,000-dairy cows, and during the cold period up to 3,000-dairy cows are fed. HDF will prevent and control fly population growth through diligent cleanup and sanitary practices regarding any trash and food waste, as well as through efficient manure management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The timing and application of nutrients will correspond with plant uptake, soil properties, and weather conditions. For more information on nutrient balance and planning, refer to EIS-Section 3.5, and Draft EIS-Appendix D.

A study of invertébrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes presence or absence of native species or pest associated with cattle and livestock. Invertébrate species were noted in the survey of the site. A full report and list of invertébrates species observed on the HDF site are provided in Section 4.11 of the Draft EIS. The project location does not provide any habitat for drosophila, or stable flies. A full report of the study is located in the high-elevation koa-forest.

The horn fly, the latter known for biting cattle, is an important insect to minimize fly-breeding habitat in nature. In the drosophila, two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are not noted in the survey of the site. A full report and list of invertébrate species noted in the survey of the site are provided in Section 4.11 of the Draft EIS. The project location does not provide any habitat for drosophila, or stable flies. A full report of the study is located in the high-elevation koa-forest.

The timing and application of nutrients will correspond with plant uptake, soil properties, and weather conditions. For more information on nutrient balance and planning, refer to EIS-Section 3.5, and Draft EIS-Appendix D.

Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will be facilitated by the dairy and other methods including moving cattle to and from the Dairy.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizer, organic fertilizer, cattle manure, and animal waste. Nutrient management is the practice of managing the amount, rate, timing, and placement of plant nutrients and soil amendments.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizer, organic fertilizer, cattle manure, and animal waste. Nutrient management is the practice of managing the amount, rate, timing, and placement of plant nutrients and soil amendments.
manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pads in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po'ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ah Kinoiki Road between Kōloa and Po'ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofer, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment associated with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waima volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepi Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the
unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhūʻulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poʻipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two water bodies within Māhūʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaiʻi Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhūʻulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and will not remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhūʻulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhūʻulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poʻipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two water bodies within Māhūʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaiʻi Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhūʻulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and will not remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhūʻulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauaʻi community.

**Regional Water Demand:** The adjacent, developed Kōloa-Poʻipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauaʻi will increase county-wide by 17,300 residents by 2030. The South Kauaʻi region is projected to encompass 19.2 percent of the County population. For the South Kauaʻi region (the Kōloa - Poʻipū - Kalaehe districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhūʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hāʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery.

Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kauaʻi Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to evaluate the data.
to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Mâhâulepú Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a Sanitary Survey of the Mâhâulepú and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Mâhâulepú Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the tops of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Efficient Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Mâhâulepú will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major to fall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kūloa-Po’ipū region were also calculated. Nitrogen input to the marine environment in the Po’ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po’ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment:** An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator
bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impairment report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EBS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours— in two separate milking cycles—moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical application. No State or Federal regulations for greenhouse gas emissions from farm operation units in residential areas. Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within a area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odor winds from east to west would be less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.
GREENHOUSE GASSES: Draft Environmental Impact Statement (EIS) Sections 4.19 and 4.26 address the potential for greenhouse gas emissions by Hawai'i Dairy Farms (HDF). Estimates of GHG emission rates from a pasture-based dairy, including methane and nitrous oxide, were calculated using the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas Inventories. Parameters for Oceanic dairy cattle in warm climates were selected as most applicable to conditions at HDF. Long-term operational impacts were modeled using the IPCC guidelines and conversions, and estimated the emissions potential for GHG at the dairy at the committed herd size of 699 milking cows to be 2,693 CO2e metric tons per year. This equates to roughly 1.02 percent of the utility power generation sector on Kauai in 2013, which does not include vehicle emissions and other GHG emitters on the island.

Potential GHG emissions for HDF at the contemplated herd size of up to 2,000 milking cows was modeled as described in Section 4.19.3 using the IPCC guidelines and conversions. The estimated total of 7,702 CO2e metric tons per year (8,490 tons) is 5,009 CO2e metric tons (5,521 tons) greater than the committed herd size of 699 milking cows. This equates to an increase equivalent to 1.91 percent of GHG produced on Kauai for power generation by the utility in 2013 (Hawaii Island Utilities, 2013). Power generation does not include vehicle emissions and other GHG emitters on the island.

While the presence of cows may increase GHG, a long-term beneficial impact of the grazing fields is the sequestration of carbon as CO2 captured by the process of photosynthesis by the grass. According to recent studies in the Soil Science Society of America Journal, converting formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, which enhances soil quality, grass production, and has the potential to offset up to one-third the annual increase in CO2 production on an area.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii's Dairy Farms", http://tiger.unl.edu/OEQC/11A1

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Hawai‘i Dairy Farms

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

The following responses are offered to your comments:

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaching fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

SOIL conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soil Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ke‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, calcium, magnesium, organic matter, salinity, micronutrients, and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline for runoff and infiltration conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

SOIL conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in
As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL:

The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPDD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā‘ulepū Ahupu‘a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

NOISE:

Existing noise conditions of the project site and the surrounding Māhā‘ulepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai‘i Department of Health (DOH) rules use the A-weighting sound network (DIA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the “soft ground” absorbs extra sound as it passes. The Hawai‘i Dairy Farms (HDF) site in Māhā‘ulepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than $250,000. Mitigation measures to minimize construction noise will...
include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai’i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production, the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kūloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā’ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary remnants of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the...
ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōkō-Poʻipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two water bodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County’s Kōkō F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōkō F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment log around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.
recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CBW to conduct a "Sanitary Survey" of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CBW noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create water strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downstream from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively dispenses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.
Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be initiated in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CBWL dairy neighbors and the local Kaua‘i community.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site is via Māhāʻulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from Māhāʻulepū Road.

Roadways in the project area operate smoothly with no periods of heavy traffic. On average, traffic in the region is much lower than urban areas in the state due to the low population of Kaua‘i and rural agricultural demographics of the south Kaua‘i area and Māhāʻulepū. Traffic on Māhāʻulepū Road consists of agricultural vehicles, residential and resort/visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhāʻulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Kōloa Road was 8,000 and 6,500 cars daily. HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Kōloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai‘i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odors. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farming operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions. Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM2.5 is 0.61 μg/m³, well below the State standard of 15 μg/m³.
is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search “Hawaii Dairy Farms”: http://tinyurl.com/OKCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

Re: EISP - Hawaii Dairy Farm

Mahā'ulepu. The place name evokes fondest memories. Since discovering this pristine spot on a guided walk with Mahama Mahā'ulepu President, Beryl Balish in 2006, Kaua'i's last undeveloped watershed has been the "special hike" we've taken with family and friends. Everyone recognizes immediately its spectacular beauty; preserving its rare character is naturally a topic of our conversations.

Now we're learning about Wai'opili Stream pollutants from Dr. Carl Berg's water tests, confirmed and retesting done currently by Hawaii State Dept of Health. And that Hawaii Dairy Farms (HDF) wants to install a dairy farm on this land of not only priceless beauty but of historically significant archeological sites — holualoa burial, petroglyphs, tide pools, salt beds — and cultural practices performed to this day. Several visits to Makauwahi Cave Reserve greatly inspires Mahā'ulepu's protection.

Kyle Datta, general partner Ulupono Initiative states the dairy's purpose is "to produce fresh, local milk for families across Hawaii State at prices everyone can afford" and that the dairy "will strengthen the ability of the agricultural sector to continue to provide meaningful jobs and valuable economic support for Kaua'i." Highly debatable.

In my opinion, the strengths of Kaua'i are our Environment — clean Air, clean Water, clean Land, clean Ocean — and the Spirit of our Citizenry. Environmental degradation continually takes place from chemical sprays, fuels, exhaust, landfills, poor practices such as discarding plastics and nets in the sea, the presence of people and animals, and so forth.

I oppose HDF's dairy plan. Collective manure calculations, clay soils allowing manure/urine run-off into the vital land and surrounding sea are recipes for disaster. Hawaii State Dept of Health should fear well-water contamination. Dr. Katherine Muzik, Marine Biologist, told me her dive in waters off Mahā'ulepu revealed a gorgeous living coral, large as a car. How long will our land and seas sustain viability with constant cow mess run-off? We cannot keep compromising our environment with unchecked development after unchecked development.

HDF plans copious water withdrawals from the Waipoua Reservoir. That must not be allowed to happen. Water belongs to everyone per our Hawaii State Supreme Court.

And the odoriferous stink! No one wants to smell a dairy farm, not even residents or visitors. Think reduced residential and business property values. Think residents suffering (if they can) and leaving; think visitors flying elsewhere.

Flies. They always accompany cows. HDF plans to keep importation, a foolish if not absurd idea. Dealing with a negative with another negative results in two (2) negatives. Example: importation of guinea grass to feed earlier livestock has resulted in island-wide, invasion or that crisis.

Subject: Hawai’i’s Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā’ulepū Road
Kaua‘i, Hawai‘i

TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Sharon Goodwin:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai’i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-294. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with prehistoric and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā’ulepū Ahupua‘a, and has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā’ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the
HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for drosophila musaphilila, the only Kauai species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-ʻōhiʻa forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhā‘ukū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pads in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po‘ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ae Kinoiki Road between Kōloa and Po‘ipū, and it is probable that livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawaii’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk will be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii’s Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement.
Groundwater

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimānalo volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 1.05 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day.

Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai’i Department of Health Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua’i community.

Regional Water Demand: The adjacent, developed Kōloa-Poipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DREDT) projects the population of Kaua’i will increase county-wide by 17,300 residents by 2030. The South Kaua’i population is estimated to reach 16,855 in 2035, when it is projected to encompass 192 percent of the County population. For the South Kaua’i region (the Kōloa - Poipū – Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Surface Water

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the ʻHaʻupu...
Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and area upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” [here](http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that can capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-PO‘ipu region were also calculated. Nitrogen input to the marine environment in the PO‘ipu region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater
and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kauai' community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odor and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. ES sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kauai¹ and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

ODOR emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy feeders and effluent ponds were adopted to reflect the HDF facilities.

ODOR emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of
panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1.670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawaii’s Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Questions and Concerns Re EIS for HDF

Group 70 International Inc.
Attn: HDF a Project
Honolulu, HI 96813

Hawaii State Dept of Health
environmental Planning Office
Honolulu, HI. 96914

To whom it may concern:

MAHA’ULEPU is a living museum with its diverse ecologies, endangered species and cultural sites. It is imperative that the E.I.S. process acknowledges that there may be many more discoveries yet to be unveiled. How can these be protected and managed? Recent findings by HDF of petroglyph rocks and heiau are examples of this. Please address protection issues for any existing cultural artifacts such as petroglyph rocks and heiau and the ability of the Native practitioners to be able to continue their practices.

The type of soil in the valley is particularly suited for Kalo cultivation. Surely the run off from the proposed Dairy will impact the existing soil preventing production of Kalo or anything else in the future? How will run off affect the quality of the soil and the Former Salt Pans which can be restored?

Will there be percolation tests conducted? Ground water and surface water contamination is of major concern as the high water table is down from the dairy site. The valley floor is subject to flooding, the possible impacts of run off, spillage etc into the aquifer and ocean must be determined. Waiopli stream cannot afford more pollution and the impacts on the health of beach goers, as well as the oceans, reefs, fishing and endangered sea creatures could be dire. How is this being assessed?

Will a hydrology study be conducted to include both Maha’ulepu and Pa’a?

How will the odors and flies be controlled? Using chemicals and introducing other species to ameliorate flies could result in more environmental and pollution problems.

There are endangered species existing in the valley itself how will these be protected?

The flies, odor and degradation of the beaches would have severe economic and health impacts on the South shore community and visitor industry. Already there are less visitor bookings for 2016 due to the possible Dairy. There are thousands of people whose livelihoods depend upon the visitor industry whereas the Dairy will be employing very few. Please explain how this can be good for our community.

Hawaiians had sustainable ag without milk. Milk is well known to not be good for human consumption. If the milk is shipped off island to be processed how is this sustainable ag and where is the economic validity in such a process? Who is going to make money?
How will the dairy operations impact the local roads? Will more roads need to be built? What are the traffic implications on already congested roads? Will more roads be built in the Valley? If so how will this impact the environment?

What are the implications of the island wide increased bovine populations on our island as a whole?

How can this EIS be non biased with Group 70 as the provider?

This is a Sacred Place please let’s treat it with the respect it deserves and do everything that can be done to ensure that there is no damage to this area.

Thank you for your consideration.

Subject: Hawai’i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā‘ulepū Road
Kaua‘i, Hawai‘i

Dear Yojana Grace:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBVIOUSLY:

Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai‘i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai‘i Revised Statutes and the “Environmental Impact Statement Rules” (Chapter 200 of Title 11, Hawai‘i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai‘i Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70’s
growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure fertilizer. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai’i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhūale’ip property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai’i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua’i and Niihau region of the Hawaiian Islands...
has experienced tremors from earthquakes originating further south in the island chain and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs of the potential cultural resources, practices or beliefs of Native Hawaiian people. The cultural assessment concluded that no adverse effect would be expected from the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The sixteenth historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the affected Kauai sites are located along the proposed project line. Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and are located within or along the established survey area. Only one of the sites is believed to be associated with prehistoric or early historic times. State Site 50-30-102398, the agricultural heiau, and State Site 50-30-102399, a carved petroglyph boulder, are all located outside of the project area.

Preparedness is the best protection for natural disasters. Structural design of dairy structures is necessary, as explored through survey and subsurface exploration. The project will be fully covered and enclosed by perimeter fencing along the boundary of the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and C.

An emergency preparedness plan for protection of animals has been prepared for both the dairy site and surrounding area. The emergency plan also includes provisions for protection of the dairy project and animal health. The plan includes procedures for evacuation, containment, and control of any disease outbreak. The plan is designed to ensure that animals are protected and that the project is not impacted during any disease outbreak.

Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the Site 50-30-102398. The sites are located along the northern boundary of the proposed project, Site 50-30-102398 and Site 50-30-102399, are located outside of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and are located within or along the established survey area. Only one of the sites is believed to be associated with prehistoric or early historic times. State Site 50-30-102398, the agricultural heiau, and Site 50-30-102399, a carved petroglyph boulder, are all located outside of the project area.
Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are plants that occur or could survive if planted, native plants will be used in the stabilization. HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species list. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōoa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to protect specified areas, marking tall structures and fencing with white visibility polystyrene, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roosts within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

**PESTS:** A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarized the presence or absence of native species or pest species associated with cattle manure in the general Māhā'ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai‘i’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plauché Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.
The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include technical consultants conducted field studies and analysis on water quality:

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā’ulepū Valley and the HDF site ranges from 10.5 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipu region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā’ulepū Valley and the HDF site ranges from 10.5 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipu region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis conducted for this Draft EIS examined whether the two waterbodies within Māhā’ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational, at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk
Rules require that potable water be used for milk production, both in the milking parlors and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōkā F well, will result in no adverse impact to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot distance between the Kōkā F well is agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōlā-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōlā - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3,242 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off the south slope of the Hā‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Economic Development and Tourism (DBEDT) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either marine recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent waterheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library”. (http://health.hawaii.gov/cwb)
TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site along Highway 530 via Koa Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from the ditch. The rapid decrease is likely a result of physical mixing of water and nutrient inputs in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that extends to the ditch. The rapid decrease is likely a result of physical mixing of water and nutrient inputs in accordance with best management practices.

The minor contributions of nutrients from episodic rainfall are anticipated to occur just 10 days annually from dairy operations, which would be conducted during such weather events. Establishments of buffer and pasture grasses, keeping nutrient applications away from streambanks, will be established. Nutrient applied in the nearshore water monitoring program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern.

TRAFFIC: The Draft Environmental Impact Statement (EIS) Section 4.18 and 4.25 includes an evaluation of roadways and traffic conditions, along with potential impacts of the dairy farm construction and operation. Primary access to the site along Highway 530 via Koa Road. Within the project area, there is a network of unimproved private agriculture haul roads that provide access to and from the ditch. The rapid decrease is likely a result of physical mixing of water and nutrient inputs in accordance with best management practices.
area and Māhā‘ulepū. Traffic on Māhā‘ulepū Road consists of agricultural vehicles, residential and resort visitor traffic.

During construction, the proposed project is not expected to have a significant short term impact on traffic operations in the project vicinity. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations. There will be no change to traffic patterns or infrastructure related to the public roads.

Traffic operations along Māhā‘ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 cows would include 5 daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. Daily traffic along Ala Kinoiki Road and Köloa Road was 8,000 and 6,500 cars daily. HDF-related traffic would add less than one percent additional trips. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

At a contemplated herd size of up to 2,000 cows, an additional 11 vehicle trips per day would access the HDF site, for a total of 23 vehicle trips daily. Projections for daily vehicle movements in 2035 for Ala Kinoiki Road and Köloa Road are 7,200 and 9,500 daily vehicles. HDF-related traffic would add less than one percent. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area. Traffic data is presented in the Draft EIS Sections 4.18 and 4.24.

Construction equipment mobilization will comply with Hawai‘i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

**AIR QUALITY:** As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. ER sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the **Clean Air Act of 1970** (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own *State Ambient Air Quality Standards (SAAQS)* that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄; from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kau‘a‘i and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.
Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odor would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawaii Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

To Whom It May Concern:

I am writing as a concerned citizen and business owner in Poipu, Kauai that would be greatly affected by the proposed Hawaii Dairy Farm site near the coastline of Mala‘ulepu. Should a dairy farm be allowed to put cows near an already contaminated stream it could not only affect the marine life in our small community, but our island’s entire economy. Our main source of income for the island is tourism.

The proposed dairy site is on one of the most pristine destinations on our island with historical significance and the home to endangered species. I personally live in the area that would be affected by the constant smell of feces and flies as do the majority of my employees. My husband and I also own a vacation rental management company with the majority of our properties in the Poipu area. I can say for certain that NO ONE will want to stay in Poipu if they have to endure that kind of environment. They will go to Maui or perhaps not even come to Hawaii at all.

As a licensed real estate broker on Kauai I know that our overall property values will also be greatly diminished.

I strongly urge you to oppose the construction of a commercial dairy farm at Mala‘ulepu.

Sincerely,

Amy Grant, R

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua‘i, Hawai‘i

TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001: 001 portion

Dear Amy Grant:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $60,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E...
and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

Though this study was intended for local use, the results could be significant for similar projects. The shallow groundwater body in the alluvium, which lies in the lower portion of the valley, is the source of potable water. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths. The alluvial material blanketing the valley floor is less permeable than the Parent material. The alluvial material at depth, which is the source of potable water, is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

GROUND WATER

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the dairy and the groundwater in the alluvial layer, which is the source of potable water, will result in no adverse impacts to ongoing use of groundwater in the alluvial layer. Therefore, water movement through soils under the proposed dairy site is 10 times lower than the nearby agricultural area.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater and the alluvial surface water in the shallow aquifer within the alluvium are documented in Table 1. Future groundwater monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department.

Potable Water: Once fully operational, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater and surface water. Should HDF decide, in the future, to expand to the contemplated 2,000 mature dairy cows, the dairy will utilize 50,000 gallons per day (gpd) which is 0.05 million gallons per day (MGD), of potable (drinking water quality) water from groundwater and surface water. The State Department of Land and Natural Resources, Commission on Water Resources, and the Hawaii Department of Health, DoH, will be involved in the review of HDF’s application to use off-site water resources. HDF has a formal agreement with the University of Hawaii to use their lab facilities for groundwater analysis, and has explored the possibility of using their lab facilities for surface water quality analysis.
through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery.

Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and a area upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The demo canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainage way (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The nitrogen fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 423 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater
and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipio Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were evaluated, and currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai'i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua'i, and the total concentration was compared to the State ambient air quality standards. Only the contoured herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-192).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adopted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of
panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 240 hours, or 44 hours per year, within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai’i Dairy Farms”: http://tqurl.com/050CKAUA

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kīlauea series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhūle‘upā Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhūle‘upā may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhūle‘upā 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhūle‘upā 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of...
Groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kīloa Fowell in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauaʻi community.

Regional Water Demand: The adjacent, developed Kōā-Poʻipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauaʻi will increase county-wide by 17,300 residents by 2030. The South Kauaʻi population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauaʻi region (the Kōā - Poʻipū - Kalåheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhūʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauaʻi Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data; however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhūʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhūʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator bacteria levels found in ditches running through Māhūʻulepū Valley. The ditch confluence at the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to...
create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūʻalepā will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment.** An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipōlī Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occur rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively dispenses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Dear Kathleen Hadwin:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice. HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system.
The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system. Instead, the term “hydrostatically designed” has been used in the document. The term “hydrostatically designed” is defined as a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the nutrients in the water and any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. The irrigation water supply is provided to the farm from Waiola Reservoir, and will be filtered and pumped to the various irrigation component parts on the farm. The irrigation water is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pastures will be managed or restored to reduce erosion, improve stability of ditch banks, and increase net carbon storage, and improve and maintain water quality. The practice of irrigation and/or effluent application on the pastures is supported by utility and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

The pastoral rotational-grazing dairy provides a local feedstock—grass—as the herd's primary food source. Reducing imported feedstocks and providing a local food source closer to the natural diet of cows stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in defining the practice of rotational grazing for the proposed dairy operation. The results of these trials were instrumental in defining the practice of rotational grazing for the proposed dairy operation. The committed herd size of 500 mature dairy cows will be highly unlikely that the storage pond will be full at any time for the contemplated 2,600-cow dairy and nearly impossible for the committed 600-cow dairy operation. Every 45 days, to ensure that the pond is kept at manageable levels.

The irrigation system will be designed to not discharge pollutants into waters of the United States. The irrigation system and distribution of livestock water will include storage tanks and labor-efficient storage ponds. In the event of the storage pond being full, excess water is planned for discharge into the nearest drainage ditch every 45 days. Irrigation water is provided to the farm from Waiola Reservoir. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The value of the practice of irrigation and/or effluent application on the pastures is supported by utility and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.
699 mature dairy cows at the Māhūʻalepū site applies to mature dairy cows. Cattle in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhūʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Ni‘ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhūʻulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhūʻulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhūʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhūʻulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.
The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and potable water in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Po‘ipi‘i region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa-Po‘ipi‘i-Kīhei districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Care Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch near the bridge accessing Makauwahi Care Reserve and the State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa-Po‘ipi‘i-Kīhei districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.
within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices. HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The nutricler run-off from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent per year, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīlōa-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occur rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to the nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at
levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH OWR, dairy neighbors and the local Kaua'i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

To Whom it May Concern:

I’m writing to express my opposition to the dairy farm proposed in the Maha‘ulepu Valley as it is currently structured. While I appreciate the intention of promoting sustainable food practices for Kauai, I don’t feel a dairy of the size proposed is appropriate for this special island. I won’t go into all the reasons for opposing this operation...I know you have heard them from people more knowledgeable and eloquent than I...but I did want to participate in letting my concerns be known to those in decision-making positions!

Please take great care and consideration in determining if and how this plan should go forward. Kauai is an extremely unique gem on this planet and I do believe it can be a shining example to the world of how sustainability can be done RIGHT (and preferably organically, in my humble opinion). Please don’t just green-wash with all the right words; truly examine all the motives behind your decisions and do the right thing.

Mahalo for your time and consideration,

Beth Hagan
Dear Beth Hagan:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds’ diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrient source and minimizes stress to the animals. Cows tend to be

---

Beth Hagan  
May 26, 2016  
Page 2 of 4
healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCs provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawaii is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua'i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rHST or rBGH.

To Whom it May Concern,

I'm writing to express my opposition to the proposed dairy farm at Maha'ulepu. It seems to me that if the goal is to do something sustainable, the amount of cattle on the land is truly more of a gamble than sustainable. If you want to do something agricultural (and cattle and agriculture are two different things) with an ecologically minimal impacts, why not do something with native plants and do it organically?

Let's think very, very long term.

Sincerely,

Pat Hagan
CAFO is a system designed to capture and store nutrient resources from manure and waste liquids in the production of livestock. CAFOs are subject to federal and state regulations designed to control nutrient discharges into surface waters. However, nutrients would be introduced to the HDF site with any use of the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through the ground and surface waters. The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. The principal potential impacts posed to the five endangered species include those described in DEIS Section 4.10.2.

**ALTERNATIVES:**

The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, the DEIS examines the environmental impacts of implementing each alternative in its intended manner and location, including the proposed dairy project.

Four possible land uses that would not meet the project purpose are discussed. Reforesting the land to support the development of an Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

**Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing flora and fauna of the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting. This survey included identifying any species listed as endangered, threatened, or of special concern or potential concern. The survey results are included in the draft EIS.

A survey was also conducted to establish baseline data on the presence of plants currently listed as endangered, threatened, or of special concern within the boundaries of the project area. The survey results are included in the draft EIS.

Avian and mammalian surveys were conducted in August 2014 by Rook Biological Consulting. The surveys were conducted to identify potential threats to sensitive species. The surveys were conducted in the natural habitat, which is consistent with the site's natural setting. The surveys were conducted in the natural habitat, which is consistent with the site's natural setting.

The principal potential impacts posed to the five endangered species include those described in DEIS Section 4.10.2.

Avian and mammalian surveys were conducted in August 2014 by Rook Biological Consulting. The surveys were conducted to identify potential threats to sensitive species. The surveys were conducted in the natural habitat, which is consistent with the site's natural setting. The surveys were conducted in the natural habitat, which is consistent with the site's natural setting.
The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient continuous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- The alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).
- After years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Criterion 8).

Dear Ms. McIntyre:

Attached please find my letter which expresses my concerns regarding the proposed industrial dairy for the South Shore of Kauai as well as my specific comments on the EISPN.

Thank you for your review and consideration of my comments. As you know, the EISPN is a critical component of the overall EIS process and I value this opportunity to provide my input.

Sincerely,

Julie M. Hagensen
Koloa, HI
(808) 742-6688

February 22, 2015

State of Hawaii, Department of Health
Laura McIntire, Environmental Planning Office
919 Ala Moana Blvd Room 312
Honolulu, HI.

Dear Ms. McIntyre,

This letter is to express my grave concerns regarding the proposed Industrial Dairy on the South Shore of Kauai. I have owned a home in Poipu with my mother for nearly thirty years and am very familiar with site HDF proposes for their operation. I have read their materials thoroughly and have researched information concerning the many problems associated with such a large scale operation – most notably contamination of drinking water, groundwater, surface water and soils. Although effects on the environment and public health are my primary concern, I am also concerned about the economic and community impacts that the industrial dairy will have on the tourist industry, home values, cultural sites, and local business.

I have concluded that Maha’ulepu is the wrong location for such an operation and urge The Department of Health to do the right thing for the environment, the people and businesses of Kauai.

My comments on the EISPN are centered on the potential cumulative effects of an industrial dairy and the areas I feel must be addressed in the EIS.
Criteria 8: Is individually limited but cumulatively has considerable affect upon the environment or involves a commitment for larger actions.

The HDF plan is not individually limited in its effect on the environment, the economy or the social wellbeing of the community. A responsible EIS will need to address the numerous impacts on water, air and soil quality, threatened species, coral reefs and the local economy. Cumulatively, over a relatively short period of time, the HDF operation will compound the negative effects in all these areas.

The HDF plan does involve a commitment to a larger action. According to EIS requirements, any proposed action must be described in its entirety. HDF plans to begin operations with 699 cows to avoid classification as a CAFO and acknowledges plans to grow the herd to 2000 over time. Therefore the EIS must address the ultimate herd size and its management now. Questions such as composition of cows (e.g., the mix of dry and milking cows), how all animals (cows, calves, bulls) will be fed, housed, transported, slaughtered (bull calves and non-producing cows), and the management of their wastes must be addressed at the 2000 cow mark.

In addition to the growth and accumulation of pollutants as the herd size increases, other effects from greater numbers must be estimated and addressed. These include but are not limited to: noise from bawling and distress calls from cows separated from their calves which can go on 24-7 for days as well as the loud, anxious calls from cows in heat. How far will these noises carry? Data using climatic, wind and geographic conditions of the specific site must be used; Odor sources and levels from each and every aspect of the operation from lagoons and wash areas to liquefied manure that is sprayed on the land. Reports from farmers acknowledge that is takes days for the odors to subside and when it rains it begins again. On even slight slopes not only pollution and contaminants are carried off site but also accompanying foul odors. An analysis up to the 2000 cow mark must again be specific to the geography, weather and wind conditions at and near the site. How far will these odors travel on a good day? A bad day? Average wind and climatic conditions will not suffice. The impacts to soils, groundwater, streams and ocean from dairy wastes including the use of hormones, antibiotics, and vitamins must be again addressed at the 2000 head level.

HDF proposes a zero discharge operation. By its very nature, discharges to lagoons, run off from cleaning and milking operations and direct discharges from cows on sloped lands cannot be viewed as a “zero discharge” and will, together, have a cumulative impact to underground water resources, streams, ditches, beaches, and ocean below. To consider the thousands of sources of pollution from this operation as “nonpoint” is also a misnomer. For each contaminant there is a source. Obtaining a zero discharge NPDES permit is not useful in this case as it will not take into consideration the hundreds, if not thousands, of point sources of pollution that will accumulate at the site, adjacent lands, and downslope beaches, caves and ocean. As clearly demonstrated by both US EPA and citizens in the State of Washington, drinking water wells as little within a few mile from a feedlot or dairy have been contaminated over time. In the state of California, land has been declared hazardous and unusable due to years of dairy farm operation.

As noted in the DOH and Surfrider water quality samples, pollution levels in the Waipioi stream already far exceed State and Federal water quality standards. The addition of 699-2000 cows and a large scale milking operation will only compound a situation that is already detrimental to human health and the environment.

The HDF EIS must address the following cumulative effects from its operation:

1: Former uses and treatment of the land. Describe any and all former uses of the site, including adjacent lands. Provide data on current conditions of soils, flora, fauna, air and water. This is necessary to set a baseline and to monitor future cumulative effects resulting from the proposed HDF operation. Note: This must include any and all alterations to the landscape started or completed by HDF prior
to the EIS, including the permits obtained or required. It must also include the mitigation efforts HDF will take to contain, decrease, and repair accumulated pollution levels already in existence on site. Also detail how will this work will be monitored and by whom.

2. **Present uses of the HDF site and adjacent lands** -- agricultural, industrial and human related-- including the taro farm located at the bottom of the HDF site and the quarry located NW of the cave. This must include Human recreational uses such as pig hunting, hiking, and bathing. For example, HDF must explicitly outline provisions it will take to protect the taro farm from any incursions or adverse effects to the soils and food value of the crop.

3. **Future uses of the HDF site and adjacent land** should the dairy fail. Address the potential adverse effects from soil and groundwater contamination on the land that will or may limit future uses.

4. **Cumulative Weather conditions** and effects on the proposed operation. Historical data of rain fall, flooding, high winds and hurricanes must be examined in the context of reliable probabilities of flooding, runoff, destruction of buildings, paddocks and lagoons resulting in contamination of beaches below and South shores. Worst case scenarios must be described as well as impacts to human health and the environment.

5. **Cumulative Economic effects**: The EIS must address cumulative effects, over time, on property values, the tourist/hospitality industry and small businesses in the area. As noted in other locations where large dairies have operated, there will be a cumulative effect on public knowledge of odors, flies, and pollution. Perhaps initially the effect will be small but word of mouth, articles in magazines and trade journals will impact a vibrant industry that currently accounts for a large percentage of the island’s financial resources. The ripple effect could eventually affect the entire island in terms of jobs, property values and taxes, and indeed all businesses who depend on tourists for their livelihood.

---

Thank you for your review and consideration of my concerns.

Julie M. Hagensen
2211 B Pane Rd
Koloa, Kauai HI 96756
Dear Julie M. Hagensen:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice. Your comments were received by the State of Hawai‘i Department of Health Environmental Planning office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of...
the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds’ diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhāulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “moos”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer; productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.
Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepi site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepi site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH. As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS engineering economics, wildlife biology and other disciplines to aid landowners in implementing conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices guide design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kāhili Clay at 32 percent, Kā‘ena Clay Brown Variant at 29 percent, and Lualua Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium. Poorly drained soils have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on water bodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon...
The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**NATURAL HAZARDS:** The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā'ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Ni‘ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā'ulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

**Preparedness** is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā‘ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

**ARCHEOLOGICAL AND CULTURAL:** The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burial, and no bone was found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā‘ulepū Ahupua‘a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.
The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Employment multipliers, indirect employment related to Dairy construction would be created on O'ahu.

Dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 dairy cows, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 44 million gallons (367,219,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.
WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimānalo volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silt and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils at the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanics series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.05 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kauai community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalalau districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface
Water Hydrologic Unit, which features relatively high precipitation with relatively low temperatures in the summer. The HDF is located on the north side of the Ha'upu Ridge, which is a natural barrier between the Ha'upu Valley and the Waiopili Ditch drainage area. The HDF is situated within the Ha'upu Valley, which is a part of the Waimea River Basin. The HDF is connected to the Waimea River Basin through the Ha'upu Valley, which is a natural drainage area for the Waimea River Basin. The HDF is located in a relatively remote area, with no significant urban development in the immediate vicinity.

The HDF is an important natural resource, providing a significant amount of water for the Waimea River Basin. The HDF is also a valuable natural resource for its biodiversity, supporting a variety of plant and animal species. The HDF is located within the Malaekahana State Park, which is a popular recreational area for hikers, mountain bikers, and other outdoor enthusiasts.

The HDF is in close proximity to several other natural resources, including the Waimea River and the Waimea Canyon. The Waimea River is an important water resource for the Waimea River Basin, providing water for irrigation, domestic, and industrial uses. The Waimea Canyon is a popular recreational area, attracting hikers, rock climbers, and other outdoor enthusiasts.

The HDF is also in close proximity to several other natural resources, including the Malaekahana State Park and the Waiopili Ditch. The Malaekahana State Park is a popular recreational area, providing opportunities for hiking, mountain biking, and other outdoor activities. The Waiopili Ditch is a man-made drainage ditch, which is used to collect and transport water from the Ha'upu Valley to the Waimea River Basin. The HDF is located within the Malaekahana State Park, which is a popular recreational area for hikers, mountain bikers, and other outdoor enthusiasts.
To provide perspective, nutrient inputs from the adjacent Kilolo-Po’ipu region were also calculated. Nitrogen input to the marine environment in the Po’ipu region is calculated to be 38,510 pounds annually, or 35 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po’ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater- and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waloipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological contaminants are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kau‘ai community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours in two separate milking cycles—a moving to and from the barn for the 15- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the site of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4.19).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were
applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,790 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown, it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Aloha,

Thank you for your comments. I have forwarded them to the project consultants for review and consideration.

Mahalo,
Laura

Subject: COW DUNG

Remember how long the Kilauea Farm smelled and only a few cows pasture in the location. My friends currently in New Zealand are sending info on devastating results of farming cows in pristine areas.

Vivian Hager

May 26, 2016

From: vhager [mailto:vhager@msn.com]
Subject: Hawai‘i Dairy Farms

Dear Vivian Hager:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhū‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy.” The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations...
Cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high-quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. The term "grass-fed" was used in the EIS. This term was used to identify the proposed dairy operations that could pass through ground and surface waters. The pasture rotational-grazing dairy provides a local feedstock—grass—as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in establishing appropriate varieties of grass, and suitable sites to support sufficient dry matter grass yields essential to a cow's diet. Additional projects conducted on the 2,000-cow dairy operations will be discussed in Draft EIS Section 3.3, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock—grass—as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in establishing appropriate varieties of grass, and suitable sites to support sufficient dry matter grass yields essential to a cow's diet. Additional projects conducted on the 2,000-cow dairy operations will be discussed in Draft EIS Section 3.3, Pasture Management.

The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the different pastures. The irrigation water supply is provided to the farm from Waiau Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5, and Draft EIS Appendix D.
other partner ranches as needed for animal health and dairy productivity. This will help boost the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe the use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Wai‘ōnau volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black alaly clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day.

Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts on ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū 14 well and the County’s Kōloa F well will result in no adverse impacts on ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts on ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū 14 well and the County’s Kōloa F well will result in no adverse impacts on ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development.
The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2080. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōlia - Po‘ipū - Kalāheo districts), water use in 2085 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makuwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors to the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Green Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the...
current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūʻulipā will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 9 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 9 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kūloa-Pōʻipū region were also calculated. Nitrogen input to the marine environment in the Pōʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Pōʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downstream from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waïpōʻipu Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be initiated in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient
Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity/mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": [http://tinyurl.com/OEQCExAUA](http://tinyurl.com/OEQCExAUA)
To Whom it May Concern:

As a long time resident of the Poipu area in South Kauai, I would like to express my vehement opposition to the proposed Māhā‘ulepū dairy farm, which is in the planning stages in South Kauai. My family has reviewed all of the pertinent facts surrounding this project, which has not been well planned from the outset.

The very thought of invading a pristine residential environment, coupled with a premier resort complex, is ill advised at best. The many faceted negative ramifications of this proposed project are obvious to the most uninformed group of residents on Kauai.

At the top of the list is the destruction of the current traditional environment, nurtured by the Hawaiian community. The negative impact on the water supply is certainly paramount in the lengthening list of problems that the local community is facing. This is clearly followed by the odor, which will grossly affect the standard of living in nearby communities. These key factors are followed by the fly infestation, which will be evident and indefensible. The health problems will be inflated immeasurably and should fall under the jurisdiction of the environmental authorities.

Initial tests on the water supply in the area are irrefutable, inasmuch as they prove beyond a reasonable doubt that the water supply in the future will be affected by the increasingly large herd of cattle. With regard to the tax base on the island of Kauai, it is predictable that real estate prices will decline, hence, lowering the real estate taxes collected by the County of Kauai should the project move forward.

Your appropriate negative action relating to his matter, will be most appreciated, not only by my family, but to the large group of voters on the island of Kauai. In the interests of all concerned, if the project was moved to a more suitable location, it would resolve this issue immediately.

Respectfully submitted,

John & Terri Halliday

2355 Hoohu Road
Koloa, HI 96756
and State Site 50-30-10S094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāʻulepū Ahupuaʻa, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-10S094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāʻulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for drosophila musophila, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-ʻōhiā forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawai‘i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which harries manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhāʻulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pads in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōā-Poi‘ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ala Inōkī Road between Kōā and Poi‘ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal waste in the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix I.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on ʻOahu. Construction
employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 44 million gallons (367,197,800 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

Hydrology: The area’s hydrology is shaped by its geology. The Kūloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths — as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane operation period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.
plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

Towards the south.

The assessment concludes that the modest potable water demand from the dairy and the groundwater in the volcanic aquifer layer, which is the source of potable water.

Groundwater in the alluvium will not impact the County drinking water well.

Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing the amount of material used on-site; creating and implementing a Stormwater Management Plan; and establishing an Engineering and Construction Planning Permit.

The HDF site is located on the bottom-fed by several intermittent streams coming off the south slope of the Ha'upu Ridge. These normally dry streams converge in the terminus of Waiopili Ditch, of surface water and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Makalapa and adjacent watersheds. CWB conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. CWB also provided its data, however, DOH was unable to confirm the CMU’s recommendations.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and increasing demand for potable water for community and resort development.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to confirm the CMU’s recommendations.

Water Hydrologic districts, which are not perennial streams in the upper Makalapa Valley, which is flooded by several intermittent streams coming off the south slope of the Ha'upu Ridge. The HDF site is located on the bottom-fed by several intermittent streams coming off the south slope of the Ha'upu Ridge.

The HDF site is located on the bottom-fed by several intermittent streams coming off the south slope of the Ha'upu Ridge.
maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35 feet from the top of drainageway (totaling 70 feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass core with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Koʻola-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipoli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditch down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the
NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4.19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity/mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2.780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES:

As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed project. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The
alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy-soil science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy-soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of State’s fresh milk demand thus reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy-soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEIC website at the following URL, search "Hawai‘i Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

Comments to be considered in preparation of an Environmental Impact statement for:
Project Name: Hawai‘i Dairy Farms
Island: Kaua‘i
District: Poipu
TMK: (4) 2-9-003:001 (portion); 006 (portion)
(4) 2-9-001:001 (portion)

To whom it may concern:

Waters of the State and United States:

The scope of the EIS must include a thorough consideration of the Public Trust Doctrine as articulated by Article XI of the Constitution of the State of Hawaii. The Hawaii State Supreme Court has authored at least four major Decisions enforcing the Public Trust Doctrine and its constitutionally intended protection for the waters of the State: Waiahole I (1994), Waiahole II (2000), Na Wai ‘Eha (2012), and Kai‘ai Springs (2014). Each of these cases dealt with situations in which water on agricultural land was either being diverted or taken for use by an agricultural operation or bottling company. In all cases the Court found that such uses constituted a violation of the Public Trust Doctrine. There is no reference to this doctrine in HDFE’s EIS. Hawaiian Dairy Farm’s Waste Management Plan also fails to refer to or consider this doctrine. It needs to be addressed by both HDFE’s Plan and the EIS.

Hawaii Dairy Farms (HDFE) plans to irrigate the pastures at the Maha‘ulepu site with 2.93 million gallons of water daily (MGD) from the Waiakea Reservoir according to HDFE’s Waste Management Plan (WMP), pages 31, 37 and 44. Per HDFE’s leases with Grove Farm, their lease with Grove Farm entitles them to 3 MGD (million gallons daily) as a term of their lease contract. It may not be uncommon to have an agricultural lease include the use of water that is available on the agricultural site. In this case, however, the water that is available from the Waiakea Reservoir, an off-site reservoir that happens to be on other Grove Farm property, in water that collects from the Hulaia Stream diversion which now feeds the Waiakea since the cessation of cane cultivation in 1996. The volume of water HDFE plans to consume with irrigation of its 517 acres of grazing pasture (2.93 MGD) is substantial. But for the 100% diversion of the Hulaia Stream, the Puna District used to receive water from the Hulaia Stream, previously a major water resource for the natural watershed of the Nīnīnī River, the A‘eka‘a Fishponds and several native Hawaiian fishponds. The farmers of the Puna District (covering the area where the Hulaia waters flowed prior to the construction of the 100% diversion; in 1957) are currently involved with the Department of Land and Natural Resources (DLNR), Commission on Water Resource Management (CWRM) seeking restoration of the natural watershed and revision/take down of the Hulaia Stream diversion. HDFE’s planned water consumption from the Waiakea Stream operations exceed the Kai‘ai Springs 1000 (5 Gallon) containers of water per day that Kai‘ai Springs planned to draw from the stream flow. Kai‘ai Springs, Hawaii Supreme Court, SCWC-29440, 28-FEB-2014, pages 3-4. If the Public Trust Doctrine applied in Kai‘ai Springs it should certainly be a compelling consideration with the planned use of 2.93 MGD. Not only is the intended daily volume of water an issue, but of equal concern is the proposed new use of the water, the liquidation of massive amounts of waste (3 million gallons of wet manure and 200,000 gallons of urine monthly from the start-up herd of 699 and 8.5 million gallons of wet manure and at least 600,000 gallons of urine monthly if the herd reaches 2,000 as planned). Clearly, a thorough evaluation of HDFE's proposed new use for the waters of the Waiakea is warranted as well as a detailed analysis of the impact to "instream" and "out of stream" or "nonstream" flow standards.

Grove Farm acquired the Kokua Sugar Plantation which, like most sugar plantations, relied on an extensive ditch system to irrigate its crops. The Hulaia Stream diversion, a lengthy concrete diverter, covered by a steel grate that was is designed to divert 100% of the instream flow of the Hulaia Stream, located mauka of the Kaumuali‘i Highway/Route 50 provided the majority of the water relied on by Grove Farm for cultivation of the Kokua Sugar Company’s cane. When Kokua Sugar ceased operation in 1996, the extensive irrigation system was no longer in use. The 100% diversion of the Hulaia Stream was never revised. Despite the substantial decrease in need since the Kokua Sugar Company ceased its operations. Thereafter the diverted waters continued flowing in the Hulaia and flowed to the Waiakea Reservoir. The Waiakea has since become the largest reservoir in the State of Hawaii. There is little question that these waters are waters of the State coming from the South slope of the Kohala range in Kohala Mountain. The water runs from the 100% stream diversion into a concrete catchment and then flows through a tunnel in the Hapu‘u mountain range, ending in the Waiakea Reservoir. The EIS needs to include HDFE’s proposed new use and its probable impacts as well as an analysis and evaluation of the degree of impact from the proposed use on the existing downstream users, instream flow, instream habitats, and dependent wildlife species.

Although generally accepted that water use is included in the leases for agricultural purposes, the daily quantity of water needed for the proposed HDFE operation (2.93 million gallons per day from the Waiakea) plus the potable water to be drawn daily from the Maha‘ulepu wells far exceeds the typical agricultural use on Kaua‘i.

