Director Scott Glenn
Office of Environmental Quality Control
Department of Health, State of Hawai‘i
235 S. Beretania Street, Room 702
Honolulu, Hawai‘i 96813

Subject: Hawai‘i Dairy Farms Draft EIS
TMK: (4) 2-9-003: 001 portion and 006 portion and (4) 2-9-001: 001 portion
Kōloa District, Kaua‘i

Dear Director Glenn:

On behalf of Hawai‘i Dairy Farms, Group 70 International hereby transmits the documents package for the Draft Environmental Impact Statement for publication of a notice of availability in the Environmental Notice. The Draft EIS has included copies of all written comments received during the early consultation period and during the 30-day public consultation period for the EISP.

Also enclosed is a distribution list for the verification of OEQC under Section 11-200-20, Hawai‘i Administrative Rules. Upon receiving verification from OEQC (along with the bulletin proof of the notice containing the pertinent details for commenters), we will make the Draft EIS and the bulletin proof available to those so indicated on the distribution list, so they will have the full 45-day statutory period to review and provide comment.

Finally, enclosed is a completed OEQC Publication Form, four copies of the draft EIS, an Adobe Acrobat PDF file of the same, and an electronic copy of the publication form in MS Word. Simultaneous with this letter, we have submitted the summary of the action in a text file by electronic mail to the OEQC.

If there are any questions, please contact me at (808) 523-5866.

Sincerely,
GROUP 70 INTERNATIONAL, INC.

Jeffrey H. Overton, AICP, LEED AP
Principal Planner

cc: Hawai‘i Dairy Farms

Environmental Planning Office
## Project Name:
Hawai‘i Dairy Farms

## Project Short Name:
(please use no more than five succinct words; count not to include document status, e.g., EA)

## HRS §343-5 Trigger(s):
To be determined

## Island(s):
Kaua‘i

## Judicial District(s):
Po‘ipu

## TMK(s):
(4) 2-9-003:001 (portion); 006 (portion); (4) 2-9-001:001 (portion)

## Permit(s)/Approval(s):
USDA NRCS Conservation Plan; DOH National Pollutant Discharge Elimination System Construction Stormwater General Permit; DOH Review of Animal Feeding Operation/Large Concentrated Animal Feeding Operation; DLNR Chapter 6E-42 Historic Preservation Review; County of Kaua‘i Building Permit

## Approving Agency:
State of Hawai‘i, Department of Health
Virginia Pressler, M.D., Director

### Status (select one)

#### DEA-AFNSI
Submit 1) the approving agency notice of determination/transmittal letter on agency letterhead, 2) this completed OEQC publication form as a Word file, 3) a hard copy of the DEA, and 4) a searchable PDF of the DEA; a 30-day comment period follows from the date of publication in the Notice.

#### FEA-FONSI
Submit 1) the approving agency notice of determination/transmittal letter on agency letterhead, 2) this completed OEQC publication form as a Word file, 3) a hard copy of the FEA, and 4) a searchable PDF of the FEA; no comment period follows from publication in the Notice.

#### FEA-EISPN
Submit 1) the approving agency notice of determination/transmittal letter on agency letterhead, 2) this completed OEQC publication form as a Word file, 3) a hard copy of the FEA, and 4) a searchable PDF of the FEA; a 30-day comment period follows from the date of publication in the Notice.

#### Act 172-12 EISPN
(“Direct to EIS”)
Submit 1) the approving agency notice of determination letter on agency letterhead and 2) this completed OEQC publication form as a Word file; no EA is required and a 30-day comment period follows from the date of publication in the Notice.

#### DEIS
Submit 1) a transmittal letter to the OEQC and to the approving agency, 2) this completed OEQC publication form as a Word file, 3) a hard copy of the DEIS, 4) a searchable PDF of the DEIS, and 5) a searchable PDF of the distribution list; a 45-day comment period follows from the date of publication in the Notice.

#### FEIS
Submit 1) a transmittal letter to the OEQC and to the approving agency, 2) this completed OEQC publication form as a Word file, 3) a hard copy of the FEIS, 4) a searchable PDF of the FEIS, and 5) a searchable PDF of the distribution list; no comment period follows from publication in the Notice.
The approving agency simultaneously transmits to both the OEQC and the applicant a letter of its determination of acceptance or nonacceptance (pursuant to Section 11-200-23, HAR) of the FEIS; no comment period ensues upon publication in the Notice.