In Re "Hawaii Ground Water Management Area High-Level Source Water Use Permit Applications and Petition to Amend Interim Instream Flow Standards of Waihe‘e River and Waikī, Wai‘ele, Waipako Streams Contested Case Hearing Hawaii Supreme Court, No. SCAP-30603 August 15, 2012, the Court concluded that the Water Commission (WRM) erred in balancing instream and noninstream uses, and therefore, the Interim Instream Flow Standards (IFS) do not properly protect traditional and customary native Hawaiian rights, appurtenant water rights or the public trust, p. 3. Based on the cultural practices as well as the historic and archeologic sites of Maha‘ulepu, there is an equal if not greater risk at Maha‘ulepu. The EIS needs to consider, environmental concerns, native Hawaiian practices, outdoor and recreational activities, and aesthetic and scenic values, as required by the water code, p. 12-13 Those considerations are equally important the analysis of "offstream public trust uses, such as the public water supply."

p. 16: "... the water code and our case law interpreting the code have affirmed the Commission’s duty to establish IIFS that ‘protect instream values to the extent practicable’ and ‘protect the public interest’..." In re Water Use Permit Applications "Waikīhole III", 105 Hawaii 1, 11,
In Kaua‘i Springs the Court concluded that the water Kaua‘i Springs uses for its operations originates from an underground spring located several miles from the Property, 1,000 feet up Kahili Mountain. Kaua‘i Springs apparently “purchased” or “licensed” its water from EAK Kaua‘i Trust (Kaua‘i Trust), the owner of the land where the spring is located. The water is transmitted to the Property by a privately-owned gravity-fed system dating back to the 1890s, which is owned by Kaua‘i Trust and operated by Grove Farm Company (Grove Farm)." Hawaii Supreme Court, SCWC-29440, 28- Feb-2014, pages 3-4.

In Kaua‘i Springs, the State Department of Health offered “[t]here may be potential for ground or surface water degradation/contamination,” and therefore “recommend[ed] that approvals for this project be conditioned upon a review by the State Department of Health and the developer’s acceptance of any resulting requirements related to water quality.” The Water Commission further commented that “[g]round-water withdrawals from this project may affect streamflows, which may require an instream flow standard amendment.” Finally, the Water Commission stated that although a water use permit was not required because the island of Kaua‘i was not a designated ground-water management area, other permits from the Water Commission may be required if the source of Kaua‘i Springs' water was modified:

The Island of Kaua‘i has not been designated as a ground-water management area; therefore, a water use permit from the Commission is not required to use the existing source(s) or to change the type of water use. However, if the source needs to be modified in any way, a well modification permit from the Commission may be required. In addition, if a pump is to be installed to induce additional water flow, a pump installation permit from the Commission would be required. If the source is modified to induce additional water flow, and the modification results in impacts to surface waters, a petition to amend the instream flow standard for affected surface waters must be made and approved prior to use of the water.

In fact, in Kaua‘i Springs, the Office of Hawaiian Affairs (OHA) argued that the Commission “upheld its public trust responsibilities by denying Kaua‘i Springs’ permit applications without prejudice, until the applicant can show, and the appropriate agencies can concur, that Kaua‘i Springs’ proposed use is reasonable/beneficial and will not interfere with public trust purposes.” Supreme Court, SCWC-29440, 28-FEB-2014, page 18. Shouldn’t Maha‘ulepu deserve the same if not greater protection for its rich sites, cave reserve, habitats, delicate ecosystem when a much greater environmental impact is threatened by the proposed industrial dairy than that posed by Kaua‘i Springs.

Example policy: the public trust doctrine requires an applicant to demonstrate the feasibility of alternative sources of water. The findings do not indicate whether Applicant complied with this requirement. “[P]ermit applicants must . . . demonstrate the absence . . . of alternative water sources. Such a requirement is intrinsic to the public trust.[J]” Walter I, 94 Hawai‘i at 161, 9 P.3d at 473; see also Kakai (Mohala), Inc., 116 Hawai‘i at 496, 174 P.3d at 335 ("[T]he Agency cannot fairly balance competing interests in a scarce public trust resource if it renders its decision prior to evaluating the availability of alternative sources of water.

Supreme Court, SCWC-29440, 28-FEB-2014, page 105

The Court held: "T. To assist agencies in the application of the public trust doctrine, we distill from our prior cases the following principles:

1. The agency’s duty and authority is to maintain the purity and flow of our waters for future generations and to assure that the waters of our land are put to reasonable and beneficial uses.

2. The agency must determine whether the proposed use is consistent with the trust purposes.

3. We provide this framework for assistance and do not indicate that it is mandatory or that it precludes other analytical approaches that are consistent with the public trust doctrine.

4. The Agency is to apply a presumption in favor of public use, access, enjoyment, and resource protection.

5. The agency should evaluate each proposal for use on a case-by-case basis, recognizing that there can be no vested rights in the use of public water.

6. If the requested use is private or commercial, the agency should apply a higher level of scrutiny.

f. The agency should evaluate the proposal under a "reasonable and beneficial use" standard, which requires examination of the proposed use in relation to other public and private uses.

Applicants have the burden to justify the proposed water use in light of the trust purposes.

8. Applications must demonstrate that the proposed use is reasonable and beneficial and will not interfere with public trust purposes.

a. Permit applicants must demonstrate their actual needs and the propriety of draining water from public streams to satisfy those needs.

b. The applicant must demonstrate the absence of a practicable alternative water source.

c. If there is a reasonable allocation of harm to public trust purposes, then the applicant must demonstrate that there is no harm in fact or that the requested use is nevertheless reasonable and beneficial.

"because it involves the use of an important public trust resource - fresh water - for personal financial gain," Supreme Court, SCWC-29440, 28-FEB-2014, page 17. This is all relevant to the HDF proposed industrial dairy as HDF’s impetus is certain to be of much greater consequence to the Helu Stream flow standards than Kaua‘i Springs ever intended to be.
d. If the impact is found to be reasonable and beneficial, the applicant must implement reasonable measures to mitigate the cumulative impact of existing and proposed diversions on trust purposes, if the proposed use is to be approved.

note 44 Wai-ale-ale v. Hawaii at 162, 9 P.3d at 474.

note 45 M. at 161, 9 P.3d at 473.

note 46 Kauai (Mokala), Inc. v. Hawaii at 499, 174 P.3d at 338.

note 47 Wai-ale-ale v. Hawaii at 143, 161, 9 P.3d at 455, 473.

note 48 The ICA held that the circuit court's COAs § 63 (record was "devoid of any evidence that Kauai Springs") existing or proposed uses might affect water resources subject to the public trust"); § 71 and § 72 (saying that Planning Commission "may" have public trust duties in this case) were "incornered in that they do not recognize the Planning Commission's public trust duties to consider and review Kauai Springs' water usage in its water bottling operation." Kauai Springs, 130 Hawai'i at 423, 312 P.3d at 299. In its Application, Kauai Springs do not challenge the ICA's conclusion that the Planning Commission had a duty to consider Kauai Springs' water usage in reviewing its permit application. Rather, Kauai Springs argues that the ICA erred in vacating the circuit court's COA because the circuit court recognized the Planning Commission's public trust duties and correctly found that the Planning Commission fulfilled these duties.

Supreme Court, SCWC-29440, 28-FEB-2014, pages 85-88

Alternatives:

In the EISPN, the discussion of alternatives, offering only one other location to be considered, fails to satisfy a real alternative evaluation for an operation that is well known for its significant adverse environmental impacts. Clearly, the EIS must explore at least three other locations at a minimum.

In its discussion of a Confined Dairy Operation Alternative, HDF proposes a "Confined Dairy Operation". Assuming the public trust water rights are adequately protected and preserved, if HDF chooses to proceed with a true CAFO, the EISPN offers only that the Māhā'ulepū location would require additional manure management as nutrients would not be returned to pastures. Additional grain and forages would be imported to sustain dairy cows. The Confined Dairy Operation Alternative would utilize large barns to house and feed the cows. Animals would be confined within the barns and milking parlor; no pasture area would be required. No manure would be deposited on pasture grasses and grass would not be utilized as a locally available feed source. The EIS must address why feed cannot be cultivated on the property, why a methane digester cannot be implemented saving electricity consumption from the Grid that would also help to collect manure, lowering the odor, fly and other pest problems to potentially feasible levels. To address alternatives, the scope of the EIS must be expanded to include these and other related considerations.

Important Agricultural Land (IAL), Hawaii State Constitution, Article XI, Section 3.

The EIS must consider HDF's website boast that it intends to be the "first commercial use of IAL land". Is that what the State intended when the provisions of the IAL enactments were adopted? Is IAL land even appropriate for a commercial agricultural operation? This must be addressed by the.

HDF's claim that their proposed industrial dairy will lead to agricultural self-sufficiency must be substantiated in the EIS, especially when the WMP calls for shipping the milk off island, selling the milk wholesale to another company who would then process, bottles and distribute for sale at locations they select.

Sugar cane cultivation has left the proposed farm soils "depleted of essential nutrients" pg 56 HDF WMP, Section 8.1. The EIS needs to substantiate the scientific support for their claim that the proposed dairy would in anyway improve the soil at Māhā'ulepū. Hooves from 1200 pound cows are in themselves degrading to soil, contributing to erosion and nutrient loss. The addition of nutrients does not remediate soil and the EIS needs to address the claimed benefit of an industrial dairy to the soil composition at Māhā'ulepū.

Table 6 - Potential Impact Categories for Liner Failure
1. Any underlying aquifer is at a shallow depth and not confined
2. The vadose zone is rock
3. The aquifer is a domestic water supply
4. The site is located in an area of solutionized bedrock such as limestone or gypsum.

Considerations for Minimizing the Potential of Waste Storage Pond Liner Failure.
Sites with categories listed in Table 5 should be avoided unless no reasonable alternative. 313 p 6 of 7

NRCS, PI

April 2012

Table 4 - Potential Impact Categories from Leak of Embankment or Accidental Release
1. Surface water bodies — perennial streams, lakes, wetlands, and estuaries
2. Critical habitat for threatened and endangered species.
3. Riparian areas
4. Farmland, or other areas of habitation
5. Off-farm property
6. Historical and/or archaeological sites or structures that meet the eligibility criteria for listing in the National Register of Historical Places.

Cultural Practices, Historical and Archeological Sites are at risk. The foregoing considerations are from the NRCS manual stepped to the back of the WMP but were not specifically incorporated in or addressed by the WMP. The EIS needs to address these aspects of the NRCS and others as well to cover this risk which from our present evaluation, especially based on the findings of the Custom Soil Resource Report of the NRCS, dated June 5, 2014.

Respectfully,
Robert and Bridget Hammerquist
States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

Subject: Hawai'i Dairy Farms Environmental Impact Statement Preparation Notice

Māhāulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Bridget Hammerquist:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISP), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAND) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP. This term was used to identify HDF's intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd's diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhāulepū site on Kaua'i have been conducted for more than 19 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mob", mimicking the natural social order of herds. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximize grass as the
cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be
healthier and live longer, productive lives with access to fresh air, high quality feed,
and exercise while they forage. The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setsocks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural water depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. More information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā‘ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā‘ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with hormone growth referred to as BST or rBGH.

**SOILS:** Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watersheds-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselected parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.
The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kailhi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micromutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrates to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai’i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHEOLOGICAL AND CULTURAL: The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIR Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The six historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burial, and no bome were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Mā‘ai‘elepu‘u Ahupua’a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.
WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kūloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Sapolilite, a soft, thoroughly decomposed rock. The Māhā’ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black alluvial clays and loams.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in feet per day. It is a measure of how easily water will move through the ground. The hydraulic conductivity of the alluvium that underlies Māhā’ulepū Valley and the HDF site ranges from 0.3 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kūloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā’ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā’ulepū 14 well during the sugarcane plantation era. All potable water used as water for livestock will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā’ulepū 14 well and the County’s Kūloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā’ulepū Valley, HDF established a 1,000-foot setback surrounding the Kūloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kūloa-Poipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kūloa - Poipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā’ulepū Surface
Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data; however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffer: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageways (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainages such that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainages. Only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.
To provide perspective, nutrient inputs from the adjacent Kīloa-Pōpuʻi region were also calculated. Nitrogen input to the marine environment in the Pōpuʻi region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Pōpuʻi region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipio Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the DraftEIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kauaʻi community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaiʻi Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kauaʻi; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kauai in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).

The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.

Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawaii Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

Hawaii Dairy Farms will create a commercial scale pasture-based dairy operation in Hawaii, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

The planned action will generate new long-term employment in the agricultural sector on Kauai, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).
Comments submitted regarding HDF Environmental Impact Study (E.I.S.):

Aloha,

My legal and hereditary name is Kalani'ukumil Koa Moka'aniu 'O Na Ali'i Hanohano. I was born in, and am a native resident of Koloa, Kauai. I am established in the Hawaiian custom, as a lineal descendent of the aboriginal Stewards (7th generation), of the Koloa Moku, or District, which includes Maha'ulepu. My Kupuna's "Anokale" or Uncle, Kaluhiwai Nakapa 'ahu, was a noted native medicinal practitioner (Marvin Bremecrke 1953), who gathered medicinals in Maha'ulepu and Pua'a. His father, Kalipolokolien Nakapa 'ahu, Alli 'Ili l Nui of Koloa District (Moku, owned, and resided on a nine acre parcel in Aweoweoa (Hidden Valley- adjacent to Maha'ulepu). I have followed in his footsteps for more than a quarter century. As a native spiritual practitioner representing a registered Hawaiian non-profit Interfaith Ministry (Hui Hanai), continuing cultural practices and observances at Maha'ulepu, this Dairy will affect cultural resources that I am dependent upon. I proclaim myself to be a vested party-at-interest seeking Intercourse status.

As a participating member of the Iloolu'okalani Coalition, alert to Incursions or Intrusion on Cultural sites or practices; as Pastor of "Hui Hanai I ka Huna Loa" a registered non-profit Interfaith Ministry; as Steward of: "Malamo Maha'ulepu" 501 c-3); "Friends of Maha'ulepu" and Koloa 'Aha Moku Council, I do not speak for or represent these organizations, but share with them and desire address of their, and my concerns.

I will be directly impacted by the Dairy installation introducing high volumes of nitrate rich untreated solid waste and urine affecting three precious qualities to which I, and the Community have inalienable rights, that of Clean Water, Environmental contamination protection, and Quality of Life.

Neighbors in the nearby communities of Kauai's South-Shore will also be impacted by the degradation of water quality (ocean & aquifers), contamination of soil, odor caused by prevailing winds, or lack thereof, biting flies, affecting residential and Visitor Destination "Quality of Life" issues along with economic collapse of one quarter of the island's tax-base.

Land and aquatic life in the downslope and drainage watershed from the proposed site will be impacted by the inability of HOF to achieve complete containment of seepage resulting from the Dairy operation into the surrounding areas. This is substantiated by the NRCS Custom Soil findings commissioned, distributed, but not taken into consideration by HDF.

ISSUE of conflict w/ use of Group 70 conducting the E.I.S.: "Group 70" developed the existing Waste Management Plan and prepared architectural blueprints for all of HOF's proposed Dairy Installation. As analysis of this Plan and projections has been reviewed by qualified independent experts to contain serious flaws and misrepresentations questioning the credibility of their research and facts, does it not stand to reason that in the interest of propriety and competency, that an unbiased third party conduct the E.I.S.?
lava tubes permeating the impacted area; Nene, Limu, Opilik, Wana He'e, Loli; Honu, & Monk Seals, vegetation and sea-life important to Hawaiian culture and PASH resource management populations are at risk from run-off and inundation.

10: Detritally affects air or water quality or ambient noise levels: Odors, biting flies, bacterial colonies, ambient noise during seasonal cessation of winds, penetration into public water supply, ammonium interactions with the ambient atmosphere affecting vegetative growth.

Issues of Water quality, contamination of public drinking water, penetration of contaminants into the aquifer; soil and lava tube run-off projections calculated to include events such as the 1948 Forty-two day and 2006 30-plus day rain events.

11: (Affects or is likely to suffer damage by being located in an environmentally sensitive area such as a flood plain, tsunami zone, beach, erosion-prone area, geologically hazardous land, estury, fresh water or coastal water): Soil categorization by NCRCS as High to Very High risk of run-off impacting Wetlands, beach zones, estuaries, tide-pools, reef, coastal and shoreline waters impose eventual wide-spread damage as suffered by New Zealand, Washington State, Wisconsin and New Mexico.

12: No comment at this time.

13: No comment at this time.

The 2001 Office of Hawaiian Affairs Report to Jennifer Dines of the Federal Communications Commission (FCC) identifies the Haupu Range (including it's Maha'ulepu Valley), as a Hawaiian Spiritual Sanctuary and Mausoleum of Ancestral remains. Widespread native burials throughout the region including the single largest Burial In the Pacific (Awao'weonut) establish qualification of "Sacred Spaces" designation as defined and protected under the 1978 Religious Freedom Act (American Indian [i.e., Indigenous natives/ Alaska; Hawaii/ American Samoa].

Unmarked sites, burial grounds, ceremonial "Wahi Pu'a", Sub-surface cultural layer material, proximate wetlands known but undisturbed, require a thorough cultural resources study and ensure mitigation measures to ensure protections.

Consider impact to and degradation of Indigenous cultural use of natural land and aquatic resources protected under PASH.

Alternative uses of area: Restoration and encouragement of Kalo (Taro), cultivation and production of a natural resource (Kalo) qualifying for protection under the U.S. Supreme Court [1944] "Religious Freedom" determination that "Cattlinite" (Pipatame), was a protected "Spiritual" natural element integral to established Indigenous religious practices. The Court codified protections ensuring that the metamorphosed natural ceramic conductive substance, religiously employed as a Spiritual conductor, would be protected and available to recognized tribal members at no cost using traditional seasonal harvesting techniques, (decision subsequently bolstered by President Clinton's 1978 Executive Order).

As it is well established that every part of the process in Hawaiian Kalo cultivation, preparation and ingestion is a religious act, in honouring "Haloa", a recognized cultural deity, the rare hydromorphic "plastic-like" clay soil providing the optimum conditions for Kalo cultivation qualifies for protections under "best and highest use" of the land as well as PASH protection as a rare natural resource culturally sustained in Religious practice.

(similarly protected culturally used natural resources used in Religious practices include Awa (Kava), alle (mineral), "Tschulch" (Indian Celery), and Peyote).

Alternative agricultural uses: Bio-mass generation, Sustainable energy production; endemic biodiversity and cultivation of medicinal herbs such as Cats-claw, Danelo (Turneric), crops of Taro, sweet potato or yams, conforming to the "highest and best" sustainable practices of land use.

Fails to address: Overflow discharge of effluent ponds resulting from tropical storm and hurricane rainfall amounts historically reoccurring with frequency over affected area with high to very high run-off potential.

Proximity of Ditch to Milking facility yard and "lot" sized rotating pens vulnerable to nitrate penetration. "Lots" of open rotating four to five acre fenced parcels, cannot sustain intended herd population size with adequate room, native and introduced grasses, subsequently requiring an estimated 25% supplemental imported grain based feed with no details as to its' source or GMO status. As such, it fits the definition of a "Feed Lot" (albeit rotating) operation subject to additional limitations, controls and restrictions on operation.

Employment of mechanized distribution of aerosolized manure with re-deployable equipment crossing or in proximity to ditches, we sites, or seasonal wetlands used by native endangered waterfowl is in conflict with reviews of current Industry standards and practices.

Note: The American Public Health Ass. (also Canada & Michigan) have called for a Nationwide Moratorium on industrialized Dairy operations (2003) such as this present Plan. Does HDF contest or refute these findings? How do they substantiate this?

Implications of the total of increased cattle populations on Kaua'i resulting from maintaining consistency of Dairy herd size, i.e., How many heifers, steers, cows (inactive or inacam), will be in addition to an eventual Milking herd of two thousand cows? A

Issue of a flawed and Inadequate Cemetery Plan failing to contain nitrate penetration into downhill watershed. Current projections fail to address aftermath of catastrophic events from weather or disease. Designation of a 694 foot double row of interments two feet apart cannot adequately provide sanitary containment. Furthermore, seepage and penetration into downhill watershed is inevitable and deleterious to the environment.

The watershed of Maha'ulepu Valley (and HDF's proposed 578 acre industrial dairy site) comprises waters from the Haupu mountain range, the Waipio Stream, as well as the irrigation ditches, all of which are "hydro-logically linked" as they emerge and converge at the Mauioahui Cave on their direct path to the ocean. Based on that critical feature, all waters being hydro-logically linked, how can HDF protect the wetlands, the endangered species, the reefs, the rare and sacred sites and the ongoing native Hawaiian cultural practices from contamination caused by the massive amounts of wet manure and urine produced daily even with their start-up herd of 699 pregnant dairy cows? Short of lining the entire surface of the proposed farm site, the established hydrological link between the various components of the Maha'ulepu watershed make runoff, discharge and contamination unavoidable.

For the aforementioned concerns and issues raised, I urge that HDF agree to an alternative contractor to perform the E.I.S. and address of all issues raised or alluded to in these comments.
I again urge Olapa, HDF, and Grove Farm Co. to reconsider and relocate their intended Dairy operation to a more appropriate location.

Dear Kalanikumai Ka Maka 'uli 'uli 'O Na Ali'i Hanohano:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**GROUP 70 OBJECTIVITY:** Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State, and Federal agencies. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepu Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepu site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gan irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and...
Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua’i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kālāhi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrates to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

irrigation water. Nutrient management is the practice of managing the amount, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepū site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; before (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of management. Managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainfall for use during dryer periods, to filter and buffer potential pollutants from leaching fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversity to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawaii at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.
The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs, and its potential to impact offsite. The assessment's findings are documented in the project's Cultural Assessment Report.

The project area includes historic properties, including the Hawaiian Heiau, a carved petroglyph boulder, and a number of historic-era bridges, ditches, and culverts. These resources are located outside the project area and are not expected to be impacted by the project.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened, or proposed for listing under Federal or the State of Hawaii's endangered species programs. Located onsite are four species of endangered waterbirds, including the Hawaiian Goose, the Nene, the Hawaiian Coot, and the Hawaiian Stilt. These species were recorded on the site and at the nearby taro farm located within the HDF site. Although the area does not provide critical habitat for endangered species in the upper Mahaholu Valley, four species of endangered waterbirds were recorded on this site, which may provide critical habitat for these species.

Avian and mammalian surveys were conducted in August 2014 by Ranah Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian and mammalian species on the property. The survey determined that the site is not critical habitat for any species, and no rare or endangered species were identified. However, the survey did identify a total of sixteen historic properties, which have been assessed for significance by the State Historic Preservation Division (SHPD) under Hawaii State law and the National Historic Preservation Act (NHPA). The SHPD is responsible for ensuring that these sites are protected and preserved for future generations.

The project area includes a number of historic-era sites, including the Hawaiian Heiau, a carved petroglyph boulder, and a number of historic-era bridges, ditches, and culverts. These resources are located outside the project area and are not expected to be impacted by the project. The proposed project is fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous exercise of native Hawaiian rights.

In Summary, the proposed project is unlikely to have a significant impact on any of the cultural resources, practices, or beliefs examined during the cultural assessment. The project is fully enclosed by perimeter fencing, and all potential cultural resources, practices, or beliefs identified outside the project area are expected to be protected and preserved.
A healthy population of dung beetles can help control flies by burying dung in the soil. This process contributes to the diet of flies such as the stable fly and horn fly. The stable fly, which requires approximately 21 days within the dung patty for the immature life stage, is common in areas with high pet populations. These pests are successful during the day, while the horn fly, which requires 5-20 days, is present at the HDF site. Pest in sects such as flies can negatively impact livestock and therefore are actively managed to prevent stress and loss of productivity at dairy operations.

Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Beneficial insects include primary decomposers such as earthworms, and biodiverse bee hives. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Introduction of dung beetle species resulted in a significant reduction in flies. The study also evaluated the potential impact of introducing predatory species to the site. Predatory species such as parasitic wasps were observed in the manure, and it was found that species-specific wasps could be introduced to the site. The study concluded that the introduction of dung beetle species to the HDF site would be beneficial in controlling fly populations. The study also evaluated the potential impact of introducing predatory species to the site. Predatory species such as parasitic wasps were observed in the manure, and it was found that species-specific wasps could be introduced to the site. The study concluded that the introduction of dung beetle species to the HDF site would be beneficial in controlling fly populations.
in accordance with regulatory labeling requirements. HDF will implement long-term integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua‘i may choose to engage with the State Department of Agriculture to translocate dung beetle species already introduced on Kaua‘i to Māhā‘ulepū and other areas where manure-related flies may be a problem.

**IMPACT OF SPRAYS ON BEES**

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bees or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal.

**PESTS:** A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā‘ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix E.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for drosophila muscipula, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-‘ōhi‘a forests.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai‘i’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix K.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, mokers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10% of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of...
milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 44 million gallons (36719780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER
Hydrology: The area’s hydrology is shaped by its geology. The Kīlauea area was built by Nāpali formation lavas of the Waimea volcanic series. Surface lavas of the Nāpali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ule‘pū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kīlauea series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the aquifer that underlies Māhā‘ule‘pū Valley and the HDF site ranges from 100 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kīlauea–Pā‘ū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ule‘pū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health (HDF) Rules require that potable water be used for milk production, both in the milking parlors and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ule‘pū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ule‘pū 14 well and the County’s Kīlauea F well will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.
Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa Well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction

Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the National Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;
only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:**

The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūle`ipai will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). As this nutrient run-off would not occur as chronic daily releases, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kūka`a-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Po`ipu region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po`ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment:**

An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipio`pū Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:**

Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CBW, dairy neighbors and the local Kau`a`i community.

**AIR QUALITY:**

As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a wind rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai`i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours - in two separate milking cycles - moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM0.5 and PM2.5) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM0.5 is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM2.5 is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the ES include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action's purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6. The DEIS evaluates alternatives that could attain the objectives of the action's purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai'i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Reusing the land for resort or residential development, or a potential conservation or condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-
Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": http://hawaiifarms.org/OEQC/KAUA

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Aloha,

I have very serious concerns about the proposed dairy at Mahaulepu Valley on Kauai. I am glad that an EIS will be prepared and hope that it will address the many issues, environmental, social and cultural, that a dairy in this location presents. While HDF states they are voluntarily doing this process, to truly be pono, this should have been done well in advance of any infrastructure changes or the announcement that a dairy IS going in at this location, as the EIS is designed to determine whether a project like a dairy should go in by providing substantive data that indicates that it will not be environmentally, culturally or socially harmful.

NUMBERS

Beginning with the proposed herd and the recent “reduction” in herd size to 699 (a significantly chosen number as 700 cows is classified as a Large Confined Animal Feed Operation). What is not noted by HDF with this revised herd size is that those 699 cows will be shipped in pregnant, thus there will be double that number after gestation. Males will then be thinned out through outsourcing and killing of a certain amount, so that 699 would be about 900 cows on the land after gestation. Regardless of this claim of a reduced herd size, the EIS must evaluate the plan based on the proposed final herd size of 2,000.

WASTE

According to the EPA, waste estimates for dairy cattle are equivalent to 164 times the amount of humans, thus the 2,000 cows would produce waste equivalent to approximately 328,000 people, fully 5 times the population of the entire island. Microorganisms causing health risks to humans like E. Coli, enterococcus and leptospirosis are common in the feces of cattle, these organisms could likely end up in the adjacent streams leading to the ocean as well as groundwater.

SOIL

HDF should be required to do a detailed, accurate soil survey to determine once and for all if the soil is able to handle the amount of waste that will accumulate and be applied via airborne spray as fertilizer. Again, had HDF followed proper protocol and done an EIS at the outset, perhaps they would have provided more accurate information on the soil in the area in question. Their initial plan stated that soil in the area was porous volcanic, which it is not. A later NRCS survey of the soil indicates that most of it is primarily clay with “very limited” capability to handle manure load and has a high potential for runoff.

DRINKING WATER WELLS

HDF should be required to do an extensive groundwater study to assess effects of waste applied to the soil. Their current Waste Management Plan does not identify all of the nearby drinking water wells and misrepresents the distance of some of those that are identified on the map. Most significantly, one well (Koloa F) is very near to the area in which their wastewater treatment plant will apply the sludge that accumulates in the ponds.

AIRBORNE CONTAMINANTS

HDF plans to spray waste from the effluent ponds on the fields as fertilizer. These spray machines are very tall and with dominant trade winds the possibility of spray affecting homes and businesses downwind is a potential problem. The EIS must address airborne contaminants produced by the dairy and the environmental, health, and social impacts.

SOCIAL CONCERNS

The Mahaulepu area is popular for nature oriented activities and subsistence such as fishing, hiking, beach-going activities, bird watching and more. The EIS must address how these activities would be impacted by environmental effects from a large dairy of this size upstream of the beach-going area.

The Koloa/Poipu area is home to approximately 3,000 residents, all of whom will be downstream of the dairy and thus affected by any airborne contaminants or odor. The area is also one of the top 3 visitor destinations, providing significant income to both County and State through property, TAT, general excise and other taxes. Environmental air, water and vector control concerns from the dairy would reduce property values and make the area less desirable to visitors. The largest private employer for the island is within 2.5 miles of the proposed dairy and a thriving visitor industry encompasses the entire Koloa/Poipu area, a decrease in visitors to the area would adversely affect those employers thus causing loss of jobs and income for island residents. Reduced property values and visitors to the area would not only affect the local economy through loss of jobs/decreased incomes for residents, but reduced revenues for the State and County as well.

The above noted concerns should all be fully addressed by the EIS for Hawaii Dairy Farm’s proposal at Mahaulepu Valley. Given the open, available, leasable land on the island, particularly that owned by Lessor Grove Farm, this seems to be one of the most ill-suited locations for such an operation. It’s proximity to freshwater sources, the ocean, nearby homes and businesses make this an extremely poor location.
location for a dairy, especially given that all milk will have to be trucked to the port in Nawiliwili for shipment to Oahu for processing. The above noted environmental, health & social concerns in addition to this fact, render this a plan that will negatively impact the environment and economy of Kauai.

Mahalo for your careful consideration of my concerns and your diligence in evaluating the impacts of this project.

Lisa Hartman

Subject: Hawai’i Dairy Farms
Environmental Impact Statement Preparation Notice
Mahalapu Road
Kaua‘i, Hawai‘i

Dear Lisa Hartman:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Mahalapu Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations...
(CAP) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP. This term was used to identify HDF's intent to utilize a locally-produced feedstock - grass - for more than 70 percent of the dairy herd's diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.2.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock - grass - as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials and on-site pasture management practices developed on the Ma'ili site on Oahu have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet. Improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mob," mimicking the natural social order of bowies. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, raccoon fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditches banks, increase net carbon storage, and improve and maintain water quality.

Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system. The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waiai Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

The NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for Hawai'i is the parenthetical inclusion of the word "nutrients." Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. The effluent storage ponds will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Ma'ili site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Oahu to be raised off-site. The committed herd size of 699 mature dairy cows at the Ma'ili site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and the committed herd size of 2,000 mature dairy cows at the committed herd site.
other partner ranches as needed for animal health and dairy productivity. This will however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows that the soils are depleted of nutrients, which is typical for lands formerly used for sugar cane. The soil nutrient status and fertility demand of the primary crop, Kikuyu grass, will be raised until ready to return to application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microorganisms to flourish and diversity to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and movement of water within or from the soil profile. Poorly drained soils, which have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. Poorly drained soils typically will have low hydraulic conductivity or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

Conservation services is a core principle behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using scientifically validated tools and standards in agriculture. Chapter 3, Section 3.2: these practices codes identify design and construction Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using scientifically validated tools and standards in agriculture. The user would like to display the developed Conservation District in December, 2013. The dynamic on ranch and healthy grass growth will build organic matter in the atmosphere, which benefits soil quality and enhance crop yields. According to current studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to organic management with a conservation approach can drive substantial accumulation of organic carbon in soil, with a soil nutrient status and fertility demand of the primary crop, Kikuyu grass, will be raised until ready to return to application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microorganisms to flourish and diversity to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and movement of water within or from the soil profile. Poorly drained soils, which have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. Poorly drained soils typically will have low hydraulic conductivity or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).
ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside of the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burial, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhū'ulepū Ahupua'a has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36.719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.
Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kīloa area was built by Napali formation lavas of the Waimāne volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kīloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The unalluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transmit water given a hydraulic gradient and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kīloa-Po‘ipi‘i region is on the order of 201 – 501 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Portion Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.055 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kīloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kīloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kīloa-Po‘ipi‘i region is on the order of 201 – 501 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kīloa-Po‘ipi‘i region is on the order of 201 – 501 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Regional Water Demand:** The adjacent, developed Kīloa-Po‘ipi‘i region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2030, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kīloa - Po‘ipi‘i - Kalalahe districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well
Water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūʻulepi Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūʻulepi watershed.

The HDF site is located on the bottom-land of the upper Māhūʻulepi Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūʻulepi Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kauaʻi Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhūʻulepi Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhūʻulepi and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: Waiopili Ditch Sanitary Survey, Kauaʻi, Part 1. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhūʻulepi Valley. The ditches carry along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageway; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows. A small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūʻulepi will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.
The groundwater engineer estimated potential nutrient pass-through to provide an evaluation of air quality and odors, including a wind rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) Regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for pollutants that are believed to present a significant health risk. The NAAQS serve as a trigger for state and local regulatory authorities to establish air quality standards for governing emissions from small businesses currently exist. No State or Federal regulations for greenhouse gas emissions from livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄), nitrous oxide (N₂O) and CFCs. The estimated concentration for PM₁₀, which is measured from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day, was 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅, which is measured from the same areas, was 0.17 μg/m³, less than half the Federal standard of 3.5 μg/m³ (see Table 4.19.1).

Potential odors and emission levels for air pollutants relevant to dairy operations will be conducted during such weather events.

As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor emissions during milk production and application. No State or Federal regulations for greenhouse gas emissions from livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄), nitrous oxide (N₂O) and CFCs. The estimated concentration for PM₁₀, which is measured from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day, was 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅, which is measured from the same areas, was 0.17 μg/m³, less than half the Federal standard of 3.5 μg/m³ (see Table 4.19.1).

Dust will be generated as cows move along soft limestone walkways that connect Dust Ditch with the paddocks and lead to and from the milking parlor. Potential fugitive dust emissions were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the emission rates from this available literature greatly overestimates the minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment resulting from HDF. Cows in the rotational-grazing system will be on pasture 22 hours each day and spend 2 hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using an atmospheric dispersion modeling system (ADMS), the rates were scaled to the size of the pasture areas used by cows in HDF. Emission rates added to the plan of Kanu's and the total concentration was compared to the State ambient air quality standards. The estimated concentration for PM₁₀ was 2.0 μg/m³, which is well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ was 0.2 μg/m³, well below the Federal standard of 3.5 μg/m³ (see Draft EIS Section 4.19 and Table 4.19.1).

Air Quality

As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor emissions during milk production and application. No State or Federal regulations for greenhouse gas emissions from livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄), nitrous oxide (N₂O) and CFCs. The estimated concentration for PM₁₀, which is measured from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day, was 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅, which is measured from the same areas, was 0.17 μg/m³, less than half the Federal standard of 3.5 μg/m³ (see Table 4.19.1).
leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Principal Planner
Dear Alfred P. Havas:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice. Your comments were received by the State of Hawai‘i Department of Health Environmental Planning Office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows‘ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

LAND USE: The historical and existing land uses of the project site and surrounding Māhā‘ulepū Valley were examined in the Draft Environmental Impact Statement (EIS), and uses proposed by the Hawai‘i Dairy Farms (HDF) project were evaluated in the context of county and state land use designations for the area. The evaluation of land use is presented in Draft EIS Chapter 4.4, and the project’s consistency with government plans and policies is presented in Draft EIS Chapter 5.0.

Sincerely,

Alfred P. Havas

Subject: Hawai‘i Dairy Farms

Environmental Impact Statement Preparation Notice
Māhā‘ulepū Road
Kaua‘i, Hawai‘i

TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion
The south shore of Kaua‘i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils (with “A” representing the class of highest productivity soils and “E” representing the lowest). The large tracts of farmland, including those of Mahaulepu Farm and Grove Farm, allow for stability in support of farm ventures, help maintain regional water systems and provide agricultural employment for Kaua‘i residents in addition to fresh, local food.

The project site is an agricultural land in Māhāʻulepū Valley, an area with a long history of agricultural use as it was the first place in the island chain where sugarcane was commercially grown. The site is in the Agricultural District per State Land Use District designations, and per the County of Kaua‘i zoning ordinance. The site consists of land classified as Prime per the State Department of Agriculture’s Agricultural Lands of Importance to the State of Hawai‘i (ALISH). The HDF site is outside of the County-designated Special Management Area under the Coastal Zone Management Program.

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The designation process determines land meet physical requirements including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high quality soil agricultural productivity ratings under the Land Study Bureau of University of Hawai‘i.

In 2011, Mahaulepu Farm LLC filed a petition with the State of Hawai‘i Land Use Commission to designate 1,533 acres of agricultural lands in Māhāʻulepū (including 557 acres that make up the HDF site) as IAL. IAL designation meets the objectives of the State HRS §205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. See Figure 4.4-2 in DEIS Section 4.4.

The designation process determined that the land meets a number of physical requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil agricultural productivity rating of “B” per criteria established by the Land Study Bureau of University of Hawai‘i.

The development and long-term operation of HDF will be in full compliance with its agricultural State Land Use District designation, ALISH classifications, and County zoning. The dairy farm will embody the intent of the IAL designation per the Hawai‘i State Constitution, by using these protected lands for the intended purpose of diversified agriculture, food production and agricultural self-sufficiency. HDF development of a dairy also supports the “secondary intent” for lands in the Agriculture land designation, to provide an opportunity for Kaua‘i citizens to reside in an agricultural community. This is in contrast to the described “agricultural subdivisions” that have changed parts of Kaua‘i intended for a rural landscape, with development as quasi-suburban landscapes dotted with residences on large lots.

Overall, the project provides long-term benefit and support of agricultural lands and industry through continued use in keeping with zoning and IAL designation. Long-term operation of the dairy does not preclude the region for future protection in a coastal park at Māhāʻulepū.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Hawaii Dairy Farms, LLC

From: Donald E. Heacock, Aquatic Biologist

Hawaii Dairy Farms (HDF) proposes to establish and operate the first zero-discharge dairy in Hawaii using sustainable farming methods on 578 acres of land in Maha'ulepu, Kauai.

General Comments:
The HDF, as planned, is extremely unlikely to establish a zero-discharge dairy at this site in Maha'ulepu, Kauai, for the following reasons:

- Lack of appurtenant water rights,
- Located primarily (65%) on soils classified as “hard clay, impervious to water”;
- Located adjacent to streams and Class A marine waters along the Maha'ulepu coastline that is classified as Class 1 critical habitat for Hawaiian monk seals, seabirds and green sea turtles that live there;
- Receiving waters that are already polluted (with indicator bacteria and Nitrogen/Nitrate) as compared to Hawaii's Water Quality Standards,
- No mitigation plan: if something goes wrong, like thousands of gallons of manure/urine discharged into the ocean, the cumulative and negative impacts on public trust resources (like coral reefs), which may never recover.

Specific Comments/Recommendations:

1) Lack of Appurtenant Water Rights

The proposed HDF is dependent upon Grove Farm supplying them with irrigation water from Waitea Reservoir; Waitea Reservoir is dependent upon water diverted from the Huleia River by Grove Farm. However, neither HDF nor Grove Farm have appurtenant water rights to water from the Huleia River. The water now being diverted from the Huleia River to fill Waitea Reservoir results in the complete dewatering of the river (i.e., dry river bed below the diversion for 100-250 yards downstream), which blocks the migration of native Hawaiian stream animals which need to migrate upstream to their adult habitat, and downstream to spawn; 90% of native Hawaiian stream animals (‘o’opu, ‘ope‘ae and hiihau‘au’ are endemic, found nowhere else on Earth; furthermore, this severe dewatering of the Huleia River and its negative biological impacts, is-it-in violation of the Federal Clean Water Act (which requires the protection of the biological integrity of water bodies) and is contrary to the Hawaii State Water Code which is to protect the beneficial instream uses (such as production of fish and wildlife, swimming, aesthetic enjoyment).

Also a local group of native Hawaiians, two farmers and Kuleana land owners have formed “Hui Ho'opuapapua Na Wai o Puna” (lit: the people who want to restore the waters of Puna) to restore the instream flows of the Huleia, Hanamaulu, Wailua and other rivers and streams in the Puna District. The Hui is working with Earth Justice and will petition the State Commission on Water Resources Management (CWRM) to establish the Hanamaulu Aquifer (which includes the Huleia River to the South fork of the Wailua River as a “Ground and Surface Water Management Area”) and to restore instream flows to the streams and rivers within the Hanamaulu Aquifer. Because of the president’s of previous Hawaii Supreme Court Decisions and Orders (Waiahola, 2000 and Na Wai Eha (2014), the outcome of the Hui’s petition to CWRM can legally be determined.

Recommendation: Therefore, the EIS should include specific data/documentation establishing Grove Farm’s and HDF’s having appurtenant water rights to the water of the Huleia River for public trust beneficial uses.

2) Coastal Receiving Waters Already Polluted

Currently, according to water quality monitoring data collected by Dr. Cari Berg, Surfrider Foundation, Kauai Chapter, the nearby receiving waters are polluted far beyond the Hawaii Water Quality Standards with indicator bacteria and with nitrogen/nitrate. Therefore, any polluted storm water runoff from the proposed HDF site will further and cumulatively negatively impact coastal water quality, the coral reef ecosystem, and other public trust natural resources.

Because the recently completed USDA/NRCS detailed soil analysis of the HDF site, showing that the dairy site is composed primarily (65%) of hard clay soils impervious to water (which HDF neglected to cite/mention in their Farm Conservation Plan), it will be virtually impossible to prevent polluted runoff from the HDF site with such high cow stocking rates during periods of heavy rains. These discharges will cumulatively add to coastal eutrophication, coral reef degradation and to losses of public trust natural resources.

Recommendation: Therefore, with these points in mind, and based upon the Precautionary Principle, no NPDES permits should be issued until the existing water pollution in the area is cleaned up, and additionally, until HDF shows conclusively that they can prevent storm water discharges containing pollutants from the dairy.

Sincerely,

Donald E. Heacock, Aquatic Biologist

Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Donald E. Heacock:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

HAWAII STATE WATER QUALITY CLASSIFICATION AND WATER RIGHTS

Water quality maps available on the Hawai'i State Department of Health website with a date of June 2014 and labeled “Draft” do not reflect the current Hawai'i Administrative Rules (HAR) §11-54, Water Quality Standards. Per §11-54-5.1 Inland water areas to be protected, and §11-54-6 Uses and specific criteria applicable to marine waters, all waters to be protected are listed in Appendices A, B, and C (dated July 1, 2014) of the HAR. No inland waters in the Māhā'ulepū watershed are included in the HAR §11-54 Appendix A. Therefore, no Class 1 Inland Waters exist in or around the HDF site. Marine waters downstream from the HDF site fall into open coastal waters Class A, as no embayments, marine waters, or open coastal waters in the area are included in the appendices of HAR §11-54 for special protection.

HDF’s right to use water from Waita Reservoir for irrigation and other purposes derives from Grove Farm. Grove Farm has advised HDF of its authorization from the Commission on Water Resource Management to divert the water that flows into the Waita Reservoir, and therefore does not need to have appurtenant rights to use surface water.

SOILS:

Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainfall for use during dry periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversely to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai'i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kaua'i, Hawai'i." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soil classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kāne'a Clay Brown Variant at 29 percent, and Laulaula Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, and microorganisms and other constituents. The results illustrate that the soils are depleted of nutrients which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu
grasses, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus, calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grassed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.
The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po‘ipū region were also calculated. Nitrogen input to the marine environment in the Po‘ipū region is calculated to be 36,510 pounds annually, or 35 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,250 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment.** An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**MITIGATION**

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua‘i community.

The potential for environmental accidents at the dairy farm will be minimal. Reviews and approvals are required from the State Department of Health for the waste management facilities. Standards and regulatory requirements must be met, and capacity beyond the required volumes has been added to provide additional backup storage. A secondary containment system has been designed as an additional safeguard. Risks to surface water quality are minimized with application of best management practices including vegetated buffer zones and 35-foot setbacks to exclude cows from farm drainageways. Effluent irrigation will not occur within 50 feet of agricultural ditches on the farm. Fuels and chemicals used at the dairy facilities will be used and stored following established rules and protocols.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: search "Hawai‘i Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

**GROUP 70 INTERNATIONAL, INC.**

Dear Mr. Healy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice. HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**GROUP 70 OBJECTIVITY:** Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State, and Federal agencies. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scope process involves Group 70's...
experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai‘i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”; http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Subject: Hawai'i Dairy Farms Environmental Impact Statement Preparation Notice

Dear Stephen Hee:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-

Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāulepū Ahupa'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua'i but not seen at the
HDF site include the house fly, the dog dung fly and the chicken dung fly. These pests are common in areas with high pest populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for *drosophila musophila*, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa‘ohi forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhā‘ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

In the Kōloa-Po‘ipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog cat, and chicken flocks. Beef cattle graze in the region on agricultural lands along Ah Kinoiki Road between Kōloa and Po‘ipū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

HDF: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 39,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii’s Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evaporate-irrigation cycle. Long-term groundwater supply impacts are not anticipated to be significant.
The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well. Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3,242 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CBW to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations: Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top...
The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Mäbaulepi will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōoa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of 10,000 pounds per year, and one percent of phosphorus (totaling 900 pounds per year). Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provided an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure...
application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drypox" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairies hens and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site, in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazig location. Actual odorous impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

**ALTERNATIVES**

As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaii Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid,
reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai'i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua'i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of feed for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": http://tinyurl.com/OEOCKAUAI

Thank you for your participation in the environmental review process.

Subject: Hawai'i Dairy Farms Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001: 001 portion

Dear Gary and Jackie Heinen:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

ARCHAEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,
development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $140,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $80,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($75,000 total versus $68,000 for the committed herd size). The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E
and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths - as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāʻulepū Valley and the HDF site ranges from 1.5 - 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poʻipū region is on the order of 201 - 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SANDWATER**

The State Department of Land and Natural Resources Commission on Water Resources Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hāʻupu Ridge. These normally dry streams converge into man-made channels running

Page 5 of 11
through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makaawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā'ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā'ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua'i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā'ulepū Valley. The dune canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes with the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.2.3 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Īlōlo-Po'ipū region were also calculated. Nitrogen input to the marine environment in the Po'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater
and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipu region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipu‘u Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downstream to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agro/mixed science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food
in production utilizing Important Agricultural Lands, demonstrating the
importance of long-term agricultural leases and capital investment for
agricultural infrastructure, water systems and support facilities. (Criterion 3).
However, after years of trying, it appears there was limited interest in such a
venture.

- Finally, addressing the range of potential environmental impacts (natural,
cultural, social and economic) (Objective 8) the two alternative development
scenarios would generate fewer beneficial impacts and produce impacts that
could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of
Hawai'i Dairy Farms, was determined to be the most viable option and is the
preferred alternative. Of all the alternatives considered, this is the only approach that
achieves project objectives and meets each of the four Evaluation Criteria.

- Hawaiian Dairy Farms will create a commercial scale pasture-based dairy
operation in Hawai'i, with the capability to provide more than 1,000,000
gallons of the fresh milk demand, reducing dependence on imported milk
(Objective 1).
- The planned dairy location meets the requirements of minimum land area,
soil properties, slope conditions, water supply, land tenure and availability,
and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the
agricultural sector on Kaua'i, including pasture agronomy/soil science,
veterinary and animal husbandry, environmental resources management,
milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion
3) will occur with the proposed action, demonstrating the importance of long-
term agricultural leases, and the ability to draw capital investment for
agricultural infrastructure including water systems and support facilities
(Criterion 3).
- Address the range of potential environmental impacts by utilizing 100
percent of manure as natural fertilizer to grow the majority of food for cows
(Criterion 4). The alternatives evaluated would generate fewer beneficial
impacts and produce impacts that could potentially exceed those anticipated
from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains
agriculture, retains open space, and provides buffer between highly utilized
resort and residential development and sensitive natural or cultural resources
(Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact
Statement (EIS). The Draft EIS is available on the OEQC website at the following
URL search "Hawai'i Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhāʻulepū Road
Kaua‘i, Hawai‘i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Larry Heller:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai‘i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai‘i Revised Statutes and the “Environmental Impact Statement Rules” (Chapter 200 of Title 11, Hawai‘i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai‘i Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70’s
experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai‘i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Ku‘ai to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Ku‘ai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Wa‘ia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and...
irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepi site and provided essential colostrum and nutrients for a healthy start. During the calves' initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepi site applies to mature mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of management. Managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds' welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**SOILS:** Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainfall for use during dry periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kaua‘i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kaua‘i, Hawai‘i.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihī Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies.

In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).
As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbon in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**WATER QUALITY**

Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimāna volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths — as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is comprised of dark brown to black silt and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 1.05 — 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 — 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD) of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD plant established a 1,000-foot setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.
Regional Water Demand: The adjacent, developed Kōloa-Po'ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kauaʻi will increase county-wide by 17,300 residents by 2030. The South Kauaʻi population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kauaʻi region (the Kōloa - Po'ipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Surface Water

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hanapepe Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leakage or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauaʻi Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particular pollutants during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to
increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiʻoli Ditch provides the majority of freshwater input to the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kauaʻi community.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawaiʻi Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condensation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Convention Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kauaʻi; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and
neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2), grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities (Criterion 3).

However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search “Hawai‘i Dairy Farms”.

Thank you for your participation in the environmental review process.

Sincerely,

Jeffrey H. Overton, AICP, LEED AP

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhūʻulepū Road
Kaua‘i, Hawai‘i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Tom and Ann Hennessy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhūʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Ni‘ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.
Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhāʻulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhāʻulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasc Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, electricians, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $69,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices C and E. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**
The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāuleπī Valley well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāuleπī Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Unit and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipu region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa-Po‘ipu-Kaláheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāuleπī Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāuleπī watershed.

The HDF site is located on the bottom-land of the upper Māhāuleπī Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāuleπī Road. This ditch, named Wai‘ōpili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.
Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; the National Pollutant Discharge Elimination System (NPDES) – Construction only irrigation water will be used in these areas as needed to maintain the vegetated pasture. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makaawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.
Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiolii Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a wind model depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more stringer than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be
dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": http://tiwurl.com/OEQCKAUA

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED-AP
Principal Planner

February 23, 2015

Dear Planning Staff members:

Most people on Kauai support agriculture if it is done right. If you really want to have a farm and you really want the support of the citizens, create a model that does not pollute the aquifer, does not use artificial chemical fertilizers, does not use GMO feed, and is sustainable. I would suggest an organic grass fed only beef cattle farm which puts the correct amount of animals on the land that the land can support. The beef would be in high demand for local residents who would be proud to support such a venture.

The idea of an extensive dairy operation producing excessive amounts of effluent and using chemical fertilizers that pollute the aquifer, streams, beaches and coral is something that many community members cannot support. The importation of GMO feed is questionable. Water pollution and the use of non-indigenous insects to control the flies would adversely affect the tourism industry and businesses and jobs in the Poipu area.

The obvious choice for Grove Farm is to work with the community and be a hero.

Best regards,

Tom Hennessy

cc: Group 70 International, Inc., Hawaii Dairy Farms LLC
Dear Tom Hennessy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawaii’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, machine operators, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā‘ulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā‘ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCs, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawaii’s Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, machine operators, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.
The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the tourist industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property values or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**
The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Måhå‘ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Måhå‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Po‘ipu region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipu - Kalāhēo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

### Surface Water

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Måhå‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Måhå‘ulepū watershed.

The HDF site is located on the bottom-end of the upper Måhå‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Måhå‘ulepū Road. This ditch, named Waipōlī or Waipōlī ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

### Potential Impacts from Construction

The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopōlī Ditch near the bridge accessing Makauwahī Cave Reserve in April of 2014. The group reported high levels of enterococci to the County. Complaints from the public citing the high levels of enterococcus in Waiopōlī Ditch and concerns about the proposed dairy prompted CBW to conduct a "Sanitary Survey" of the Måhå‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopōlī Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: Waiopōlī Ditch Sanitary Survey, Kaua‘i, Part 1. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Måhå‘ulepū Valley. The dense canopy along the makai end of Waiopōlī ditch blocks ultraviolet rays, which could help reduce bacteria levels. (CBW noted that Waiopōlī Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations: Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top
Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waioli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the marine environment revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWBR, dairy neighbors and the local Kauai community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act
Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure
application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1.670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEOCKAUA

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Hawai‘i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā‘ulepu Road
Kaua‘i, Hawai‘i
TMK: (4) 2-9-003:001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Herb Herndon:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**NATURAL HAZARDS:** The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā‘ulepu property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and Niihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.
Although they occur infrequently, Kaua'i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā‘ulepū region during and following the hurricanes that affected Kaua'i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā‘ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua'i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Nāpali formation lavas of the Wānena volcanic series. Surface lavas of the Nāpali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is overlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.
Through the waterbody in which the County well occurs is confined and established a 1,000-foot setback from the Kalani Fishponds, prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include silt fence installed and drainage ditches. The Kalani Fishponds, located adjacent to Waiopili Ditch, provide overflow to the Kalani River and are an important fishery and wildlife habitat.

The Kalani Fishponds is a man-made drainage channel and is not an inviting recreational body of water utilized by people. The State Department of Land and Natural Resources, in cooperation with the State Department of Health, has conducted water quality sampling at Waiopili Ditch and Kalani Fishponds. The Kalani Fishponds is a man-made drainage channel and is not an inviting recreational body of water utilized by people. The State Department of Health and the Waiopili Ditch Sanitary Survey, Kauai, Part I, found no significant impact to the ditch from any activity that could be attributed to the ditch. Fish and animal waste degrading organic debris and inputs impacted the ditch. The ditch along the Kalani Fishponds was created by the US Army Corps of Engineers in 2013. Additional practices that may impact the ditch are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices. hdf operations will follow the practice standards of the National Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Another setback restricts application of effluent within 50 feet of the drainageways.

Waiopili Ditch Sanitary Survey, Kauai, Part I

The Waiopili Ditch, located adjacent to Makauwahi Crater Reserve in April of 2014, is the major drainage channel and is not an inviting recreational body of water utilized by people. The ditch along the Waiopili Ditch was created by the US Army Corps of Engineers in 2013. Additional practices that may impact the ditch are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices. hdf operations will follow the practice standards of the National Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Another setback restricts application of effluent within 50 feet of the drainageways.

SURFACE WATER

The State Department of Land and Natural Resources, in cooperation with the State Department of Health, has conducted water quality sampling at Waiopili Ditch and Kalani Fishponds. The Kalani Fishponds is a man-made drainage channel and is not an inviting recreational body of water utilized by people. The State Department of Health and the Waiopili Ditch Sanitary Survey, Kauai, Part I, found no significant impact to the ditch from any activity that could be attributed to the ditch. Fish and animal waste degrading organic debris and inputs impacted the ditch. The ditch along the Kalani Fishponds was created by the US Army Corps of Engineers in 2013. Additional practices that may impact the ditch are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices. hdf operations will follow the practice standards of the National Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Another setback restricts application of effluent within 50 feet of the drainageways.

Another setback is a stormwater pollution prevention plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES).
only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā'ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). This nutrient run-off would not occur on chronic daily rainfall. Rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m3, well below the State standard of 150 μg/m3. The estimated concentration for PM2.5 is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawai‘i Dairy Farms": http://tinyurl.com/OEQCAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
To whom it may concern:

I am opposed to the proposed dairy farm in the Mahaulepu Area, Kauai due to its effect on air quality in the area in which I live, the Poipu area south of Koloa. Because of my proximity to dairy farms where I have previously resided, I am acutely aware of the effect on air quality of effluent holding ponds on areas downwind from the farm. In the case of HDF, we are located directly downwind from this facility due to the prevailing trade winds common to this area. Regardless of the feeding process of this proposed dairy farm, the milking area generates large quantities foul odor waste due to cattle elimination waste and the water used to remove it from the milking area.

Without highly effective water treatment facilities it will be impossible to control the odor emanating from this area. I question whether studies concerning the holding area for waste consider guarding against rains of the magnitude of those received by this area during March of 2006, amounting to approximately 40 inches for the month.

Your thoughtful consideration of these concerns will be greatly appreciated.

Sincerely yours,

Joyce W. Herndon

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhāʻulepū Road
Kauaʻi, Hawaiʻi

Dear Joyce Herndon:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

Your comments were received by the Department of Health Environmental Planning Office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**NATURAL HAZARDS:** The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāʻulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas

Group 70 International • 928 Bakah Street, 5th Floor • Honolulu, HI 96813-4307 • tel. 808.523.5866 • fax. 808.523.5874 • www.group70int.com
Hydrology: The area’s hydrology is shaped by its geology. The Kīloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kīloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāulepū Valley and the HDF site ranges from 105 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kīloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable drinking water. Water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.
The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāʻulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Poʻipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Poʻipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface Water Hydrologic Unit, which features relative high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahine Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococci in Waiopili Ditch and concerns about the proposed dairy prompted CBW to conduct a “Sanitary Survey” of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CBW noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top
of drainerageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainerageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of 10,000 pounds per year); and one percent of phosphorus (totaling 900 pounds per year). The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient concentrations in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

**AIR QUALITY:** As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odor, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaiʻi has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrogen oxide (NOₓ) emissions from manure...
application. No State or Federal regulations for greenhouse gas emissions from farm
operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect
the paddocks and lead to and from the milking parlor. Potential fugitive dust
emission rates were estimated from published literature, where particulate matter
(PM) is measurable from the “drysloits” of confined dairy operations where animals
walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates
potential emission resulting from HDF. Cows in the pastoral rotational-grazing
system will be on pasture 22 hours each day and will spend two hours – in two
separate milking cycles – moving to and from the barn for the 10- to 15-minute
milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to
the size of the non-pasture areas used by cows at HDF. Results were added to the
background concentration of particulate matter (both PM0.1 and PM2.5) measured on
the island of Kauai, and the total concentration was compared to the State ambient
air quality standards. Only the contemplated herd size of up to 2,000 mature dairy
is likely odor detection beyond the HDF boundaries will be less frequent.
cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust
impact would be negligible. The estimated concentration for PM2.5 is 2.01 μg/m3,
well below the State standard of 150 μg/m3. The estimated concentration for PM0.1
is 0.23 μg/m3, well below the Federal standard of 35 μg/m3 (see Draft EIS Section
4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of
organic matter in manure. No animals or dairy facilities currently exist in the area
leased by HDF, so air dispersion models were used to determine potential odor
levels. Local weather data was used in conjunction with the AERMOD modeling
system, and published rates for manure odors emissions for dairy heifers and
effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture
fields, irrigation water containing diluted nutrients from effluent, the effluent
storage ponds, and the dairy buildings. Odor rates from published research were
applied. Odor isopleths (a line used to map all points having the same numerical
value) were created to display the model findings. Odor is described in “odor units”
at the threshold of perception, which is defined by the point at which 50 percent of
panelists, in laboratory conditions, cannot smell the odor but 50 percent of the
panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low
wind velocity / mixing). Generally, tradewinds will disperse odors to less than
detectable levels beyond the HDF site; in periods of no wind, odor may not be

Results for the committed herd size of 699 mature dairy cows show that odors may
detectable by 50 percent of the sensitive population once per 200 hours, or 44
hours per year, within an area that extends approximately 1,670-feet (within one-
third of a mile) beyond the dairy farm boundary, and does not reach recreational or
residential areas. Results for the contemplated expanded herd size of up to 2,000
mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF
boundary (just over half a mile), again not reaching recreational or residential areas,
and again with detection limited to 50 percent of the sensitive population
approximately 44 hours per year. The parameters used in the analysis were
intentionally conservative, and the impacts shown assume an unlikely confluence of
worst-case meteorological data, irrigation location, and grazing location. Actual
offsite odor impacts are likely to be much lower and/or less frequent than shown; it
is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact
Statement (EIS). The Draft EIS is available on the OEQC website at the following

Is Mahā‘ulepū a Particular* Landfill?  

Prior to any approval from government agencies allowing the Mahā‘ulepū area to be used as a site for a possible health hazard / water polluting dairy farm, or any other agricultural endeavors, this Kaua‘i resident recommends that an "independent civil investigation" be conducted concerning the possibility that environmental violations have occurred in the above mentioned area resulting in the creation of a clandestine "Solid Waste Disposal Facility"; commonly referred to as a "landfill".

Over the past decade and a half, both private (business) and public (government) sector's records indicate evidence that certain solid waste materials, namely Construction & Demolition debris (C&D) along with hazardous waste (asbestos & red lead paint), have been disposed of in un-supervised fashions. Such acts of possible circumvention of legitimate, best industry practices, are considered crimes; both civil and criminal, and need to be clarified. Why add more possible pollutants to an area that may already be polluted? Let's find the truth.

Not only does it create the possibility of exposing the Poipu - Koloa - Mahā‘ulepū area residents, vacationers, businesses, schools ...our children... to health and life threatening issues, such actions also deprives our County of Kaua‘i much needed revenues generated from tipping fees which support our government and our island. ALOHA.

John Hoff

* Def: "distinctive among others of the same general category"
Environmental Protection Agency related to concentrated feeding operations in the States. As noted previously, the HDF system is designed to utilize 100 percent of the feed required to maintain cows at the site. The term "grass-fed" was used in the HDF EISP. This term was intended to identify the use of the collective term "grass-fed," the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.1. Agricultural infrastructure and utilities required for the dairy operations will be provided by the irrigation system. The irrigation system is controlled using computer software and GPS receivers to allow the irrigation system to be managed or restored to reduce runoff, improve water quality, and exercise while they forage.

The cattle will be divided into paddocks as they roam the site. The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigation systems. The pivot irrigation system is controlled using computer software and GPS receivers to allow the irrigation system to be managed or restored to reduce runoff, improve water quality, and exercise while they forage.

The ef fluent is planned for the storage pond on a 30-day storage schedule for 699-cow dairy. Throughout the less than 30-day storage period, effluent is expected to be applied every four days, and the slurry application is expected to be applied every 65 days of storage for 699 mature dairy cows. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of the cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mob"s, mimicking the natural social order of bovines. Cows spend 22 hours of each 48-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped pastures, walkways and races minimize the impact of drainage ways throughout the site. Existing vegetation within the setbacks will be mowed or restored to reduce runoff, improve water quality, and exercise while they forage.

The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance and fertilizer effectiveness, see Draft EIS Section 3.5.3, and Draft EIS Appendix D.
Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and the refuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

Hydrology: The area’s hydrology is shaped by its geology. The Kūloa area was built by Napali formation lavas of the Waima volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silt and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kūloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD) of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milk operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāulepū 14 well and the County’s Kūloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāulepū Valley, HDF established a 1,000-foot setback surrounding the Kūloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.
Regional Water Demand: The next 20 years will see a significant increase in the demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the number of people living in the County to increase by nearly 1 million gallons per day. A projection that the island population will increase by 172,000 people by 2035. The Department of Health (DOH) must account for this increase in demand to prevent a deficit and require commercial supplementation. Gray yields are anticipated to fall under the exemption for commercial supplementation.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and areas upstream, and initiated a series of investigations by the State Department of Health (DOH). The Sanitary Survey found no significant impact to the ditch from any activity that could carry particles into surface waters. Fences will be erected 35 feet from the top edge of drainageway (totaling 70 feet in width) to keep cows away from surface waters. Another setback restricts application of effluent within 50 feet of the drainageway. Only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Lungmen Quesitons. Settlers and holdiers. Normal ongoing firming and machining practices are exempt from the Clean Water Act (CWA). The National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and buffer and pasture grass, keeping nutrient applications away from waterways.

Potential Impacts from Construction: The dairy facility and associated infrastructure could carry particles into surface waters. Fences will be erected 35 feet from the top edge of drainageway (totaling 70 feet in width) to keep cows away from surface waters. Another setback restricts application of effluent within 50 feet of the drainageway.

NUTRIENT SOURCES: Agricultural activities are expected to drop from 3 tons per acre per year to 1 ton per acre per year. The project area is located in the Waipio Valley Water Resources District, U.S. Army Corps of Engineers (USACE) in 2013. Additional ridge. These normally dry streams converge into man-made drainageway, running through the HDF site across the valley floor, and meets a concrete drainageway (totaling 70 feet in width) to keep cows away from surface waters. Only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass. The Dairy Facility and associated infrastructure are expected to contribute nutrient sources of 1 ton per acre per year. The project area is located in the Waipio Valley Water Resources District, U.S. Army Corps of Engineers (USACE) in 2013. Additional ridge. These normally dry streams converge into man-made drainageway, running through the HDF site across the valley floor, and meets a concrete drainageway (totaling 70 feet in width) to keep cows away from surface waters. Only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass.
increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa-Pōʻipū region were also calculated. Nitrogen input to the marine environment in the Pōʻipū region is calculated to be 38,510 pounds annually, or 35 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Pōʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipio Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua‘i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”:

To Whom It May Concern:

My name is Maureen Holt. My husband Howard and I founded Trustile Doors Inc. in Denver Colorado in 1995. Trustile is an MDF door manufacturer. MDF is a product made from wood dust and compressed into sheets that are cut and styled into doors. It is an environmentally green product. We built a state of the art 50,000 square foot plant and we burned our waste to create the energy we needed to run our equipment. The air quality leaving our plant was actually cleaner than the air coming into our facility. We provided a safe workplace and created 168 American jobs. We sold our company and in 2006 we moved to Kauai.

We had vacationed in Kauai 7 different times before the actual move. We loved Kauai for its weather, natural beauty, and its lifestyle. We purchased a home in Kolua Estates on the South Shore of Kauai near the world famous Poipu Beach. The air and water quality are much better here than that of the mainland Howard breathes easier here and doesn’t have to take as much medication for his Asthma. The warm weather is easier on me with my arthritis and lower back pain. It is a great place to live. We spend most of our time outdoors while our friends and family on the mainland have to live indoors during the cold winter.

We are extremely concerned about an industrial sized dairy coming to our island. On the mainland dairies are usually located off busy highways on huge parcels of land away from housing developments and pristine coastlines. We have driven by dairy farms and had to hold our breath due to the odor caused. Dairies are notorious for bringing in flies. One expert that happens to live on the north shore of Kauai stated there would be one billion flies. The odor and the flies would ruin our quality of life here. We like to eat outside, enjoy swimming in our pool, gardening and playing Frisbee with our labradoodle Rosie. We will have to invest in expensive air conditioning instead of enjoying the cool trade winds and shut our windows to avoid the odor and the constant buzzing and biting flies. It is estimated that our property values could drop as much as 40% which would affect the property tax revenue base for the county. Our house is paid in full and we would have to walk away from our investment, most people have loans and would walk away from what they paid leaving the bank their home.

The dairy is only going to create 15 jobs and it has the potential to completely destroy tourism on our beautiful South Shore. Tourists are not going to spend all the money it takes to get here to smell cow dung and eat flies. The amount of jobs lost if tourism drops could be in the thousands. Kauai depends on tourism for its sustainability. The Grand Hyatt hotel has filed a lawsuit against the dairy. The Hyatt has already lost business since conventions are booked years in advance and just the threat of an industrial sized dairy coming in such close proximity to the Hyatt has caused businesses to find other locations for their conventions. The Hyatt was planning to expand its location to add more hotel rooms to the south shore which would create more jobs for the largest employer on the island. The Hyatt is a good steward of the land and keeps the grounds very pristine and welcoming, and is an excellent company to work for. Our son works for the Hyatt in Beaver Creek Co. and he loves his job.

The Hawaiian people want to be good stewards of the land their “inau, homa” and keep it for future generations. There are several significant sites that are considered sacred and need to be undisturbed by the dairy. The waste from the dairy could destroy already endangered plants, birds, coral and several species of ocean life.

We are concerned about the dairy location only 750 feet from our wells for our drinking water. We feel the amount of waste generated by the industrial dairy will make our drinking water unsafe, due to the large amount of urine and manure left on the grazing land.

The dairy is modeled after dairies in New Zealand and we just need to look to what has happened there and realize this is not right for Kauai. The beaches there are not black sand they are black from manure deposits with swimming and fishing becoming a thing of the past.

Dr. Carl Berg of Surf Rider has tested the water quality and it is already polluted with human and animal waste and the Department of Health agrees with their findings. We need to find the sources of the pollutants and see that Steve Case the owner Grove Farm cleans up the water prior to a dairy being established on the site. The Friends of Mala‘ulepu offered to put up signs on the beaches to discourage swimming in the polluted water and Grove Farm refused to post the signs. They don’t want to discourage tourism, however there is a health risk associated with swimming in the polluted water.

We believe in the American dream and Peter Omidyar created a great thing with EBAY. We as previous business owners commend him on his success; however leasing the land from Grove Farm to build an industrial sized dairy is a really bad idea for Kauai. Peter needs to create jobs at the same time take care of the environment and not affect surrounding communities. His legacy should be to improve the quality of life here on the island.

We want to trust that our government officials will protect us against the damaging effects this dairy will cause our island. We believe the Environmental Impact Study will prove that this site is unsuitable for and industrial sized dairy. We are so blessed to live in such a desirable place, let’s keep it that way for future generations.

Sincerely,
Howard F & Maureen C. Holt

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhāʻulepū Road
Kaua‘i, Hawai‘i

Dear Howard & Maureen Holt:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāʻulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy.” The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herds’ diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed.” The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed,” the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, including storage tanks and silos, effluent storage ponds, livestock water systems, and irrigation systems. The dairy facilities will include drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhāʻulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diets; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diets.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob,” mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and the energy expended by the mature dairy cows as they graze are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways

Howard & Maureen Holt

Page 2 of 15
and cows. These are designed to provide a comfortable path under hoof. The other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and fossil fuels in Hawaii and promote sustainability. This will reduce the need for feed that is not sustainable. A high-quality diet will ensure optimal weight gain and productivity.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of animal care to minimize stress and ensure optimal health. Antibiotics may be prescribed as needed for treatment of illnesses. Adherence to guidelines for the use of antibiotics approved by the Food & Drug Administration (FDA) will be followed. Healthcare will include laboratory tests for traces of antibiotic residue, routine Bovine Acid Stool, and Cow Milk Test (AML) and Cattle Identification (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

ARCHEOLOGICAL AND CULTURAL: The Hawai'i Dairy Farms (HDF) project is subject to a historic review, as well as a State Department of Land and Natural Resources, State Historic Preservation Division (HRS) review of archaeological and cultural resources, with technical studies in Appendix G and H. A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area. Six historic properties are within the project area and six sites occur in the extended survey area. One of the sites is believed to be associated with pre-European settlement, and four of the sites are believed to be associated with the many Land Commission Awards in the project area were not successfully identified as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic byproducts, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, and timing of nutrients applied to the land to meet the crop's nutrient requirement for optimal growth, yield, and quality. Recommended rates are based on soil tests and crop needs. The timing and application of nutrients can be controlled to provide immediate benefits, such as increased crop yields, and sustained benefits, such as improved soil fertility and water quality. The effluent storage ponds are designed to accommodate 30 days of storage for up to 120,000 head of cattle, and 45 days storage for up to 60,000 head of cattle. The effluent from the ponds is planned for application to the pasture on the dairy farms. The ponds are designed to have a 20,000-cow capacity and nationwide 30-day storage period, with a load of at least 700-cow capacity for every 10 days, and a load of at least 700-cow capacity for every 30 days. The ponds are designed to have a 20,000-cow capacity and nationwide 30-day storage period, with a load of at least 700-cow capacity for every 10 days, and a load of at least 700-cow capacity for every 30 days.
Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē gosse collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-specific areas, marking tall structures and fencing with white visibility polytype, limiting nighttime lighting, and shielding any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammal species.

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenhouse fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for drosophila mu сбор, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-‘ōhi‘a forests.

Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AE COS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawaii’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plant species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhāulepū Valley.
Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate indirect full-time equivalent jobs on O'ahu, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

In the Kōloa-Poi'pū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ah Kinoi Road between Kōloa and Poi'pū, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on O'ahu, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on O'ahu, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

GROUND WATER: Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by丕 option formation lavas of the Waimea volcanic series. Surface lavas of the丕 option formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with
The groundwater and surface water analysis conducted for the Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The results demonstrate the ability of soils to transport water given a hydraulic gradient and are expressed in units of feet per day. It is a measure of how easily water will move within the soil system. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

Groundwater in the alluvium will not impact the County drinking water well. Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Permit. The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Mahlu‘upal Bailey 14 well and the proposed dairy site, will result in no adverse impacts on the existing groundwater system. Groundwater in the alluvium will not impact the County drinking water well.
Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makaawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” [http://health.hawaii.gov/cwb].

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways;

only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 1.62 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily discharge; rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 14 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal
area. Water chemistry measurements made by MRCl identified mixing of ditch water occurs rapidly and within a short distance of the shoreline. The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CBW, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. ER sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1 Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milk cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of the panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.
Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search “Hawaii Dairy Farms”; http://tinyurl.com/0EOCKAUAJ

Thank you for your participation in the environmental review process.

Sincerely,

Subject: Hawai‘i Dairy Farms  
Environmental Impact Statement Preparation Notice  
Māhāulepū Road  
Kaua‘i, Hawai‘i  
TMK: (4) 2-9-01003:001 portion and 006 portion  
(4) 2-9-003:001 portion

Dear Jens Houby:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of EU99, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**GROUP 70 OBJECTIVITY:** Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai‘i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai‘i Revised Statutes and the “Environmental Impact Statement Rules” (Chapter 200 of Title 11, Hawai‘i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agencies. On numerous past EIS projects, the Hawai‘i Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70’s experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai‘i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

**AIR QUALITY:** As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a win rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

**Clean Air Act**

Under the Clean Air Act of 1970 (CAA), amended November 1990, the US Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

**DUST**

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy...
cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM$_{10}$ is 2.01 μg/m$^3$, well below the State standard of 150 μg/m$^3$. The estimated concentration for PM$_{2.5}$ is 0.23 μg/m$^3$, well below the Federal standard of 35 μg/m$^3$ (see Draft EIS Section 4.19 and Table 4-19.2).

**ODOR**

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

Re: Hawaii Dairy Farms Environmental Impact Statement

Dear Mr. Overton,

My wife and I reside in Poipu, Kauai, approximately 6 months out of the year and we want to provide our deepest concerns regarding the Hawaii Dairy Farm (HDF) proposed for construction in the pristine area of Mahulepu located in the SE coastal area of Kauai County.

While we realize that Hawaii desires additional economic drivers for its economy, this cannot come at the certain degradation to its environment and protected wildlife. This is particularly true when the benefits are miniscule as compared to the considerable negative impacts this non-critical business venture would certainly bring to this beautiful and highly regarded tourist and resort area of Poipu.

We are asking that the Hawaii Department of Environmental Protection and the Hawaii Department of Health thoroughly evaluate and at a minimum require very strict stipulations for this operation.

As to how this operation would negatively impact us personally and directly (and others like us) is the high probability of it causing health issues. Both my wife and I are retired and she has an impaired immune system that makes her highly susceptible to infections – particularly sinus infections. The reason we purchased a home in Kauai (and Poipu in particular) is its pristine conditions – most notably its air. The location of a potentially high density dairy operation less than 3 miles upwind of our home would create a host of health issues for people with upper respiratory and sinus conditions that visit here for the benefits of breathing pristine salt air carried in by the prevailing northeasterly trade winds. These trade winds travel thousands of miles unencumbered by human interference and pollution. These conditions would be considerably degraded and in our case could lead to my wife catching infection from microscopic particles carried in on the trade winds from the dairy. If this happens we will be forced to try and sell our property (no doubt it will be worth less than we paid for it 10 years ago) and relocate to another area. Because we are retired and planning to spend more time in Kauai, the fate of this HDF will have a significant impact on our future plans as well as the well-being of my wife. My wife’s infectious disease doctor in Denver (as well as her ear, nose, and throat doctor) recommends that we consider living in Poipu full time due to its pristine conditions and the noticeable improvements in her health when we are on Kauai.

We have spent most of our adult lives in the Denver metropolitan area and even though we are over 50 miles away from similar dairies as the proposed HDF, when the wind shifts to the NE the odors from the dairies are overpowering even in Denver. I personally spent 2 decades working on projects close to several dairies in Weld County (that I will not name), but several are located near Platteville, CO. I can say firsthand that the stench from the dairies on certain days was overpowering. Those days (fresh rain, high humidity, and warm temperatures) made working near the dairy unbearable. While these conditions are few in number in the high arid conditions of Colorado, they are an everyday occurrence at the proposed site in Mahulepu. I will barely address the proliferation of insects at dairies in Colorado except to say, when working near the dairies my crew and I could not eat within a mile of the facility without sitting in our trucks with the windows rolled up and the air conditioning on or otherwise
daily hatching flies fresh from eating manure and feasting on the green slime of the catch ponds would invade us and land on our lunches making them inedible. Conversely, people(residents and tourists) come to Poipu to eat fresh seafood outside and enjoy the views and smell of gardens and the salt air....NOT the stench from the catch ponds at the proposed dairy and be continually irritated and potentially harmed by disease carrying flies (and mosquitoes as well).

The bottom line is unlike the pastoral setting of cows grazing in a field that Group 70 purposefully put on the cover of their document to present a perceived peaceful ambiance for their project, a working dairy is a dirty, smelly, disease ridden place where crew wear knee high rubber bogs, arm length rubber gloves, walk around in ankle deep filthy sludge and wear masks to protect their lungs as it is a very unhealthy place to be around or even be near.

Dairies should not be positioned near any populated area as many studies have shown. We would respectfully ask the DOH and HEPA to consider these issues as well as several other points that were glossed over or completely ignored in the preliminary document provided by Group 70 regarding the proposed HDF:

1. Soil conditions - as a licensed engineer with a minor in geology and 40 years working with geologists I can say that soil conditions in any large area is highly variable and is certainly not homogenous. Therefore, we would request that a more thorough and rigorous soil analysis be performed of the dairy site including multiple soil samples taken at various depths in a multitude of areas before reaching any conclusion about whether or not the soil would have enough permeability to transmit effluent urine and feces residue down to groundwater. In an area of 570+ acres there will no doubt be areas where the clay content is limited to minimal and will allow percolation of contaminated fluids into the groundwater. But at the same time, high clay content in other areas will hold fluid and result in significant run off of fluids downslope to the ocean. What will be the plans to prevent this and what is the penalty when this inevitably occurs? Pay a fine for continuing to pollute?

2. Along the same vein, there needs to be a data driven monitoring set of processes to insure no contaminated effluent gets to groundwater such as drilling monitoring wells along the perimeter of the property as well as wells offsetting the “effluent catch basins” to insure they are not leaking. Likewise, the design and construction of these “catch basins” need to be clarified including how (and with what they will be lined) and how much head board (bem) will be included to insure they will not be overrun when extended heavy rains occur.

We are incredulous that there will be county and private potable drinking water wells located within 750' from this operation. A study as to fluid transport through this type of soil has to be required including transmissibility rates and directionality. Potable drinking water on Kauai (as well as the other islands) is priceless...just check ask Molokai!

3. A detailed plan regarding dust particulate mitigation is needed and not just during the construction period. More importantly will be continual mitigation efforts during the permanent operation when equipment is continually moving in and out of the facility relocating cases around the facility, bringing in other needed farming and milking equipment, daily transportation of the milk to its final processing plant. Group 70 did not mention that the limited road infrastructure into this area is dirt.

4. A detailed cost/benefit analysis is needed to measure the benefits of this dairy (how many actual permanent jobs will be created and expected tax revenues) vs. several scenarios of estimated reductions in tourist traffic (and loss of established permanent jobs to hotels and homes that are seasonal vacation rentals) due to the odors
originating just 2.5 miles upwind of one of the two largest tourist destinations on Kauai. Once word gets out regarding the odor problem in Poipu, the average tourist will choose to spend his/her vacation elsewhere.

5. In addition, a larger and more specific data set should be required regarding current occupancy rates of residences at Poipu. The vague statement that 56.2% of the housing units are vacant does not appear current or factual. How was this one number derived and where did it originate?

6. From first hand observation the Hawaiian Monk Seal and Green Sea turtles reside in the waters and beaches ½ mile downslope from this proposed operation. Also, the threatened and endangered (T&E) Humpback whale frequents the waters on this side of Kauai. These specific animals (along with lots of large sea birds) are seen daily in this area. The EIS needs to provide protection for these sea creatures from any potential damage to their habitat from contaminated run off that could occur during monsoonal rains and floods such as the “40 days of rain” that occurred in the Koloa and Poipu area a few years back. Also protection is needed to prevent birds (particularly T&E fowl) from landing in the filthy and disease ridden “catch basins”.

7. It is a faulty argument to equate historic sugar cane production that ended decades ago as equivalent to a high density dairy operation. Tons of sanitary waste (urine and feces) were not created with these operations and the cultural aspects of the area (including the extremely rare Makawahi Cave) were unknown when these operations began. Now we know that this particular cave is very rare and holds tremendous palaeoecological and archaeological data and has been described as “maybe the richest fossil site in the Hawaiian Islands and perhaps in the entire Pacific Island region”. The area around this site has been painstakingly improved and is becoming a favorite visiting site for locals and non-locals to visit and learn about the ancient history of this area. This area is directly offsetting the HDF to the south and will be severely impacted by foul odors emitted from the dairy.

Data is needed in the EIS referencing similar high density dairy operations in a “tropical environment” loaded with cultural artifacts and what measures are needed for a setting such as Makawaha Valley.

8. Finally, even though this is referred to as a “zero discharge” facility which sounds nice, but in reality means all the manure and urine stay on-site...that is TONS and TONS of it. As Group 70 boasts the tons of cow manure will be spread throughout the property to fertilize the grass. Assuredly that much manure when it is spread back as fertilizer is quite a large point source of odor. With a little rain, the smell is horrific.

My personal experience from being around dairies is grazing cows (often in groups of 20 or more) urinating and defecating when they feel like and where they feel like it. If you have witnessed cows urinating and defecating first hand, it is not a small volume of urine or feces and certainly not a pleasant event to smell. How will all of this waste be handled? Will it be gathered daily into a pile? What about the urine? All of this will provide opportunity to potentially damage to groundwater in the high permeability areas and, of course, the odor emissions when the herd reaches 2,000 cows will be significant.

While quite a bit of statistical data was included in the notice from the Group 70 regarding the amount of milk that the HDF would produce, nothing was included regarding how much urine, manure, belching and flatulence would be produced daily and the resulting methane (greenhouse gas) that would be released into the atmosphere. Published data support that cows emit a massive amount of methane through belching and flatulence. Statistics vary regarding how much methane the average dairy cow expels but some say it’s up to 500 liters (132 gallons) per day or an amount comparable
to the pollution produced by a car in a day. While the Group 70 report refers to HDF using a "smaller" "kiwi cross cow'', the difference in size is primarily in height not girth and the weights are nearly identical. The "kiwi cross cow'' is a hybrid of a cross breed of Holstein and Jersey cows. Coincidently, in New Zealand a tax proposal on dairy cow flatulence has been considered and the "kiwi cross'' dairy cow is used almost exclusively there. Please note the photo of a herd of "kiwi cross'' dairy cows below.

In conclusion, with all due respect to the HEPA and the HDOH, simply requiring "Best Management Practices'' as part of the permit approval process will not prevent breaches and lapses in the HDF daily operating practices. One only has to do a case study on permitted facilities to see citation after citation issued for infractions where permit BMPs are continually violated. This often results in protracted legal battles over fault; arguments over the magnitude of the violations and after much time passes minimal fines are sometimes collected. This does little to correct the environmental damage done. How this will be handled will need to be part of the EIS. A suggestion is that the DOH and HEPA have personnel on island and in the immediate area to monitor the operation and issue citations quickly when infractions occur...in the real world, self-monitoring and self-reporting simply does not work.

We respectfully ask that all these factors be given serious consideration during the EIS preparation and review process.

Sincerely,

David and Linda Howell
1568 Po'e Road, #212
Kapaa, Hawaii 96756
Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i

Dear David & Linda Howell:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy". The term "zero-discharge" under the U.S. Environmental Protection Agency related to concentrated feeding operations (CARO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows' manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term "zero discharge" as it was construed as no nutrients into the system.

The term "grass-fed" was used in the HDF EISP PN. This term was used to identify HDF's intent to utilize a locally-produced feedstock - grass - for more than 70 percent of the dairy herds' diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of "grass-fed". The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed", the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area "footprint" will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock - grass - as the herd's primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient "dry matter" grass yields essential to a cow's diet. Additional project-specific trials at the Māhā'ulepū site on Kaua'i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as "mob", mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The...
Animals in various stages of lactation and rest will be transferred between HDF and cows' primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, benefit both the dairy and infuse the beef market in Hawaii with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management practices and pasture model applied by HDF maximizes grass as the primary nutrition source and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, animals to minimize stress and ensure the herd's welfare. A licensed veterinarian will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow operation. The committed herd size of 699-cow dairy, and nearly impossible for the committed 699-cow operation. For more information on nutrient balance implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction of nutrient balance, water quality, and wildlife protection. Soil conservation is a critical component of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed approach using science-based tools and standards in agronomy, properties and weather conditions. For more information on nutrient balance, water quality, and wildlife protection. Soil conservation is a critical component of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed approach using science-based tools and standards in agronomy, properties and weather conditions.
the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soil classifications and descriptions provide a good information base, however, in-field soil testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrate to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing season. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

ARCHAEOLOGICAL AND CULTURAL: The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-10-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were nonexistent, as explored through survey and subsurface exploration. The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā‘ulepū Abu’a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-10-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the
exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

**DEMOGRAPHIC AND ECONOMIC** The potential impacts of Hawai’i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County annually by selling 699 cows, 40% cow herd, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

Hydrology: The area’s hydrology is shaped by its geology. The Kāloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kāloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhāʻulepū Valley and the HDF site ranges from 105 – 500 feet per day. The hydraulic conductivity of soils in the adjacent Kāloa-Poʻipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic
material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deeper aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii’s Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site well, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kāloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kāloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animal manure will deposit masure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the volcanic aquifer layer, which is the source of potable water. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors, and the local Māhā'ulepū community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DREDT) projects the population of Māhā’ulepū will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa-Po‘ipū-Kālihea districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā’ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā’ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā’ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā’ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed on a 10-acre site located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Mākawahi Cave Reserve in April 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā’ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā’ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could...
be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce run-off that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways. Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kēōkea-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 36,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua’i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations...
were modeled, as currently there are no cows on-site. The EIS sections 4.19 and 4.25 of the DEIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 64 hours per year, within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet (just under half a mile) beyond the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological conditions (low wind velocity / mixing), and all odors detected by 50 percent of the sensitive population value (the threshold of perception). The odor quality standards are defined by the point at which 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be detected by 50 percent of the sensitive population within an area that extends approximately 1,670 feet (within one-third of a mile) beyond the HDF boundary, again not reaching recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows would not extend beyond 2,780 feet (just under half a mile) beyond the HDF boundary (just over half a mile), again not reaching residential or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological conditions (low wind velocity / mixing), and all odors detected by 50 percent of the sensitive population value (the threshold of perception). The odor quality standards are defined by the point at which 50 percent of the panelists can detect the odor.

Re: COMMENTS ON HAWAI'I DAIRY FARM'S ENVIRONMENTAL IMPACT STATEMENT PREPARATION NOTICE, DATED JANUARY, 2015.

Aloha,

I have very serious concerns about the proposed dairy at Mahaulepu Valley on Kauai. I am glad that an EIS will be prepared and hope that it will address the many issues, environmental, social and cultural, that a dairy in this location presents. While HDF states they are voluntarily doing this process, to truly be pono, this should have been done well in advance of any infrastructure changes or the announcement that a dairy IS going in at this location, as the EIS is designed to determine whether a project like a dairy should go in by providing substantive data that indicates that it will not be environmentally, culturally or socially harmful.

NUMBERS

Beginning with the proposed herd and the recent “reduction” in herd size to 699 (a significantly chosen number as 700 cows is classified as a Large Confined Animal Feed Operation). What is not noted by HDF with this revised herd size is that those 699 cows will be shipped in pregnant, thus there will be double that number after gestation. Males will then be thinned out through outsourcing and killing of a certain amount, so that 699 would be about 900 cows on the land after gestation. Regardless of this claim of a reduced herd size, the EIS must evaluate the plan based on the proposed final herd size of 2,000.

WASTE

According to the EPA, waste estimates for dairy cattle are equivalent to 164 times the amount of humans, thus the 2,000 cows would produce waste equivalent to approximately 328,000 people, fully 5 times the population of the entire island. Microorganisms causing health risks to humans like E. Coli, enterococcus and leptospirosis are common in the feces of cattle, these organisms could likely end up in the adjacent streams leading to the ocean as well as groundwater.

SOIL

HDF should be required to do a detailed, accurate soil survey to determine once and for all if the soil is able to handle the amount of waste that will accumulate and be applied via airborne spray as fertilizer. Again, had HDF followed proper protocol and done an EIS at the outset, perhaps they would have provided more accurate information on the soil in the area in question. Their initial plan stated that soil in the area was porous volcanic, which it is not. A later NRCS survey of the soil indicates that most of it is primarily clay with “very limited” capability to handle manure load and has a high potential for runoff.

DRINKING WATER WELLS

HDF should be required to do an extensive groundwater study to assess effects of waste applied to the soil. Their current Waste Management Plan does not identify all of the nearby drinking water wells and misrepresents the distance of some of those that are identified on the map. Most significantly, one well (Koloa F) is very near to the area in which their wastewater treatment...
The plant will apply the sludge that accumulates in the ponds.

AIRBORNE CONTAMINANTS
HDF plans to spray waste from the effluent ponds on the fields as fertilizer. These spray machines are very tall and with dominant trade winds the possibility of spray affecting homes and businesses downwind is a potential problem. The EIS should address airborne contaminants produced by the dairy and the environmental, health, and social impacts.