The approving agency simultaneously transmits to both the OEQC and the applicant a notice that it did not make a timely determination on the acceptance or nonacceptance of the applicant's FEIS under Section 343-5(c), HRS, and therefore the applicant's FEIS is deemed accepted as a matter of law.

The approving agency simultaneously transmits its notice to both the applicant and the OEQC that it has reviewed (pursuant to Section 11-200-27, HAR) the previously accepted FEIS and determines that a supplemental EIS is or is not required; no EA is required and no comment period ensues upon publication in the Notice.

Identify the specific document(s) to withdraw and explain in the project summary section.

Contact the OEQC if your action is not one of the above items.

---

**Project Summary**

Provide a description of the proposed action and purpose and need in 200 words or less.

HDF will establish and operate a sustainable, rotational-grazing pasture system dairy farm on 557-acres in Māhā'ulepū Valley on the island of Kauaʻi to produce fresh, locally available nutritious milk for Hawaiʻi families. The rotational-grazing method utilizes 100 percent of the cows' manure as fertilizer for pasture grass to provide the primary source of nutrients. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will provide a local food source appropriate for cow health and quality milk production, and will comprise at least 70 percent of the animals' diet. HDF has committed to establish a herd of up to 699 mature milking cows, producing approximately one million gallons of fresh milk annually. HDF may contemplate possible expansion of the herd up to 2,000 mature milking cows.
This environmental document is prepared pursuant to Hawai‘i Revised Statutes, Chapter 343, Environmental Impact Statement Law and Chapter 200 of Title 11, Administrative Rules, Department of Health, Environmental Impact Statement Rules.

MAY 2016
This environmental document is prepared pursuant to Hawai‘i Revised Statutes, Chapter 343, Environmental Impact Statement Law and Chapter 200 of Title 11, Administrative Rules, Department of Health, Environmental Impact Statement Rules.

## 1.0 PROJECT SUMMARY

1.1 Project Information Summary | 1-1 |
1.2 Proposed Project | 1-3 |
1.3 Environmental Review Under Chapter 343, Hawai‘i Revised Statutes | 1-12 |
1.4 Significant Beneficial and Adverse Impacts and Proposed Mitigation Measures | 1-13 |
1.4.1 Beneficial Impacts | 1-13 |
1.4.2 Adverse Impacts | 1-14 |
1.4.3 Proposed Mitigation Measures | 1-14 |
1.5 Unresolved Issues | 1-16 |
1.6 Summary of Compatibility with Land Use Policies and Plans | 1-16 |
1.7 Summary of Alternatives Considered to the Proposed Action | 1-17 |
1.7.1 No-Action Alternative | 1-17 |
1.7.2 Conventional Feedlot Dairy | 1-18 |
1.7.3 Pasture-Based Dairy and Off-Site Processing | 1-18 |
1.8 Listing of Required Government Permits and Approvals | 1-20 |

## 2.0 PURPOSE AND NEED OF THE PROPOSED PROJECT

2.1 Introduction and Background | 2-1 |
2.2 History of the Dairy Industry in Hawai‘i | 2-3 |
2.2.1 The Dairy Market in Hawai‘i | 2-3 |
2.2.2 Important Agricultural Lands | 2-5 |
2.3 Purpose and Need for the Hawai‘i Dairy Farms Project | 2-7 |
2.3.1 Project Purpose | 2-7 |
2.3.2 Project Need | 2-7 |
2.3.3 Project Objectives | 2-7 |
2.3.4 Evaluation Criteria | 2-8 |
2.4 Planned Dairy Development on Māhā‘ulepū Agricultural Lands | 2-8 |

## 3.0 DESCRIPTION OF THE PROPOSED ACTION

3.1 Site Description: History and Vision | 3-2 |
3.2 Conservation Practices | 3-6 |
3.3 Dairy Site Requirements and Layout | 3-7 |
3.3.1 Buildings | 3-9 |
3.3.2 Agricultural Infrastructure | 3-13 |
3.4 Herd Management | 3-18 |
4.0 ENVIRONMENTAL SETTING, POTENTIAL IMPACTS, AND MITIGATION MEASURES