SOCIAL CONCERNS
The Mahaulepu area is popular for nature oriented activities and subsistence such as fishing, hiking, beach-going activities, bird watching and more. The EIS must address how these activities would be impacted by environmental effects from a large dairy of this size upstream of the beach-going area.

The Koloa/Poipu area is home to approximately 3,000 residents, all of whom will be downwind of the dairy and thus affected by any airborne contaminants or odor. The area is also one of the top 3 visitor destinations, providing significant income to both County and State through property, TAT, general excise and other taxes. Environmental air, water and vector control concerns from the dairy would reduce property values and make the area less desirable to visitors. The largest private employer for the island is within 2.5 miles of the proposed dairy and a thriving visitor industry encompasses the entire Koloa/Poipu area, a decrease in visitors to the area would adversely affect those employees thus causing loss of jobs and income for island residents. Reduced property values and visitors to the area would not only affect the local economy through loss of jobs/decreased incomes for residents, but reduced revenues for the State and County as well.

The above noted concerns should all be fully addressed by the EIS for Hawaii Dairy Farm’s proposal at Mahaulepu Valley. Given the open, available, leasable land on the island, particularly that owned by lessor Grove Farm, this seems to be one of the most ill-suited locations for such an operation. Its proximity to freshwater sources, the ocean, nearby homes and businesses makes this an extremely poor location for a dairy, especially given that all milk will have to be trucked to the port in Nawiliwili for shipment to Oahu for processing. The above noted environmental, health & social concerns in addition to this fact render this a plan that will negatively impact the environment and economy of Kauai.

Mahalo for your careful consideration of my concerns and your diligence in evaluating the impacts of this project.

Subject: Hawai‘i Dairy Farms

Environmental Impact Statement Preparation Notice
Māhā‘ulepū Road
Kaua‘i, Hawai‘i

Dear Marisa Hurley:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will consider the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DAIRY OPERATIONS: Hawai‘i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 21, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy.” The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of “grass-fed.” The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed,” the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 65 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs,” mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways
and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflect in the title of the livestock waste guidance for Hawaii is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, method of application of plant nutrients, and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhāʻulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhāʻulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**ARCHAEOLOGICAL AND CULTURAL:**

The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6 E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-10-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burial, and no bones
were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhāulepū Ahupua'a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i's economy, which is heavily based on the visitor industry. With only two dairy operations remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact property values in the area.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and projected impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napale formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick...
Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Surface Water

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-lend of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waipōli Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; geo текстиль filter fabric and sediment logs around drain inlets.
Surface Water Quality: The Kaua'i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Māhāulepū Cave Reserve in April of 2014. The group reported high levels of enterococcus to the Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted DOH to conduct a “Sanitary Survey” of the Māhāulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2015. Agricultural practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 1.62 tons DM per acre to 20 tons DM per acre. Section 423 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge to the channel when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po‘ipū region were also calculated. Nitrogen input to the marine environment in the Po‘ipū region is calculated to be 38,510 pounds annually, or 3.5 times greater than the estimated potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipouli Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean...
water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kauai community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EB sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act
Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR
Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,570- feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were
intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai'i Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner

Subject: EIS for Hawaii Dairy Farms

I am greatly concerned about the potential affects of the proposed Hawaii Dairy Farms project which need to be carefully examined, as the project could create irreparable damage for the island of Kauai, environmentally, financially, and culturally.

I am a resident of Kauai, and have been working at the ANARA spa at the Grand Hyatt for 15 years, in the immediate vicinity of the proposed project. I ask that the study be designed to address all of the following issues.

- It is crucial that the EIS be conducted in an honest and in depth manner. It therefore should be done by an independent organization. Since Group 70 International has already been working with the HDF group, it is possible that they would be biased in their favor. It has been said, and rightly so, that it is possible to set up a study to prove what you want it to prove. Thus it is important that it not be set up to study to prove what you want it to prove. Thus it is important that it not be set up with a pre-determined bias. Performing the study should be done by some organization not already connected to HDF.

- In the overall plan for the county of Kauai, it has long been designated that Po'ipu is the primary tourist destination area. People arrive here from all over the world to experience our environment of sunshine, clean air, beautiful beaches, and swimable ocean. This area currently provides an abundance of hotels, condos, beaches, restaurants, and shopping. They will not continue to come here if their experience is one of the stench of cattle, manure, insecticides, or pesticides, or the pestering presence of flies, or an ocean that is polluted by run-off of chemicals, urine, and manure. They will not want to be driving behind cattle trucks transporting a load of cattle to various temporary pastures. Kauai is a tourist dependent economy. The number of people employed by all of the tourist dependent businesses in the Koloa-Po'ipu area far outweighs the number of people who would be employed by HDF. There are thousands of people dependent for their living on maintaining a clean, healthy, tourist-attracting environment. It is not right to endanger all of these for the profit of a single new business wanting to come in. The EIS must safeguard this community.

- Careful consideration should be given to finding a more suitable location for such a project than this one which is close and upwind from our major tourist area, and extremely close to sea level and shoreline.

- Kauai is fortunate to have one of the most beautiful and unique natural environments on the planet. It is a fragile ecosystem, so easily damaged. Any and all who are privileged to live here should hold it among their highest priorities to be the caretakers of this place, maintaining its health and protecting it. In this situation we are counting on those doing the EIS to assist us in preventing environmental damage, because once done, such damage is difficult, costly, and often impossible to reverse. I have read some of the other letters being sent regarding this issue, so I know that the particular details which need to be addressed are well documented. What I want to stress is that those doing the EIS must take seriously the potential impact this project could have on our precious Kauai.

- There also seems to be contradictory information being given about regarding the supposed benefits this project would bring. There is reference to supplying Kauai's families with a local source of milk. Yet elsewhere I have heard that HDF plans to sell most of the milk in the Far East. In some places they speak of grass-fed cows, yet elsewhere I have heard that they plan to use GMO corn to supplement the diet. So if there is any milk made available to Kauai, it will be contaminated with GMOs. If the current study aims to weigh the benefits and detrimental effects, these facts need to be checked out to see what the real situation is.

I surely hope that all of these matters will be strongly considered in designing this study. Thank you for your consideration.

Subject: Hawai’i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhāulepū Road
Kaua‘i, Hawai‘i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Kapua Janai:

Your comments were received by the State of Hawai‘i Department of Health Environmental Planning Office. The Department of Health forwarded a copy of your comments to Group 70 International in order to be included in the Draft Environmental Impact Statement (EIS) analysis. This letter was prepared in response to your comments.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the expanding of the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**GROUP 70 OBJECTIVITY:** Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai‘i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai‘i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai‘i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai‘i Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS scopes process involves Group 70’s experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai‘i Dairy Farms EIS with the level of analysis required to properly evaluate and disclose the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

**PESTS:** A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11.

A project location does not provide any habitat for *Drosophila musaphila*, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-‘ōhi‘a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawai‘i for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which bury manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhāulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pads in one to three days, a shorter amount of time than the 10-30 days flies eggs need to hatch.
In the Kōlōa-Po'i-pu region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle graze in the region on agricultural lands along Ahu Kinoiki Road between Kōlōa and Po'i-pu, and it is likely the livestock-related flies identified at the HDF site occur in this region as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animals wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of the island's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons ($36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai'i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua'i, and 2 indirect jobs on O'ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua'i and another 8 indirect jobs on O'ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER:**

**Hydrology:** The area's hydrology is shaped by its geology. The Kōlōa area was built by Nāpali formation lavas of the Waimea volcanic series. Surface lavas of the Nāpali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōlōa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material which is buried beneath thick alluvium that covers the valley floor; and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 0.5 – 50 feet per day. The hydraulic conductivity of...
soils in the adjacent Kōloa-Po'ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water-quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā'ulepū 14 well and the County's Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā'ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kaloha districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā'ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā'ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā'ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Hā'upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā'ulepū Road. This ditch, named Waipōli Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waipōli Ditch near the bridge accessing Makanawahi Care Reserve in April of 2014. The group reported high levels of enterococci to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore...
Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā`ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kapalua, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā`ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under "Library" (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā`ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa-Po`ipū region were also calculated. Nitrogen input to the marine environment in the Po`ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,280 pounds annually, or 14 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po`ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

**Impacts to the Nearshore Marine Environment:** An assessment of groundwater and surface water interaction with the marine water downstream from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.
Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB dairy neighbors and the local Kauai community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaii has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dry manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kauai, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1.670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawaii Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner

Aloha to All,

We live in a condo in Poipu six months of the year and spend our other six months in Washington state. We both grew up around dairy farms and remember the cow manure jokes and flies that grow in it. There is no way that we know of that will contain the cow manure smell from spreading out into the areas around Poipu.

The farm needs to be in another area of Kauai and not the tourist destination of Poipu and the beautiful pristine area of Mahaulepu.

Larry and Karen Jerdal
HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

PESTS: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist in January 2016. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhā‘ulepū area, as well as the parasites and predators that control those species. No federally or state listed endangered or threatened invertebrate species were noted in the survey of the site. A full report and list of species found on site is provided in EIS Section 4.11 and Appendix B.

Flies were identified on the HDF site using manure from neighboring livestock as bait for invertebrates. The two flies associated with livestock are the stable fly and the horn fly, the latter known for biting cattle. These flies and the greenbottle fly are often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could inadvertently be brought to the dairy and utilize manure as a food source. HDF will prevent and control fly population growth through diligent clean up and sanitation practices regarding any trash and food waste, as well as through efficient manure composting practices. A full list of site management measures is provided in EIS Section 4.11. The project location does not provide any habitat for drosophila muscipula, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened. Native Drosophila habitat is located many miles away in the high elevation koa-‘ōhi‘a forests.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essentially, IPM disrupts reproduction with appropriate means at key points in the pest’s life cycle. Used in Hawaii for decades, a number of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species.

An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which buries manure and incorporates it into the soil. Populations of dung beetles found on Kaua‘i and those species already in Māhā‘ulepū Valley, will increase with the increased manure food source, thus increasing and speeding breakdown of manure. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. The behavioral diversity among dung beetle species will work together to bury dung pats in one to three days, a shorter amount of time than the 10-30 days flies need to hatch.

In the Kōla-Pōpū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken feces. Beef cattle grazing in the region on agricultural lands along Ala Kinoiki Road between Kōla and Pōpū, and it is likely the livestock-related flies identified at the HDF site occur in this area as well. Localized controls to reduce pest populations need to address breeding sites in and amongst the food and animal wastes within the area. These mitigation measures will make it difficult for flies to breed, and BMPs will be enforced to address any increase in population, therefore it is expected that the dairy farm will not significantly affect recreational and resort areas.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for...
six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR
Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

ALTERNATIVES: As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural
District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua'i; and (3) milk products processing by HDF. The alternative of "No Action" is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State's fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2), grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soil science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawaii Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Subject: Fwd: Runoff to Ocean

Missent 1st time

Dear Ms. McIntyre,

Please excuse my intrusion in your time. In my "go far it" review of the new pending HDF purchase of Clover Leaf Dairy on the Big Island, I read quotes by the present owner—Ed Boteilho:

"Our land runs right down to the Pacific Ocean," said Ed Boteilho the farm's operator.

"On a clear day, you can see some of the other islands. During the winter we often see whales swimming by." (a photo was submitted)

That admission ("Our land runs right down to the Pacific Ocean,") underpins the worst environmental disaster New Zealand has faced in modern history. Under the "prevent language" of 344-1, In what manner does one alert/involve DOH to this high potential? Does DOH have steam readings of the Kahalo Ditch or at the ocean as the run off leaves the Clover Leaf dairy? Who would I talk to?

Thank You for your time.

Sincerely,

Ron

Ronald John

916-330-1924
Dear Mr Overton,

I have attached the full listing of questions, comments, concerns and questions I have organized re: the EIS of Hawaii Dairy Farms concept. I will also send by mail a hard copy. The other incomplete series sent to you by section are incomplete and should be deleted. Please acknowledge by email a receipt of the attached 57 page document.

Thank You,
Ron
Ronald John
My questions begin with a concern. As Group 70 authored the HDF proposal, why would they not, as a matter befitting objectivity, discontinue quoting questionable written statements in writing as demonstrated in the text of the EIS preparation? Composition bias is evident and confirmed by their outline. The expectation of objective fact finding is lessened by their active participation. You should never rule out what you also actively participated in creating, nor place yourself in a position of validating your own veracity or competence. To be actively involved in the EIS deliberations only exacerbates this concern and creates unnecessary suspicion. Group 70 should recuse themselves from determining any factual truths considered in the EIS study. Why do they not?

I began Dec23/2013 looking at the HDF concept while reviewing Kauai as a place to retire. After my 16 Jan 2014 Guest Opinion was published in the TGI, the HDF spokesperson with others in the room with her, called me. One of her questions to me was to paraphrase: “Why was I so concerned when I didn’t even live there?” My answer was pointed. “The gist of my response was: “Not there or anywhere should such a mistake be made.” I think I referenced the Sistine Chapel as an example. I have lived and owned property in Kauai. I have family there. For many reasons it is my favorite place on earth. Careful regard should be given to such places wherever they might be.

My personal concerns/questions are multiple and have been discussed with experts in the field of agronomy, dairy, hydrology, atmospheric/weather, seismic activity, irrigation systems, statistics, and many others. A general overview and concern is the “One size fits all” mentality demonstrated in proposal areas requiring far more specificity and accuracy. The proposal as it now stands is a collective failure of due diligence. It appears more typical of an infomercial presentation attempting to promote a point of view, but void of sensible or reasonable conclusions, it is at best, conclusory allegations that have no support, void of the serious, deliberate analysis of data HDF should have submitted. It is riddled with inconsistencies both confusing and contradictory summations denied by its own data. It is a “shoot oneself in the foot” performance, with HDF’s own data conflicting more with its concept than supporting it. By what standard was the HDF proposal written? By what standard was it judged? Their method of analytics within a few pages becomes upside assertions, hardware boiler plate specs, promises and little objective support of stated/expected outcomes. Can the EIS review process give a definitive summation of “suitability” of this proposal to present necessary information and true data based conclusions?

Is need or necessity for this proposed commercial project within the scope of this EIS? If it is then a value contrast with any other use construct for this land is warranted. The underlying premise advanced with all manner of endearing phrases by HDF is that milk and thus this dairy is a necessity, a marker of a sustainability index of Hawaii’s well being. It is not. Milk is an option not a necessity. The National Institutes of Health reports that around 65 percent of the human population has difficulty digesting cow milk. The dependency on cow milk much like the human appendix is no longer a valid argument. Its need, which in my beginning years of the 1930s depression may have been warranted, has been replaced by far better nutritional options of equal cost or lower. If Ulelepo Initiative wanted to truly meet Hawaii’s basic needs, they would best served Hawaii if staying with their stated goal of solar power.

HDF EIS PN lists proposed action: Establish and operate the first grass-fed dairy in Hawaii, utilizing a sustainable, pasture based rotational grazing system. Produce fresh, locally available nutritious milk for Hawaii families.

No part of that “proposed action” is factually true. From failure to qualify as a grass fed dairy by definition of grass fed dairy to locally available, it is pure hype and contains nothing of substance. Meadow Gold owns the milk when it comes on Island in Oahu and will mix it with other state side milk sources during the pasteurization process. Sustainability can be a deceptive generalization, often a word wrapped around “an essential
needed by "or "for the long term good of the people." Often however it is a filmy cover of a "for profit" motive only,

By HDFs own indication "qualify for international sales" the intended sales target is obvious and not just for Hawaii families. Finally why would any of Meadow Gold milk be other than nutritious whether for Hawaii families or for any one else? It is a PR green washing of new proportion. Hawaii deserves more than a spin doctor, emotional appeal. Actually the real concern voiced by Kauai residents is "price of this particular product;" on that need, HDF has not yielded one penny.

The basic information needed for any purchase or lease of land required to be a primary food source for cattle is knowing the quality of the soil, its type, its water holding capacity, the water requirements of the crop being considered, and many other related soil and water essentials. Will the EIS explain their misrepresentations? Why, after "five years of study" was this basic information advanced in error when submitting the first proposal?

HDF began the permitting process by submitting their application/proposal for approval by informing the West Kauai Soil and Water Conservation District that "the soil was free draining". They were believed at face value and approved, yet that basic assertion was both misleading and untrue. After being corrected, HDF continued to base conclusions as if it remained the same "free draining soil." One would believe that an NRCS review would have at minimum, pointed out the many deficits of HDF's original proposal. Although NRCS officials made clear they did not "approve" the proposal, HDF continued to quote "approved" as support for their actions. NRCS, in my opinion, failed their advisory/investigative capacity in this particular matter. Should this deceptive beginning be an EIS concern?

A clear indication of HDF awareness and the certainty of the farm flooding is given on pp. 73 last submitted proposal (Quote) "The dominant soils on the lower farm are Ka'ena Clay, Kala patrol Clay and Kahili clay (actually there are Ka'ena Clay and Kahili clay type soil extending much farther through the farm in all directions-writer notation) which are prone to compaction and all are characterized by poor draining. However less than two days after heavy rain, with rapid removal of the surface water during and after a significant rain event, they are observed as being dry enough to graze even without a Kikuyu thatch." Just that admission should close the door on this site selection. It is self-confronting and damming. Keep in mind there are 352 Acres of Ka'ena Clay and Kahili Clay poorly draining type soil and that type soil extends much farther into this farm site and in all directions. Will the EIS review evaluate the meaning and end result of applying this data?

"Poor draining-"rapid removal of surface water" To where? With that admission, what other indication is needed to verify that draining manure laced soil to the streams is going to happen? If there is another definition to zero discharge what is it? If there is truth in the statement regarding soil type quoted above, on what basis would this farm site qualify as "suitable soils"? (see Group 70 EIS Preparation Notice pp.2-1) The words "promote efforts which will prevent and eliminate damage to the environment and biosphere—(Chapter 344-1) are clear. What reasons, methods, or new knowledge will in reality support that the dairy project can do other than create serious damage? "Prevent" not wait until?

The land total of the soils listed on pp3-1 of the HDF EIS Preparation Notice as Kalihi and Ka'ena soils is 352 acres. These soils have a Ksat level from 0.00 (no capacity intake) to 0.20 (1 fifth of an inch per hour) (pp 12 HDF proposal) A University of Nebraska dairy expert (name given by request) indicated that those soils can run off almost instantaneously," yet on pp 42 is the explanation that a 0.39 inch of water (as the pivot is rotating) is put down on the 352 acres of that soil type. The spray is by applicators dropping that amount as they continuously move- not a same spot application over longer time duration as does rainfall. Will the EIS evaluate how it is possible that such application; approximately twice higher than the highest absorbent capacity of the soil, and on top of manure already deposited on the field, does not create a run off of a mixture of water and manure to on field drainage systems and on to the ocean? Drainage systems are not holding ponds. (see code 633 Waste Utilization page 2 of 3) "When liquid wastes are applied the application rate shall not exceed the infiltration rate of the soil and the amount of waste applied shall not exceed the moisture holding capacity of the soil profile at time of application. This is basic to every rate of application of liquid waste or water. Will the EIS review tell us what in the proposal, other than promises, display that this basic is
understood. How was the limiting factor - holding capacity of the soil in the area recognized? What is unclear to HDF about this regulation? The ignoring of this understanding is replete throughout the entire proposal. Other than an overriding intention, what other reason can explain the ignoring of such clear, necessary, appropriate agricultural regulation? It is a basic agriculture standard.

Page 40 HDF proposal indicates a pivot rotation schedule of 40 hours each pivot. Poipu (next to the dairy) has a 16.2 mile an hour average year round wind with gusts to 40-50 miles or higher an hour. Farther north toward the mountains it is higher. Sophisticated VR1 irrigation systems can interpret weather conditions, but sudden, random gusts of higher winds first have to occur before shut down is activated. All interactions have a time interval. Multiple ditches and streams traverse the areas and run off to the beach. Under these conditions, can an overspray wind drift transfer to the water ways occur? Why not?

Irrigation experts point out that VR1 equipment with so many more interactive components are prone to problems, and that the spray residue left on the pivot equipment may drop off when moving across ditches and streams. Is there a possibility that this contamination/pollution of the waterways will occur?

80 hours is required to irrigate not counting the time required for effluent spraying. Given the average yearly 16.2 wind factor, and the nutrient requirements determining the pivot use schedule, if held to a standard of no overspray wind drift can HDF demonstrate how their irrigation scheduling requirements can be reasonably meet? Does the failure of proper effluent and irrigation application scheduling effect all other nutrient variables?

On pp 39 of the HDF proposal is Table 12- is a listing of required irrigation days per month. No one should use averages in this type calculation nor apply any application on the basis of average. If the nutrient needs are spoken of as averages that too is wrong. HDF does however, indicate "significant rainfall in these months is probable and could cause the soil to exceed capacity from rainfall alone" (pp39). HDF does not show precise area soil Ksat data. The Ksat data is given as a range. Its capacity to take in moisture could be 0.00 (none) and not the highest rate of 0.20. How then can the same rapid rate pivot irrigation concept of 0.24 have any merit in reality? Isn't runoff or flooding the outcome of "exceeds capacity of rainfall alone?"

Given the information of the last question and the conceding of a 10.4 rain event by HDF, where would the millions of gallon (27,154 gallon per acre per inch of rain per hour) run off from to the other 576 acres (not counting that in the effluent ponds) when the manure covered fields receive this same rainfall amount? A 10.4 inch rain event on saturated soil will send 162,000,000 (162 million gallon) of manure laden rainfall on a downhill course 0.7 miles to the ocean. That event was described by a rancher as "water higher than the 4 foot fence posts."

A 24 hour 100 year review of storm participation was offered as proof of compliance by an HDF spokesperson 23 January 2015 (Quote Amy Hennessey Jan21/15 TGI) "Our farm's effluent ponds are designed beyond the requires size to accommodate a 24 hour 100 year rain event." HDF uses the figure of 10.4 inches in a 24 hour time frame. That data is not remotely true.

National Oceanic and Atmospheric Administration data from 1950 till 2000 (50 years) will point out how much defining data was ignored or left out by HDF. Specific to Kauai: there was Hurricane Iniki in 1990 with 52 inches falling in 4 days. Nina in 1957 with 20 inches of rainfall in 14 hours, Dot in 1959, with the eye directly over Kauai, Iwa in 1992 and all gauges down listed as Heavy rain, Iniki in 1992 all gauges down listed as Heavy rain. If anything was left standing including dairy cows, these Hurricanes would have filled the ponds and quickly brought them to an overflowing runoff stage.

Quote; "It is commonly believed from recent history that Kauai lays in a more vulnerable position than the other islands. However, in his recent analysis of Hawaiian hurricanes, Dr. Tom Schroeder of the University of Hawaii, Meteorology Department, concludes that every island has been affected by hurricanes and that no island is without risk." (NOAA report)

The unpredictable direction of hurricanes and tropical storms is a meteorologist's nightmare. Indicated in a 2002 NOAA document Atlas of Natural Hazards in the Hawaiian Coastal Zone is data showing that in just 43 years- (not 100 years) between 1950 and 1993 there were 25 hurricanes that hit the islands, and an additional 33 Tropical Storms rain events
occurred statewide. In areas of known seismic activity, construction building standards, integrating that factor, are mandatory. So too are DOH standards for properly sized effluent ponds. Given “no island is not without risk” what support if any, can HDF give for not constructing effluent ponds based on actual rainfall data? What are the new dimensions of the ponds and the capacity? Were they designed on a 2000 dairy cow basis. Page 47 indicates “The pond is oversized to allow for Phase two effluent volume requirements yet it only displays “Phase one Minimum Volume gallons. Roughly speaking 2000 cows will fill the pond 3 time quicker than 700 cows. On page 53 one reads (quote) “even twice this amount at 0.25 in won’t be excessive if the soil moisture levels allow” That statement leads one to believe that HDF hasn’t yet considered the row known and dominant major soil type (poorly draining) and ksat indication (0.00 to 0.20 in) that they are truly working with? Will the EIS review this area?

On 15 February 2015 Kayle Datta (senior partner Uleponi Initiative) in a TGI Opinion wrote “To be clear, there has been no storm event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Mahaualepu Valley” Three main concerns regarding this assertion need answering by the EIS review. One is the certainty that only at one time will the effluent ponds be totally empty. The milking parlor is in continuous use facility. The wash down and manure from the dairy cow, calving pens etc. are flowing to the ponds on a 24 hour a day cycle. What is the square footage of all areas that run to the effluent holding ponds? What is the total amount of water, manure and urine, general cleaning procedures, including wash down of each dairy cow and waste from the calving sheds etc. that will run into the effluent ponds per day? On page 26 and 43 are listings of “gpd” (gallons per day) usage of water. On page 43 we see an indication of “2840 gpd Machine wash.” In reviewing “gpd” it is difficult to find any wash down system that uses less the 6.8 gpd per dairy cow. HDF will wash down the dairy cow 2 times each day with a total of 3.7 gallon per day. If more than that amount is required a 2000 cow wash down would place a significant higher

amount of waste water in the ponds. Will the EIS be specific enough to analyze these possible variations? What are the new sizes of the ponds? Are they sized for 2000 dairy cows? If the total sq. ft area is larger than 16000 sq. ft (approx. 1 third acre) can one assume that a 1 inch rain event would by itself add approx. 9000 gallon to the ponds? If that is correct how much more is added by the 1 inch rainfall runoff from all other milk parlor areas that run off to the ponds? The second concern is the narrow weather bandwidth of “rainfall in Mahaualepu valley” as a determinant of pond size. That data needs EIS review not just of an individual rain gauge, often not working, but rainfall from a much wider area (Lihue Airport for example). NOAA weather records etc.) Third- it is not the effluent ponds that will do the most damage. It is the total rainfall amount of sustained storm events over successive days and which are significantly beyond Ksat intake ability that determines the outcome of these interrelationships. Wouldn’t rainfall numbers charted against Ksat capacity numbers reveal whether/when runoff will begin? It becomes a pollution runoff certainty when a rain event occurs and the high AU ratio to acre pod grazing method (300 to a pod) has left such a high amount of manure to be washed away from fully saturated soil. By the stocking rate(300 dairy cows per pod) the 3.2 to 4.2 acres pods become uncontaminated zones for the mixing of manure and rainwater. 2,000 cows grazing on approximately 24 per day (83 cows per acre), will result in at least 200,000 lbs. of manure and 16,000 gallons of urine left daily on the clay soils found on the farm site. On a “poorly draining” soil pod with a multi-day series of rainfall or a one day rainfall above 0.20 inch per hour, that combination of factors will result in runoff. Residents familiar with the area tells of “rapid rate rainfall that “started brown water run off all most immediately from its beginning.” Protective barriers/berms are mandated to protect from fecal runoff from roadway, raceways, runways and walkways. What protects the steams from the runoff from pods? What other explanations/outcomes are there? When used as a cane field it, as a matter of course, drained to the ocean. As the pods would now be covered in a high volume of manure that result is not allowed to happen. There are 26 single days in the last 25 years which
exceed the amount of rain that created significant flooding from run off of the HDF proposed dairy farm area. That 2 day amount of Feb 16 and 17th 2014 was 320 inches and flooding was noted. **Will the EIS confirm/answer these concerns?**

Conspicuous by its presences, and also by its disregard by HDF planning, is a Taro Farm in the lower left hand quadrant of the property. That private property requires flood irrigation, yet abuts a sludge containment area containing 2 acres and block F of 54 acres, which is described on pp73 "are perceived as heavy, flood frequently and difficult to crop. No indication of protection or concern for the Taro Farm is written and runoff, over spray or intermingling of its water with effluent mixed water is not considered. Why not? What should be done to protect the Taro farm from this intrusion? By the same token what keeps the tao farm from spilling into the HDF farm site, mixing with the 82 acre M and S area and then draining directly to the ocean?

Many states have Odor minimization plans Counties, townships etc. are growing rapidly in number as they put restriction on this form of pollution. The recognition of the profound effect foul odor can have on the physical health of residents, and the debilitating outcome it will create on the economic climate of the community is becoming more based in scientific certainty. In Kauai 1000 jobs at minimum are on the line the first time a foul odor drifts to 1.7 miles from the dairy farm to the front door of the Hyatt and other nearby resorts. That downside information will travel around the tourist industry truly at the speed of light. Residential property values will significantly decrease as well as a significant tax income deficit will hit Kauai. **The health issues are numerous and a plan must demonstrate consideration for those about them.** An EIS review should reveal if there was any evidence within the HDF proposal of this consideration. That review should assure and describe in detail on what basis these outcome will not occur. A row of Norfolk Island pine won't do it. The assurance given by HDF i.e. the cow will fart less, and nutrient supplements will make it smell less doesn't cut it so to speak.

My daughter and her family now live in Kauai. They, as I know, what Chino CA and now Tulare Co. in CA, smell like. England on a cross wind day can smell France's farm area. A farm odor of the nature of that which will be created is not compatible with the existing environment. Anaerobic digesters (which they did not select) can cut the odor down. Digester would help to minimize greenhouse gases, but nothing can stop it entirely. Even if digesters were used for the manure washing to the effluent ponds, there still remains the high tonnage of manure dropped on the paddocks each day. That element will ripen in the sun or rain and the wind speed and direction, ambient air temperature, stability class, mixing height, and precipitation and pressure, will decide "that odor is headed downtown Koloa and Poipu. HDF's manager was a CAFO manager in Vado New Mexico in 2006. That "Dairy Alley" between Las Cruces and El Paso is known and written about by a national newspaper and featured by NPR. It is infamous for its pollution and smell and well the HDF manager is aware of it. The sludge dumpage on 82 acres is environmentally intrusive and unnecessary. It demonstrates corporately insensitivity to others around them. This placement of the sludge area closest to others (1.5 to 1-7 miles) outside the lower Mahaulepu Road fence is truly an "in your face" nose thumbing at Poipu. Koloa and the Lawai valley.

A odor minimization plan appears as an HDF postscript. HDF has treated that critical area with one line "All material will be handled in a manner to minimize the generation of particulate matter, odors and greenhouse gases." (HDF pp.85 first proposal) The same lonesome line is on page 75 of the 3rd proposal. It is not mentioned in the redacted proposal. That's it? Just the word or suggestion of odor mentioned once in a 100 page industrial sized dairy proposal? An apparent fill in the blanks or after thought? "Odor Minimization" no big deal-not even a mention in the proposal table of contents? When first approaching a dairy you might first spot the silos. No later than 2nd you smell the dairy. In "Understanding Concentrated Animal Feeding Operations and their Impact on Communities" (Hirbar and Schultz National Association of Local Boards of Health 2010) one finds a more serious understanding and summation. (Quote) "One of the most common complaints associated with CAFOs are the odors.
produced. The odors that CAFOs emit are a complex mixture of ammonia, hydrogen sulfide, and carbon dioxide, as well as volatile and semi-volatile organic compounds (Heederik et al., 2007). These odors are worse than smells formerly associated with smaller livestock farms. The anaerobic reaction that occurs when manure is stored in pits or lagoons for long amounts of time is the primary cause of the smells. Odors from waste are carried away from farm areas on dust and other air particles. Depending on factors like weather conditions and farming techniques, CAFO odors can be smelled from as much as 5 or 6 miles away, although 3 miles is a more common distance. (Understanding Concentrated Animal Feeding Operations, State Environmental Resource Center, 2004)

To the writer the obvious absence of concern for this area is telling, shaming, and inexplicable. It flawed the due diligence aspect of proposal preparation. It is a glaring disregard of basics and its lack requires explanation in the EIS review. Why or how can this factor be seen as insignificant by anyone of any level of agricultural knowledge? What tangible data support can HDF give that demonstrates no odor drift? What odor carry distance data have HDF developed beyond the HDF spokesman - while in New Zealand - not being unable to smell the effluent beyond 20 feet? What is the spectrum of health risks and environmental degradation? How are those elements clearly mitigated? What is the plan? As a small example why, if only for Koloa and Poipu's well being, is the sludge area located on lower Mahaulepu Road, nearest (approximately 1.5 to 1.7 miles) to Koloa and Poipu and not located to the rear by the effluent ponds?

All of the land where the Hyatt and other resorts are located were once zoned for agriculture use. "How can this proposed dairy project location be considered compatible or justified. What is meant by "compatible usage"? Sec 8 1.5, Kauai County Code, 1987, as amended defines compatible usage as follows: "Compatible Use" means use that, because of its manner of operation and characteristics, is or would be in harmony with uses on abutting properties in the same zoning district. In judging compatibility the following shall be considered: intensity of occupancy as measured by dwelling units per acre, pedestrian or vehicular traffic generated, volume of goods handled, and other factors such as, but not limited to: vibration, noise level, smoke, odor or dust produced or light or radiation emitted. (Sec. 8-1.5, Kauai County Code, 1987, as amended) What is meant by "and other factors such as but not limited to" in the above cited Kauai County code? What does "odor" mean as mentioned in that Kauai County code? When a project at best puts up as collateral a promise that is may result in 15 jobs and a product shipped off island to be mixed with stateside milk and also clearly states it won't be lower priced; what indices justifies the risk of harm to benefit ratio?
HDF EIS PN Kauai - Ronald John

2nd Series of comments, questions and concerns

The inability of most of the soil to percolate, the limited capacity of the ponds to hold an actual measure of what rainfall could bring, and the sustained and periodic rain events which last for days or weeks, (much as the 40 plus inches Easter flood of 2008) will create an uncontrolled release of polluted matter. In February HDF was sent pictures of the "Easter" flood damage. Seeing the clear, evident flood damage and knowing that other rain events have been left out of HDF considerations; for example In Dec 15 to 16 2008 a totaled of 11.11 inches fell at Mahaulepu, why and for what reason is such information not been given due consideration by HDF? What specific reasons or improvements can HDF indicate that would explain why no pollution will leave the property? It isn't just about an effluent from the effluent ponds. Every rancher that has used this property has seen the entire area flooding and often. Just last year the road below it was flooded. It is not an uncommon occurrence.

Amy Hennessey spokesperson of HDF wrote. "Water quality management is an important part of the plans for the dairy. We will be implementing a water quality-monitoring plan to help the farm be protective of the environment." A water quality monitoring plan tells you what is or has happened. With rapid run off release that time is often too late.

What HDF doesn't seem to understand is the difference in what they say they will do, and how HDF does not have a "how to do it" plan to handle pollution run off nor how to prevent it. They speak of it as a given or an accident. Why. Monitoring stations will tell you of it, but who needs a device to tell you its flooding? Then what? Call it an accident? (Certainties are not accidents) Move the cows? The dairy cows are either trying to stand up on slick water covered, non-absorbent clay soil or perhaps learning how to swim. This area must be covered in the EIS evaluation process.

HDF has presented a concept that preceding a rain event, overflow possibility they will empty the effluent ponds out on the fields (see page 54 HDF Quote) "If warranted due to potential impact from an approaching storm event the settling pond could also be pumped empty with in an additional 40 hours") This is an intentional transfer of waste when under threat of a weather event. EPA does not approve/condone that action (see Sec 833 Page 2 of 3 under Additional Criteria to protect water Quality). "Agricultural waste shall not be land applied on soils that are frequently flooded, as defined by National Cooperative Soil Survey during the period when flooding is expected." The manure covered fields would already be facing an overflowing of a mixture of manure and rain and such an additional dumping of effluent will add to that overflow...

The basic expectation is zero discharge. The first gust of wind on a windy evening at Mahaulepu, and the tall irrigation pivots and gun arrangement will leave pollution in the water ways of Mahaulepu. According to HDF there are 14 ditches traversing the property. No reputable irrigation expert or VRI representative will tell you that these devices are free of a level of spray scatter, mist or wind drift when operating, nor will they tell you that the system is a 100 percent error free. It is generally recommended that spray application of wastewaster should be done under low wind (less than 5 mph) conditions and after mid-morning, preferably in bright sunshine. What VRI error rates were known by HDF? Given the 16.2 average
wind speed at Poipu, in what manner can HDF spray effluent when needed, and make any assurance that polluted effluent doesn’t reach the streams? What regulations have HDF adopted re: spray application and wind force?

Quots HDF spokesperson: “Most of our animals live, long, happy and milky lives.”—Compared to the human species, the dairy cow is the princess and prima donna of the bovine world. She is far more sensitive and fragile than her cousin the range cow. To some she is a liquid white gold machine; an ATM so to speak. Unlike wild animals, the dairy cow cannot leave her pasture to seek protection under harsh conditions. You need to provide it for her. She will not want to be inside all of the time. However, she will need a shelter option when the weather gets nasty for prolong periods of time, need to escape fly swarms, or simply to rest.

Few animals are comfortable when eating or laying in close proximity of fresh feces. This condition would be especially true if the dairy environment is configured as HDF has designed it. When the tightly grouped mob of 100 to 300 dairy cows on one small 3-4 acre pod begins to download tons of fresh manure at the same time, and in the same area where they are grazing, when they have been exposed to a rain event for consecutive days and standing in mud till foot rot begins, when it is unseasonably hot for days, the irrigated effluent is ripe and flies are on them from all angles what then is the remedy? Why is HDF not building a shelter for the dairy cows? If for no other reason, income studies point out the significant added income when you have a “satisfied” dairy cow.

Other groups including some civilized countries see this as humane. Be it your heart or your wallet she needs shelter. Why is HDF ignoring this need? What shelter of any sort will be provided?? When more serious storm events occur where do the cows go when flooding occurs?

HDF has not shown an active concern for a shelterbelt location.

Why not, and if they have one, how workable is it?

On Page 73 8.4.3, the Mahaulepu soils, particularly in the south central portion of the farm (Block F, figure 23) are perceived as “heavy, flood frequently, and difficult to crop.” There are like soils with the same Ksat rating. A statement that “they are “observed” as bring dry enough to graze even without a Kikuyu thatch” is below and begs any acceptable standard of verification. “Seems good -looks good” doesn’t cut it so to speak. This is a critical factor. Where is the data?

What does it say?

Why did HDF state “the dominant soil types on the “lower farm” when actually these soils extend from lower Mahaulepu Rd 2/3rd or more, through the middle of the entire property, and poorly draining soil is the dominate soil type not just of the “lower farm” but of 352 acres of the property being used for grazing purposes? How does HDF reconcile the separate and different irrigation concept for Block F and not the other 300 acres composed of the same soil type (poorly draining)? Shouldn’t the soil type define the irrigation method? These soils are group D soils (see: Department of Agriculture Natural Resources Conservation Service Part 630 Hydrology National Engineering Handbook Soils in this group have high runoff potential. ) Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a clay pan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission."

With soil type differences, different irrigation methods and nutrient limitations, has HDF successfully irrigated the kikuyu, and does proof of such successful trials exist? What is that proof? What trial data, date, and field location demonstrates the 18 day recovery
rate claimed and used to support the rotation of paddock at an 18 day level? What trial data of tests ran on different soil types at Mahaulepu supports that conclusion? Does the kikuyu yield, if any, match their indicated nutrient needs? How many acres of Kikuyu have demonstrated/met a 20 ton “kikuyu yield goal?” (page 57) What is the nutrient differences in Kikuyu and a mixture if Kikuyu-Guinea grass (pags2-2 HDF Els PN)

On page 73 a mention of “drainage system” is noted. Keep in mind that any drainage/runoff of a grazing area is an area covered by recently fresh manure and or effluent, the lower farm area is generally at 61 feet elevation, the effluent ponds are at an elevation significantly higher, the adjoining streams and drainage ditches run to the ocean. With full understanding of what “zero discharge means” how does HDF explain why stream water pollution won’t occur?

Kauai needs development that adds economic security and stability. This HDF type intrusion on the south shore of the “Garden Island” is without precedent. The negative economic impacts possibilities stand out clearly in the light of studies from other CAFO areas. Never before in the world has any one attempted to locate a CAFO close to an upscale residential, hospitality oriented, internationally known, ecological, archeological significant, and spiritual environment; one so highly rated that national park status is pending.

CAFC’s can devastate the environment and human health. The presence of a facility like a CAFO reduces overall tax revenues. Assessed evaluations of land and houses nearest this industrial dairy will consistently decreased by 20 to sixty percent in recognition of the loss of value that accompanies the odors, flies and other forms of pollution from the CAFO. Studies show that (Quote)” resulting losses in property rates are impossible to be made up from the new taxes generated by the CAFO for two reasons: first, a CAFO is specifically structured to minimize the amount of local taxes it pays and second, a CAFO is capable of polluting a substantial area around its perimeter and this area is likely to have an assessed value that far exceeds that of the CAFO.”

The Hyatt employs a thousand people. This particular CAFO, by its own admission, offers 10 to 15 jobs, which HDF indicates in their proposal, may not likely be filled by locals. That point is reinforced by reviewing HDF hiring practices so far. The present HDF Manager is a former CAFO manager from Vado New Mexico, a dairy area noted as one of the most polluted in the state and one written about nationally. So far work has been mainly by New Zealand crews under the direction of an onsite general contractor from the east coast of the USA. If the measure of this concept is jobs created and dollars left on island to circulate among other vendors on the island, then what HDF brings economically to Kauai, can be replaced by a local, quarter acre sized, locally staffed "Dairy Queen Drive In” with no downside. Has that potential downside of this experimental dairy been examined? Under the principle “First do no harm” what are the factual assurance of “no harm”?

Public Nuisance laws are being tested by this HDF dairy intrusion. The law regarding public nuisance is more and more focusing on industrial dairy intrusions. As their pollution affects are quantified there is a widening in definition. Legal interpretations often see this type of incursion as
unlawful, "an unreasonable interference with a right common to the general public, or an activity considered unreasonable as the gravity of the harm to the public right outweighs the utility (benefit) of the activity. What case law is used by HDF to support their dairy incursion on already existing neighbors?

HDF continues to reference water conduits other than the effluent ponds. On page 5 of their last know proposal, they speak of "water wells, reservoirs, irrigation ditches, drainage ways and culverts" On page 49 they speak of "existing drainage way." As previously noted, on page 73 is a mention of "drainage system." In addition 2 fixed cement water troughs per paddock would make 238 fixed water receptacles; all inside the effluent spray zones and within over spray/mist distance. It is understood why effluent ponds are required especially for close containment CAFOs, but in this new model, all the property not occupied with or by the milk parlor (570 plus acres) a receptacle (a tilted to the South East, giant saucer if you will) for a manure and urine loading not consider nor regulated in Hawaii before. The Maximum load of cattle grazed at the HDF farm site from 1995 till now has seen approximately. 300 range cattle, yet the streams running through the farm site and on to the ocean are polluted to an extreme with that load of cattle. (see Surfrider and DOH data). What created this pollution? Could it have been from the cattle being pastured there?

One fact must be emphasized. 1 inch of rain per hour drops 27,154 gallon of rain on each acre. One local rancher indicated that "heavy rains in that area have started run off almost immediately". Obviously then in this poorly draining soil- a "rapid rate of rain" fall will also create flooding conditions. HDF clearly confirms the ranchers statement of rapid rate of rain fall runoff (see page 73 Quote). "With rapid removal of the "surface" water during and after a significant rain event''. "rapid removal" of "surface water" "during"-- What other assumptions/interpretations can be made from their open admission? A serious rain event could cause a certain overflow of the effluent ponds, but an unmitigated disaster would be occurring as 8 million gallon of manure laden water per inch of rain per hour, from the rest of the 574 acres remaining, will begin a down slope runoff to the ocean just 7 tenths of a mile away. No longer, as in cane or taro production, is it supposedly just a run off of muddy water. With 3 inches of rainfall on just the 352 acres of poorly draining clay soil you would have 28 million gallon of mixed manure and rain flowing off property. That figure is 17 million gallon more than the Exxon Valdez oil spill. (11 million gallon) spilling on a world renown reef and covering a 10,000 year old "Cave full of artifacts and threatened species" that simply can't be replaced at any price...When using the 10.4 rainfall figure given by HDF and applied to 574 acre shallow dish catch basin as the farm property can be described. That full run off figure becomes a 168 million gallon run off from property. One rancher indicated that "water ran over the top of the farms four feet high fence posts. The EIS should consider the "prevent" wording of 344 State Environmental Policy. This data alone should factually support that this site is wrong and that the dairy belongs on a more suitable site. What information/data if any invalidates this high and statistically certain risk and of which HDF data confirms?