PROJECT SUMMARY
1.0 PROJECT SUMMARY

1.1 Project Information Summary

1.2 Proposed Project

1.3 Environmental Review Under Chapter 343, Hawai‘i Revised Statutes

1.4 Significant Beneficial and Adverse Impacts & Proposed Mitigation Measures

1.5 Unresolved Issues

1.6 Summary of Compatibility with Land Use Policies and Plans

1.7 Summary of Alternatives Considered to the Proposed Action

1.8 Listing of Required Government Permits and Approvals

Section 1.0 provides an overview of the contents and purpose of this Environmental Impact Statement (EIS). This section includes a summary description of Hawai‘i Dairy Farms or "Proposed Project", applicable environmental statutes and rules, and the potential impacts, proposed mitigation measures, and alternatives to the Proposed Project. The consistency of the Proposed Project with government land use policies and plans is summarized, along with a discussion of unresolved issues and a listing of required approvals.

1.1 PROJECT INFORMATION SUMMARY

Type of Report: Environmental Impact Statement
Project Name: Hawai‘i Dairy Farms
Applicant: Hawai‘i Dairy Farms, LLC
P.O. Box 1690
Kōloa, Hawai‘i 96756-1690

Planning Consultant: Group 70 International, Inc.
925 Bethel Street, Fifth Floor
Honolulu, Hawai‘i 96813
Jeffrey Overton, AICP, Principal Planner
Telephone: 808-523-5866
Email: HDF@Group70int.com

Approving Agency: State of Hawai‘i Department of Health
Contact: Laura McIntyre, Environmental Planning Office
Telephone: 808-586-4337
Email: Laura.McIntyre@doh.hawaii.gov
Project Location: Māhā'ulepū Valley
Kaua‘i, Hawai‘i (Figure 1-1)

Tax Map Key: (4) 2-9-003: 001 portion and 006 portion
(4) 2-9-001: 001 portion (Figure 1-2)

Land Owner: Mahaulepu Farm, LLC
3-1850 Kaumuali‘i Highway
Līhu‘e, Hawai‘i 96766

Project Area: 557 acres

Kaua‘i County Zoning: Agriculture

State Land Use District: Agricultural District

Existing Uses: Vacant fallow agricultural land, former sugar plantation

Proposed Use & Components: Agriculture (Dairy) use for dairy buildings, roads, sheds and
ponds, paddocks, cow races, farm roads, irrigation system,
water storage, drainage ways, setbacks/vegetated buffers.

County of Kaua‘i General Plan: Kōloa-Po‘ipū-Kalāheo Planning District

Special Management Area: No

Flood Zone Designation: Zone X

Required Reviews/Permits: County of Kaua‘i
  • Building Permit

State of Hawai‘i
  Department of Land and Natural Resources
  State Historic Preservation Division
  • Hawai‘i Revised Statutes Chapter 6E
    - Historic Preservation Review

  • NPDES Concentrated Animal Feeding Operation
  • Individual Wastewater Permit

  Department of Health, Sanitation Branch
  • Milk Producer Permit
1.2 PROPOSED PROJECT

This section summarizes the project purpose, objectives, evaluation criteria, and project overview. A summary description is provided for the dairy site requirements, buildings and support facilities, utilities, and agricultural infrastructure. The operations of the dairy are summarized for herd management, pasture management, irrigation and nutrient balance, offsite milk processing, offsite herd management and the contemplated herd size.

Project Purpose. The project purpose is to establish a sustainable, pastoral rotational-grazing dairy farm that will increase current local milk production, bolster Hawai‘i’s declining dairy industry, and reduce reliance on imported milk from the mainland United States. The rotational-grazing dairy system utilizes 100 percent of all manure on-site as natural fertilizer to grow grass. This cost-effective method reduces imported fertilizer and feed, and minimizes potential impacts to the environment.

Objectives. Hawai‘i Dairy Farms set eight objectives to achieve to bolster local milk production in Hawai‘i:

1. Provide more than 1,000,000 gallons annually of fresh, nutritious milk for Hawai‘i families and revitalize the dairy industry in Hawai‘i.
2. Apply proven, sustainable pasture-based rotational grazing system and state-of-the-art technology to reduce reliance on costly imported fertilizer and feed.
3. Grow local, quality grass as a primary feedstock optimal for dairy cow nutrition and health, utilizing results of forage research conducted at five sites across four Hawaiian Islands.
4. Design facilities to provide animal comfort, including maximum time on pasture and minimal milking time.
5. Effectively integrate dairy operations within the island community setting.
6. Optimize dairy product shipping and marketing.
7. Provide local farming employment and build the agricultural economy.
8. Protect and enhance the area’s natural, cultural, social and economic environment through sound agricultural planning, preservation of open space and sensitive resources, and development of economic benefit.

Evaluation Criteria. Within the context of the Hawai‘i Dairy Farms Objectives, HDF has established primary evaluation criteria which must be satisfied for the project to be economically, socially and environmentally responsible. The four evaluation criteria include:

1. Secure sufficient contiguous land area under long-term lease with adequate water supply (including potable water to meet standards under milk rules), suitable soil properties, gentle slope conditions, and road accessibility.
2. Generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, livestock management, veterinary and animal husbandry, environmental resources management, milk/milk products processing and dairy business management.
3. Create a model for dairy operations utilizing Important Agricultural Lands (IAL), demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure to advance food self-sufficiency.
4. Utilize 100 percent of manure on site as nutrients to grow forage for dairy cows. Grow sufficient forage to provide 70 to 85 percent of feedstock required for the herd.
HAWAI'I DAIRY FARMS
Draft Environmental Impact Statement

Hawai'i Dairy Farms has been designed to meet the guiding objectives. The project represents a directed effort to establish a pasture-based dairy in Hawai'i that will lead to improving food security for Hawai'i. The model uses a pastoral rotational-grazing system on former sugarcane plantation lands. With the demonstrated success of Hawai'i Dairy Farms, the proponents will be able to continue and expand their community leadership and social investment within Hawai'i by adapting the grazing system to other locations in the state. These objectives and criteria are the guiding parameters that ultimately define the direction for Hawai'i Dairy Farms.

Overview of the Proposed Project. The project will reinvigorate the flagging dairy industry in Hawai'i and establish a financially and environmentally sustainable, pastoral rotational-grazing dairy to provide more than one-million gallons of fresh milk for Hawai'i's families. This section describes the proposed action within the agricultural context of the Māhāʻulepū site, and individual improvements composing the Hawai'i Dairy Farms project.

HDF leases agricultural land in Māhāʻulepū Valley on the south shore of Kaua'i (Figure 1-1 Project Location Map). The 557-acre site consists of portions of three parcels leased from Mahaulepu Farm LLC (Figure 1-2 Tax Map Key). The lease area was surveyed for a metes and bounds description, which modified the acreage from an originally estimated 578-acres to the surveyed 557-acres to allow for access around the perimeter, fencing setbacks, buffers from cultural sites above the farm, and for potential future expansion of the taro farm by the lease-holder.

HDF will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāʻulepū Valley on the island of Kaua'i to produce fresh, locally available nutritious milk for Hawai'i families. The rotational-grazing method utilizes 100 percent of the cows' manure as fertilizer for pasture grass to provide the primary source of nutrients. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will provide a local food source appropriate for cow health and quality milk production, and will comprise at least 70 percent of the animals’ diet.

HDF has committed to establish a herd of up to 699 mature milking cows. HDF may contemplate possible expansion of the herd up to 2,000 mature milking cows, following the proven success of the rotational-grazing system for local milk production and better understanding the potential carrying capacity of the pasture. While additional regulatory review and public input would be required at that time, this Environmental Impact Statement (EIS) documents the potential impacts from both herd sizes for comparative purposes and full disclosure. Differences in infrastructure or operations for the two herd sizes are noted, where applicable.

Hawai'i Dairy Farms has engaged with the NRCS resource conservationist to seek technical guidance, including consultation with a technical service provider (TSP). A Conservation Plan for the project, which includes a Comprehensive Nutrient Management Plan, was reviewed and accepted by West Kaua'i Soil and Water Conservation District on December 17, 2013.
Figure 1.2-1 Island Location Map
Figure 1.2-2 Project Area Map
Dairy Site Requirements. The 557-acre site consists of 547 acres for paddocks, vegetated buffers ("setbacks") along drainage ways, farm roads, and cow races. A land use summary of the dairy facilities area and pasture area is presented in Table 1-1, and described in Section 3.0.