I do not particularly "love" the dairy cow as the HDF spokesperson has indicated. HDF does (Quote Amy Hennessey "We love animals"-Jan
29/24 TGI; but I do understand her (the dairy cow). Range cattle seem to move quicker than Dairy cows but the pace for both is slow. I have trailed cattle. I cannot conceive of a HDF workable concept that explains how to get a 300 cow mob up a raceway to the dairy parlor yard while 300 more need to leave that area and go back to the same pod they came from. I do not believe that the HDF paper concept will work under real life and varied conditions. At no time can you effectively have coming and going, intermingling mobs, cattle traffic. Such a stock traffic pattern would require clear fixed separation. It they must get one mob back to its pod before the next mob starts then the predicted time schedules are not close to real. If they use quadrant separation of the six daily required paddocks then the pivot irrigation concept is complicated at best...The outside perimeter distance of the paddock to the milking parlors appear to range between 200 yards on its west side just beyond the calving sheds to over one mile and a half south to Mahaullepu Road. It is, a mile to the northern tip and east edge of the farm. If a dairy cow is more than 900 yards from the dairy it will not work as indicated. Studies indicate the dairy cow pace at average is 1000 yards per hour. At this time there are range cows near the HDF property... Borrow one from the Mahaullepu road area and trail it up to the milk parlor area at normal pace. Keep in mind the dairy cow would be carrying an average of 110 pounds of full udder weight also, wait for reasonable intervals (as long as it would take to get her washed down, milked, fed and back to the original paddock). How did it go, or better where did the time go? The stated maximum build out of 2000 cows will result in 4000 milkings, 12 rotations, every 24 hours without interruption. **If one waits as described to get the dairy cow up and back before the next mob begin this rotation, how are the 12 mob rotations (to milk parlor and back) accomplished even under normal conditions? What data supports such practice?**

The need for continual 24 hour full operation leads to the next concern. Very few dairies exist that brings so much varied power demands at such a constant high draw level. From electric fences to refrigeration, from automatic milking machines to roads, ramps, raceways lighting, paddock fencing, system pumps, such as those for the effluent ponds, and paddock watering trough systems; what happens when power is lost as it was 2 weeks ago (mid Jan 2015)? No separate backup power is mentioned in the HDF proposal nor could a backup generation system of normal size power up enough to handle the full electricity demand of this dairy concept. In a major storm event-- power out over days-- what will be done to maintain the viability of a sensible dairy operation? Do plans exist showing an off line from main provider secondary power source? What is it? How does it work? If the solar paneled roof concept is conceived as adequate to meet an offline from main source line need, then that data must be demonstrated re: a full and complete storage/ usage/ demand comparison. That comparison must be projected over the usual common outages occurring in that area and for outage times reflecting major event disruptions. What data exists re: Photovoltaic solar Modules (solar panels): and high wind created loss of these panels by wind force? What is the possible wind load of that area of the farm?
3rd Series HDF EIS PN Kauai Ronald John

Comments concerns and Questions-Kauai

What follows is additional information re: the HDF partial review and claim of a 100 year review by their Spokesperson and used to support the size of the effluent ponds. It is an Example of content in a 2002 NOAA document: "1950 Kauai: 52 in rain over 4 days, flooding. 1957 11/30- Nina NNW, passed Kauai 928 21 35 Kauai: 20 in rain in 14 hrs, 12 homes damaged by $1,056,000 --------(Chart 5)" (Atlas of Natural Hazards in the Hawaiian Coastal Zone

It is information too important to be ignored, left unfound or not used. It changes the parameters that safety and well-being requires. Why has HDF failed to acknowledge in full all the weather events that would at minimum, significantly disrupt dairy production? Given the variability of weather patterns shouldn’t all the full island weather conditions be taken into consideration. If not why not?

If one analyzes just the Mahaulepu rain gauge data he will find 11 rain events that were 6 inches or more occurring in the last 25 years. If he reviews successive day rain events he will find 6 that were over 8 inches and which happened in the last 14 years. If evaluated by approved objective evaluation standards, you would find that in at least one of these 17 rain events (when applying only three known facts—soil type "poorly draining", 352 acre total, and Ksat level (0.00 0.10 or 0.20) Lowest average, or highest Ksat level shown—you will still have one result—flooding beyond the HDF property.

What evidence contradicts those findings?

On page 27 of the HDF proposal is a description of the 236 watering troughs HDF will use; "high enough for the animal to reach over and in but will discourage the animal from stepping in." A cow, at times, seems to become confused as to knowing which end they drink with. This has been observed as a good reason to not drink downstream from the herd. Can this misinterpretation of which end should be next to the water trough happen in regards to the HDF water troughs?

Indicated is "refill the trough as the water is consumed." What happens to the water in the trough when the paddock is emptied and the water trough is full? "Does it then automatically drain (explain this mechanism) or sit full, partially full etc. and stagnate for the next 18 day rotation cycle? Can it be filled or emptied manually if the main power is lost or if some form of pollution is noticed in the trough?

Even the best water troughs accumulates dust and other particles. Over multiple hot days it’s not unusual to see a buildup of undesired elements. Who cleans the trough? How and how often?

What set back footage figure from the troughs will be used to determined that overhead spray of effluent does not fall or be blown into the troughs? It is presumed the wheel tracks for the pivot system are set and not close to or encumbered by the fixed in place troughs? Are they?

On page 4-1 of the HDF EIS PN is the statement "identifies the region as important agriculture land for Kauai." It would appear that such terminology mainly represents the ability of the land to be used in flood irrigation type context i.e. a Cane or Taro field for example, or that the soil type was not considered in determining such land designation. Grove Farms allowed a massive dumping of Class B solids by Aqua Engineers on land in close proximity to the HDF site. That is hardly an indication of "important agriculture land" consideration, and the meaning of such designation is flawed by the obvious granting of such use. Why is this term seen by Group 70 as supporting this particular agricultural project and not more likely a PR attempt by themselves to favorably (not unbiased) represent HDF in this EIS endeavor? (Quote) "with high quality soil agricultural productivity ratings." Putting generalities to the side, what are the specific rating of this specific soil in this same area. Perhaps Group 70 should recognize the meaning of the term "null hypothesis" and take the Aqua Engineer allowed use of the same land area as dumping ground for Class B bio solids near the proposed farm with that of HDF allowed use?

The HDF banner word is "sustainability." It is a buzz word; difficult to put fact based parameters around. What in this situation does it mean? Is there any indication that HDF is going to lower price on their milk?
Will HDF lower the price on the milk produced at Clover Leaf dairy presently being purchased by them as Mr. Whitseide has just done to his Big island dairy prices? Price of product is the problem and not sustainability. No situation can actually occur in the islands that cuts milk availability/sustainability which wouldn't also cut all other resources including power loss. What alternate uses for this particular site were examined i.e. local food crop production for direct local use? With that use of Mahaulupu, it would be a true marker of one of many varied sustainability definitions.

Under the summary of page 2 in the HDF EIS PN is a reference "establish the herd of dairy cow over several years". The initial 700 dairy cows arrive inseminate through a method of sex determined means, which generally produces more heifers than male calves. In addition to the first 700, and within a few short months, there will be 700 calves mostly heifers; likely 400 heifers plus in number. The new heifer in order to produce milk has to lactate and she will, along with the initial 700 dairy cows, calf within 2 years. This geometric progression is hardly "several years" but will be far beyond a 2000 head count in less than 4 and a half years. What is gained with the "veiling of intent" "over several years" language? It isn't a matter of depending on other conditions. It is what it is by nature of dairy cow breeding practice. Along with a maximum 2000 dairy cow operation come 2000 calves. Other than the mention of "calf sheds" nothing regarding the bull calf disposal is mentioned but questions do arise. "Calves are moved into open paddocks after 3-4 weeks" Does HDF mean just heifers? Where do the male calves go? What contracts/permits exist between HDF and local ranchers for dispensing the male calves among them? Will they be slaughtered when born? For what reason and for how long are the heifers in the paddocks? Will they be contracted out and off site for repurchase later? This spin off second industry adds much more than just another grazing/feeding concept. It requires far more than a one line statement. Explain all the factors, paddock space requirement, manure increase etc. That will be created if the heifer count is added to the mix of dairy cows being milked and dry cows totals. Have they been counted in the HDF total or is the HDF numbers given only for milk producing cows? At any one time after full 2000 build out, what is the general representative number of each category i.e. milking cows, cows that have recently given birth, cows with special needs, dry cows, close-up heifers, replacement calves and heifers? What number of calves does HDF accommodate with the calf sheds as described on page 23 (new proposal)?

On page 30, a reference is made to drip tubing or tape. What irrigation expert or firm, and why would they indicated the use of drip tubing or tape as a method for an area where a 330 dairy cow "mob" will mass be placed to graze for 22 hours on pod sizes from 3.04 acres to 4.03 acres? On a normal rain, with that load, damage or hoof penetration is likely. Was the fact that the dairy cow is walking in wet soils considered when selecting this unusual irrigation concept; one more sensible for row crops than a cattle grazing area? What dairy irrigation concept supports this method of irrigation under these actual conditions?

On page 54 3rd proposal- one reads "gun type application system to area outside the liquid effluent application" Those areas are on the fringe areas of the property. On page 54 Redacted and 3rd proposal HDF reference: the gun and their 65 foot radius of spray area will be moved around the paddocks. The first application method is a mounted end gun on the pivots, and the second gun system is hydrant mounted guns used in the paddocks. Some paddocks; almost the closest property to Mahaulupu Rd will be covered by the first method. Use of the 2nd system gun system in other paddocks sets aside the assurances and claimed precision of the VRI system of irrigation. It is a wrong and primitive solution. It literally cuts corners and should not be allowed. It is a rare reader that has not been hit by wind-blown sprinkler spray or mist from a gun type application. Water ways are in its path (See page 32 (canal/ditch) running through the lower right corner of the property. A gun type irrigation system spraying effluent will with wind drift create a combination of pollution either by odor, mist or both. It is a high error primitive system never used when sensitive areas must be protected. Its error rate is high and effluent scatter is at the whim of the wind. With sensitive streams areas near there should be no error variable in play. See as follows: and substitute the word "effluent" in place of "chemical" Western Agri Res Center PO BOX 1342 BLACKFOOT, ID 83221 Performing Department
(N/A) Non Technical Summary
Application of chemicals with irrigation water is a widely adopted practice
with center pivot irrigation systems, however, the standard practice of
calibration at a constant rate results in systematic chemical
application errors ranging from 7 to 22% for center pivots equipped with a
corner watering attachment and/or an end gun. Is this a important
certainty to consider? Does the application error mean amount of
chemical (effluent) being distributed or include errors in pattern
distortion? All solid research on sprinkler efficiency mentions
"minimum of pattern distortion" What does that mean? What about"minimum" reflects zero distortion? Does it refer to distance as a
variable not a fixed precise measurement? What error variance was
considered by HDF?

It appears that the only set number given for off set allowance of a gun
irrigation system use is refers to on page 96 2nd to last paragraph. That
paragraph refers to "damage to structure" i.e. "spread the effluent no closer
than 50' feet from open water sources when applying liquid effluent with an
effluent gun travel. That system is defined as." The big gun" sprays a
huge stream of water high in the air during irrigation, which is very
susceptible to wind and evaporation losses - up to 30% or more in most
cases. HDF has touted the new Zealand model, yet in "dairynz.co.nz-A
farmer's guide to managing farm dairy effluent tells us" Some
'add on' effluent sprinklers to pivots i.e. guns have very poor
distribution uniformity. " What is different with HDF use of gun
irrigation? Can the gun irrigation concepts be seen as a reasonable
irrigation method for any area where water ways are close and
boundaries are tight? What are considered appropriate set backs for
each gun type. Why and What are these setbacks in feet? Has HDF
indicated and defined what offsets and amount of property is within
those offsets.

What HDF usage is intended for the Canal/Ditch as show on page 9
and 32 (last proposal) and explained on page 7.

Can HDF paddocks marked M and S (Manure and Sludge) on page
8 be used as a receptacle for sludge on these paddocks- at random-
and receive an unknown level of Sludge on an "as needed" basis and
still meet a specific nutrient application level for the paddocks
involved?

Given the now known soil conditions (see NRCS Customs Soil
Resource Report for Island of Kauai Exhibit D), why has HDF
determined a 20 ton Kikuyu yield is possible (see the "Is Kikuyu"
reference on page 56). What field tests support that yield level on all
grazing pods or is it yet on a theoretical "hope for" basis?

Although "Kikuyu- Guinea grass" is mentioned in the HDF EIS PN
page 2-2. It was never mentioned in the last HDF proposal. It is a
different nutrient. Will the EIS review confirm this grass
combination? Why would Group 70 have nutrient information not
framed in the submitted proposal? Is it a typo? Should it have been
indicated earlier? How does that affect all other nutrient data? What
other changes have been made in the basic parameters of the dairy
concept? Will all changes to their last proposal be made public and in
what manner? What agencies are now aware of the changes?
Fourth series of comments - questions and concerns

Quote - page 51 - first HDF proposal. "The higher altitudes that feed the reservoir from (Wai'ta) receive very regular and very large amounts of rain." From the center of the Waia reservoir to the HDF milking parlor is 3278 yards. The highest part of the mountain range behind Waia reservoir and Mahaullepu is to the NNW end corner of the Mahaullepu property and approx. 2200 ft. Haupu at the NNE is 2600 feet. In the above sentence is the admission of "very regular and very large amounts of rain." In what manner is this large amount of rain (coming from the high mountain range surrounding the HDF property - and inside a Horseshoe fashion) kept from running through the manure covered field directly into ditches and streams traversing the HDF property. Will surface runoff occur? Does this downhill run off end at the ocean. Was this known? Was it planned? If not why was this certainty ignored?

Quote: "It is commonly believed from recent history that Kauai lays in a more vulnerable position than the other islands. However, in his recent analysis of Hawaiian hurricanes, Dr. Tom Schroeder of the University of Hawaii, Meteorology Department, concludes that every island has been affected by hurricanes and that no island is without risk. The randomness of nature plays a key role in which islands are at highest risk during any given hurricane. In 1988, Hurricane Iniki was poised to hit Oahu or Maui but passed to the south. Hurricane Iniki in 1992, could have hit Oahu or missed the islands altogether, but instead tracked right over Kauai." (Quote) Altas of Natural Hazards in the Hawaiian Coastal Zone. By Charles H. Fletcher III, Eric E. Grossman, Bruce M. Richmond, and Ann E. Gibbs prepared in cooperation with University of Hawaii, State of Hawaii Office of Planning, and National Oceanic and Atmospheric Administration Geologic Investigations. Series I-2731

One of the most significant factors protecting adjoining areas from pollution or over run from effluent ponds is the gallon capacity of the ponds. Federal regulations have guidelines and compliance expectations that must be met. Serious questions have been raised and DOH has sent HDF back to the drawing board for a redo of their effluent ponds capacity. The size and manner of construction is predicated on many factors one of the most prominent is the history of weather events that would create a breach of the ponds. A 24 hour 100 year review of storm participation was offered as proof of compliance by an HDF spokesperson 23 January 2015 (Quote Amy Hennessey Jan21/15 TGI) "Our farm's effluent ponds are designed beyond the requires size to accommodate a 24 hour 100 year rain event." HDF uses the figure of 10.4 inches in a 24 hour time frame.

If only that was true - for their sake if nothing else-; but it isn't true.

A 100 years recap would take too many pages to outline this concern but just taking the high points of the National Oceanic and Atmospheric Administration data from 1850 till 2000 (50 years) will point out how much defining data was ignored or left out by HDF. Specific to Kauai: was Hurricane Hiki in 1950 with 52 inches falling in 4 days, Nina in 1957 with 20 inches of rainfall in 14 hours, Dot in 1959, with the eye directly over Kauai, Iwa in 1982 with all gauges down- listed as Heavy rain, Iniki in 1992 all gauges down- listed as Heavy rain (9 inches at least). If anything was left standing including dairy cows these Hurricanes would have filled the ponds and quickly brought them to an overflowing, runoff stage. What data supports otherwise?

In regard to the endangered shearwater bird much has been said but until recently not enough done to protect this endangered species. A brief chronology follows:

"Hawaiian County Agrees to Pay Restitution and Modify Operations to Resolve Endangered Species Act & Migratory Bird Treaty Act Violations"

HONOLULU - The county of Kauai, Hawaii, has entered into a plea agreement to resolve alleged violations of the Endangered Species Act (ESA) and Migratory Bird Treaty Act (MBTA), the Justice Department announced today. The county today entered a plea of guilty to violating the
MBTA by taking that is killing or wounding, more than 18 migratory birds, specifically Newell's shearwaters (known in the Hawaiian language as 'a'o).

The Newell's shearwater is a threatened species protected under the ESA, and a migratory bird protected under the MBTA. The species is identified as endangered on the International Union for Conservation of Nature red list.

"According to the information, it has been publicly documented since at least 1979 that fledgling Newell's shearwaters are attracted to bright lights which often causes them to circle the lights and fly more passes across any nearby obstacles. This attraction may cause the birds to fly into the light or other obstacles near the light and thereby become killed or injured, or to fly around the lights until they fall to the ground exhausted where the bird may be killed by a car, predator or starvation." On approximately Aug. 3, 2005 and Sept. 16, 2005, as well as on various other dates thereafter, the county was notified by the U.S. Fish and Wildlife Service that its facilities, particularly the lighting at its facilities, were taking protected seabirds, including threatened Newell's shearwaters.

The county was given advice over a number of years that it could minimize take and, among other things, shield its lights.

The information specifies that during each of the past five years some Newell's shearwaters have been killed, or otherwise taken, by lighting at facilities operated by the county.

Starting with the 2011 football season for any night games all lights must be shielded and a similar escrow account funded.

LIHUE — County officials announced Friday that work crews are in the process of manually re-activating the exterior lights at all county facilities to allow nighttime activities to resume.

The lights were manually disconnected just prior to the Newell's Shearwater fledging season from Sept. 15 to Dec. 15 to eliminate the sources of light attraction as part of a plea agreement between the county and the Department of Justice.

The only exceptions allowed were four evening Kauai Interscholastic Federation fall football games.

Other mitigative measures taken thus far by the county to protect Hawaii's threatened and endangered seabirds include: installation of shielded lights at Vidinha, Kapa'a and Hanapepe stadiums, Isenberg Park, Peter Rayno Park and the Lihu'e tennis courts; training on the cultural and ecological importance of the seabirds and bird-friendly practices for all county employees; and a monitoring program with respect to endangered seabirds.

At all other facilities, the lights must be inventoried and measures must be taken to minimize and monitor for take, all on a specific schedule. As of 2011, if such facility lights are to be used at night during the fall season (Sept. 15 until Dec. 15), an escrow account of $100,000 must be funded, with an option to add additional funds in increments. Again, transfers would be made related to any taking that occurs, from the escrow account to one for use to benefit seabirds on Kauai. If and when the fund is exhausted, lights at facilities with taking cannot be turned on at night for the duration of the fall season.

The plea also provides that the county will make a payment of $180,000 to partially repair the harm of past take to an account to be established at the National Fish and Wildlife Foundation for use to benefit protected seabirds on Kauai, and a payment of $30,000 to reduce the harm from anticipated future take. Within the period of probation and prior to the county acquiring an incidental take permit, to the Kauai Humane Society to augment its Save Our Shearwater program.

"The Department of Justice views the taking of protected wildlife as a serious violation of the law, and we are pleased that the county of Kauai is taking action to eliminate the risk of harm to this threatened seabird," said Ignacia S. Moreno, Assistant Attorney General for the Justice Department's Environment and Natural Resources Division. "The county's action will enable residents to continue to use county facilities, while protecting this native species that is part of Hawaii's cultural and natural heritage."
The Endangered Species Act prohibits the unauthorized taking, including harming and harassing, of species listed as threatened or endangered. The Migratory Bird Treaty Act prohibits the unauthorized taking, including wounding or killing, of bird species listed as migratory.

The case is being prosecuted by the Environmental Crime Section, Environment and Natural Resources Division, U.S. Department of Justice.

The TGI on 29 Jan 2015 publishing a concluding cost to Kauai for lighting correctly and taking to full needs of the shearwaters at. One million Nine hundred thousand dollars.

HDF is aware of the high numbers of Shearwaters nesting and flying in the Mahauapeua area of the farm. They are aware that the amount of lighting needed to effectively run the dairy through the night is high. They know they have a night lighting conflict. That conflict of needs must be resolved before or ever the lights go on. It requires a much higher response level than “we’re working on it” or “we care for the shearwater bird.” What by detail is the HDF plan to protect this endanger species? If “shielding” is a remedy what exactly does HDF mean by that term? Describe in detail intensity, glare, range etc. Does the plan met the compliance standards now agreed upon by the county?

How can HDF have lighting bright enough for cows to walk safely each way from a pod, as much as a mile and a half in night time dark conditions, a lighted milk parlor area, a lighted surrounding area for other related activities, and at the same time, protect the endangered shearwater bird as legally demanded?

The Mahauapeua area is known for gusty winds. Kite flying is a noted activity in this area. In this type weather, stability of a non-fixed or un-tethered object is at risk. In 2014 and on HDF Mahauapeua property a full pivot system blew over. The weather was of a moderate storm condition with wind gusts. This incident is fully known by the HDF farm manager Mr. Garmatz, and the New Zealand crew that was assisting construction at that time. This pivot system is a large, tall, 2 support wheel configured, and heavy system of the capacity to cover over 100 acres in a 24 hour time span. This full “rip over” if occurring while spraying effluent would have created an uncontrolled spill. No shut off system reacts on a zero time elapse basis. All VRI systems have an error dimension. What, if any method exists, stabilizes this pivot system when a large random gust hits it? As this system is susceptible to wind gusts when they occur, if operating even if it only is moved, flexed or tilted, from the intend direction, effluent spray will be emitted in uncontrolled and unintended directions. How are the streams protected? Does the farm manager confirm this wind gust blow over incident? Would this type spill be considered under “In Case if an Emergency Spill Leak or Failure during Transportation or Land application” (see proposal page 100)? Why wouldn’t these type spills be seen as a continual factor of use or a certainty over time not an emergency spill or accident? What is the upper HDF numerical limit of wind force uses to determine nonuse of the effluent Irrigation system? The average yearly wind factor for Poipu is 16.2 mile per hour. It is higher at Mahauapeua.

Pivot 1 has a pivot range as measured by Google Earth 27 D ec 2013 from approx. 130 feet at the top North arc point to approximately 70 feet to the lower edge of the pivot circle. Application measures of effluent put down during one rotation appears to be beyond the intake capacity of some soil types. Will the EIS address this issue? What consideration is shown up slope run off? As these applications occur quickly does data support this method of application? At what rate? Will the EIS address the slope issue as it relates to rapid run off rate of effluent, irrigation water or rainfall creating stream pollution?
HDF- EIS-PN Kauai-- Ronald John-

5th series of comments-questions and concerns

"Findings and Recommendations Natural Disaster Survey Report
Hurricane Iniki
September 6 - 13, 1992
Chapter 1. The Event and its Impact
Finding 1.1

‘A small but intense hurricane struck the state of Hawaii during the
afternoon of September 11, 1992. Although all islands felt the storm, the
islands of Kauai and Oahu were most impacted. Seven persons were killed
and about 100 injured; total damage was about $1.8 billion. The south
shore of Kauai near Port Allen took the brunt of the storm with wind gusts
measured to 143 miles per hour (MPH) and water levels (a combination of
storm surge and waves) nearly 30 feet above normal.
Finding 1.2

Because of the apparently weak construction of many buildings, estimates
of wind speed based on building damage may be unreliable. Estimates
based on other indicators showed sustained winds of 130 to 160 MPH
especially in areas where winds are enhanced by terrain.
Recommendation 1.2.1

The NWS should encourage the State of Hawaii to review its building
codes in light of the Iniki damage **.
Coastal Management News page 1: HAWAII INCREASES RESILIENCY
THROUGH HURRICANE FORCE WIND BUILDING DESIGN
STANDARDS
Page 2

The Federal Emergency Management Agency (FEMA)
supported the technical work for Oahu and Kauai. By mid-2008, all wind
speed studies were completed and transmitted to the State Building Code
Council (Council) and offered as technical amendments to the 2006 IBC.

HCZM participated in this effort by helping to draft legislation that
establishes the Council and serving on the State Building Code Committee,
a predecessor to the Council. HCZM provided key testimony to the council,
requesting automatic adoption of the wind standards as a part of the county
IBC adoptions. The Council adopted the wind standards for all four
counties in its final draft of the State Building Code (entering public review
later this year), and required each county to use their specific wind

standards no later than two years after state adoption of the State of
Hawaii as a Special Wind Region.”

Were all HDF buildings including calving sheds, silo storage and feed
storages reviewed and approved to meet these wind standards? What
compliance data was given. If none please explain. What amount of
wind speed/wind load were these structures approve to withstand?.
Are the approving agencies deliberations and recommendations on
this matter readily open for public review? Who approved them and
when?

This dairy is an experiment. As so, it would require a specific set of
contingency planning/ back up for a wide variety of events which might
occur. Fail safe backup assurance if you will. 30% of nutrient needs
are provided by supplemental feeding from automated silo to trough
feeding. Electricity is required. The best of machinery breaks down.
Then what? In the ranch area I came from and based on prior experience
these type needs were anticipated and set aside- be it hay or grain or
other- were available. One can’t recall a government subsidy program, as
exists now, that made up for poor planning. Unusual weather occurring
was a given, not an accident or emergency.

. In a larger purview ie. docks close, on island provider of nutrient
supplies shut down; what is the time limit when this nutrient
expectation can be meet without relying on off site delivery of
additional feed supplies? Where does that restocking come from?
These are just a few examples of an imperfect world.

Ulepon Initiative principal Kayce Datta, in an opinion posted in the
Garden Island Newspaper 15 Feb 2016, used a California dock strike as
an example of the need for their Hawaii based dairy. Wouldn’t such shut
down be more crippling of a nutrient plan that require 30% of their
feed from a state side feed source. If that USA dock strike became a
real problem there are New Zealand dairies with milk to be exported.
Can they also take care of HDF feed source needs?.

No one is against sensible, data supported, properly sited and sized
dairies. That definition does not support the HDF dairy concept nor it being
sited at Mahaulupeu. What are HDF’s fall back positions? In detail, what
major problems could disrupt their ordinary procedures? With full 24
hour operations required, what company, factory, assembly line or
any other system didn’t at some point breakdown? What amount of
down time can HDF handle? What is the remedial action for electrical
systems outages or mechanical problems? The HDF concept requires a high number per hour milking count. Who milks the cow when the milking machine is off line. When the back up solar power system becomes inoperative or depleted then what?

The mention by HDF re: wind break or shelter belt as defined in NCRS Code 380. as being "a multiple row planting of trees will be established...page 57" begs the full meaning of this concept. No effective relief is gained by the limited HDF treatment of this requirement, nor does it appear there is room for such planting. The primary wind direction in that area is from the NNW. Where then should a odor minimization wind break be placed? This area is a large concern being treated with little regard. A serious odor mitigation plan must be required. What is that plan?

The Clean Water Branch Brown Water Advisories are part of the information that would validate runoff problems of the HDF site. Most of the source of that condition in the ocean waters of Mahaulepu Beach comes from streams or ditches traversing the HDF property. This condition is frequent and has existed for years when flood irrigation was the method of irrigating the Mahaulepu Cane and Taro fields. The beginning of the now certain polluted level of the brown water is not known. Those who visit the area know of the long history of brown water there, Many have filmed it. If proof of the now existing and continual runoff displaying the polluted ability of the HDF location is necessary, then rainfall data should be available. The TGI stated in an article titled “All Washed Up” (9 Dec 2013) “According to the National Weather Service Poipu registered 4.33 inches and Kalalau had 3.76.” This was of a condition of just a week before the article and when there was an abundance of brown water in the ocean off Mahaulepu Beach for multiple days. From the data of Surf rider at that time, to the most recent findings of DOH it is definite that the "brown water was and continues to be highly polluted. Will this evidence be considered in the EIS examination of pollution issues?

Question arise regarding the intensive "grubbing, grading, planting and major alteration of the landscape. New ditches and other trenching were begun and finished before permitting. In a jump start and confident mode, it appears that HDF proceeded to do much of this type work before permitting was approved. Google Earth close up imagery Dec 17 2013 show an intensive amount of field work completed over a third at least of the property from Mahaulepu Rd for approx 1800 yards north toward the back end of the property and west to east at a max point of approx 800 yards. Planting efforts are shown and water channels have been already cleaned or created. It appears that added and improved waterways have occurred by December 17 2013. Heavy grading is noted. In addition, field trials are mentioned as having been performed earlier than the permitting date. Under what permitting statute were all the alterations allowed, and at what date did such permitting allow HDF to begin active alterations of the site? Was Grove Farm/or the planning approving agencies aware of the extent of the activity? Does this possible pre-authorized beginning of construction explain the measured significant increase of nutrient, bacteria and sediment in the Waiolopi Stream?- pollution far in excess of state standards-and occurring in higher numbers as they began "work" on the property? Does HDF acknowledge significant pre- permit and present activity beyond statute limitations? What agency onsite inspections have been made by whom and when? -Was compliance to HAR11-55-04 shown? Was a storm water NPDES permit obtained? On what date was it applied for? What dates was it issued? If not seen as needed- Why? Cite the statute that allowed HDF to disregarded HAR 11-55-04.

What “reclaim” or clean up regulations for building on previously contaminated/pollution laden sites prior to subsequent building and commercial use (even if by an ag related industrial endeavor) are required by federal, state or county requirements? If the present levels of measured pollution levels are not first mitigated, increased runoff and contaminants from the HDF addition of a significant higher level of possible pollution would be added to the present volume and level of pollution now being found. One would imagine the Clean Water Act is also involved. Please determine, review and list all “clean up rules covering site use of this existing polluted property.” In this respect advise if compliance to that standard requires the HDF property to be pollution free before beginning. If not- why not?

It appears that the definition or perhaps the difference between point source discharge and non-point discharge is blurred by this new and larger expansion of on fields use of excess manure. HDF has attempted to show its need by data supporting effluent pond use for this concept. What isn’t a
matter of opinion is the dumping of sludge on the M and S (Manure and Sludge) 82 acre Area at the lower left hand corner of the farm (less than 750 ft east of the Koloa Public wells).

HDF is a CAFO as designated by 40 C F R paragraph 412.15. The Clean Water Act 33 U S C in part would assert that this dumping of sludge at least would be in violation of this Act if not by its “storage use” i.e. “not needed” or “an addition beyond usage” but for the certainty of comingling polluted water with that of the Taro Farm. The Taro Farm located at the very bottom of the HDF farm site could become a convenient dumping area for effluent over fill or catch basin for surface water, and then the subsequent drainage to the Taro farm ditch system would run to the ocean (one source removed) as part of their operation.

Grove Farm has shown little hesitancy in removing tenants from areas need by a bigger tenant. The small approximate 13 acre Taro Farm as located, stands out as abutting and surrounded on three sides by HDF property. It is conspicuous by its presence and also by its disregard in HDF planning. That so termed private property requires flood irrigation yet abuts a sludge containment area containing 82 acres. Block F of 54 acres which is described on pp. 73 are perceived as heavy, flood frequently and difficult to crop is also next to the Taro farm. No indication of protection or concern for the Taro Farm is written, and runoff, over spray or intermingling of its water with effluent mixed water was not considered.

The Taro farm abuts Block F described as “characteristically poor draining. This location raises not just interest and suspicion but justifiable questions. A written description re: the interaction terms, and considerations made between Grove Farm, the Taro Farm and HDF needs to be examined and explained. That relationship should be clarified, including what barriers exist which would stem overrun either in or out of the Taro Farm. In that regard there should be provisions outlined in the HDF proposal for involving or protecting the Taro Farm from any type disturbance or incursion. What are these provisions? If none exist- why not? What should be done to consider/ protect the Taro Farm?

There is a high degree of confusion regarding whether the nutrient data, waste management data, etc. is for the ultimate build up of 2000 dairy cows Section 11-200-7, HAR, states: “A group of actions proposed by an agency or an applicant shall be treated as a single action when” The component actions are phases or

increments of a larger total undertaking. A proposed action must be described in its entirety and cannot be broken up into component parts, which if each is taken separately, may have minimal impact on the environment. Segmenting a project in this incremental way to avoid the preparation of an environmental impact statement is forbidden. Are all elements of the plan developed on the basis of full build out parameters? Wouldn’t all other action need to wait until the “larger total undertaking” is sent through review and permitting protocol?

The geometric progressive buildup of calving from the initial 699 dairy cows will build quickly to 2000 AU’s (Animal Units) on HDF property. Obviously an increment of heifers and bull calves, by that process will be grow progressively larger and reach the 2000 mark within 5 years. The next calving cycle beyond 2000 (14 -16 months) will progressively expand the number by that full 2000 amount. HDF will either sells or uses the heifers for additions dairy production. It will also be producing a high number of male calves for sale. There is no indication of calf pen size enlargement or additional excrement from the calf pens into the effluent pond or additional excrement on the paddock when paddock containment is being used for heifer calves. The excrement of calves both in calf pen and on paddock must be represented. What are the amounts considered? Are they shown in the present proposal? That information affects all HDF computations from effluent pond size to nutrient plan. What is the procedure to cap the total number at 2000? Does that 2000 number include calves, yet lactating heifers, and dairy cows? The proposal as written is unclear and unacceptable without more definitive clarity on these multiple issues.

No mention of “dry dairy cow” or “sick dairy cow” is given. Where are they pastured? Are they moved from paddock to paddock? Are they separated and how? Other than the one line on page 91 (last proposal) “Animal Mortality Management Plan”, no mention of a necessary veterinary space location or the cleanup of such area is given.

Recently legal findings were made re: Kauai Bottling Company right to use the Waia reservoir water for commercial sales. Grove Farms testimony is through out some of the narrative. Pioneer has a claim to water (page 31 first proposal) from the pipeline water also used by HDF. If more is needed
by Pioneer HDF would have to acquiesce to their usage of the pipe line water usage if necessary. Quote pp 31 "the pipeline is unlikely to be able to supply required water for irrigation when Pioneer is in full on take." The possibility that future legal action could cloud the entire water use of Waia reservoir use is evident. This must be recognized in an EIS review and a consideration if HDF planning. Has it been? In what manner?

Little if any data used to support the present concept is usable to support a Confined CAFO conversion or to start initially as one. See 2-3 HDF EIS PN What factors supports this alternate as a "viable" one? Why?

Page 5 -1st proposal under Design Consideration indicates “Cow races need crossing solutions (culvert and bridges) at three points over the stream which passes through the dairy farm” No explanation of how the stream is protected from manure and feces deposited while traversing these cross over points exist. Are protective side curbs on those direct outlets provided? Both, at the approach to these culvert and bridges while on the bridges and at exit points, would side barrier containment? Where does the excrement during these crossing go and how is it contained?

There is a fresh water "Lake Pond" abutting the HDF property line (upper left corner and on pp20) (Redacted proposal) shown as discharging into a "canal/ditch" traversing the property and then leaving the property just above the area marked milking parlor at pod 10S. No protection of that ditch from pollution from the cited gun style (65 feet range) effluent emission spray or other excrement spillage is given. Why?

Given a 2000 number of perfect automated cows and perfect systems working at max level, the time to transition a mob of 300 cows both up to the milking parlor, milk, and feed, and back to that same pod relies on human workers and with that less than perfect variable, it is questionable that all the perfect cows could be milk in the time required for 2 milkings per day. Add to the slow walking dairy cow of reality, carrying a full udder of an average 10 lbs weight as she goes to the milking parlor and down time becomes a serious draw back of a scheme based on what might work for a Confined CAFO setup. No rancher nor any one who has trailed cattle would tell you otherwise. If two mobs are grazing on padds near one another you cannot get the first of the two mobs of 300 back to its same pod (most pod distances are at least 800 yards from the milking area and many a mile away) while at the same time bring the next 300 cow mob up the same raceway. This is not “3 little pigs going to market”, but 300 dairy cows strung along “walkways and races” 16 to 20 feet in width (page 21 last HDF proposal) and often in poor, sloppy, weather. This concept won’t work. At this time a reality based plan must be defined and explained. What is that plan?

Waste Utilization-Field Office Technical Guide NRCS Section IV
Where the residues of energy production are to be land-applied for crop nutrient use or soil conditioning, the criteria listed above shall apply.
CONSIDERATIONS
The effect of Waste Utilization on the water budget should be considered, particularly where a shallow ground water table is present or in areas prone to runoff. Limit waste application to the volume of liquid that can be stored in the root zone. Agricultural wastes contain pathogens and other disease-causing organisms. Wastes should be utilized in a manner that minimizes their disease potential. Priority areas for land application of wastes should be on gentle slopes located as far as possible from waterways. When wastes are applied on more sloping land or land adjacent to waterways, other conservation practices should be installed to reduce the potential for offsite transport of waste. It is preferable to apply wastes on pastures and hay land soon after cutting or grazing before re-growth has occurred. Minimize environmental impact of land applied waste by limiting the quantity of waste applied to the rates determined using the practice standard Nutrient Management(590) for all waste utilization. Consider the net effect of waste utilization on greenhouse gas emissions and carbon sequestration.

It is difficult to examine the HDF proposal and find really based concepts that effectively meet these NCRS criteria. Some of the NCRS criteria have been simply ignored in the HDF proposal, and that is a significant concern. By field elevation data obtained from Google Earth one finds a number of varied field level elevations within the overall 100 ft elevation decrease extending from the northern most end of the HDF property to Mahaulepu Road. Measuring across the fields- West edge to East edge- multiple
The expected procedure in this area? Will the EIS review process examine the question of whether nutrients overwhelm the absorptive capacity of the soil, and either run off or will be leached into the groundwater? The maximum allowable rate of application (inches per hour) to prevent runoff depends on the intake rate of the soil. This basic underpinning of application rate is continually conflicted by HDFs own indications. Will the EIS review this specific compliance need?

Conspicuous by its presences and also by its disregard by HDF planning is a Taro Farm in the lower left hand quadrant of the property. This private property requires flood irrigation yet abuts a sludge containment area containing 82 acres and block F of 54 acres which is described on pg73 as perceived as heavy, flood frequently and difficult to crop. No indication of protection or concern for the Taro Farm is written, nor is runoff, over spray or intermingling of its water with effluent mixed water considered in the HDF proposal. Why not? What should be done to protect the Taro Farm?

HDF on page 73 explains Block F-Special Management. They restrict the Block size to 54 acres. Abutting and continuing north of Block F are Pod 211 through 218 and still connected farther north include Pod 121 through 124 and to their west Pod 101 through 104. All these connected and additional pods are of like soil types. Why is the total area of connected like soil i.e. "heavy, flood frequently" "characteristically poor draining" treated in a different manner.
A general rule but specific to the HDF flow of multiple proposals is: "When a significant and substantive change or changes occur in a proposal document creates a significant and substantive difference in the body of the proposal (multiple data points/factors) the entire approval process must begin again." Was West Kauai Soil and Water Conservation District notified that the proposal as presented contained direct opposite soil ratings? After that acknowledgement did West Kauai Soil and Water Conservation District approve and NRSC examine the most recent proposal? What actual data should have been considered by these agencies? What adjustments did DOH have to make when the true data was given to them?

There is a conflict by nomenclature misrepresentation implicit in the HDF statement page 7- 2.2.1 Quote "The drainage ways within Mahalepu Valley and within the project-----these canals and ditches flow—These are other water ways than ditches and canals on this property, HDF calls them "unnamed drainage way" Why wouldn't they know the names? Actually, two historical streams (Kapunakea and Waialau) consolidate into one and enter the class A ocean at the end of Mahalepu Beach near the Makuwahi Cave Reserves. The HDF type of generalized terminology is replete throughout the proposal and should be noted and considered in the EIS review.

In earthquake planning for retrofitting or design of new buildings the terms "worst case scenario" or "significant events" are primary to setting the parameters to be met. From Waste management through Nutrient plans, HDF appears to misunderstand that basic protective need. HDF proposal language speaks in terms of "average" There is nothing precise in that term. Words like "assume" have no place nor is a sensitive, critical factor presented as "observed." "Average" is not "actual." "Average" is an artificial indicator of a wide bandwidth of conditions not one specific condition only. You do not develop plans for developments such as an experimental dairy project based on average, generalizations, or probability but build on a standard of "possibility of" and specifics. Does HDFs proposal content met that necessary threshold and does EIS reviewers see this specificity as necessary? The bar of acceptance for approving the contents of their proposal data would be below any normal standard of acceptance if a dairy design of this nature was given a permit based on such loose linguistic presentation."

When specifics are given such as page 39 first proposal- sentences like "Buried pipe will be installed at sufficient depth below the ground surface to provide protection from hazards by traffic loads, farming operations freezing temperature----this level of document preparation speak of "cut and paste" and no attention to content applicability. "Freezing temperature" this after 5 years of studying? This parameter for a Hawaii based dairy farm? Isn't specificity and accuracy required in proposals of this nature? If anyone is to find legitimate support for this project, conclusory assertions must be replaced by data and that data being interpreted correctly. At this time the deficits in HDF's presentation are obvious and if left to stand unacceptable. It is a seriously flawed attempt pointing to little academic discipline and an abundance of unconcern. What should/can be done to gain the precision required? In itself this proposal is as flawed as its concept, and by its self should be rejected. On what merit is this proposal deemed acceptable by any objective reviewer?

What can one determine from the admission of Quote pp. 53 first proposal? "Water application will be at rates that minimize transport of sediment, nutrients, and chemicals to surface waters, and that minimize transport nutrients and chemicals to ground water." From "establish and operate the zero discharge grass fed dairy" in next breath to "minimize transport" to surface waters and ground water. Is this admission not clear in its intent? Minimize does not enhance nor describe compliance to "zero discharge." What does minimize represent to HDF? What outcome is unclear in that admission statement?

The continuous effluent bath of the pods already holding a significant amount of fecal material will over time significantly affect the water systems and ground water. That is a certainty as is the eventual
nonproductive capacity of the soil. Why is this ignored? What information or data in the proposal support a different conclusion?

Quote New Zealand Dairy Farm Guide “Sloping land (>7”) or land with hump and hollow drainage refers to soils which are gently rolling to steep. Also includes soils which have been humped and hollowed. The main risk is runoff on these soils. Management tips: application depth must be less than soil water deficit and application rate must be less than soil infiltration rate.” Page 12 HDF proposal lists 7 of the soil types having slopes in excess of that rule. What does HDF do to rectify this discrepancy in irrigation concept? Was humped and hollowed contouring done on the HDF property? Were contours sloped toward the water outlets when grading was being done? What contour maps were used during the grading of the HDF property? What contour changes were made? Prior ground elevations are available on Google Earth. What does present satellite imagery show?

The HDF pivot system is a large, tall, 2 support wheel configured, heavy system of the capacity to cover over 100 acres in a 24 hour time span. The full “tip over” of 2014 if occurring while spraying effluent would have created a uncontrollably spill. No shut off system reacts on a zero time elapse basis. All VR1 systems have an error dimension. What if any method exists, stabilizes this pivot system when a random unpredictable gust hits? As this system is obviously susceptible to wind gusts when they occur, even if only moved, flexed or tilted, from the intend direction, effluent spray will be emitted in uncontrollable and unintended directions. How are the waterways protected? Does the farm manager confirm the 2014 wind blow over incident? Would this type spill be considered under “In Case if an Emergency Spill Leak or Failure during Transportation or Land application” (see proposal page 100)? Why would the 2014 blow down not be seen as a factor common to its use not an accident? What is the upper HDF numerical limit of wind force uses to determine nonuse or “stand down” of the effluent/irrigation system? The average yearly wind factor for Poipu is 16.2 mile per hour. It is higher and more varied as you go up toward the mountains. What are those readings?

What are the weight and size dimensions of the pivot system wheel sets, their width and weight per unit? How many wheel systems per pivot and what is the total weight load on an individual wheel section when in full operation. What is the distance to the outer gun system and what is the tracking speed of the outer pivot? Wheel rutting is common to all pivot systems. It is more so when one is as large and heavy as that HDF is using. What are the single wheel width and weight dimensions? Within a short time of use distinctive tracking/rutting paths will occur. When either prepped as a hard surface or becoming one when in the clay areas of the fielding-how will rutting be prevented and runoff not occur from these tracks? As these tracks become fixed, permanent pathways, they will become quickly visual and distinct. They will become multiple miles of circular conduits where any irrigation water or effluent can be carried away. These certain depressions will either hold or runoff to other areas. If the tracks are hard surfaced by design then they now become pathways/walkways, much as raceways etc. They, by known function, become “discharge” areas. If intended they will, if not hard surface designed, become depressions holding standing water in stagnating pools. If accessible, animals of all types drink from them. As much or more than walkways raceways etc, these certain channels must be considered and runoff to them and beyond controlled. Will the EIS address that need? There is considerable fluctuation of elevations determined by Google Earth Dec 2013 which not only impedes a pivot system but can as well stall or shut one down. What is the shutdown emergency reaction time? Why did it not work in the 2014 tip over? How many wheel sections are in Pivot 1 and Pivot 2? What is the circumference of the pivot circles? What is the combined total mileage length of the different pivot tracks?

Do the pivots/wheel systems cross waterways? By what means? A pivot system cannot be shielded in such manner that pollutants aren’t
carried and dropped into waterways from the body parts/hardware of the pivot equipment while passing over it. The entire functional reality in this context must be evaluated. What is the lag time between signal and full shut off (no residual drip)? Is each section of the pivot system pressure regulated? What is the lag time from shutoff signal to pressure to zero on the outgoing flow?

In trials ran on VRI equipment (ASABE Technical Library) a catch can test on a S3-VRI equipped pivot system resulted in evaporation and drift loss at an average of 9.3% and ranged from 1% to 19% the question again is: Given that data how can zero discharge be assured?