The dairy facilities will occupy an area of approximately 10 acres on the western boundary of the site. The developed area “footprint” will be less than 0.1 percent of the total farm area. Four buildings will be constructed to serve different functions, supported by utilities and infrastructure. Utilities needed for the dairy facilities include a potable water distribution system from the private on-site well, one domestic individual wastewater system (IWS, a DOH-approved septic system) for the employee restroom, and utility-provided electrical power and communications.

Buildings and Support Facilities. A summary list of buildings and support facilities is provided herein, and described in detail in Section 3.0.

- **Milking Parlor.** The largest building at the dairy, approximately 256-feet long by 88.5-feet wide and 33-feet tall, including a covered loading area, 60-stall rotary milking area, holding pens, mechanical room and pump room, office space, veterinary space and storage, staff restroom and milk storage.
- **Implement Shed.** An implement shed will be used to store equipment, tools, and supplies, and to provide space for farm machinery. Sized at approximately 65-feet long by 26-feet wide by 15-feet tall, the implement shed will be an open bay steel structure on a concrete slab with a metal roof.
- **Calving Sheds.** Newborn calves are kept on the farm until they are approximately 90 days old, housed in sheds to provide for their welfare until they are ready to transition to pasture. The calf sheds are open-bay steel structures with metal roofs on concrete slabs. Each of the two sheds will be approximately 81-feet long by 26-feet wide, and 15-feet tall.
- **Holding Yard.** Cows waiting to enter the milking parlor will move through the holding area as a mob, designed to hold a mob of up to 330 cows at any one time. The yard is approximately 12,300 square feet (150-feet long by 82-feet wide) of concrete slab with surrounding curbs to contain manure captured while the cows await milking and return to pasture; half of the area will be covered with roofing.
- **Effluent Ponds.** Manure and urine will be washed from the holding yard frequently to provide a healthy environment for the cows. Washdown water will be collected and transferred to effluent pond through underground pipes. The collected effluent will be diluted and utilized as natural fertilizer to provide nutrients for pasture grass.
• **Access Road and Tanker Truck Turnaround.** The primary access to the dairy will be from the existing farm road central to the site, via a newly paved 20-foot wide road within the dairy facility. Milk tanker trucks will utilize the Access Road to load milk and to transport milk off-site.

**Utilities for Buildings and Support Facilities.** Utilities servicing the buildings and support facilities are summarized below, and described in detail in Section 3.0.

- **Electrical Power.** Electrical power will be provided through an overhead service connection to the Kaua‘i Island Utility Cooperative (KIUC) grid via existing overhead line. A new three-phase, 75-300 kVA transformer will be installed. Electrical lines will be extended to the dairy in a concrete-encased conduit routed underneath the access road. Additional 500 kW power will be supplied by photovoltaic (PV) panels mounted to structure roofs.

- **Potable Water.** Potable water will be sourced from the existing Māhā‘ulepū Well Battery located within the project site. Water storage tanks holding up to 80,000 gallons will be located adjacent to the milking parlor, and will distribute water into the milking parlor, buildings and paddocks via small booster pumps. Total demand will initially be approximately 30,000 gpd.

- **Domestic Wastewater.** The facilities will be serviced by an individual wastewater system (IWS) to treat wastewater on-site using DOH-approved system (e.g. septic tank). The system will be designed for a flow of 700 gpd, with a 1,500-gallon capacity.

- **Communications.** Telephone and internet service will be provided through an overhead service connection via drop pole to the same subgrade trench as the electrical power, in a separate duct conduit that feeds into a 2-ft. by 4-ft. Hawaiian Telcom pull box.

- **Storm Water Drainage.** Gutters, curbs and swales will direct surface sheet flow. Metal roofing material on dairy buildings will be sloped to adequately sized gutters and downspouts. Roof run-off will be discharged directly to landscaped areas surrounding the buildings. Run-off from areas with the potential for manure will be routed to the effluent storage ponds.

**Agricultural Infrastructure and Utilities.** Agricultural infrastructure and utilities for the dairy operations include storage tanks and silos, effluent storage ponds, irrigation and livestock water systems.

- **Storage Tanks and Silos.** The dairy farm will have milk storage tanks, potable water tanks, gasoline and diesel fuel tanks.

- **Livestock Water Distribution System.** Potable water will come from Māhā‘ulepū Well 14 and be stored in two tanks totaling 80,000 gal capacity. Small diameter water mains will deliver water to raised concrete troughs in each paddock, fitted with valves that allow water flow.

- **Effluent Storage Ponds.** Collection and storage of effluent allows the dairy manager to control the schedule, timing, and mix of nutrients to be applied, as presented in detail in Chapter 3. Sizing of the storage facility allows flexibility in scheduling land application when weather and field conditions are suitable. Design guidance for effluent storage requires sizing of the pond to contain all wastewater, manure, clean water, solids accumulation, net surface rainfall including runoff, and the direct precipitation sized for a 25-year, 24-hour rainfall event. In consideration of the contemplated possible expansion of the herd, the ponds for HDF will be sized to accommodate the potential maximum effluent generated by up to 2,000 milking cows. For the committed herd size of 699 milking cows, the ponds would have excess capacity and minimum storage of 394,956 gal (30-day storage). As a safeguard, the HDF ponds will be sited within a secondary containment area, which provides greater backup containment capacity than called for under the regulatory requirements.
Irrigation for Nutrient Utilization. The utilization of nutrient-laden water in the storage pond will be accomplished through irrigation applications, planned once every four days. The irrigation schedule will be adjusted depending on field conditions. Liquid effluent will be mixed with non-potable water from the Waïta Reservoir, and applied to pastures through a GPS-controlled pivot irrigation system. Slurry created by mixing the solids with non-potable water will be applied through a mobile hard-hose reel dispensed through a gun nozzle, referred to as a gun irrigation system.

Herd Management. The pasture-based model allows cows to move about freely, and to lie down and rest, which is part of the digestion cycle. The animals are managed in social groups known as “mobs”, mimicking the natural social order of bovines. Cows will spend 22 of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks, walkways and races minimize the energy expended by the milking cows as they graze or are transferred to and from the various paddocks and the milking facility; surfaces of the walkways and cow races are designed to provide a comfortable path under hoof. The management practices and pasture model applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows tend to be healthier and live longer productive lives with access to fresh air, high quality feed, and exercise while they forage (NRCS, 2007). Following twice-daily milking in the barn, the cows are returned to paddocks. Offsite herd management by Kaua‘i ranchers, which involves raising calves and resting cows, is addressed in Section 3.7.

Pasture Management. The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass. Additional project-specific trials at the Māhāʻulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.

Paddocks. The 478.5 acres of pasture will be divided into 122 paddocks ranging from 3 to 5 acres in size. Smaller paddocks are located near the dairy facility and will be used as temporary pasture for cows or calves being moved on or off the farm.

Setbacks. To protect water quality of surface water and downstream areas, paddock fences are set 35-feet back from the top bank of drainage ways. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

Fencing. A permanent perimeter fence will be constructed steel t-posts installed every 10 feet, and a wooden post placed every 50 feet. The fence will include 42-inch woven wire topped with a strand of straight wire at 48-inch height, with a strand of barbed wire at ground level to deter feral pigs. Within the perimeter fence, paddock fencing will consist of two or three strands of electric wire mounted on wooden posts.
• **Forage Productivity.** Kikuyu and Guinea grasses brought in as cattle forage decades ago will be sown to transform the former sugar cane fields into pasture. As the cows excrete on the Kikuyu thatch, nutrients are incorporated into what is effectively an organic net. Due to the high moisture and moderate temperatures, the microbial activity in the thatch is very high and the excreted manure and effluent will be largely broken down by microbial activity within 24 hours. Microbes such as bacteria, protists, and fungi will break down the manure and effluent through decomposition into its nutrient components to make these readily available for uptake into the grass crop and plant matter. Even with the applied manure and effluent nutrients, the grass will need additional nutrient application with conventional fertilizers to maintain optimum grass growth and yield goals at 699 mature dairy cows.

**Irrigation and Nutrient Balance.** Irrigation is the primary method of applying natural fertilizer from the effluent ponds. This section discusses irrigation methods, setbacks, and determination of nutrient application rates.

• **Irrigation.** The total pasture area of the farm is 470 acres. The majority of the pastures will be irrigated with irrigation water and/or diluted effluent through the pivot irrigation systems, with the remainder through gun irrigators. Irrigation water supply is provided to the farm from Waia Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The pivot irrigation system utilizes two central pivots that feed water to an overhead, rotating sprayer supported by trusses mounted on wheeled towers that rotate in a 1,000-foot diameter. Nozzles are suspended approximately four feet from the ground to guide water directly onto the pasture grass. Gun irrigators will be used for areas not covered by the pivots. The gun irrigators utilize a hard-hose reel, which can be moved throughout the farm as needed. The pivot system uses GPS tracking and automation to ensure the ditches and buffer zones do not receive irrigation water.