Page 54 mentions a "4 inch underground pipe to a number of hydrants" for carrying suspended solids to the paddocks. 4 inches under the ground-ground now disturbed/looseened by the burial of pipe and, heavy weight pivot wheel systems crossing these pipes. Can that pipe withstand the weight load of a pivot system wheel section? Is this gun section limited to the 82 acres M and S area only or all areas "outside the liquid effluent application" (page 54 new proposal). What paddocks by number are involved in this concept?

At this point of time, (4Feb 2014) measured levels of pollution have been determined at multiple levels above a safe number and these polluted waters running into the ocean affect the "protect conditions" exactly as described above. The reason for the disregard/disconnect from regulatory statues listed above and the certain continued pollution must be explained in reality based parameters. In that context HDF must explained, beyond the usual generalities, how they intend to meet non pollution requirements.

There are multiple general explanations intermingled with varied specifications of acreage that will be used for grazing/paddock. With all setbacks considered: raceways, milk parlor silo, storage, graveyard etc. What is the specific total number of acres that a dairy cow will generally occupy for grazing purposes only? Please detail those pods and acre amounts?.

With the average mortality rate given dairy cows what data justifies and supports the small ("about 4400 sq. feet") only set aside (see page 101)? Two thousand dairy cows and a tenth of acre "Animal Cemetery" is not a sensible projection. The average mortality rate of dairy cows at this time is in the 5% yearly range. "The new and higher rate may be due to regulatory change in the United States. when at end of December 2003 new regulations required euthanasia of downer cows to prohibit use in human food supply channels(USDA, 2003). That change would be expected to shift DHI reporting of reason for lactation termination from "sold for slaughter or salvage" (formerly "sold for beef") to "died" (Animal Improvement Programs Laboratory,2007), as noted by Fetrow et al. (2006). On page 12 and 13 Table 5 One category displays "Depth to Water table" That soil category of the Animal Cemetery is shown as greater than 80 inches. On page 97 HDF indicates "Pits will never go deeper than 8 ft (96 inches) This is but one example of disjointed, multiple and serious conflicts in their own data. For all they know that's at a water level or close. What burial depth can one assume will be used? At full build out of a 2000 dairy cow, the annual 5% mortality rate would mean approximately 100 burials a year in a space no bigger than most single family building lots. What explains this discrepancy in space requirement needs? In addition, the placement of the HDF "Animal Cemetery" is near a stream, and in situated in an area where mountainside rain runoff is peak. None of this placement makes sense and it must. What should be considered as an appropriate site and size if the Animal Cemetery carcass disposal is as planned? Given storm water infiltration: at the level of burial depth when does leaching of the decomposing carcasses occur and percolate to the ground water begin? Do the math: 2 ft wide- 5 ft minimum length -3 ft separation of burial site. Where and when does HDF start the next site? Was any conversations held with any slaughterhouse owners re: disposal of the dairy cows? Was conversations re: this matter held with slaughterhouse owner Willie Sanchez? What are HDF slaughter house needs? For what purpose will HDF use a slaughter house?
In seismic planning for retrofitting or design of new buildings the terms “worst case scenario” or “significant events” are primary to setting the parameters to be met. From Waste management through Nutrient plans HDF’s presentation appears to misunderstand that basic expectation. HDF language speaks in terms of “average.” There is nothing precise in that term. Words like “assume” have no place, nor is a sensitive factor presented as “observed.” “Average” is not “actual” nor does it bear the weight of requirements that must be based on actual measurements. Average has a wide bandwidth, not one singular condition only. You do not develop plans for developments, such as an experimental dairy project, based on average, generalizations, or probability, but build on “possibility of” and specifics. If anyone is to find legitimate support for this project, conclusory assertions must be replaced by data and that data being interpreted correctly. At this time the deficits in HDF’s presentation are obvious and if left to stand unacceptable. What should be done to gain the validity and precision required for this proposal?

The well system serving Koloa and Poipu is not as depicted (Quote: Page 12 HDF proposal) “The Koloa F well is located 1/2 mile away.” The purpose of that HDF statement denies reasonable explanation and frankly is suspect. Wells F and other public wells in the same area are within 350-750 feet. There is a host of questions. How and why can such mistake in measurement be committed? Were any water officials consulted? When? With whom, and for what reason? Did HDF know that the County wells provided water for all of Poipu and most of Koloa? What EIS reviewers will be involved in reviewing this area? The same footprint over the aquifer where the well is sited is shared by the 82 acre Manure and Sludge area of HDF. Were the county officials made aware that abutting the actual well system was 82 acres of drip system irrigated manure and sludge (M and S) not only next to but on top of the ground water aquifer feeding those wells? The questions now listed concerning this matter are but few of those in this specific area that require scrutiny and factual explanation. Why in particular was “1/2 mile” used as an indicated offset distance figure from the wells, and not the true figure?

On page 54 3rd proposal one reads “gun type application system to area outside the liquid effluent application” Those areas are on the fringe areas of the property. On page 54 Redacted and 3rd proposal they reference the gun and their 65 foot radius of spray area will be moved around the paddocks. The first gun type is mounted on the pivot ends. The second gun system is hydrant mounted guns used in the paddocks. Some paddocks, almost the closest property to Mauahulepu Rd will be covered by the first method. Use of the hydrant mounted gun system in other paddocks sets aside all the assurances and claimed precision of the VR system of irrigation. It is a known wrong and primitive solution never to be used to spray potential pollutants in sensitive areas. It literally cuts corners (see 442-page 8 FOTG “Irregularly shaped pen areas that are impractical to treat with a sprinkler system”) How many of the paddocks are irregularly shaped? Gun sprinklers should not be allowed. It is a rare reader that has not been hit by wind-blown sprinkler spray of gun type. At the Mahaulepu site are multiple water ways within a sprinkler span. For example (See page 32 (canal/ditch) running through the lower right corner of the property and which they will irrigate by pivot end gun use. A gun type irrigation system spraying effluent will with wind drift create a combination of pollution either by odor, mist or both. Its error rate is high, it precision and sprinkler uniformity low. The sweep is outward, frequently random and its scatter at the whim of the wind. With sensitive stream areas nearby no error variable should be in play. Given the multiple streams proximity and irrigation systems What data exists that would support this method as a reasonable irrigation method for either irrigation application concept HDF intends to uses? Why?

HDF must demonstrate how they will comply not just they will comply to irrigation standards. Under NRCS FOTG Sec. 4 page 6 through 9 they must specifically relate each of the requirements to their field irrigation concept, and to the hardware used for such irrigation. HDF must demonstrate an understanding of and compliance to all regulations governing dairy operations. That compliance must be written, and open for EIS review.
The HDF Impending purchase of Clover Leaf Dairy on the Big Island, should be considered under "cumulatively has a considerable effect" language or "commitment for larger actions" criteria 8 of the ESI Significant Criteria. Will this matter be reviewed? This purchase is HDF's second effort toward an announced 10000 dairy cow constellation. That figure points to a additional 10000 calving number every 14 to 16 months and higher each lactation period. Quotes by the present owner, Ed Boteiło, raise serious concern. The following quote is part of an article "Dairy farming in Paradise: Dairying Across America: Hawaii"

"Our land runs right down to the Pacific Ocean," said Ed Boteiło, the farm's operator. "On a clear day, you can see some of the other islands. During the winter we often see whales swimming by." (2 full color photos were included with captions)

The admission ("Our land runs right down to the Pacific Ocean.") underpins the worst ecological/environmental disaster New Zealand has faced in modern history.

The picture as captioned in the article is of itself revealing. A single dairy cow grazing as a giant cruise liner passes by. However, what it reveals is not to many a magnificent, bucolic scene depicting the grandeur of spectacular agricultural setting. It could as well illustrate the greatest ecological/environmental disaster yet experienced in New Zealand and certainly all over England, France and the America's to name but a few of those area devastated by a lack of environmental concern. It could represent the single rule we are learning much to slow. "Large consolidations of cattle enclosed in confined spaces next to or over water bodies can create serious and lasting pollution."

Under the "prevent language" of 344-1, In what manner does one alert/involve government agencies regarding this pollution possibility? Does DOH have stream pollution readings of the Kahalo Ditch or at the ocean as the stream run off leaves the Clover Leaf Dairy? All major dairy pollution started with a small amount of dairy cows. Hawaii must take in advisement the yet unstudied environmental impact of this collective HDF effort. What regulations cover the cumulative pollution possibility of this next step toward an intended 10000 dairy cow build up? 10000 dairy cows mean within 14-16 months 10000 calves. Then what?

If this uncontrolled concept can ruin New Zealand (an island) as it has, the Big Island area size pales in comparison.

Prior to HDF's last proposal submittal a "NRCS Customs Soil Resource Report for Island of Kauai Hawaii" was published. Interestingly it covers and is limited to the Mahaulpeu HDF property site. It points out clearly what HDF should have noted and considered in the last submitted proposal. It has been indicated by NRCS that the reason for that research report at that time and requesting agency are secret and protected, yet no search of the series 401 regulations, have been found that impose such secrecy/privacy protocol.

General Manual
Part 450 - Technology
Who requested the above referenced specific NRCS Customs Soil Resource Report for Island of Kauai? When? When was it given to the requesting party?

If HDF was aware of this data, an intentional disregard for the data contained in the NRCS Customs Soil Resource Report for Island of Kauai Hawaii has occurred. That significant "error of omission" requires open explanation. Will the EIS process evaluate this concern? If HDF was the requesting party then ignoring its content creates a serious breach in protocol governing multiple governmental agencies. The aforementioned report is an objective analysis. It points out with critical science based data why HDF is not a project suited to this particular site. Did HDF have knowledge of the existence of the NRCS Customs Soil Resource Report for Island of Kauai? If not—Why not? Has effort been made by HDF to now integrate or respond to the data in this report? What efforts by detail have been made?

No expert, shown this report by the writer, including one former farm loan bank officer, have found it as supporting- in any way- this concept- at this site. On the contrary the report is a stand alone analysis of which no one could deny its data or impact. One reviewer with shaking head ask what is their real intent for the use of this land? Is the financial backing source—Pierre Omidyar- or Kyle Datta aware of the findings contained in this report? Is Pierre Omidyar aware of the EIS review or this report? Why was it clear, concise findings ignored? Why even now is it ignored,
not acknowledged or considered by HDF in formal presentations? What data based facts can outweigh the burden of evidence contained in the NRCS Customs Soil Resource Report for Island of Kauai? Will the EIS take in consideration the full import of this report? In what manner and by which of the review agencies will it be considered?

In the area of professional preparation: has Group 70 ever developed or evaluated a Waste Management Plan of a dairy similar to the one proposed by HDF? When? Where? What other dairies have they designed waste management plans for?

In closing: Proposals made to approving entities are to explain not to confuse. They should alleviate fear or tensions, assure that no damage or harm exists in what is proposed. Some include a clear validation of its need or necessity. This expectation was not met by the one now being considered.

Those of us voicing concerns are for reasonably sized and sited dairies. None of us believe Mahualepu is a legitimate choice. As there exists a difference between legal and ethical, there too is a difference between could and should.

Pierre Omicyar, Ulepono Initiative, and Hawaii Dairy Farms should do the right thing.
Dear Ronald O. John:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**GROUP 70 OBJECTIVITY:** Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai'i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawai'i Revised Statutes and the "Environmental Impact Statement Rules" (Chapter 200 of Title 11, Hawai'i Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawai'i Chapter of the American Planning Association has recognized Group 70's professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70's experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai'i Dairy Farms Environmental Impact Statement.
A second round of field sampling was conducted in 2015 and focused on evaluating soil electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of growth, to absorb and hold rainwater for during dryer periods, to filter and reduce the potential for impacts on waterbodies. Poorly drained soils are not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil profile. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential to off-set up to one-third of the annual increase in atmospheric carbon dioxide.

Soil conservation is a core principle behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in the United States. NRCS is a technical consultant that can be engaged to provide services for soil conservation, and to provide habitat for soil microorganisms. The NRCS provides a wide range of technical assistance to landowners, including soil conservation, water quality, and wildlife management. NRCS technical assistance can include soil testing, field studies, and analysis on water quality and ground water resources in the area. The NRCS was established to define an area of interest, conduct data collection, and generate a Custom Soil Conservation Plan (CSCP). The CSCP includes a CAPRIC (Conservation Assessment Plan Research Information Catalog) database that is customized for the area of interest.

The NRCS, with its classification and descriptions, provides a good information base for developing and implementing conservation practices. The NRCS classification system is designed to provide a comprehensive assessment of soil properties, including soil type, texture, structure, and depth. The NRCS system is used to identify existing soil nutrient levels and to define areas of interest. This is particularly important for dairy farms, as the quality of groundwater and surface water is documented.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States, and NRCS personnel are engaged in the assessment of soil type, texture, structure, and depth. The NRCS uses a variety of methods, including soil testing, field studies, and analysis on water quality and ground water resources in the area. The NRCS provides a wide range of technical assistance to landowners, including soil conservation, water quality, and wildlife management. NRCS technical assistance can include soil testing, field studies, and analysis on water quality and ground water resources in the area.

Soil conservation is a core principle behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in the United States. The NRCS provides a wide range of technical assistance to landowners, including soil conservation, water quality, and wildlife management. NRCS technical assistance can include soil testing, field studies, and analysis on water quality and ground water resources in the area.
Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā`ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F Well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Po`ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po`ipū - Kāhele districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā`ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā`ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā`ulepū Valley, which is fed by several intermittent streams coming off the south slope of the Ha`upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and empty into the lower Māhā`ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction...
Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and a areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part 1 of its report: Waiopili Ditch Sanitary Survey, Kauai, Part 1. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Efficient Irrigation and Commercial Fertilizer Application. The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size, supplemental nitrogen will be needed, and assurance/quality control requirements, and it could not be used for regulatory purposes. The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa- Po‘ipū region were also calculated. Nitrogen input to the marine environment in the Po‘ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal
area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhā‘ulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua‘i and N‘ahāhau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhā‘ulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent pond since rainfall has been recorded in Māhā‘ulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricanes, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a wind rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line. Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling technique to estimate odor dispersion under various meteorologic conditions.
...odors may be introduced to the HDF site with effluent ponds. The HDF system is designed to utilize 100 percent of the treated wastewater effluent as a local food source.

The term "grass-fed" was used in the HDF EIS. This term was used to identify the amount of nutrients anticipated from the manure of cattle grazing at HDF. Manure from cattle grazing on pasture is a natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed, thereby reducing the cost of production for dairy cows at HDF. This term is not used in the EIS.

Odor emission sources identified for modeling at HDF were manure in the pasture and effluent ponds. Odor models were adapted to reflect the HDF facilities. Modeling results were generated for worst case meteorological conditions (low wind speed, high humidity). The odor plume would extend to the south of the HDF site. Results for the committed herd size of 699 mature dairy cows show odor would not exceed 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odor would not exceed beyond 2,780 feet outside the HDF boundaries. The potential odor plumes would be limited to 50 percent of the sensitive population. The results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area footprint will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.5, Architecture and Engineering.

The pastoral rotational-grazing dairy provides a local food source — grass — as the natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed, thereby reducing the cost of production for dairy cows at HDF. This term is not used in the EIS.

This cost-effective method will reduce reliance on imported fertilizer and feed, thereby reducing the cost of production for dairy cows at HDF. This term is not used in the EIS.
Healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through the pivot irrigation system or through gun irrigation. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm. The pivot irrigation system is controlled using computer software and GPS receivers to allow for very precise application of irrigation and/or diluted effluent on the pasture. The growth, to absorb and hold nutrients, is highly unlikely that the storage pond will be full at any time for the committed cow herd. HDF will follow the developed Conservation Plan, which is in accordance with the regulations for animal agriculture activities. Two rounds of independent soil sampling and laboratory tests of soil for traces of antibiotic residue will be conducted. HDF will utilize the Soil Conservation Standards that provide a scientific basis for the effects of animal agriculture activities on the environment.

Towards maintaining water quality, the United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) provides technical guidance on applying agricultural waste. The NRCS Conservation Practice Standard 260, Nutrient Management, applies to the fields. It covers the management of surface water and groundwater, and non-point source pollution from animal agriculture activities. The standard is based on the Science-Based Tools and Standards in Agronomy, Water Quality Management, and Water Quality Protection, Handbook 233, developed and published by the USDA NRCS.

The soil on the site is a loamy silt, which can be managed to provide nutrients for plant growth. The soil is also used as a resource, it is being used for the constituent components that provide benefit. The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic byproducts, waste water, organic matter, and water quality. The standard is based on the Water Quality Management Handbook 233, developed and published by the USDA NRCS.

The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) provides technical guidance on applying agricultural waste. The NRCS Conservation Practice Standard 260, Nutrient Management, applies to the fields. It covers the management of surface water and groundwater, and non-point source pollution from animal agriculture activities. The standard is based on the Science-Based Tools and Standards in Agronomy, Water Quality Management, and Water Quality Protection, Handbook 233, developed and published by the USDA NRCS.
The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalbi Clay at 32 percent, Kāʻena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, microminerals and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained", and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies. In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai‘i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**DEMOGRAPHIC AND ECONOMIC**

The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, up to a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately 8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.
Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**FLORA AND FAUNA:** Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plant species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā‘ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kūlos area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include lowering construction cranes at night, using conservation fencing to project-specific areas, marking tall structures and fencing with white visibility polytype, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable roost trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawaii Dairy Farms”: [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

**GROUP 70 INTERNATIONAL, INC.**

Koloa, HI 96755-1690

Dear Madam or Sir:

I am responding for my wife and I to the Call for Inputs that will help to define the scope of the Environmental impact Statement ("EIS") to be prepared during the coming months related to the proposed Hawai'i Dairy Farm ("HDF") in Maha'ulepu Valley, Kauai, Hawaii. We have the following concerns and hope they will be subjects of investigations during the EIS preparation:

1. We own a unit in the Poipu Sands condominium located in the Poipu Kai Resort situated just west of the Grand Hyatt Hotel and Resort. The trade winds generally come from the northeast which would bring any odors from the HDF through our property. As past Wyoming cattle ranchers we know of the odors that develop from a stationary herd of cattle. These smells are expected around ranches and other areas where cattle are confined, but are not expected in Hawai'i. If these odors transit from the proposed HDF it will impact not only our enjoyment of stays on Kauai but also income we obtain by transient rentals of our condominium unit. There is also the possibility (likelihood?) that the sounds of cattle mooing will be carried on the trade winds and heard through the day and night at the Hyatt and in the Poipu Kai Resort.

2. We have owned our condominium unit for 25 years and have enjoyed the Maha'ulepu Beach area during that period although we now hear that the waters in the area are unfortunately polluted, although investigations are underway to find out why and to try and recover the beach water quality. But this will possibly be impossible if cattle waste causes soil damage that permeates and/or transits to the south and to the Maha'ulepu Beach. This we believe should be avoided to preserve the environment in and around the Maha'ulepu Valley and beach area.

3. The two concerns above would, if negatively impacted by the HDF, cause a large financial loss to the County of Kauai. With the ease of transferring information through the public domain using today's internet system, it would soon become common knowledge that the south shore of Kauai is no longer the place to vacation and/or live. This would create a large hardship for current property owners within a few miles of the HDF facility (and likely throughout the rest of the south shore resort area), and would certainly cause very large income reductions at the Grand Hyatt Hotel and Resort. All of these financial impacts would certainly change the current economic welfare of the community south of Koloa, Kauai, Hawai'i and a very significant reduction of County of Kauai property tax revenues and State of Hawai'i GET and TAT revenue collections.

4. Finally, we are unaware of an environmental restoration plan should the HDF be allowed to proceed with their plans which eventually do cause unacceptable damage even though the damage was not anticipated.

These are just a few of our concerns as long-term owners of south shore property, property whose financial value would likely be significantly damaged by HDF operation. If this occurs, the Kauai south shore area will certainly degrade and become drastically different than it is today.

Very truly yours,

Vince and Fran Jones
Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials operations and applicable engineering standards. HDR will follow the developed Conservation Plan, which was approved by the West Kaua'i Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this project were generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data sets are included as Appendix C of the Draft EIS.

In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016). As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soils types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawai'i soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy's focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

NOISE: Existing noise conditions of the projectsite and the surrounding Māhū'ulepū valley area are evaluated in the Draft Environmental Impact Statement (EIS), along with anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (DBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhū'ulepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 7 decibels or that cost a total of more than $250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Pusch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua'i, and 8 on O'ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment associated with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai'i Island), approximately 10 percent of Hawai'i's milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (367,197,780 pounds) of milk would be
The groundwater and surface water analysis for this Draft EIS examined four studies that were conducted in the vicinity of the proposed dairy site. The studies examined the potential impact of the dairy on groundwater quality, water levels, and the quality of surface water. The studies were conducted by independent consultants and included a review of existing data and the development of new data.

The results of the groundwater studies indicate that the proposed dairy may affect the quality of groundwater in the area. The studies found that the proposed dairy may increase the concentration of nutrients in the groundwater. The studies also found that the proposed dairy may increase the concentration of metals in the groundwater. The studies did not find any significant increase in the concentration of pesticides in the groundwater.

The results of the surface water studies indicate that the proposed dairy may affect the quality of surface water in the area. The studies found that the proposed dairy may increase the concentration of nutrients in surface water. The studies also found that the proposed dairy may increase the concentration of metals in surface water. The studies did not find any significant increase in the concentration of pesticides in surface water.

The results of the groundwater and surface water studies indicate that the proposed dairy may have a significant impact on the quality of groundwater and surface water in the area. The results also indicate that the proposed dairy may have a significant impact on the quality of surface water in the area. The results of the studies are included in Appendix D.
Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 3,24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the Department of Health (DOH) and provided its data; however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a ‘Sanitary Survey‘ of the Māhā‘ulepū and adjacent watershed. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations: Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles 15 feet from the source of drainage (totaling 70-feet in width) to keep cows away from surface waters. Fences will be erected 35 feet from the edge of drainageway. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Potential impacts from dairy operations: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) - Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the Department of Health (DOH) and provided its data; however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a ‘Sanitary Survey‘ of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations: Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles 15 feet from the source of drainage (totaling 70-feet in width) to keep cows away from surface waters. Fences will be erected 35 feet from the edge of drainageway. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.
a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Wainiha Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water and ocean water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring. Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kauaʻi community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawaiʻi has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.
Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₁₀ is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM₂.₅ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in "odor units" at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the "worst case" scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas, and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: "Hawaii Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Dear Laura McIntyre and State of Hawai‘i Department of Health,

We received the notice from Group 70 International regarding the Preparation of Environmental Impact Statement for Hawai‘i Dairy Farms, LLC. We await the delivery of the Environmental Impact Statement with keen interest in reading its contents. We are vacation rental condo owners at Regency 512 in Poipu Kai and are concerned about the impact the dairy farm may have on the enjoyment and value of our property, and on the environmental well-being of Kauai in general.

Sincerely,

Gayle Jorgens and Stanley Wai
Regency 512
1831 Poipu Road
Koloa, HI 96756
May 26, 2016

Dear Jorgens, Gayle and Wai, Stanley:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice. HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. Ongoing dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to ongoing dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $60,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons ($6,219,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($78,000 total versus $60,000 for the committed herd size). The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.
This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OBEQ website at the following URL: http://tinyurl.com/OBEQKAUI

Thank you for your participation in the environmental review process.

To Whom It May Concern:

This letter is being written to identify the issues which need to be addressed in the Hawaii Dairy Farms EIS related to the New Zealand Method Dairy Farm project to be established on Kauai’s south shore at Maha‘ulepu.

1. Procure an impartial party to conduct the EIS.
2. Assess the current levels of pollution in the soil, stream and ocean at Maha‘ulepu.
3. Integrate the conclusions of the existing soil and water quality studies that have been done in the area.
4. Include the projected herd size into the EIS.
5. Address the lethality of the proposed effluent ponds.
6. Address the stench that will permeate the surrounding residential and tourist area and decimate our local tourism economy resulting in lost jobs and access to our pristine beaches in the area.
7. State the cumulative effects on the environment.

Thank you for the opportunity to voice my deep concerns related to developing this dairy farm at Maha‘ulepu.

Please notify me of everything that happens on this issue in the future phases of the EIS.

Sincerely,

David Judd
4460 Ikena Place # 37
Kailua, HI 96741
Dear David Judd:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaii. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

GROUP 70 OBJECTIVITY: Group 70 International, Inc. (Group 70) is responsible for the preparation and processing of the Hawai’i Dairy Farms Environmental Impact Statement (EIS). The EIS was prepared in accordance with the requirements of Chapter 343 Hawaii Revised Statutes and the “Environmental Impact Statement Rules” (Chapter 200 of Title 11, Hawaii Administrative Rules). The environmental planning team at Group 70 has prepared several hundred Environmental Assessment and EIS documents over the past 40 years, and every document has been accepted by the responsible County, State and Federal agency. On numerous past EIS projects, the Hawaii Chapter of the American Planning Association has recognized Group 70’s professional work with Chapter awards for excellence in environmental planning. Part of the EIS scoping process involves Group 70’s experienced team of technical sub consultants that are well-known and qualified in their respective fields of study. For this project, Group 70 is preparing the Hawai’i Dairy Farms EIS with the level of analysis required to properly evaluate and forecast the existing environmental conditions, probable impacts with mitigation, and potential cumulative and secondary effects.

DAIRY OPERATIONS: Hawai’i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'uolepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals’ diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients within the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.
The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted across the Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā’ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs,” mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximize grass as the cows’ primary nutrition source and minimize stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, paddock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for Hawaii is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā’ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of 699 mature dairy cows at the Māhā’ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and enhance the beef market in Hawai’i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herd’s welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as BST or BGH.

SODIS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during drier periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai’i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.
Soil conservation is a core principal behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices order identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Services (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a “Custom Soils Resource Report for Island of Kauai, Hawaii.” The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaua’i Brown Clay at 29 percent, and Laualaulae Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, was used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen phosphorus calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrates and nitrites to gaseous forms, which reduces the potential for impacts on waterbodies.

In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to absorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawaii’s soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing season. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**DEMOGRAPHIC AND ECONOMIC:** The potential impacts of Hawai’i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plach Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kauai’s, and 8 on Oahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kauai’s.

The HDF project would contribute to diversification of Kauai’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawaii’i Island), approximately 10 percent of Hawaii’i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kauai’s, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to ongoing dairy operations would be created on O’ahu.
HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For ongoing operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and alluvial surface water resources in the area, and evaluated the potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.14, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

**Hydrology:** The area’s hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimānalo volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Mānāleʻē Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black alluvial clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Mānāleʻē Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipu region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Mānāleʻē may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Mānāleʻē 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Mānāleʻē 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Mānāleʻē Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no
animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Po‘ipu region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipu - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site's western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makawahi Canoe Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of Enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and it is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposited directly to pasture and effluent collected...
which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua‘i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act
Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH4) from enteric fermentation, and both methane and nitrous oxide (N2O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST
Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emission rates were estimated from published literature, where particulate matter (PM) is measurable from the "drylots" of confined dairy operations where animals walk over dirt and dried manure throughout the day.
Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the island of Kaua‘i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM10 is 2.01 μg/m³, well below the State standard of 150 μg/m³. The estimated concentration for PM2.5 is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Modeling results were generated for worst case meteorological conditions (low wind velocity / mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths.

Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1,670-feet (within one-third of a mile) beyond the dairy farm boundary, and does not reach recreational or residential areas. Results for the contemplated expanded herd size of up to 2,000 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching recreational or residential areas.

and again with detection limited to 50 percent of the sensitive population approximately 44 hours per year. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL: search "Hawaii Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
We attended the HDF meeting for EIS, aka “dog and pony show”
in Koloa town, held only 3 days prior to the deadline for comments.
It felt more like “snake oil” salesmen, attempting to sell their magic Elixir (milk) at a traveling circus!

More troubling was what I witnessed; The station presenters, repeatedly instruct their “scribes” as to WHAT to write, transforming many comments and concerns into watered-down questions.

For example:
I asked “Why is Water not considered or included In the Cultural Impact Statement (CIS) / Cultural Impact Assessment (CIA)?”
The scribe wrote “Is water included in the CIS?”
The latter requires a simple No for an answer.
I observed this occur more than once.

Also, I QUESTIONED ALL OF THE STATIONS, of which there were four: Water, Air , Cultural and Waste management.
A bit puzzling, as there many other triggers for an EIS, as in ENDANGERED SPECIES CONCERNS,
or PUBLIC HEALTH CONCERNS. Neither had a presenter to address these important issues.

I therefore believe and request that another unbiased EIS evaluator act in the capacity of consultant, not Group 70.

I brought up SUB-SURFACE CONSIDERATIONS, as related to AIS, CIS/CIA, Water and Waste management.

Also, we informed the Oahu presenters of the incredible WINDS we have here on the southshore, the air is bad enough from VOG.

And what about the COWS in the event of a Tsunami? We have evacuated three times in the past three years, there is not an emergency plan is HDF proposal.

Participants were also encouraged to LEAVE the Comment sheet provided.
Will these REALLY be addressed in the EIS, or just published, written down on paper, as THEY STATED?

As for the proposed Dairy, we have many concerns that need to be addressed in the EIS.
Please be advised we have filed a report with DLNR, Aha Moku Advisory Committee, of which Billy Kaohelaulu'i is the KONA MOKU for Manokalanipo (Kaua'i), Document attached, dated 12/08/2014.

PLEASE consider this information, as it has been currently filed with SHPD.
Maha’ulepu is a SACRED SITE, and must be protected for future generations.

Appropriate, sustainable farming is what the IAL designated lands were meant to provide in Maha’ulepu Valley, not an inappropriate INDUSTRIAL venture. The unique soil type (grey Hydromorphic with high clay component) is perfect for Kalo (Taro).
Other appropriate crops would also fare well in this valley.

AND THEN THERE IS THE WATER;
THREE wells that provide our drinking water for our community, uncomfortably near their proposed location.
HDF cannot guarantee these wells will not be contaminated, or what they will do if they are contaminated.
The close proximity to our beautiful undeveloped beach is also at great risk of contamination, as well as the entire FRAGILE REEF ECOSYSTEM.
There is already evidence of contaminated Waiopili spring and in the Maha’ulepu /Gillian’s Beach ocean area (Blue Water Task Force/ Surfrider Kaua’i).
THIS MUST BE ADDRESSED IN THE EIS.
Please find the dairy another location, preferably in another STATE.

Sincerely,

Billy Kaohela`uli (Kona Moku, Manokala`ipo)

and

Terrie Hayes
2249 Kau Rd.
Koloa, Hi. 96756

Hard copy to follow.
4. If applicable, describe the steps (if any) taken so far to try to resolve the issue:

5. Describe any practice in use presently that is consistent with (a) maintaining the health of the area affected and (b) maintaining established indigenous Hawaiian customs:

6. Have there been any other efforts to resolve the issues discussed above?

7. Are there any residents of the identified area who have opposing views, contrasting management methods, or other interests?

If possible, can you suggest a compromise or alternative solution that you are willing to consider, that can help resolve the issue in a way that satisfies both parties’ positions, in keeping with the principles of resource protection and traditional Hawaiian practices?

* The Aha Moku Advisory Council needs to know this information in order to fully assess the reported issue, determine whether or not the reported issue is consistent with our directives as an advisory council advocating traditional Hawaiian Resource management, and to help us determine our recommendations to forward to the Department of Land and Natural Resources.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhūʻalepō Road
Kaua'i, Hawai'i
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Hayes, Terrie and Kaohelauli'i, Billy:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

NATURAL HAZARDS: The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards. The Māhūʻalepō property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai'i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone. The Kaua'i and Ni'ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands.
Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands. Land management personnel in the Māhūulepū region during and following the hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

There has been no rainfall event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhūulepū Valley. The effluent pond capacity has been designed above the regulatory requirement to contain the 25-year, 24-hour rainfall event. An emergency containment berm with additional capacity for another 30 days is included in the design. This design exceeds regulatory requirements, with containment in excess of the major rainfall events recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for HDF internal use that addresses hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area; so this scenario is not planned for in the disaster plan. The disaster plan relies upon knowledge of cow behavior, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

**ARCHAEOLOGICAL AND CULTURAL:** The Hawaii Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhūulepū Ahupua‘a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

**FLORA AND FAUNA:** Botanical, avian, and mammalian surveys of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project.
Hayes, Terrie and Kaohelauli'i, Billy
May 26, 2016
Page 4 of 11

property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plant species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Māhā'ulepū Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nēnē was also seen on the site. State Division of Forestry and Wildlife biologists have noted nēnē are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kēōka area, and the habitat present on parts of the site is suitable for nēnē nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include bivering construction cranes at night, using conservation fencing to protect specified areas, marking tall structures and fencing with white visibility polytype, limiting nighttime lighting, and shading any outside lights used at night. Ongoing mitigation strategies will be implemented for day-to-day preventative measures, including an Avian Species Protection Plan. Mitigation measures are further described in DEIS Section 4.10.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis. While caution will be taken during any potential disturbance or vegetation removal, there are almost no suitable moat trees within the dairy site, thus it is expected that the dairy farm will not affect this listed mammalian species.

**WATER QUALITY:** Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai'i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

**GROUND WATER**

Hydrology: The area's hydrology is shaped by its geology. The Kēōka area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā'ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kēōka series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā'ulepū Valley and the HDF site ranges from 105 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kēōka-Poipū area is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā'ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 39,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai'i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā'ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.
The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāʻulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

**Groundwater Monitoring:** Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

**Regional Water Demand:** The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development.

The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2030, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalāheo districts), water use in 2035 is projected to be 324 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and demand anticipated in the region through 2035.

**Surface Water**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhāʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhāʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhāʻulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhāʻulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhāʻulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels (CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” [http://health.hawaii.gov/cwb].

**Long-term Operations: Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top...
of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhāulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Pō'ipū region were also calculated. Nitrogen input to the marine environment in the Pō'ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of 10,000 pounds per year, and one percent of phosphorus (totaling 900 pounds per year). Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a wind rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EIS sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a wind rose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.
Dust will be generated as cows move along soft limestone walkways that connect the pastures and feed lots and wear and tear on manure that is exposed to the atmosphere. Dust will be detected by 50% of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 0.67 miles (within one third of a mile) beyond the dairy farm boundary, and does not reach residential areas. Results for the committed herd size of 699 mature dairy cows show odors may be detectable by 50% of the sensitive population once per 200 hours, or 44 hours per year, within an area that extends approximately 1.67 miles (within one half mile) beyond the dairy farm boundary, again not reaching residential areas.

Applying the emission rates from this available literature greatly overestimates odor potential emission resulting from HDFF. Odors in the pasture, manorial grazing system will be on pasture 22 hours each day and will spend two hours – in two 1-hour sessions – in the barn for the 10- to 15-minute milking sessions. Using atmospheric dispersion modeling system (AERMOD), the emissions were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the Island of Oahu, and the total concentration was compared to the State ambient air quality standards. Odor emissions from manure fields were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor plumes (a line used to map all points having the same numerical value) were generated from the AERMOD modeling system, and published rates for manure odors for dairy heifers and cattle were used to reflect the facilities.

Applying the emission rates from this available literature greatly overestimates odor potential emission resulting from HDFF. Odors in the pasture, manorial grazing system will be on pasture 22 hours each day and will spend two hours – in two 1-hour sessions – in the barn for the 10- to 15-minute milking sessions. Using atmospheric dispersion modeling system (AERMOD), the emissions were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM10 and PM2.5) measured on the Island of Oahu, and the total concentration was compared to the State ambient air quality standards. Odor emissions from manure fields were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. Odor rates from published research were applied. Odor plumes (a line used to map all points having the same numerical value) were generated from the AERMOD modeling system, and published rates for manure odors for dairy heifers and cattle were used to reflect the facilities.

Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor.

Results for the committed herd size of 699 mature dairy cows show odors would not extend beyond 2,780 feet outside the HDF boundary (just over half a mile), again not reaching residential areas, and again with detection limited to 50 percent of the sensitive population.

Future moduli were generated for worst case meteorological conditions (low wind velocity/mixing). Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site, in periods without normal tradewind flow, the odor plume would extend to the south of the HDF site. Sections 4.19.2 and 4.25.2 of the EIS include graphics of the potential odor isopleths. The parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location; actual odor impacts are likely to be much lower and/or less frequent than shown; it is likely odor detection beyond the HDF boundaries will be less frequent.
Dearest Suzanne Kashiwaeda,

If you've ever had to provide 24/7 care to a person, you'd understand the critical need for respite to get away from the physical and emotional responsibilities, to recharge and renew your energy and spirit to continue to care for loved ones. Mahaulepu is a place many of us go for solitude, solace and spiritual renewal.

Taking a holistic and longterm perspective, my concerns are many:

- A large industrialized dairy operation of 2000 cows would alter the quiet, peaceful and pleasant ambience of Mahaulepu.
- Runoff and pollution of nearby wells, aquifer, ocean impact on reefs, coral, fish, other marine life can seriously and negatively impact both natural and economic resources.
- We are an island community and the time-honored Hawaiian concept of ahupua’a need to be seriously considered. TMK: (4) 2-9-003: 001 portion and 006 portion (4) 2-9-001:001 portion
- If HDF follows in the footsteps of other Kauai dairies and ceases operations, what are plans for restoration of the land, pollun of ocean and health of reefs? Do roads, buildings and other infrastructure remain?
- Aren't there any other farming options for this land that would be more compatible with this area?

I understand from the meeting Group 70 held this past Thursday that individuals submitting comments will be 'consulted parties' and will receive notices, updated and pertinent information about this project. I look forward to learning more and trust that the EIS process will be thorough and objective.

Sincerely,

Suzanne Kashiwaeda

Subject: Hawai'i Dairy Farms Environmental Impact Statement Preparation Notice
Māhūʻulepū Road
Kauaʻi, Hawaiʻi
TMK: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Suzanne Kashiwaeda:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawaiʻi. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhūʻulepū Valley on the island of Kauaʻi to produce fresh, locally available nutritious milk for Hawaiʻi families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 21, 2015, described the proposed pasture-based rotational grazing system.
as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency relates to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with the draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock - grass - for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agricultural (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock - grass - as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kauai have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

The 470 acres of pasture will be divided into paddocks averaging 3 to 5 acres in size. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality of surface water and downstream areas, padock fences are set back 35 feet from the edge of drainage ways throughout the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3 and Draft EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected to last at least once every 45 days, to ensure that the pond is kept at manageable levels.

Cows lastate milk following the birth of calves. Newborn calves will be housed on the Māhā‘ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kauai to be raised off-site. The committed herd size of...
Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

**ARCHAEOLOGICAL AND CULTURAL:** The Hawai‘i Dairy Farms (HDF) project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of the project area and an extended survey area of 100 meters of the northern boundary. Six historic-era sites occur in the project area and 10 sites occur in the extended survey area. Only one of the sites is believed to be associated with pre-Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Even historic-era cultural materials associated with the many Land Commission Awards in the project area were non-existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the archaeological consultant and the dairy project is anticipated to have no impact on these sites. No further archaeological work is recommended for the sites. Two of the sixteen sites are considered significant under multiple criteria, but occur outside the project area on lands owned by a different landowner. Both sites will not be adversely affected by the proposed dairy project. No site is related to burials, and no bones were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place. Information received from the community indicates the Māhā‘ulepū Ahupua‘a, has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. It is clear that the gathered plants, trails, State Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of the project area.

The project will be fully endorsed by perimeter fencing along the boundary of the leased premises, which will ensure that project activities and any related impacts are contained within the project area. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search Hawaii‘i Dairy Farms: [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

**GROUP 70 INTERNATIONAL, INC.**

COMMENTS re EIS on Hawaii Dairy Farms proposed for Mahaulepu, Kauai  

To Whom It May Concern:  

Please tell me that this is not a “done deal.” Damage to nature cannot be healed in one’s lifetime. There is so much conflict of interest involved in this process, I can’t believe fairness can be achieved.

I think the “Head” of the Health Dept. should visit this area before making this decision.

Sincerely,  
Delano H. Kawahara

Concerned retired biology teacher – Kapaa High School, Kapaa, Kauai  
5753 Noni St., Kapaa, HI 96746-9659

as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency relates to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term is not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source nearer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian islands were instrumental in identifying appropriate varieties of grass and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā'ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mob”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of

The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Wai‘a Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow a very precise application of irrigation and/or diluted effluent on the pasture. The pivots can rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm.

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Reflected in the title of the livestock waste guidance for Hawai‘i is the parenthetical inclusion of the word “nutrients.” Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The timing and application of nutrients will correspond with plant uptake, soil properties and weather conditions. For more information on nutrient balance management see Draft EIS Section 3.5.3, and Dra EIS Appendix D.

The effluent storage ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000-cow dairy, and nearly impossible for the committed 699-cow dairy. Throughout the less than 30-day storage period, effluent is planned for application every four days, and the slurry application is expected at least once every 45 days, to ensure that the ponds are kept at manageable levels.

Cows lactate milk following the birth of calves. Newborn calves will be housed on the Māhā'ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised off-site. The committed herd size of
Animals in various stages of lactation and rest will be transferred between HDF and other partner ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai’i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food & Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
Dear Dawn Fraser Kawahara:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**LAND USE:** The historical and existing land uses of the project site and surrounding Māhāulepū Valley were examined in the Draft Environmental Impact Statement (EIS), and uses proposed by the Hawai‘i Dairy Farms (HDF) project were evaluated in the context of county and state land use designations for the area. The evaluation of land use is presented in Draft EIS Chapter 4.4, and the project’s consistency with government plans and policies is presented in Draft EIS Chapter 5.0.

The south shore of Kaua‘i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils (with “A” representing the class of highest productivity soils and “E” representing the lowest). The large tracts of farmland, including those of Mahäulepū Farm and Grove Farm, allow for stability in support of farm ventures,
help maintain regional water systems and provide agricultural employment for Kaua‘i residents in addition to fresh, local food.

The project site is on agricultural land in Māhā‘ulepū Valley, an area with a long history of agricultural use as it was the first place in the island chain where sugarcane was commercially grown. The site is in the Agricultural District per State Land Use District designations, and per the County of Kaua‘i zoning ordinance. The site consists of land classified as Prime per the State Department of Agriculture’s Agricultural Lands of Importance to the State of Hawai‘i (ALISH). The HDF site is outside of the County-designated Special Management Area under the Coastal Zone Management Program.

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The designation process determines land meets physical requirements including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high quality soil agricultural productivity ratings under the Land Study Bureau of University of Hawai‘i.

In 2011, Mahanaele Farm LLC filed a petition with the State of Hawai‘i Land Use Commission to designate 1,533 acres of agricultural land in Māhā‘ulepū (including 557 acres that make up the HDF site) as IAL. IAL designation meets the objectives of the State HRS §205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. See Figure 4.4-2 in DEIS Section 4.4.

The designation process determined that the land meets a number of physical requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil agricultural productivity rating of “B” per criteria established by the Land Study Bureau of University of Hawai‘i.

The development and long-term operation of HDF will be in full compliance with its agricultural State Land Use District designation, ALISH classifications, and County zoning. The dairy farm will embody the intent of the IAL designation per the Hawai‘i State Constitution, by using these protected lands for the intended purpose of diversified agriculture, food production and agricultural self-sufficiency. HDF development of a dairy also supports the “secondary intent” for lands in the Agriculture land designation, to provide an opportunity for Kaua‘i citizens to reside in an agricultural community. This is in contrast to the described “agricultural subdivisions” that have changed parts of Kaua‘i intended for a rural landscape, with development as quasi-suburban landscapes dotted with residences on large lots.

Overall, the project provides long-term benefit and support of agricultural lands and industry through continued use in keeping with zoning and IAL designation. Long-

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai‘i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Planch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, masons, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 23 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the
committed herd size). The State will derive approximately $360,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.

**Alternatives:** As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include: Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios.

Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements:

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand. However, this alternative would not reduce reliance on costly imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2) and would not secure a dairy location that meets the purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).

Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawaii Dairy Farms": [http://tinyurl.com/OEQCKAUAI](http://tinyurl.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner
The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the alluvium that underlies Māhā‘ulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kīlauea–Poʻipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifier in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kīlauea F well, will result in no adverse impacts to ongoing use of as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kīlauea series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.
Groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhūʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kīloa Fowell in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community.

Regional Water Demand: The adjacent, developed Kōlā-Poipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōlā - Poipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

**SURFACE WATER**

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhūʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhūʻulepū watershed.

The HDF site is located on the bottom-land of the upper Māhūʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhūʻulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment log around drain inlets.