• **Nutrient Balance.** Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The NRCS Conservation Practice Standard 590 Nutrient Management applies to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. The timing and application of nutrients should correspond as closely as practical with plant uptake, soil properties and weather conditions. The results from soil testing, manure testing, and forage testing will be utilized to update and inform the nutrient management process for HDF. Application of agricultural waste can be beneficial to soils by improving organic matter, increasing infiltration of water, and improving the soils’ ability to support pasture growth and root establishment.

Nutrient mass balance is described in detail within EIS Section 3 and Appendix D. A concise tabulation of the nutrient mass balance for the committed herd size (up to 699 mature dairy cows) and contemplated herd size (up to 2,000 mature dairy cows) are shown in the tables below.

Off-site Milk Processing. Under the proposed action, milk processing is currently planned via an off-take sale agreement with a milk processor (e.g. HDF sells raw milk wholesale to processor and bottler). Pasteurization must occur on Kaua‘i prior to shipping the fluid milk to O‘ahu for processing to retain product freshness. Milk processing includes pasteurization, bottling and packaging of milk, and possibly other dairy products such as yogurts and cheese. Another potential option for offsite milk products processing would be for Hawai‘i Dairy Farms to process and package the raw milk and possibly create additional dairy products, such as yogurt and cheese. The final products would be sold on Kaua‘i and elsewhere statewide. The offsite processing element of the proposed action would significantly reduce the overall time for milk and milk products to get from farm to table, and would maximize Kaua‘i-based agricultural industry employment. The processing facilities would contain a process unit office, refrigeration units, bulk product storage, bulk product transfers to containers, finished product packaging, and trans-shipment staging and loading.
Offsite Herd Management. Animals in various stages of development/maturity and rest will be transferred between HDF and other existing Kaua’i ranches as needed for animal health and dairy productivity. This will benefit both the dairy and infuse the beef market in Hawai’i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (young female calves that haven't given birth) will be raised until ready to return to the HDF herd as a birthing/milking cow.

Two ranches on Kaua’i will initially work with HDF. Makoa Ranch near Kapa’a is an active cattle ranch run by the Farias family. The ranch will care for dry cows during an annual resting period, and raise calves until ready for return to HDF pasture. Calves suitable as beef cattle will be incorporated into the Makoa Ranch herd or sold to other ranching operations. “Close-up cows” or those cows returning to milk production will initially be transferred to Omao Ranch for transition.

Annually, dairy cows are rested, or “dried” for 60 days before returning to milk production. The existing ranch operations are established and require no additional facilities, permits, or improvements to work with HDF. The fluctuation in herd numbers is typical of cattle operations and poses no impact to the Makoa or Omao Ranches or areas outside the project area. Only the 699 milking cows and calves less than 90 days old will reside on the farm.

Contemplated Herd Size. The committed Proposed Action calls for a herd size of up to 699 milking cows. The contemplated Proposed Action calls for a possible expanded herd up to 2,000 milking cows. The number of animals moving through the dairy facilities would increase under the contemplated herd size. The building design and agricultural infrastructure is capable of accommodating both herd sizes.

1.3 ENVIRONMENTAL REVIEW UNDER CHAPTER 343, HAWAI’I REVISED STATUTES

This Environmental Impact Statement was prepared in accordance with Hawai’i Administrative Rules Title 11 Chapter 200, implementing Hawai’i Revised Statutes (HRS) Chapter 343. An Environmental Impact Statement (EIS) is being prepared by the Applicant to analyze the potential environmental impacts and mitigation measures associated with agricultural operations at Hawai’i Dairy Farms (HDF) at Māhā’ulepū, Kaua’i.

The environmental review process for this project was initiated with the publication of the notice of availability of the Environmental Impact Statement Notice of Preparation (EISPN). The notice was issued by the State Office of Environmental Quality Control (OEQC) in the Environmental Notice issue of February 8, 2015, which underwent a 30-day review period from February 9 through March 11, 2015. All substantive comments received during the review period are addressed in the Draft EIS. Section 7 includes a list of consulted parties (agencies, organizations and individuals), with the comment letters and HDF responses presented in Appendix 3.