**Surface Water Quality:** The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the Department of Health Clean Water Branch, dairy neighbors and the local Kaua'i community. According to the public citing the high levels of enterococci in Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhūʻulepū Valley. The State Department of Economic Development and Tourism (DBEDT) projects the Waiopili Ditch Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffers:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads. HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of the drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to...
create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhūʻulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Poʻipū region were also calculated. Nitrogen input to the marine environment in the Poʻipū region is calculated to be 38,510 pounds annually, or 35 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,250 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Poʻipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the

Waipio Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occur rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches downgradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH CWR, dairy neighbors and the local Kaua‘i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai‘i Dairy Farms": http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Re: Hawaii Dairy Farms, Kauai

Comments to be considered in preparation of an Environmental Impact statement for:
Project Name: Hawaii Dairy Farms
Island: Kauai
District: Poipu
TMK: (4) 2-9-003:001 (portion); 006 (portion)
(4) 2-9-001:001 (portion)

Aloha Ms. McIntyre:
After carefully reviewing the plan for the Hawaii Dairy Farm (HDF) provided to the public for comments to be considered in drafting the Environmental Impact Statement I would assert that HDF has caused serious environmental impacts during their grubbing and grading process prior to the arrival of cows and that upon arrival of the cows the impacts would be significant. HDF will not be able to mitigate the cumulative impacts HDF will have on the environment, public health and local businesses.

First and foremost HDF must prove that there will never be discharge of pollutants from direct surface runoff or ditch discharge into Waipili stream, and that percolation into both shallow and deep groundwater will not contaminate streams, estuaries, and near shore coastal waters. It would appear there are multiple areas and weather events that could cause possible breaches. Please identify all possible areas and weather events that could cause breaches.

On the third page of the EISPN HDF uses the words “Grass-fed dairy”. What are the USDA requirements for a dairy to call itself “grass-fed”?
Why does HDF represent themselves to our community as being “grass-fed”? Does HDF meet the USDA standards to be called “grass-fed”?

How are the barns referred to in the EISPN going to be used?
Please define and be specific as to what “several years” to establish the herd means.

What range do the nutrient readings need to be in to determine that it is not wise to bring another cow onto the site? What percentage of the paddocks will need to be in the correct range of the nutrient analysis to bring more cows? What percentage of the paddocks need to be in the detrimental range to halt the addition of cows? How often will the nutrient analysis be done on all of the paddocks? What will HDF do with their cows if the nutrient analysis doesn’t support the number of cows they have?

What about the herd’s health, why isn’t that being used to determine if HDF has too many cows? For the health of the cows becomes a limiting factor, what are the standards and parameters HDF will use? (number of downer cows?)

How is HDF’s plan any better than the NZ Model when it comes to the degradation of the water, air, and the environment? Please incorporate into the EIS the common breaches occurring in New Zealand on properties abutting or containing waterways so we can examine them in direct comparison to the HDF plan’s impact.

How does the site being in the Flood Zone X impact the environment when looking at the weather hazards (hurricanes, tropical depressions and storms, etc.) that have occurred on our small island? If the soils are “supportive of nutritious grass types” as stated in the EISPN then why did the grass planted last spring fail to thrive?

What leads HDF to believe Grove Farms can supply them with 3 million gallons of water per day that they require to operate, when Grove Farms is not a utility company? The water belongs to the people of Hawaii under the state constitution (Public Trust Doctrine) have you asked the people if they want 3 million gallons of water per day diverted to HDF?

What will HDF do to get 3 million gallons of water per day when, as in Maui, the water is returned to its natural course?

What size bond is HDF putting up for cleanup when a natural disaster occurs? If there is no bond what is the rationale behind that when anyone that lives here knows it’s a matter of when not if?

What will be done to protect the cows during flash floods, tropical storms, tsunamis and hurricanes? What will be done to protect the cows from the extreme heat (over 90 degrees and up to 104 degrees per pg. 59 of HDF waste management plan) of the valley as there are no trees for them, only Norfolk pine trees to line the entry road?

The Waipili stream originates from the HDF site via springs, ground water and, mountain runoff and goes to the ocean. It has the highest bacteria count of any stream on Kauai. The ocean has high reading in front of Gillian House where the stream is polluting the ocean. Older
readings by the Department of Health show that 2008 and 2010 readings for this area were in acceptable range. What steps has HDF taken to prevent soil from being washed into the stream during grubbing and grading? How will HDF clean up the stream before bringing cows? What is HDF’s expected total cost for all improvements? How much are the tax credits valued at for these improvements because of IAL designation of the property?

Where did you get your computations and information on the distances to populated areas? The Gillin house in much much closer as well as the Hyatt Resort and all of Poipu Kai homes and condos and Poipu Aina development of home sites and existing homes are less of a distance than Koloa town. What are the distances to the aforementioned properties from the closest corner of the HDF site not the effluent ponds? Please measure again these distances. Please cite where you found the information that there were concerned citizens over the loss of Ag land that wanted Grove Farms site (HDF site) protected under IAL?

HDF states the quality of the land was studied during the designation process and was determined to be high quality soil? How is that? Where is this study, who did the study and what are their qualifications? Why does that statement contradict 2014 NRCS soils report? The EISPAN states the most abundant soils are Kalihi and Ka`ena, brown variant, which the 2014 NRCS study states those soils have a very slow infiltration rate (high runoff potential), how can this be considered high quality soil?

If an invasive species is already on the island of Kauai, explain your thought process that more is better or alright to establish in respect to Kikuyu grass. How will the wetlands be protected from the invasive Kikuyu grass? The EISPAN states Kikuyu grasses are to be used. One is a matting grass and the other a clumping grass, how are they not going to compete with one another? Kikuyu grass is toxic to cows if they eat it down past a certain point, how is HDF going to monitor the grass so the cows are sickened? Who are your horticultural experts and what are they saying in regards to the attempts that have been made to grow Kikuyu? Where are their reports as it would appear even to a layperson that the Kikuyu is suffering from failure to thrive?

The EISPAN states that DOH regulates waste management utilizing EPA’s requirements. What are these requirements and how does HDF’s plan meet or fall short on these requirements? The EISPAN states that in September and October 2014 a waste management plan was reviewed by the DOH. Was the waste management plan approved by DOH? If so please furnish the paperwork stating approval of the waste management plan. Doesn’t the DOH refer to a dairy of 699 cows as a medium size CAFO? Isn’t HDF a medium size CAFO?

Aren’t the cow walkways sloped so water will runoff and not destroy the integrity of the walkway? What is the distance from the edge of the walkway to the closest edge of the reopened drainage ditches that are connected to the Waipili Stream? Will the manure and urine from the cows twice a day trek to the milking barn be cleaned up off the walkways that are sloped towards the reopened ditches? What precautions were taken during grubbing and grading to protect the ditches from soil runoff? What was done to protect the receiving waters of the Waipili Stream and ocean during the cleaning out and reopening of the ditches from soil erosion? Are the future plans for maintenance of the ditches the same as during grubbing and grading?

What will be done with the milk in the storage tank should the milk’s temperature reach above 45 degrees? How will this affect the ditches, the stream and the ocean? How many gallons of milk would this be if the storage tanks are completely filled? Before HDF gets approved for their operating permit from DOH won’t they need to get approval from DNLR?

Has HDF considered eliminating the settling pond and instead first removing all of the particulate from the wash down water, using a passive or automated incline screen followed by a continuous sand filter, like a Dymasand? If so why did you not explore this option as by using this process you would have a higher quality effluent to hold in the irrigation pond, making a flooding event considerably less damaging to the environment? For what reason would you not use a system that the solid waste would be dewatered at the source and easily used for composting or waste-to-energy? If this system was used with aeration of the pond then the odor would be minimized. Why would you not be a good neighbor and minimize the odor through this process? HDF talks about covering the effluent ponds when speaking with the community, why not commit?

Who is the veterinarian for the cows? How often will he be checking the entire herd for health related issues, which are multiplied by the number of cows in close proximity to each other and standing in their own and other cows’ manure that is left on the ground in the paddocks?
If you chose the CAFO alternative and used the Dynasand method then less water would be needed. Why not use less water? Why not consider using smaller multiple sites for your cows, when considering alternatives, this would be more environmentally sound? Is it all about the money or is the environment worth spending more money to protect it? What large land owners besides Grove Farms in the Hawaiian Islands have you contacted and taken a serious look at the feasibility of their sites? Would any of them be more protective of the environment? How many of the sites be more protective of the environment? If the sites were more protective, what was the rationale behind rejecting the sites? Do you believe the Important Agricultural Land designation with all its tax benefits was intended to help small farmers succeed and not for large profitable corporations? HDF states in the EISP that initial operations are permitted to begin with up to 699 cows. Where is the operating permit? Could you make a copy available to the community? What access will the community be allowed to the cultural sites? How are these sites to be protected from the effects of acid rain that is produced when hydrogen sulfide produced by the cows meets with rain? How often does the temperature in the valley exceed 86 degrees? What are the highest of the temperatures that exceed 86 degrees? How will the cows be protected during this extreme heat? How many times has the rainfall exceeded 50" per annum? When was the longest and most extended rainfall event recorded on Kauai? What major events happened during this time? How would this effect soil erosion in the valley? Where will the cows go during such events? How will they be protected? The EISP states no known seismic activity has originated among these northern islands then why does the earthquake map from USGS, Atlas of Natural Hazards in the Hawaiian Coastal Zone show one on their map in Maha'ulepu area? There are new flood maps, what was the date of the flood map that was cited in the EISP? The EISP states that during hurricanes, operational plans for safekeeping of the dairy's livestock will be identified in the Draft EIS. What about the enormous quantity of manure on the ground, how will that be protected from leaving the dairy during a hurricane that comes with torrential rains?

The EISP states the average annual rainfall in Maha'ulepu is 50" why is this figure so different than the 60" to 100" mean annual precipitation cited in the 2014 NRCS Snail report? The change in number of inches of rain due to climate change needs to be accounted for in the EIS draft. How far away is Koloa drinking water well F from the proposed desludge site, block H at its closest point? What is the ability of the soil to transport water/liquids in Block H? How long would it take for the liquids from the desludge to migrate through this type of soil after a rain storm? What are the readings from the baseline air quality test? If HDF hasn't done a current air quality study before any cows come, why not? What are the noise readings from HDF baseline study? If HDF hasn't done a baseline study, why not? How many decimals is the bawling of a new mother cow when separated from her calf? How many decimals higher in terms of human hearing is the bawling at night when ambient sounds disappear? Based on HDF's plan approximately 333 cows will be separated from their new born calves every two months. What is the decimal reading of 333 cows bawling after being separated from their calves? How many days on average do mother cows bawl for their calves and how many hours per day on those days? What is the EPA permissible noise level in a populated community? How does the EPA level compare to the noise level of cows bawling? Will HDF have an air monitoring system on location? What type of system? How is it calibrated for accuracy? Who will be responsible for recording the readings and alerting the community and officials when it surpasses Hawaii's or EPA standards, will it be an unbiased person or an HDF employee? How often will the reading be reported to the community so as to alert community members with respiratory problems? What are the readings on the six pollutants for air quality established by EPA (NAAGs) that should not be exceeded? What will HDF do to resolve the problem of poor air quality if it should occur for each of the six pollutants? How will the farm workers be protected from air pollutants seeing as they would get the brunt of the pollution? What kind of health insurance will be provided for the workers? In regards to your irrigation system. What is the dimensions of the 2 pivots circles- radius etc.? How many wheel assemblies are there and what is the tonnage load per wheel section both empty and full? How are the certain ruts treated? What is the total mileage of the
individual wheel section tracks? What are the specs re: slope climbing ability of the HDF pivot system? Where is it emptied out when transitioning between effluent spreading and irrigation use? What is the uniformity/spread certainty, error rate distance of the end gun system that HDF proposes? Rutting is a common problem with wheels/booms getting stuck. Will this create an over application of effluent? How is HDF going to deal with wheel rutting problems causing new ditches in which the water/effluent can flow into the stream?

The plan states that discharging "hydrants which have a "gun sprinkler" with a 5/8 inch nozzle attached via a length of flexible hose", does this meet code?

What is the exact amount of water usage per dairy cow per pre-milking wash down?

The plan that West Kauai Soil and Water Conservation approved in 2013 is no longer as that plan was unacceptable to DOH and a complete new plan (July 2014) has been adopted by HDF. When is HDF going to submit the new plan for approval to the West Kauai Soil and Water Conservation?

What is the depth to Water Table for the soil (KavC) pod 159 of the burial pits? Are you planning on leaving 2 feet of soil above the water table before HDF buries a cow? Are you planning on spacing the dead cows 2 feet apart horizontally? HDF’s archaeologist said at the Feb 19th, 2014 meeting that the water table was at 3.5 feet deep. If you need to leave 2 feet above the water table that would only leave 18 inches. How wide are dead cows? What are your calculations on how many dead cows you can bury in your cemetery? Where is HDI going to put them after the cemetery is full? Will the cemetery seep deteriorated matter to the nearby wetland on the property next door? What steps will be taken to stop possible seepage? Should there be seepage how would this impact the endangered water birds? How is HDF going to stop the large rain runoff from coming down the mountain and floating up the dead cows?

Where is the large depression referred to in the Kaua’i Reconnaissance Survey? What is being done to protect it?

How will the Makauwahi cave that floods every couple of years, be protected from contaminated runoff from the HDF site? This contamination would include manure, urine, fertilizers, antibiotics, hormones and phosphorous and nitrates.

How is HDF going to protect the community from being bit by the biting flies while trying to enjoy the beach? How is HDF going to protect the community at large from biting flies? Will HDF be responsible for all medical bills, pain and suffering inflicted by the biting flies as a vector for disease?

Have you studied the diseases caused by flies as a vector? Why not? Are you going to make the study available to the community at large?

What is HDF going to do to protect the wetlands and nesting environments from becoming inundated with the invasive kikuyu grass causing the endangered species loss of their forage?

What will be done to protect the waterbirds, the Newell Shearwater, the migratory birds, the indigenous species, the terrestrial Invertebrates, the marine vertebrates, the reef fish, the arthropods and the seaweed that the local people gather? Please address these individually citing their habitat needs and how those are being protected? What will be done in the event of a breach to insure that these species are not desecrated?

The social-economic impacts will be greatly significant. How much will house values drop within 5 miles of the dairy? Please denote these figures for every half mile increment. How far can flies travel? Once a fly reaches another moist area, how far will it fly from there? How many larvae does each fly lay? What is the exponential number of flies after a year of the dairy opening if we start with one fly per cow (2,000 flies)? How will this affect homes with pools value within 5 miles of the dairy? How far will the odor travel based on an average day’s northeasterly or easterly wind speed of between 15-17mph? How will HDF protect the community including Keiki and Kapuna from the gases and particulate produced in the air by the dairy? What about the community members that have compromised lungs? Will HDF pay for their medical expenses if their conditions take a turn for the worst after the dairy is in? Many dairies purchase the homes that are impacted by their operations, how many will HDF purchase?

The EIS must study the impacts to the environment and study the potential Impacts to the Poipu visitor economy which will be significantly impacted by the environmental consequences of such an intensive land use in the Maha’ulepu valley. How many jobs would be lost at the Hyatt because of odor and flies? Does HDF plan on remunerating the Hyatt for lost business? What about the owners at Poipu Kai and other vacation rentals loss income? What will HDF do to address the impact of acid rain created by the off gassing of their cows?
Will HDF be saying the county to accept their solid waste? What is the county’s cost per ton for their HDF? How much will HDF pay per ton?

The EISPN states that the site has a system of ditches to channel storm water through the area, as well as to drain fields. Are these the same fields where the manure and urine are left on the ground? Would this not be considered nonpoint source discharge? Wikipedia defines nonpoint source discharge as, “Nonpoint source (NPS) pollution refers to both water and air pollution from diffuse sources. Nonpoint source water pollution affects a water body from sources such as polluted runoff from agricultural areas draining into a river, or wind-borne debris blowing out to sea.”

Specifically how is HDF’s operation any different than as defined nonpoint source discharge?

I hereby incorporate all of the questions and/or concerns voiced by the community at the Feb 19, 2014 meeting at Koloa Cafeteria that HDF and Group 70 put on for the community.

Please respond to the above questions in your draft EIS as they speak to several of my concerns over Hawaii Dairy Farms operation and their choice of locating their dairy in an environmentally sensitive area.

I wish to be a party to this EIS and receive any and all notifications and emails.

Subject: Hawai'i Dairy Farms Environmental Impact Statement Preparation Notice

May 26, 2016

Dear Eileen Kechloian:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai’i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā‘ulepū Valley on the island of Kaua‘i to produce fresh, locally available nutritious milk for Hawai‘i families. The rotational-grazing method utilizes 100 percent of the cows’ manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPN), published January 23, 2015, described the proposed pasture-based rotational grazing system as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISP/N. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at six sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 95 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestive cycle. The animals are managed in social groups known as “mob”, mimicking the natural social order of bovines. Cows spend 12 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways...
The health of the herd is of primary importance as the success of a dairy relies on cows being healthy and productive. This will be achieved by a nutritionally balanced diet, the management practices and pasture model applied by HDF. Grass is the primary source of nutrition for the cows, and the management system applied by HDF maximizes grass as the cows' primary nutrition source and minimizes stress to the animals. Cows are healthier and live longer, productive lives with access to fresh air, high quality feed, and a comfortable path under hoof. The pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven’t given birth) will be raised until ready to return to the HDF herd as birthing/mature dairy cows. For more information on off-site herd management, refer to Section 3.7 of the Draft EIS.

The climate conditions. Climatic conditions affect the growth of forage and the health of dairy cows. Heat stress can reduce the productivity of dairy cows, and suitable climate conditions, as occasional storms can generate strong Kona winds from the southeast. Changes to solar radiation and the hydrologic cycle large enough to affect climate conditions, as occasional storms can generate strong Kona winds from the southeast. Changes to solar radiation and the hydrologic cycle large enough to affect climate conditions, as occasional storms can generate strong Kona winds from the southeast. Changes to solar radiation and the hydrologic cycle large enough to affect climate conditions, as occasional storms can generate strong Kona winds from the southeast. Changes to solar radiation and the hydrologic cycle large enough to affect climate conditions, as occasional storms can generate strong Kona winds from the southeast.

Rain gauge data for a rain gauge located near the site of the main highway was used to develop a weekly rainfall event-frequency for the site. Rainfall events for 30 years were recorded (a total of 10,357 days from 1948 to 2013), and ranked based on the days of consecutive rainfall (DPR) and the corresponding rainfall amount. The data used was from 1974 to 2013 for the period of record. The data used was from 1974 to 2013 for the period of record.

The ef fluent storage ponds are sized to accommodate 30 days of storage for up to 200 milk cows. The storage pond is located at the site of the effluent storage pond. The storage pond is located at the site of the effluent storage pond.

Every 45 days, to ensure that the ponds are kept at manageable levels. The timing of the application of irrigation water is crucial. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The timing of the application of irrigation water will be determined by the desired use of the irrigation water. Irrigation water is applied to the pastures at the right time, to ensure that the pastures are properly used and irrigated with nutrient balance.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, time, and placement of nutrients applied to land. The timing and application of nutrients are critical for nutrient management. The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. The timing of the application of irrigation water is crucial. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The timing of the application of irrigation water will be determined by the desired use of the irrigation water. Irrigation water is applied to the pastures at the right time, to ensure that the pastures are properly used and irrigated with nutrient balance.

The timing of the application of irrigation water is crucial. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The timing of the application of irrigation water will be determined by the desired use of the irrigation water. Irrigation water is applied to the pastures at the right time, to ensure that the pastures are properly used and irrigated with nutrient balance.
processes. The 557-acre site is not large enough to have a regional influence on climate.

Annual rainfall, prevailing winds, and solar radiation conditions at the HDF site are well suited to growing dairy pasture grass and conducting pasture-based dairy operations. Neither the committed herd size of 699 mature dairy cows nor the contemplated herd size of up to 2,000 mature dairy cows will affect climate conditions over the short-term or long-term. No significant impacts are anticipated, and no mitigation would be required.

**SOILS:** Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawaii at Manoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.

Soil conservation is a core principle behind establishment of the NRCS, which was formed out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices. NRCS conservation practices are listed in Chapter 3, Section 3.2; these practices codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan, which was approved by the West Kauai Soil & Water Conservation District in December, 2013.

The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this EIS included a "Custom Soils Resource Report for Island of Kauai, Hawaii." The report was generated from the USDA NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

The NRCS soil classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalahi Clay at 32 percent, Ka‘ena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

A second round of field sampling was conducted in 2015, and focused on evaluation of soils characterized as "poorly drained," and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity, or a slow rate of groundwater movement through the soil. This slow movement can create anaerobic conditions, which typically result in higher rates of denitrification. This is the conversion of potentially nitrate and nitrite gases to gaseous forms, which reduces the potential for impacts on waterbodies.

In this way, "poorly drained" soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than "well drained" soils (Yost, 2016).

As a result of reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. Under the NRCS phosphorus leaching index for Hawaii’s soils, HDF soils show low risk for leaching. With low risk, phosphorus can be applied at rates greater than crop requirements if manure or other organic materials are used to supply nutrients.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.

**NATURAL HAZARDS:** The potential impacts of natural hazards are evaluated in the Draft Environmental Impact Statement (EIS), including flooding, tsunami, earthquakes, and hurricanes. Draft EIS Section 4.6 addresses natural hazards.

The Māhāulepū property is not known to experience flooding conditions. The area is located within Federal Emergency Management Agency (FEMA) Zone X, areas determined to be outside the 0.2% annual chance floodplain. The proposed location for Hawai‘i Dairy Farms (HDF) lies between the 60 and 150 feet elevation, outside
the tsunami evacuation zone. The Kaua‘i and Niihau region of the Hawaiian Islands
has experienced tremors from earthquakes originating further south in the island
chain, but no known seismic activity has originated among these northern islands.

Although they occur infrequently, Kaua‘i has received a greater amount of damage
from hurricanes when compared to the other Hawaiian Islands. Land management
personnel in the Māhā‘ulepū region during and following the hurricanes that
affected Kaua‘i in 1962 and 1992 observed defoliation of vegetation, and no flooding
events in the period following passage of the storms.

Preparedness is the best protection for natural disasters. Structural design of dairy
facilities will meet International Building Code (IBC) 2006 standards with local
amendments. Provisions in design will address wind loading (including hurricane
gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of
the area recommended Seismic Site Class D under IBC standards be utilized for
foundation design where the barns and agricultural infrastructure will be
constructed.

There has been no rainfall event that would exceed the capacity of the effluent
ponds since rainfall has been recorded in Māhā‘ulepū Valley. The effluent pond
capacity has been designed above the regulatory requirement to contain the 25-
year, 24-hour rainfall event. An emergency containment berm with additional
capacity for another 30 days is included in the design. This design exceeds
regulatory requirements, with containment in excess of the major rainfall events
recorded on Kaua‘i over the past three decades.

An emergency preparedness plan for protection of animals has been prepared for
HDF internal use that addresses hurricane, fire, and potential flooding hazard
scenarios. HDF is not in a tsunami inundation area, so this scenario is not planned
for in the disaster plan. The disaster plan relies upon knowledge of cow behavior,
and is based on extensive guidance for livestock protection from NRCS, the Florida
State Agricultural Response Team (SART), Pennsylvania State College of Agricultural
Sciences, and Cornell University Cooperative Extension. The plan includes safety
procedures during any disaster, follow up actions, and emergency contacts for
assistance before, during or following the event. Further information is provided in
the Draft EIS Section 4.6.2.

ARCHAEOLOGICAL AND CULTURAL: The Hawai‘i Dairy Farms (HDF) project is
subject to a historic preservation review by the State Department of Land and
Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter
6E and Chapter 13-284. An Archaeological Inventory Survey (AIS) and a Cultural
Impact Assessment (CIA) were conducted by Scientific Consultant Services (SCS) for
the proposed project. EIS Sections 4.7 and 4.8 provide an evaluation of archaeology
and cultural resources, with technical studies in Appendix G and H.

A total of sixteen historic properties were identified through a pedestrian survey of
the project area and an extended survey area of 100 meters of the northern
boundary. Six historic-era sites occur in the project area and 10 sites occur in the
extended survey area. Only one of the sites is believed to be associated with pre-

Contact and/or early historic times. State Site 50-30-10-2250, the agricultural heiau,
and State Site 50-30-103094, a carved petroglyph boulder, are all located outside of
the project area. The remaining sites consist of historic-era bridges, ditches, culverts,
retaining walls, and a flame system dating from the 20th century and are affiliated
with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not
surprising given the massive landscape modifications that occurred during intensive
sugarcane cultivation on the valley floor. Even historic era cultural materials
associated with the many Land Commission Awards in the project area were non-
existent, as explored through survey and subsurface exploration.

The sixteen historic properties have been assessed for significance by the
archaeological consultant and the dairy project is anticipated to have no impact on
these sites. No further archaeological work is recommended for the sites. Two of the
sixteen sites are considered significant under multiple criteria, but occur outside the
project area on lands owned by a different landowner. Both sites will not be adversely
affected by the proposed dairy project. No site is related to burials, and no bones
were found. Such sites have been reported along coastal areas in sand dunes.

The cultural assessment examined the potential effect of the project on cultural
resources, practices or beliefs, its potential to isolate cultural resources, practices or
beliefs from their setting, and the potential of the project to introduce elements
which may alter the setting in which cultural practices take place. Information
received from the community indicates the Māhā‘ulepū Ahupua‘a, has been and is
currently used for traditional cultural purposes. However, the dairy project area has
not been included in these activities. It is clear that the gathered plants, trails, State
Site 50-30-10-2250, the agricultural heiau, and State Site 50-30-103094, a carved
petroglyph boulder, are all located outside of the project area.

The project will be fully enclosed by perimeter fencing along the boundary of the
leased premises, which will ensure that project activities and any related impacts
are contained within the project area. Based on the research and comments received
from the community, it is reasonable to conclude that, pursuant to Act 50, the
exercise of native Hawaiian rights or any ethnic group related to numerous
traditional cultural practices will not be impacted by establishment of the dairy.

FLORA AND FAUNA: Botanical, avian, and mammalian surveys of the property were
done by AECONS Consulting to assess existing species on site, including identifying
any species listed as endangered, threatened, or proposed under any state or federal
endangered species programs in or near the property. EIS Sections 4.9 and 4.10 evaluate the address of flora and fauna
resources, with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECONS
Consulting to assess existing plant species. The survey also investigated the
presence of plants currently listed as endangered, threatened or proposed for listing
under Federal or the State of Hawai‘i’s endangered species programs, located onsite
or within the immediate vicinity of the dairy site. The nature of the land and its
present and historical uses for intensive agriculture very much limit the natural
invertebrate species were noted in the survey of the site. In particular, the greenbottle fly is
often confused with the house fly. Risks known to exist on Kauai and in the greenbottle fly are
inherent to the dairy and utilize manure as a food source. HIPI will prevent and control practices. A full list of site-specific measures is provided in ES
Section 4.1.4. The project location does not allow any habitat for drosophilids
in the high elevation koa woods.

Fly populations of HIPI will be monitored through pasture management practices. A point
management plan is used (PI M). Dung beetles are specialists in the very important natural process of
breaking up and quickly recycling bovine manure pads. The behavioral diversity
among dung beetle species will work together to bury dung pats in one to three
days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

Mammals were encountered on the property. It is probable that some nest on or adjacent to the site as this species nests
to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web
among species.

The principal potential impacts posed to the five endangered species include those
potentially associated with construction activities, and those associated with dairy
operations following build-out. Measures will be adapted to avoid potential
mitigation strategies will be implemented for drosophilid species. The

Appendix A lists the threatened and endangered species and potential impacts. The survey
covers the dairy site area and immediate vicinity. Common birds and terrestrial
mammals were encountered on the property. There is no critical habitat for

Four species of endangered waterbirds were recorded on the site and at the nearby
roosting site located within the HDF site. Though the area does not provide critical
habitat, seabirds that nest in upland areas of Kauai may overfly the site. The
behavioral diversity among drosophilid species will work together to bury dung pats in one to three
days, a shorter amount of time than the 10-30 days flies eggs need to hatch.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis.
While caution will be taken during any potential disturbance or vegetation removal,
mitigation measures are further
described in DBES Section 4.1.2.

It is also likely that Hawaiian hoary bats overfly the project area on a seasonal basis.
While caution will be taken during any potential disturbance or vegetation removal,
mitigation measures are further
described in DBES Section 4.1.2.
dairy farm and planned mitigation actions. Draft EIS Section 4.12 addresses noise conditions.

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that cause undue stress on cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai'i Department of Health (DOH) rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes. The Hawai'i Dairy Farms (HDF) site in Māhō'ulepū Valley is approximately 2 miles from the resort area, and 1.5 miles from the closest residential areas (on land zoned for agriculture). Typical noise currently generated near the HDF site includes truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

Construction work at the project site will involve activities that may generate an increase in noise levels. However, such exposures will be a short-term condition, occurring during daylight hours. Construction vehicles and activities must comply with DOH Administrative Rules. DOH noise control regulation requires a permit for construction activities that emit noise in excess of 78 decibels or that cost a total of more than $250,000. Mitigation measures to minimize construction noise will include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms (HDF) to the existing economy were evaluated in the Draft Environmental Impact Statement (EIS), including a fiscal impact assessment report completed in April, 2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local construction personnel and local material suppliers. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Construction employment would be expected to average about 12 jobs per year during the development period. Thus direct-plus-indirect employment association with construction would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i.

The HDF project would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Hawai‘i Island), approximately 10 percent of Hawai‘i’s milk is locally supplied. The HDF project, with an established herd of up to 699 mature dairy cows, will increase the supply of local fluid milk by approximately 1.2 million gallons of milk annually, a 50 percent increase in statewide milk production. On-going dairy operations at the committed herd size will provide approximately 16 direct and indirect full-time equivalent jobs on Kaua‘i, including 5 farm jobs and about 11 indirect jobs. An additional 6 indirect jobs related to on-going dairy operations would be created on O‘ahu.

HDF is expected to generate a net income of approximately $68,000 to the County when the 699 cow herd is established. When the dairy has matured to full production for the 699 cow dairy, net income to the State is calculated at $160,000 annually. With the potential contemplated herd size of up to 2,000 mature dairy cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 mature dairy cow herd is estimated at approximately 3 construction jobs plus 4 indirect jobs on Kaua‘i, and 2 indirect jobs on O‘ahu for a total increase of 9 jobs. For on-going operations at the contemplated herd size, an additional 5 full-time farm jobs would be added, with approximately 15 additional indirect jobs on Kaua‘i and another 8 indirect jobs on O‘ahu.

The dairy is expected to generate a net additional contribution to the County of approximately $8,000 for improvements related to expansion for the contemplated herd size of up to 2,000 mature dairy cows ($76,000 total versus $68,000 for the committed herd size). The State will derive approximately $160,000 annually in revenues from the contemplated 2,000-mature dairy cow dairy.

Results of technical studies and the findings of this Draft EIS show no unmitigated nuisances that could affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will impact resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area.
WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawaii Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area's hydrology is shaped by its geology. The Kōloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths - as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhāʻulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black alluvial clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move through the ground. The hydraulic conductivity of the alluvium that underlies Māhāʻulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawaii Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,800 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāʻulepū 14 well during the sugarcane plantation era. All potable water used as water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāʻulepū 14 well and the County's Kōloa well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Poipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,300 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Poipū - Kalāheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

SURFACE WATER

The State Department of Land and Natural Resources Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface
Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘apu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

**Potential Impacts from Construction:** The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

**Surface Water Quality:** The Kauai Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococci to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococci in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a "Sanitary Survey" of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels observed in ditches running through Māhā‘ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

**Long-term Operations, Setbacks and Buffer:** Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, US. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 15-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

**Nutrients from Effluent Irrigation and Commercial Fertilizer Application:** The natural fertilizer from manure deposed directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 16.2 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than ground water, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.
To provide perspective, nutrient inputs from the adjacent Kīloa-Pō'ipū region were calculated. Nitrogen input to the marine environment in the Pō'ipū region is calculated to be 38,510 pounds annually, or 35 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Pō'ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment. An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waipōlū Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report is included in the Draft EIS as Appendix F.

Establishment of Water Quality Monitoring: Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH GWR, dairy neighbors and the local Kauā'i community.

AIR QUALITY: As a part of the Environmental Impact Statement (EIS), existing air quality conditions and project impacts were evaluated, including dust and odor. Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. EB sections 4.19 and 4.25 provide an evaluation of air quality and odors, including a windrose depicting wind speed and direction in the area (see DEIS Section 4.1, Climate). The full air quality technical report can be found in Draft EIS Appendix I.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants. The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) that are as strict or, in some cases more strict than the NAAQS. State standards prohibit any visible emissions of fugitive dust from construction activities at the property line.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH₄) from enteric fermentation, and both methane and nitrous oxide (N₂O) emissions from manure application. No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

DUST

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential fugitive dust emissions relevant to dairy operations or small businesses currently exist.

Applying the emission rates from this available literature greatly overestimates potential emission resulting from HDF. Cows in the pastoral rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM₁₀ and PM₂.₅) measured on the island of Kauā'i, and the total concentration was compared to the State ambient air quality standards. Only the contemplated herd size of up to 2,000 mature dairy cows was modeled, as at the lower threshold of 699 cows, the potential fugitive dust impact would be negligible. The estimated concentration for PM₂.₅ is 2.01 μg/m³ well below the State standard of 150 μg/m³. The estimated concentration for PM₁₀ is 0.23 μg/m³, well below the Federal standard of 35 μg/m³ (see Draft EIS Section 4.19 and Table 4-19.2).

ODOR

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels. Local weather data was used in conjunction with the AERMOD modeling system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Odor emission sources identified for modeling at HDF were manure storage ponds, and the dairy buildings. Odor rates from published research were
value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of panelists can detect the odor.

The analysis, therefore, focuses on alternatives that meet the project purpose. Although the alternatives are not directly comparable to the proposed action, they were reviewed to assess how well they might reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include (1) the development of a Conventional Feedlot Dairy (as defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4)).

The essential differences as compared to the proposed action are highlighted in the following statements.

- ALTERNATIVES: Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai’i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feed stock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows. Alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua’i in a wide range of positions, including as agronomists, land managers, and agricultural infrastructure, water systems and support facilities. Alternative (Residential Alternative) could also demonstrate the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3).

Four possible land uses that would not meet the project purpose are discussed. The potential consequences in terms of environmental benefits, costs, and risks of each reasonable alternative are evaluated against those of the proposed action. (Criterion 1). The project’s objective is to identify and evaluate a range of reasonable alternatives against those of the proposed dairy project. Further discussion of alternatives that could not meet the objectives of the action’s purpose and need, and compare environmental benefits, costs, and risks of each reasonable alternative and the proposed action. The potential consequences of the proposed action, and environmental benefits, costs, and risks of each reasonable alternative and the proposed action are evaluated against those of the proposed action. (Criterion 1).

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compared to the proposed action and the four other alternatives. The potential consequences in terms of environmental benefits, costs, and risks of each reasonable alternative are evaluated against those of the proposed action. The potential consequences in terms of environmental benefits, costs, and risks of each reasonable alternative are evaluated against those of the proposed action. (Criterion 1).
Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai'i Dairy Farms was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai'i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai'i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua'i, including pasture agronomy/soil science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL search "Hawai'i Dairy Farms": http://tinyurl.com/OEQCKAUAJ

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70 INTERNATIONAL, INC.

Comments to be considered in preparation of an Environmental Impact statement for:
Project Name: Hawaiʻi Dairy Farms
Island: Kauaʻi
District: Poipu
TMC: (4) 2-9-003:001 (portion); 006 (portion)
(4) 2-9-001:001 (portion)

To whom it may concern,

The following is my response and comment to the Hawaii Dairy Farms EISPN, posted on January 23rd, 2015. Each of the comments below need to be included and fully addressed by the Hawaii Dairy Farm EIS due to the substantial adverse environmental impact likely to be sustained if an Industrial Dairy is allowed to operate at Mahaʻulepu on Kauaʻi:

As all wildlife has what is known as a ‘tolerance range,’ once that range is exceeded the wildlife and threatened and endangered species may leave an area or die. Those amphibians that can’t leave will die. For this reason each rare or endangered species, necessary habitat, mating behaviors, sensitivity to sound, sensitivity to methane gas, hydrogen sulfide, acid rain, and sensitivity light & glare, needs to be addressed in the EIS on an individual, per species, basis. The cumulative effect of all of these sensitivities on their survival as well as their potential inability to increase their numbers needs to be addressed. The necessary environment required to enhance the livability of our Federally threatened endangered species must be addressed in the EIS.

Specific Endangered birds

The native and endemic endangered birds known in the Mahaʻulepu area are the Hawaiian Coot (ʻalae kiʻokeʻo), Common Moorhen (ʻalaeʻula), Hawaiian Duck (Koloa), Hawaiian stilt (ʻaeʻo) and Hawaiian Goose (nene). The impacts to each of these endangered birds need to be addressed separately in the EIS as each has its own nesting habits, food sources and environmental requirements.

Wetlands and Endangered birds

The Intermittent streams and wetlands at Mahaʻulepu and Kipu Kai provide habitat for these endangered birds. The placement of a cow burial site near the edge of the HDF’s property just adjacent to, and upland from, a known wetland needs to be addressed especially in light of the hydrologic interconnection of the valley, according to the Mahaʻulepu, Island of Kauaʻi Reconnaisance Survey (completed by the National Park Service, U.S. Dept. of the interior in 2008) on page 29. The 600+ dead cows that HDF needs to dispose of per year is an environmental threat to the wetlands and the endangered birds that live or frequent there. (Dead cows tally on record at the county council meeting in May 2014.) This significant adverse impact needs to be addressed in the EIS. The specifics of the method used and the value judgments made need to be disclosed by HDF to enable proper review of significant adverse impacts that may occur. Any manure or urine left on the paddocks that are upland of wetlands needs to be addressed in the EIS because of the possibility of runoff contaminating the wetlands with total nitrogen, ammonium nitrogen, nitrate and nitrite phosphorous, Enterococcus and hormones.
Waterbirds

Along the Māhā‘ulepū watershed coastline, other small wetland ecosystems fed by rain and groundwater lie just inland of the dunes. These, too, attract native waterfowl; biologists believe they once supported larger populations, and have excellent restoration potential. Resource specialists told NPS that Māhā‘ulepū and Kīpū Kai, in combination with Hulē‘ia, provide a much-needed mosaic of varied wetland habitats that should be reliably available for endangered Hawaiian waterbirds. (MIKRS) All wetlands small and large need to be individually identified in the EIS. Protection of these wetlands or potential wetlands needs to be addressed in the EIS. The specifics of the method used and the value judgments made need to be disclosed by HDF to enable proper review of significant adverse impacts that may occur.

Taro Patch and rain event

“According to a state source, nēnē, koloa and other waterfowl frequent the taro lease land in Māhā‘ulepū valley, and a broad natural depression in the valley that fills with water after heavy rain draws many waterbirds. Sixty Koloa individuals were counted during one such event (Kaiakapu 2007).” (Page 39 MIKRS) The exact area of the “broad natural depression” needs to be determined and protected for the wild birds. The area of the depression needs to be established with the necessary fauna and flora to provide the bird’s habitat. If the depression area has been disturbed by the grubbing and grading that occurred in 2014 by HDF, it needs to be restored. The specifics of the restoration need to be spelled out in the EIS. If the depression area is still viable then the area needs to be protected for the wild birds and named in the EIS. Any potential significant adverse impacts from dairy operation such as grazing, irrigation, herd movement, etc., must be addressed in the EIS. Additionally protection measures taken must be elucidated in the EIS.

Newell’s Shearwater

Newell’s Shearwater, a threatened native bird species, and nests on Ha‘upu ridge, just above the dairy site (USFWS Recovery Plan for Newell’s Shearwater). The fledglings leave their nests on Ha‘upu ridge and fly towards the ocean directly over HDF’s facilities. “Kauai is home to 90% of the total population of Shearwaters” (The bird that Darkened Kauai” by Coco Zickos).

“Transitioning to bird-friendly lighting at all county facilities has been one of our priorities, so we’ve budgeted for the retrofits for several years,” Mayor Bernard Carvalho Jr. wrote in an email. “The new lights, Rapozo said, will be available seven days a week from 6 to 10 p.m. during ‘non-fledgling season’ — dates outside of the Shearwaters’ fledgling season, which runs from Sept. 15 to Dec. 15. The systems at each facility include a push button to turn the lights on for an hour at a time and an alert system at the end of each hour that will warn users that the button needs to be pushed again for additional use. If the button is not pressed, the lights will turn off, which could save the county money on its electricity bill” (The Garden Island January 29th, 2015).

“The upgrades were one of the steps taken by the county to comply with a 2010 Justice Department plea agreement in which the county and Kauai Island Utility Cooperative admitted to violating the Migratory Bird Treaty Act. The charges, at the time, blamed the deaths of Newell’s shearwaters on the lighting policies at county facilities. Officials said seabird fledglings can become confused by stray light during their first nocturnal flight from their nesting burrow to the sea. Some of these birds end up falling inland, where they can become prey for predators” (The Garden Island January 29th, 2015).

The Waste Management Plan for HDF submitted to the DOH states, “Rotary Milking System of 60 clusters that provides for a throughput of 360 cows every hour and allows for a maximum milking time of 6 hours approximately per milking and 12 hours per day.” To accomplish milking the herd it will take approximately 12 hours. Additional time will be needed for cleaning out the facility and directing the waste to the effluent ponds, maintenance of equipment, to convey feed from 2 large silos to disc mill, and to take processed feed from mill to 904 feed system silo then to convey the feed to the feed shed. Additional time will be needed for delivery of grains to facility and maintenance of the feed system. These and many other processes will take beyond 12 hours per day. In fact, HDF at their public meeting in Lihu‘e at KCC, on March 27th, 2014, stated that the milking would begin at 4am and go until 3am then start again at 4 pm, going until 10 pm. The issue here becomes many of these processes needing to be done at night and the lighting that would be needed. This will interfere with the migration of the shearwater fledglings to the ocean. The Migratory Bird Act comes into play here. The county stopped all games at the stadiums at night to comply. How will HDF comply when in fact there isn’t enough daylight to run their operations? This
needs to be addressed in the EIS. The specifics of the method used and the value judgments made need to be disclosed by HDF to enable proper review of significant adverse impacts that may occur.

Migratory Birds

"Four migratory bird species that winter in Hawaii and return to the Arctic to breed were noted in the study area." The Pacific Golden Plover, Ruddy Turnstone, Wandering Tattler and the Sanderling (MIKRS). There are additional migratory shorebirds that frequent the coastline occasionally, and other seabird species likely transit the coast. A State study notes that seabirds use the coastal sea cliffs and foothills for nesting and loafing (OSP 1992). The environmental requirements of these migratory birds need to be addressed in the EIS as well as the impact of the dairy’s runoff, grey water, and predatory animals attracted by the dairy operation and the waste produced. The presence of rats and egrets, known to consume bird eggs, need to be addressed. Rats are currently having a substantial impact on the bird population in Koke’e. The State is also presently addressing a major rat infestation in Lehua, the island adjacent to Niihau. Steps to protect these birds from all adverse externalities need to be addressed in the EIS.

The cattle egret may consume the young of endemic waterbirds (USFWS 2005) and compete with native waterbirds for food (Hawaii Audubon Society 2005). The number of egrets attracted by 2,000 cows needs to be addressed in the EIS. Protection of food sources for waterbirds needs to be addressed in the EIS.

Native Species

Five native species are known to frequent the area: the Black Crowned Night Heron, White Tailed Tropicbird, Great Frigate bird, Wedge Tailed Shearwater, and Red Tailed Tropicbird. The Black Crowned Night Heron finds breeding habitat at Huli’ia NWR and was spotted during the survey. Biologists describe Frigate bird sightings at Māhā’ulepū and on Mt. Hā’upu. MIKRS These birds, their special needs and what methods will ensure their survival need to elucidated in the EIS.

Terrestrial Invertebrates

Two notable and extremely rare terrestrial invertebrates live in the Māhā’ulepū area: the Kaua’i Cave Wolf Spider (Adelocosa anops) and the Kaua’i Cave Amphipod (Speleoorchestia Hanamā‘ulūna). In 2000, both the spider and the amphipod were Federally listed by USFWS as endangered species. All known populations occur in the Kōloa basin on Kaua’i, within a 4-square-mile area (CBD 2007). Both species have been reduced to a few small populations; exact numbers remain unknown. Researchers say the spider is seen regularly in only one cave with a population of 16 to 28 individuals (USFWS 2005). The cave-faced corridor along the Māhā’ulepū coast of the study area, from Makawehi Point to Kawelikoa Point, is designated by USFWS as Critical Habitat for both of these endangered species. How is HDF going to protect their Critical Habitat from a deluge of manure-laced water coming down the Waipii Stream and flooding the cave and vicinity during a rain event, tropical storm, or Hurricane? The cave floods from the rising waters of the Waipii approximately every four years. This issue needs to be thoroughly addressed especially in light of the fact that Māhā’ulepū Valley is hydrologically connected to the cave. MIKRS

The Marine Vertebrates

The beaches and near shore waters are home to three important large marine vertebrates: the endangered Hawaiian Monk Seal, known in Hawaiian as ‘Ilio holo ika uaua (Monachus schauinslandii), the endangered Humpback Whale or kohala (Megaptera novaeangliae), and the threatened Green Sea Turtle or honu (Chelonia mydas).

Successful Monk Seal pupplings occurred at Māhā’ulepū in 2000 and 2007 (MIKRS). Monk seal occurrences within the study area take on increasing significance as the overall population continues declining at about 4 percent each year. The updated Recovery Plan for the Hawaiian Monk Seal, released in August 2007, states that the species ‘is headed to extinction if urgent action is not taken.’ Its recovery strategy calls for actions to ensure continued growth of the Seal population in the main Hawaiian Islands (NOAA 2007b). Fast forward to February 2015, The Garden Island Newspaper states, ‘The Marine Conservation Institute is calling for the National Oceanic and Atmospheric Administration to redouble its efforts’ to conserve and recover the endangered Hawaiian Monk Seal. ‘Although NOAA’s field staff has made progress on some fronts to protect and save the lives of individual seals, we think NOAA can— and must— do more to slow down and eventually reverse the decline,’ MCI’s Conservation Advisor William Chandler said during a teleconference Thursday. Despite continued efforts, the population of between 900 and 1,100 seals is declining at an annual
rate of 4 percent — a trend MCI estimates would halve the population in less than 20 years" The impact on Monk Seals due to rain events, tropical storms and hurricanes polluting the ocean via Waipio Valley with manure, urine, nitrogen, phosphorous, hormones and other fertilizers used by HDF needs to be address in the EIS.

Fish

The Reef Environmental Education Foundation recorded 24 species of fish at Kawaiola Bay (Māhā’ulepū), and 43 species at Kīpū Kai. An additional eight appeared in records kept by proprietors at Kīpū Kai. Kaua‘i residents describe the near shore waters of the study area as a “prime fishing area.” Telltale pipes for holding fishing poles are embedded at favored sites along the shoreline. Fish abundance is also implied by the presence of monk seals — the seals feed on reef fish as well as octopus, lobster, and eel (MIKRS). The EIS needs to address how HDF will protect the fish species during rainy season, how the algae causing pollutants will be monitored and how the stream and ocean would be cleaned up. The EIS needs to address coral death caused by nutrients and algae blooms as coral is an intricate part of the environment. Climate change needs to be addressed in the EIS as the culminate effect of higher nitrogen and phosphorous levels in the waterways could cause faster algae blooms leading to rapid coral death.

Algae

“We saw no invasive or alien algae” (MIKRS) This is the condition of Maha’ulepupu waters now, but in New Zealand it’s a different story. “Already choked with weeds and algae, waterways will get even worse as the dairy industry continues to boom,” the Environment Commissioner says. Poor-water quality is caused by the run-off of nutrients from farm land, which breeds invasive weeds, slime and potentially toxic algal blooms” (Waterways will get worse – Commissioner, article in NZFarmer.co.nz 2013). Nutrients, urine, manure entering the waterways and groundwater from runoff is likely because of the low Ksat of the two major clay soil types found on HDF site (Custom Soil Resources Report for Island of Kauai 2014) (CSRRIL). These issues need to be elucidated in the EIS. The likelihood of contamination of seaweed that is collected for human consumption needs to be addressed in the EIS.

Wetlands

The portion of Māhā’ulepū watershed that lies within the study area stretches from the Hā’upu ridgeline southward through Māhā’ulepū valley and eastward to the coast. Agricultural operations began in the mid-1800’s in Māhā’ulepū valley; its intermittent streams and wetlands were long ago modified for irrigation purposes. The landowner Grove Farm operates a water system that includes wells, ditches, tunnels and reservoirs. Māhā’ulepū Reservoir, at the back of the valley, is part of that system. Both it and the County-owned Pu‘u Hā reservoir (at the very southern end of the study area) serve as important attractors for Hawai‘i waterfowl.

A broad natural depression in the valley also fills with water after heavy rains and temporarily draws water birds in large numbers. Though Māhā’ulepū valley’s streams and wetlands were modified, their remnants remain. These expand and become especially visible during wetter periods. The former Waipio Valley Stream, largely subsumed by the ditch system within the cultivated area at Māhā’ulepū, emerges in more natural form near Makauwhai Cave at the south end of the study area, where it joins forces with a natural spring and a remnant of the once much larger Kapunakea Pond. This wetland junction attracts waterbirds and serves as nursery habitat for native fish. It is linked hydrologically to the important Makauwhai Cave Reserve, a critical habitat for endangered arthropods that rely on seepage of nutrient-rich water (MIKRR).

Restoring and protection from cows, manure & urine polluted water of this large wetland area needs to be addressed in the EIS. Protection of the two mentioned area reservoirs needs to be addressed in the EIS. Protection of the area around and in the broad natural depression needs to be addressed in the EIS.

Because all of Maha’ulepupu valley is hydrologically linked to the Makauwhai Cave, any breaches of the effluent ponds have a likelihood of ending up in the cave from weather events, hurricanes, to tropical storms and flash flooding this needs to be addressed in the EIS. The feasibility and positive impacts to the environment of disconnecting the direct access of the irrigation ditches to the Waipio stream and instead being processed as waste water prior to entering the stream needs to be addressed. (Especially in light of the high bacteria counts and turbidity readings of the Waipio this last year- DOH & Surfrider).
We do not want the Waiopili stream to become like the New Zealand streams. "We also need to have a long-term vision about what sort of land use is appropriate according to the sensitivity of the receiving waters" (Waterways will get worse — Commissioner, article in NZFarmer.co.nz 2013). HDF’s land use needs to be reconsidered in Mahaʻulepu, an environmentally sensitive site, in the EIS.

**Arthropods**

Intensifying and adversely impacting land uses and activities poses current and potential threats to important natural and cultural resources within the study area. Kauaʻi’s endangered arthropods in the study area are especially vulnerable to impacts from quarrying and other activity on the marginal agricultural soils overlying their cave habitats. Grading, fill, and excavation result in disturbance, compaction or blockage of the subterranean cracks where these species find refuge during drought. Blocked areas break up the cave system into separate areas, isolating the already small populations and increasing their risk of extinction (MKRS). The further endangering of the arthropods through grubbing and grading activities

**Makauwahi Cave and Sinkhole**

Makauwahi cave and sinkhole is equally important for the light it sheds on Hawaiʻi’s human story. According to scientists working at the site, it contains "in a single stratigraphic sequence an encapsulated view of the full span of human occupation, including the millennia preceding human arrival, earliest human evidence, subsequent population increase and cultural change, European contact, and modern transformation" (Burney and Kikuchi 2006). Due to its neutral pH environment, Makauwahi’s fossil and artifact finds are exceptionally well preserved. Its sinkhole walls surround an ordered column of sediment layers that tell a nearly unbroken tale of conditions on Kauaʻi, from before the arrival of people through the changes wrought by a millennium of human activity. Researchers are piecing together new and detailed views of Kauaʻi’s past based on analysis of the Cave’s sediments, combined with oral and archival sources (MKRS). With the Cave’s hydrological linking to the valley it would seem that cow urine would possibly change the pH of the water going into the Cave, thereby destroying all the perfectly preserved extinct life forms. The possibility of pH change and the impacts thereof need to be addressed in the EIS. An active sand quarry excavation operates adjacent to Makauwahi cave and sinkhole—so close that one small cave opening in the west sinkhole wall rises diagonally only about 50 feet before it ends in a surface collapse at the edge of the quarry (Burney and Kikuchi 2006). Heavy equipment in use at the quarry can sometimes be felt within the cave environment, causing fear of potential rockfall or collapse. A heiau on the quarry site has already suffered significant damage. A future quarry site farther north at ʻĀweoweo may potentially impact dune burials (MKRS). The quarry on HDF’s site needs to be addressed in the EIS for possible burial site as well as artifacts.

**Invasive Alien Plant Species**

Non-Native species dominate parts of the study area, and threaten or encroach on significant resources or the shoreline, at Hulâlia, and on Hāʻupu ridge. Once established, some of these aliens are difficult to remove. Ungulate disturbance destroys native vegetation, increases erosion, and provides fertile ground for invasive species (MKRS). Cows could cause ungulate disturbances thereby increasing soil erosion and giving invasive species a foothold at the expense of the native species. This needs to be addressed in the EIS.

**Weather Hazards**

Environmental events such as hurricanes, fires, tsunamis and landslides are potential study area threats that can not only wreak direct havoc, but also set into motion long-term landscape changes, such as erosion and alien plant invasion, that gradually degrade and destroy native habitats. State officials report that two hurricanes in recent decades damaged the Newell’s Shearwater habitat on Hāʻupu ridge, and allowed invasive species to spread across newly-eroded slopes. Kipu Kai representatives say the mountainsides above their valley were lushly vegetated before the hurricanes. By the time of the National Park Service (NPS) site visit, the slopes were bare and roamed by goats, and a small recent landslide was apparent on the upper part of the access road (MKRS).

The entire study area shoreline is highly vulnerable to storms and hurricanes. Long-term coastal erosion hazard is high at Mahaʻulepu Beach and moderately high at Kawaiola Bay, Hāʻūia, Kipu Kai beaches, and the southern portion of
Niulau (KC 2003). Potential tsunami hazard intensity is considered high along the Māhā‘ulepū coast between Punahoa Point and Hā‘upu Bay, and at Long Beach in Kīpū Kai. These moderately sloped areas are also vulnerable to coastal stream flooding from seasonal rainfall (KC 2003). The EIS needs to address where and how the cows will be protected and or evacuated and the possibility that the cows will be swept into the ocean during a hurricane. The EIS needs to address what will happen to the manure that has been left on the fields near the stream that takes runoff from Ha‘upu ridge and delivers it to the ocean. The EIS needs to consider the alternative of collecting the manure from the fields vs. the planned land application to minimize the threat to the environment. The EIS needs to address the possibility of using the collected field manure in methane gas generators/digesters to produce bio-gas energy.

HDF must prove that there will never be discharge of pollutants from direct surface runoff or ditch discharge into Waiopili stream as it courses directly into the ocean, and that percolation into both shallow and deep groundwater will not contaminate stream, estuarine and coastal waters, especially in light of the hydrologic linking of the valley, streams, aquifers and ocean.

Several state planning documents related to tourism, recreation, and historic trails emphasize the importance of recreational access and resource protection along this coast, especially in light of increasing public use (OSP 1992).

In 1992, Hawai‘i’s Office of State Planning conducted a land use review that recognized Māhā‘ulepū’s “combination of outstanding coastal recreational areas, native coastal strand vegetation, significant physiographic, archaeological and scenic resources.” Anticipating future development pressure, it said “measures will need to be taken to assure that the sensitive resources here will be protected.” Suggested ways to achieve that protection include transfer of development rights and purchase of easements (OSP 1992). The possibility of transfer of development rights needs to be explored/addressed in the EIS.

NCRS Custom Soil Resource Report

On June 5th, 2014, the Natural Resource Conservation Service published a Custom Soil Resource Report focused specifically on the parcel of land intended for use by Hawaii Dairy Farms. The fact of this report, and its findings, was not referenced or included by Hawaii Dairy Farm’s when submitting their current Waste Management Plan for approval to DOH (July 23rd, 2014). Since that filing, Hawaii Dairy Farms has never corrected this omission or explained their lack of any reference to this document or its findings. That omission must be corrected, and the NCRS findings need to be specifically addressed by the EIS.

The Custom Soil Resource Report states that, virtually all of the soils underlying the site have “very limited” capacity for disposal of manure through irrigation. The soils were also determined to be highly susceptible to surface water runoff. The study concluded that the soil types in the area have anywhere from “medium” to “very high” likelihood of surface runoff. The study further concluded that soil remediation on the scale necessary was not feasible.

Water

There are at least three County Wells (F, C, and D­ in order of proximity) dangerously close to the proposed farm property that would be covered by planned land applied waste from grazing cattle as well as pumped de-sludged waste residue. These three wells provide the potable water for all of Poipu and most of Koloa. Well F, the nearest, is less than 750 ft. from Block H, a parcel specifically designated for receipt of pumped de-sludge residue. When this same area is actively grazed by cattle (HDF’s Plan identifies specific grazing paddocks at this same site), there will be no less than 100,000 lbs of wet manure, and at least 6,000 gallons of urine applied to and left on this site each day. Unfortunately, this same area happens to contain some of the best draining soil of the farm site (as per NCRS Study and HDF’s latest Plan). Consequently, the migration of both bacteria and harmful nitrates into the wells is a certainty. The EIS needs to establish how this can be prevented.

Conclusion

Not only does the EIS need to address the foregoing, but its EISP is notably deficient in its proposal to consider Alternative Locations. In fact, HDF’s idea of alternatives is to consider taking no further action at the proposed site, operating a CAFO at the same site, or finding one other potential site. If HDF approaches the EIS process using the methods commonly followed during an EIS process, alternatives should encompass consideration of more than one other location at
which their proposed plan could proceed if necessary. In this case however, HDF has predesigned a very limited alternative consideration and the single alternative site, not yet identified, is inadequate to satisfy the intent of the EIS process. It is interesting to note that when discussing the one alternative location in their EIS, HDF states, “The micro-climate requires soil conditions favorable for nutrient absorption with access to a reasonable priced irrigation water source, to sustain nutritious grass pastures.” The EIS needs to address how HDF could possibly proceed at Mahaa‘ulepu when both the NRCS and their own Iowa Based Soil Study indicate that the soils there are anything but “favorable for nutrient absorption.” HDF needs to solidly refute the obvious conclusion that the sensitive ecosystem o’ Mahaa‘ulepu would be irreparably harmed if their Industrial Dairy is allowed to proceed as proposed.

Sincerely,

John (Jay) Kechloian

Subject: Hawai‘i Dairy Farms
Environmental Impact Statement Preparation Notice
Mahaa‘ulepu Road
Kaua‘i, Hawai‘i
TMK: {4} 2-9-003: 001 portion and 006 portion
{4} 2-9-001:001 portion

Dear John (Jay) Kechloian:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

SOILS: Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dry periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem healthy. Two rounds of independent soil sampling were undertaken at HDF to understand and characterize available soil nutrients and conditions. Section 4.3 of the Environmental Impact Statement (EIS) characterizes soil conditions, and anticipated impacts from effluent and supplemental nutrient application. Recommendations from Dr. Russell Yost and Nicholas Krueger of the University of Hawai‘i at Mānoa are summarized. Their baseline nutrient report is included as Appendix C of the Draft EIS.
In this way, "poorly drained" soils may represent less risk of nitrate and nitrite formation out of the Soil Conservation Service to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering, economics, wildlife biology and other disciplines to aid landowners in...
FLORA AND FAUNA: Botanical, avian, and mammalian species of the property were conducted for the Draft Environmental Impact Statement (EIS) to assess existing species on site, including identifying any species listed as endangered, threatened, or proposed under any state or federal endangered species programs in or near the property. EIS Sections 4.9 and 4.10 address the evaluation of flora and fauna resources with technical studies in Appendix A and B.

A botanical survey of the dairy property was conducted in August 2014 by AECONS Consulting to assess existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawaii’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The nature of the land and its present and historical uses for intensive agriculture very much limit the number of plants on the property anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize skieres. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

Avian and mammalian surveys were conducted in August 2014 by Rana Biological Consulting, Inc. This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Common birds and terrestrial mammals were encountered on the property. There is no critical habitat for endangered species in the upper Makaaulepu Valley.

Four species of endangered waterbirds were recorded on the site and at the nearby taro farm located within the HDF site. Though the area does not provide critical habitat, seabirds that nest in upland areas of Kauai may overfly the site. The endangered Hawaiian goose, nene was also seen on the site. State Division of Forestry and Wildlife biologists have noted nene are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kauai area, and the habitat present on parts of the site is suitable for nene nesting.

The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nene goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project site activities, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present and historical uses for intensive agriculture very much limit the number of plants on the property anticipated to occur on this land. Complete species lists are included in the EIS, and no protected botanical species occur on the project property. The project will include vegetated buffer strips along the drainage ways as part of the Conservation Plan to reduce erosion and stabilize skieres. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.

INVERTEBRATE SPECIES: A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist. The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Makaaulepu area, as well as the parasites and predators on site that control those species. Fieldwork was conducted during September 15-16, 2014. The entire study is included in Draft Environmental Impact Statement (EIS) as Appendix B.

CAVE AND LAVA TUBE INVERTEBRATES

There are no known caves or lava tubes found at or adjacent to the dairy farm property. The Kauai Lava Tube System, which provides habitat for two endemic cave species, the Kauai's Cave Wolf Spider and the Kauai's Cave amphipod, is located several miles away from the dairy farm property. Both invertebrates are listed as endangered under the US. Endangered Species Act. Not all caves in the Kauai area contain these invertebrates, as many do not contain the optimal climatological conditions required by these organisms. Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area near the Hawaii Dairy Farms (HDF) site. Thus no cave invertebrate species will be affected by the dairy farm.

INTRODUCED PREDATOR INSECTS

An invertebrate study of manure-associated insects was conducted for the Draft EIS. The principal potential impacts posed to the five endangered species include those potentially associated with construction activities, and those associated with dairy farm operations following build-out. Measures will be adopted to avoid potential seabird and nene goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to project-site activities, and is based on extensive guidance for livestock protection from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. The plan includes safety procedures during any disaster, follow up actions, and emergency contacts for assistance before, during or following the event. Further information is provided in the Draft EIS Section 4.6.2.
present at the HDF site. Pest insects such as flies can negatively impact livestock in accordance with regulatory labeling requirements. HDF will implement long-term integrated pest management, which utilizes knowledge of the ancient food web among species by disrupting the manure habitat required to complete the fly life cycle. HDF and other ranchers on Kaua‘i may choose to engage with the State Department of Agriculture to translocation dung beetle species already introduced on Kaua‘i to Māhā‘ulepū and other areas where manure-related flies may be a problem.

IMPACT OF SPRAYS ON BEES

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Honey bees are an essential part of any agricultural ecosystem, and were observed on site during the invertebrate species survey. Pesticides and herbicides can reduce populations of beneficial insects, which is why HDF will utilize an integrated pest management approach.

It is expected that honey bees will visit water sources set up for the HDF herd. Preventative measures will be built into any open water source to prevent bees from being trapped, and HDF will contact local beekeepers for advice regarding any bee or bee colonies encountered on site. Safe application practices for any unavoidable herbicide or pesticide will be utilized in order to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself a local beekeeper will be contacted for advice and removal.

WATER QUALITY: Technical consultants conducted field studies and analysis on groundwater and surface water resources in the area, and evaluated potential impacts from the proposed Hawai‘i Dairy Farms (HDF) actions. Existing conditions and probable impacts are presented in the Draft Environmental Impact Statement (EIS) sections 4.16, 4.17, 4.22 and 4.23; the technical reports are in Appendices E and F. The location and connectivity of groundwater bodies were determined, and the quality of groundwater and surface water was documented.

GROUND WATER

Hydrology: The area’s hydrology is shaped by its geology. The Kūloa area was built by Napali formation lavas of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū Valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kūloa series. The alluvial material is highly weathered lava and is comprised of dark brown to black silty clay and clayey silt.

The groundwater and surface water analysis conducted for this Draft EIS identified two groundwater bodies within the valley: (1) groundwater located in a deep aquifer system within unweathered volcanic material, which is buried beneath thick...
alluvium that covers the valley floor, and (2) groundwater in the thick alluvium. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents a comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Groundwater Monitoring: Four groundwater monitoring wells were installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Baseline data on water quality for both groundwater in the alluvium and groundwater in the deep aquifer were documented. Future monitoring will allow comparison between conditions prior to, and during, HDF operations. Results from the monitoring program will be shared with the Department of Health Clean Water Branch, dairy neighbors and the local Kaua‘i community.

Regional Water Demand: The adjacent, developed Kōloa-Po‘ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase county-wide by 17,500 residents by 2030. The South Kaua‘i population is estimated to reach 16,855 in 2035, when it is projected to encompass 19.2 percent of the County population. For the South Kaua‘i region (the Kōloa - Po‘ipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day. An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water. Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

Potable Water: Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 0.3 MGD produced by the on-site, existing Māhā‘ulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Although the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhā‘ulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.

Surface Water

The State Department of Land and Natural Resources (DLNR) has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhā‘ulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge. There are no perennial streams in the Māhā‘ulepū watershed.

The HDF site is located on the bottom-land of the upper Māhā‘ulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Ha‘upu Ridge. These normally dry streams converge into man-made channels running through the HDF site across the valley floor, and meet a concrete ditch that parallels lower Māhā‘ulepū Road. This ditch, named Waiopili Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south.

Potential Impacts from Construction: The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site. A Stormwater Pollution Prevention Plan (SWPPP) has been developed as part of the application for the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; and prohibiting leaking or poorly-maintained construction equipment and machinery. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; geotextile filter fabric and sediment logs around drain inlets.
Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted ORA to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kaua‘i, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The deme canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honouliuli District. US Army Corps of Engineers (USACE) in 2013. These protection practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageway; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162.5 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge to the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches. The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient runoff would not occur as chronic daily release, rather, the runoff contribution would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kīloa-Po‘ipū region were also calculated. Nitrogen input to the marine environment in the Po‘ipū region is calculated to be 38,510 pounds annually, or 3.5 times greater than the estimated potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downgradient from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean
water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the surface and marine water impact report are included in the Draft EIS as Appendix F.

**Establishment of Water Quality Monitoring:** Long-term ocean water quality monitoring will be instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze the nearshore ocean waters. The ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring program will be shared with the DOH GWB, dairy neighbors and the local Kaua‘i community.

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search "Hawai‘i Dairy Farms": [http://thegwb.com/OEQCKAUAI](http://thegwb.com/OEQCKAUAI)

Thank you for your participation in the environmental review process.

Sincerely,

GROUP 70INTERNATIONAL, INC.

Subject: Comments on Hawaii Dairy Farm Draft EIS

Aloha,

I am very concerned about the proposed dairy at Maha‘ulepu. I have lived in Lawai for the past 14 years and a 27 year resident of Kauai. I plan to spend the rest of my life on Kauai.

I have some areas of concern that should be included in the Draft EIS:

- I am interested in being a consulted party for the draft EIS clear.
- I am writing today to advocate for a thorough examination of waste management.
- I am writing today to advocate for a thorough examination of air and water quality protection.
- I am writing today to advocate for a thorough examination of herd growth triggers, cultural impacts, alternative actions (including alternative site selection), binding mitigation measures and alternative agricultural uses.

From the base of Mount Hanalei down to the beach, there exist many unmarked sites and burial grounds, as Hawaiians did not label grave sites. We do not know exact locations of many of these sites. I have to know that these sites will not be ruined. The EIS must include a thorough cultural resources study and provide measures to protect these resources.

The EIS must include an integrated pest management plan for fly control with intended biological, mechanical and potential pesticide measures.

There must be testing done to ensure against the drifting of effluent smells into Poipu/Koloa.

Because Maha‘ulepu is one of the last remaining open spaces on the south shore and is beloved by both residents and visitors it is important that binding mitigation measures are included in the EIS. An environmental remediation bond, monitoring regimes with guaranteed community involvement or even a “good neighbor agreement” are examples of mitigative measures that could be binding.

The EIS must include plans for site remediation for when the lease ends or HDF ends operations. How will HDF guarantee that Maha‘ulepu will be fully restored to its current condition? The operation includes buildings, holding ponds, gates and pens, raceways, piping, fencing, and other infrastructure. Will a remediation fund be set up to cover the cost of returning the site to its natural state?

Thank you for accepting my testimony.

Mary Lu Kelley
PO Box 289

as a “zero-discharge, grass-fed dairy”. The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. In January 2016, the U.S. Department of Agriculture (USDA) Marketing Survey created a narrow legal definition of “grass-fed”. The USDA standard defines what animals can and cannot be fed. The Food Alliance, a project of several northwest colleges, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture or a forage-based diet. Due to the evolving definition of “grass-fed”, the term in not used in this EIS.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 2 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Additional building information can be found in Draft EIS Section 3.3.1.

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Draft EIS Section 3.5, Pasture Management.

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass, and suitable sites to support sufficient “dry matter” grass yields essential to a cow’s diet. Additional project-specific trials at the Māhā‘ulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows spend 22 hours of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways are as a "zero-discharge, grass-fed dairy". The term “zero-discharge” under the U.S. Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to not discharge pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the cows’ manure on-site. However, nutrients would be introduced to the HDF site with any use; the Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Therefore, HDF elected to discontinue use of the term “zero discharge” as it was construed as no nutrients into the system.

The term “grass-fed” was used in the HDF EISPN. This term was used to identify HDF’s intent to utilize a locally-produced feedstock – grass – for more than 70 percent of the dairy herd’s diet. The gently sloped paddocks, walkways and races minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the mature dairy facility; surfaces of the walkways...
Management practices and pasture model applied by HDF maximize grass as the animals in various stages of lactation and rest will be transferred between HDF and healthier and live longer, productive lives with access to fresh air, high quality feed, and exercise while they forage.

Of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/mature dairy cow. For more information on off-site herd for cows or calves being moved on or off the farm. To protect the water quality of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of animal health, nutrition, and management. At HDF, all animal health care and any treatment is prescribed use of antibiotics approved by the Food & Drug Administration (FDA) for the treatment of illnesses. Adherence to guidelines for laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH. The majority of the pastures will be irrigated with non-potable water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Wai'a Reservoir and will be filtered and pumped to the various irrigation components on the farm. The irrigation system is controlled using computer software and GPS receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The US Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) has mapped and classified soils for more than 95 percent of the United States. Comments received during the initial scoping for this report were generated by the USDA NRCS website, which allows any Internet user to search an area. The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, and method of application of nutrient materials in order to ensure that the nutrients are utilized as a resource, and not being used for the constituents or components that provide benefit.

The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. Nutrient management is the practice of managing the amount, rate, and method of application of nutrient materials in order to ensure that the nutrients are utilized as a resource, and not being used for the constituents or components that provide benefit. The NRSR provides technical guidance on applying agricultural waste depending on the water quality standards, related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan Document in December, 2013. The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) was established by Congress in 1934, as a part of the Farm Service Agency (FSA) to provide technical assistance and financial assistance to farmers and ranchers to help them conserve the nation's natural resources. The NRCS provides technical guidance on applying agricultural waste depending on the water quality standards, related to drainage, materials, operations and applicable engineering standards. HDF will follow the developed Conservation Plan Document in December, 2013. The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) was established by Congress in 1934, as a part of the Farm Service Agency (FSA) to provide technical assistance and financial assistance to farmers and ranchers to help them conserve the nation's natural resources.
The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kalihi Clay at 32 percent, Kaena Clay Brown Variant at 29 percent, and Lualualei Clay at roughly 14 percent of the dairy site. Laboratory analysis of soil samples collected in 2014 identified levels of pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

The historical and existing land uses of the project site and surrounding Māhāulepū Valley were examined in the Draft Environmental Impact Statement (EIS), and uses proposed by the Hawai‘i Dairy Farms (HDF) project were evaluated in the context of county and state land use designations for the area. The evaluation of land use is presented in Draft EIS Chapter 4.4, and the project’s consistency with government plans and policies is presented in Draft EIS Chapter 5.0.

The south shore of Kaua‘i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils (with “A” representing the class of highest productivity soils and “E” representing the lowest). The large tracts of farmland, including those of Māhāulepū Farm and Grove Farm, allow for stability in support of farm ventures, help maintain regional water systems and provide agricultural employment for Kaua‘i residents in addition to fresh, local food.

The project site is on agricultural land in Māhāulepū Valley, an area with a long history of agricultural use as it was the first place in the island chain where sugarcane was commercially grown. The site is in the Agricultural District per State Land Use District designations, and per the County of Kaua‘i zoning ordinance. The site consists of land classified as Prime per the State Department of Agriculture’s Agricultural Lands of Importance to the State of Hawai‘i (ALISH). The HDF site is outside of the County-designated Special Management Area under the Coastal Zone Management Program.

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency, and assure the availability of agriculturally suitable lands. The designation process determines land meet physical requirements including contiguity, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high quality soil agricultural productivity ratings under the Land Study Bureau of University of Hawai‘i.

In 2011, Māhāulepū Farm LLC filed a petition with the State of Hawai‘i Land Use Commission to designate 1.533 acres of agricultural lands in Māhāulepū (including 557 acres that make up the HDF site) as IAL. IAL designation meets the objectives of the State HRS §205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. See Figure 4.4-2 in DEIS Section 4.4.

The designation process determined that the land meets a number of physical requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil to long pasture-growing season. Long-term soil impacts are anticipated to result in improvement to the physical, chemical, and biological condition of the soil.
The cultural assessment examined the potential effect of the project on cultural resources, practices, or beliefs. The potential to isolate cultural resources, practices, or beliefs which may alter the setting in which cultural resources, practices, or beliefs are found and is currently used for traditional cultural purposes. However, the dairy project, as proposed, does not affect the setting in which cultural resources, practices, or beliefs are found and is currently used for traditional cultural purposes.

No site has been found that has been used or modified by traditional cultural practices. The Hawaii State Cultural Heritage Act, 3-12-17-6, is a federal law which requires the review of cultural resources in federal projects. The cultural assessment examined the potential effect of the project on cultural resources, practices, or beliefs. The potential to isolate cultural resources, practices, or beliefs which may alter the setting in which cultural resources, practices, or beliefs are found and is currently used for traditional cultural purposes. However, the dairy project, as proposed, does not affect the setting in which cultural resources, practices, or beliefs are found and is currently used for traditional cultural purposes.

Agricultural productivity rating of “B” per criteria established by the Land Study Bureau of the University of Hawaii. The agricultural productivity rating of “B” per criteria established by the Land Study Bureau of the University of Hawaii.

Overall, the project provides long-term benefits as it supports diversified agriculture, food production, and agricultural self-sufficiency. HDF is a multi-criteria project that supports diversified agriculture, food production, and agricultural self-sufficiency. HDF is a multi-criteria project that supports diversified agriculture, food production, and agricultural self-sufficiency.

A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of native Hawaiian rights or any ethnicity-related group related to the land. A botanical survey of the dairy property was conducted in August 2014 by AECOS Consulting to assess existing plant species. The survey also investigated for the presence of native Hawaiian rights or any ethnicity-related group related to the land.

Avian and mammalian surveys were conducted in August 2014 by Rama Biological Consulting, Inc. to assess the potential presence of avian or mammalian species currently listed as endangered, threatened, or proposed for listing under either Federal or the State endangered species lists. The survey covered the dairy site area and immediate vicinity. Four species of endangered waterbirds were recorded on the site and at the nearby Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). Essential ly, IPM disrupts reproduction with appropriate invertebrates and a bird (the cattle egret) were introduced between 1898 and 1950 in the vicinity of the dairy site. The cattle egret is a generalist predator of invertebrates, and its introduction to the area is believed to have had a negative impact on local invertebrate populations. As a result, the cattle egret has been targeted for removal as part of the IPM program at HDF.

The aquifer of highest value and use resides deep within the unweathered volcanic material. The aquitard material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. It is a measure of how easily water will move within the ground. The hydraulic conductivity of the aquifer that underlies Māhāʻulepū Valley and the HDF site ranges from 10.5 – 50 feet per day. The hydraulic conductivity of soils in the adjacent Kōloa-Poipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area.

The groundwater and surface water analysis for this Draft EIS examined whether the two waterbodies within Māhāʻulepū may be connected. Four studies were conducted to determine whether the shallow groundwater in the alluvium material might discharge into the lower aquifer confined in the unweathered volcanic material at depth, which is the source of potable water. The results demonstrate there is no hydrologic connection between the deep aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Section 4.16.1 of the Draft EIS provides further detail.

**Potable Water:** Once fully operational at the committed herd size of 699 mature dairy cows, the dairy will utilize 30,000 gallons per day (gpd), which is 0.03 million gallons per day (MGD), of potable (drinking water quality) water from groundwater provided through an on-site well. The State of Hawai‘i Department of Health Milk Rules require that potable water be used for milk production, both in the milking parlor and for milking operations; another potable water use will be for livestock drinking water. Should HDF decide, in the future, to expand to the contemplated herd size of up to 2,000 mature dairy cows, potable water demand will increase to 84,000 gpd (0.085 MGD). These demands are a small fraction of the 3 MGD produced by the on-site, existing Māhāʻulepū 14 well during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Long-term groundwater supply impacts are not anticipated to be significant.

The assessment concludes that the modest potable water demand from the dairy operation, and the 4,500-foot distance between the Māhāʻulepū 14 well and the County’s Kōloa F well, will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer, which is the source of potable water. Groundwater in the alluvium will not impact the County drinking water well.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow groundwater in the Māhāʻulepū Valley, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Additional setbacks to protect water resources are included in the Surface Water section.
Surface Water Quality: The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. The group reported high levels of enterococcus to the State Department of Health (DOH) and provided its data, however, DOH was unable to utilize the data as it did not meet Clean Water Branch (CWB) quality assurance/quality control requirements, and it could not be used for regulatory purposes. CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā‘ulepū Surface Water Hydrologic Unit as the remote areas are on private lands.

Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā‘ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I. The Sanitary Survey found no significant impact to the ditch from any activity that could be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā‘ulepū Valley. The dene canopy along the makai end of Waiopili ditch blocks ultraviolet rays, which could help reduce bacteria levels. CWB noted that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The Sanitary Survey can be accessed on the DOH Clean Water Branch website under “Library” (http://health.hawaii.gov/cwb).

Long-term Operations, Setbacks and Buffers: Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. HDF operations are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

HDF operations will follow the practice standards of the Natural Resources Conservation Service (NRCS). These practices include setbacks to reduce runoff that could carry particles into surface waters. Fences will be erected 35-feet from the top of drainageway (totaling 70-feet in width) to keep cows away from surface waters. Vegetated buffers will be established between the fences and drainageways to create filter strips that could capture particulates during stormwater runoff events. Another setback restricts application of effluent within 50 feet of the drainageways; only irrigation water will be used in these areas as needed to maintain the vegetated buffer and pasture grass, keeping nutrient applications away from waterways.

Nutrients from Effluent Irrigation and Commercial Fertilizer Application: The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 mature dairy cows, and supplemental commercial fertilizer will be required. Nutrients required to sustain the 470 acres of pasture are the same for the future contemplated herd size of up to 2,000 mature dairy cows, though the proportion of nutrients supplied as natural fertilizer (manure and effluent) and commercial fertilizer changes. With the potential future contemplated herd size, supplemental nitrogen will be needed, and a small excess of phosphorus could occur. However, with an increase in dry matter (DM) yield (a measure of grass growth) of one ton per acre, phosphorus would be in a deficit and require commercial supplementation. Grass yields are anticipated to increase more than three tons DM per acre with dairy establishment, from the current 162 tons DM per acre to 20 tons DM per acre. Section 4.23 of the EIS provides additional information.

The groundwater and surface water analysis conducted for the Environmental Impact Statement estimated that surface water from Māhā‘ulepū will carry three times more nutrients than groundwater, due to the poor permeability of the alluvium. Groundwater can discharge from the alluvium when it rises in wetter periods and intersects the deep drainage ditches. Such discharge to the channels could occur on an episodic, seasonal basis when rainfall exceeds 0.8 inches.

The groundwater engineer estimated potential nutrient pass-through to groundwater from the HDF nutrient budget at two percent of nitrogen (totaling 10,000 pounds per year), and one percent of phosphorus (totaling 900 pounds per year). Again, this nutrient run-off would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall over 0.8 inches. Such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually. Per best practices, no effluent application would be conducted during such weather events.

To provide perspective, nutrient inputs from the adjacent Kōloa-Po‘ipū region were also calculated. Nitrogen input to the marine environment in the Po‘ipū region is calculated to be 38,510 pounds annually, or 3.5 times greater than the estimated potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po‘ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

Impacts to the Nearshore Marine Environment: An assessment of groundwater and surface water interaction with the marine water downdraft from the dairy site was conducted by Marine Research Consultants, Inc. (MRCI). Surface water from the Waiopili Ditch provides the majority of freshwater input in the immediate coastal area. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively dispenses inputs within several meters from shore. Comparing nutrient constituents in surface water samples taken from the HDF site and the agricultural ditches down gradient to nutrients sampled in the nearshore ocean
water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline. Baseline water quality data and the ongoing testing program will provide feedback to the dairy management team to help ensure that nutrients and bacteriological constituents are not being released at levels of environmental concern. Data from the nearshore water monitoring system, and published rates for manure odors emissions for dairy heifers and effluent ponds were adapted to reflect the HDF facilities.

Clean Air Act

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollution. The National Ambient Air Quality Standards (NAAQS) for six criteria pollutants are established to ensure public health and welfare. Air quality conditions, and project impacts were evaluated, including dust and odor, under the Draft Environmental Impact Statement (EIS) for the HDF project. The ongoing testing program will provide feedback to the dairy management team to help ensure that emissions are kept below the threshold of perception, which is defined by the point at which 50 percent of the panelists can detect the odor. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of the panelists can detect the odor. Results for the committed herd size of 699 mature dairy cows show that odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year. The parameters used in the analysis were applied. Odor isopleths (a line used to map all points having the same numerical value) were created to display the model findings. Odor is described in “odor units” at the threshold of perception, which is defined by the point at which 50 percent of the panelists can detect the odor. intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown. It is likely odor detection beyond the HDF boundaries will be less frequent.

**ALTERNATIVES:** As a part of the DEIS, alternatives were evaluated that could attain the objectives of the action’s purpose and need, and were compared with environmental benefits, costs, and risks of each reasonable alternative against those of the proposed dairy project. Further discussion of alternatives can be found in DEIS Section 6.

The DEIS evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai’i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four possible land uses that would not meet the project purpose are discussed. Rezoning the land for resort or residential development, or a potential conservation condemnation are two uses that were examined and eliminated from analysis. These options would not be reasonably viable given the existing private land tenure and existing zoning. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.

The alternatives analysis provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4).

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai‘i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).
- None of the alternatives would secure a dairy location that meets the requirements for a pastoral, pasture-based grazing dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).
- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).
- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities, (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.
- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai‘i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai‘i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai‘i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).
- The planned dairy location meets the requirements of minimum land area, soil properties, slope condition, water supply, land tenure and availability, and accessibility (Criterion 1).
- The planned action will generate new long-term employment in the agricultural sector on Kaua‘i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).
• Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long-term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
• Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
• Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

This response letter accompanies your copy of the Draft Environmental Impact Statement (EIS). The Draft EIS is available on the OEQC website at the following URL, search “Hawai‘i Dairy Farms”: http://tinyurl.com/OEQCKAUAI

Thank you for your participation in the environmental review process.

Sincerely,

Dear Ms. McIntyre,

We have followed the notices regarding the proposed industrial dairy in Meh‘ulepua Valley. Please accept these scoping comments of ours concerning Hawai‘i Dairy Farm’s (HDF) January, 2015 “Environmental Impact Statement Preparation Notice (EISPN). We apologise if our comments lack professional presentation or fail to cite scientific reports. We are local residents alarmed that such a project would even be proposed for Ko‘olau, much less the environmentally and culturally sensitive (and environmentally unsuitable) Mahahupu‘u Valley.

Mahahupu‘u is a traditional Hawaiian ahupua‘a running from the Ha‘upu mountain range to the shoreline on Koolauloa’s southeast shore. Natural and cultural resources in this area have been identified which hold significance for the native Hawaiian population. The area also provides significant recreational and enjoyment opportunities for the general population. Please make sure these are thoroughly identified and the probable detrimental impact evaluated in the EIS.

Subject: Hawai'i Dairy Farms
Environmental Impact Statement Preparation Notice
Māhā'ulepū Road
Kaua'i, Hawai'i

TMC: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001:001 portion

Dear Frank and Marilyn Kelly:

Thank you for your letter concerning the Environmental Impact Statement Preparation Notice.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai'i. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The following responses are offered to your comments:

**DAIRY OPERATIONS:** Hawai'i Dairy Farms (HDF) will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhā'ulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as natural fertilizer to grow pasture grass as a primary source of nutrition for dairy cows. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will comprise at least 70 percent of the animals' diet. As a part of the Draft Environmental Impact Statement (EIS), the proposed facilities and operations for the dairy farm are described in Chapter 3.

The Environmental Impact Statement (EIS) Preparation Notice (EISPON), published January 23, 2015, described the proposed pasture-based rotational grazing system as a "zero-discharge, grass-fed dairy." The term "zero-discharge" under the U.S.
Environmental Protection Agency related to concentrated feeding operations (CAFO) is a system designed to monitor and control the discharge of pollutants into waters of the United States. As noted previously, the HDF system is designed to utilize 100 percent of the dairy facilities' waste products to increase net carbon storage, and improve and maintain water quality. The term "grass-fed" was used in the HDF EIS. This term is used to identify the dairy farms' primary food source, method of application, and timing of plant nutrients and soil amendments. A project of several northwest colleges, the Grass Fed Alliance, believes that when consumers choose grass-fed products there is an expectation that these will come from animals raised on pasture on a forage-based diet. Due to the evolving definition of "grass-fed," the term is not used in this EIS. The NRCS Conservation Practice Standard 590, Nutrient Management, applies to commercial fertilizers, organic manures, water, water quality, and nutrient balance. The Washington State University Cooperative Extension Service will provide technical guidance on applying agricultural waste depending on the desired use of the waste. Reflecting in the title of the livestock waste guidance for cattle is the practical application of the waste. The NWCA provides technical guidance on applying agricultural waste depending on the desired use of the waste. The Draft EIS identifies the amount of nutrients anticipated from the proposed dairy operations that could pass through to ground and surface waters. Smaller paddocks located near the dairy facility will be used as temporary pasture for cows or calves being moved on or off the farm. To protect the water quality and reduce nutrient leaching, temporary pastures are located near and away from permanent water bodies. The irrigation system is controlled using computer software and GPS receivers to allow pivots to rotate and apply irrigation water and/or diluted effluent at different rates depending on the actual irrigation needs of the farm. The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area is the area where the additional buildings will be constructed, and the buildings will be constructed using different functions, including additional buildings. The committed herd size of 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. Results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet. The ponds are designed to provide a comfortable path under hoof. The gentle sloped paddocks, walkways, and cow races are designed to provide a comfortable path under hoof. The committed herd size of 2,000 mature dairy cows, and over 85 days of storage for 699 mature dairy cows. Results have identified sufficient yield and nutrition to supply 70 percent of the cows' diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows' diet.
Animals in various stages of lactation and rest will be transferred between HDF and the user would like to display. These user-generated reports are not evaluated by other partner ranches as needed for animal health and dairy productivity. This will be handled by the NRCS.

The NRCS soils classifications and descriptions provide a good information base, however, in-field soils testing is needed to identify existing soil nutrient levels and conditions. The most abundant soil types at the HDF site are Kahili Clay at 32 percent, Haina Clay at 29 percent, and Kahili Clay at 14 percent. Laboratory analysis of soil samples collected in 2014 identified organic matter, salinity, micronutrients, and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for agriculture and rely on the ability of water to enter the soil surface, whereas "drainage" refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

Laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will implement a sampling plan that ensures the safety of milk and minimizes the risk of contamination. The dairy's focus on robust and healthy grass growth will build organic matter in the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbon in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide.

The dairy’s focus on robust and healthy grass growth will build organic matter in the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbon in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide. With low risk, phosphorus can be applied at rates greater than crop requirements if the potential soil organic matter and carbon dioxide sequestration benefits are likely greater in highly degraded soils in warm subtropical climates, partly due to low temperatures and high rainfall.
exercise of native Hawaiian rights or any ethnic group related to numerous
cultural practices will not be impacted by establishment of the dairy.

DEMOGRAPHIC AND ECONOMIC: The potential impacts of Hawai'i Dairy Farms
(HDF) to the existing economy were evaluated in the Draft Environmental Impact
Statement (EIS), including a fiscal impact assessment report completed in April,
2016 by Plasch Economics Pacific. Draft EIS Section 4.15 addresses demographic
and economic factors, with the complete report in Appendix J.

The HDF project would create short-term benefits through jobs for local
construction personnel and local material suppliers. Such jobs would include
equipment operators, cement workers to lay foundations, metal workers,
carpenters, plumbers, electricians, monitors, supervisors, painters, etc. Based on State
employment multipliers, indirect employment related to Dairy construction would
be expected to average about 12 jobs per year during the
development period. This direct-plus-indirect employment association with construction
would be expected to average approximately 36 jobs, of which 28
would be on Kaua'i.

The HDF project would contribute to diversification of Kaua'i's economy, which is
heavily based on the visitor industry. With only two dairies remaining in the State
(both on the Hawaii Island), approximately 10 percent of Hawaii's milk is locally
supplied. The HDF project, with an established herd of up to 699 mature dairy cows,
will increase the supply of local fluid milk by approximately 1.2 million gallons of
milk annually, a 50 percent increase in statewide milk production. On-going dairy
operations at the committed herd size will provide approximately 15 direct and
indirect full-time equivalent jobs on Kaua'i, including 5 farm jobs and about 11
indirect jobs. An additional 6 indirect jobs related to on-going dairy operations
would be created on O'ahu.

HDF is expected to generate a net income of approximately $68,000 to the County
when the 699 cow herd is established. When the dairy has matured to full
production for the 699 cow dairy, net income to the State is calculated at $160,000
annually. With the potential contemplated herd size of up to 2,000 mature dairy
cows, approximately 4.4 million gallons (36,719,780 pounds) of milk would be
produced. This would double local milk production currently supplied by operational