Upon its formal submittal and acceptance by the State of Hawai’i Department of Health for publication, the Draft Environmental Impact Statement (DEIS) will undergo a 45-day agency and public review. The substantive comments received during this review period will be addressed, and a written response provided and incorporated into the Final EIS prior to its filing.
1.4 SIGNIFICANT BENEFICIAL AND ADVERSE IMPACTS & PROPOSED MITIGATION MEASURES

Development of the planned improvements for Hawai‘i Dairy Farms will result in numerous beneficial impacts. The project will reinvigorate the flagging dairy industry in Hawai‘i and establish a financially and environmentally sustainable, pastoral rotational-grazing dairy to provide more than 1,000,000 gallons of fresh milk for Hawai‘i’s families. Local and state economic benefits will include construction-related jobs. In the long term, HDF will create a significant number of full-time positions in agricultural operations, along with support for local ranchers. As such, the significant impacts of the Hawai‘i Dairy Farms are anticipated to be largely beneficial, as discussed below. Mitigative measures are proposed to offset potential adverse impacts. Section 4.0 of the DEIS presents the environmental setting, potential impacts and mitigation measures.

1.4.1 BENEFICIAL IMPACTS

Implementation of Hawai‘i Dairy Farms will provide many benefits for Kaua‘i and Hawai‘i including local milk production, food sustainability, agricultural employment, community benefit investments and youth education. A summary of these beneficial impacts is listed below.

- **Increased Local Milk Production.** Doubling of statewide local milk production to provide more than 1,000,000 gallons of fresh milk for Hawai‘i’s families. The contemplated herd size has the potential to produce over 3,000,000 gallons of fresh milk per year, and provide statewide distribution of more local milk.
- **New Long-Term Agricultural Employment.** Creation of up to 28 operational jobs, as well as construction jobs and local supplier opportunities in support of agriculture on Kaua‘i.
- **Support for Agriculture on Kaua‘i.** Hawai‘i Dairy Farms will provide the first large-scale commercial use of Important Agricultural Lands on Kaua‘i. The dairy will create a $17.5 million investment in local food production without any government subsidies. Significant opportunities for local ranchers will be created for dairy herd management support.
- **Increased Soil Conservation.** Pasture creation and management with Hawai‘i Dairy Farms will stabilize and protect soils across nearly 500 acres at Māhāulepū, reducing soil erosion and suspended sediment runoff to drainage ways and the nearshore ocean waters. In addition, the pasture based system will improve and revitalize the current soils and farming productivity of the land.
- **Investments in Community Benefits and Youth Education.** Hawai‘i Dairy Farms will provide community benefit investments in related causes through donations. HDF will work with the 4-H and FFA to educate keiki about STEM-based agricultural jobs and animal husbandry.
- **Increased Net Revenues to County and State Governments.** Hawai‘i Dairy Farms will create $6 million to $9 million in annual operating expenditures to help support Kaua‘i’s economy, providing net revenues to County and State governments.
1.4.2 PROBABLE ADVERSE IMPACTS

Implementation of Hawai‘i Dairy Farms will produce potential short-term and long-term impacts. General categories of actions for the dairy establishment and operational actions include:

- Establishment of 470 acres of grazing pasture, paddocks, fencing and farm roads
- Construction of dairy facilities buildings and support infrastructure on less than 10 acres
- Implementation of dairy operations with a committed herd size of 699 mature milking cows
- Potential implementation of a contemplated herd size of up to 2,000 mature milking cows

To complete the improvements required to establish the dairy facilities and paddocks, there will be localized short-term construction-related impacts on the environment. Potential short-term impacts due to construction-related activities evaluated in the EIS include soil disturbance, dust and soil erosion, limited excavation and grading, fauna disruption, and traffic in the project vicinity due to construction equipment and trucks, and increased noise due to construction-related operations. Potential drainage and runoff related to construction are also evaluated.

Over the long term, impacts associated with the implementation of Hawai‘i Dairy Farms are anticipated to be modest and consistent with the agricultural setting in which the farm is located. Section 4.0 addresses the potential long-term effects of the dairy farm, in categories such as archaeological resources, cultural resources, soils, air quality, water quality, traffic, employment, government revenues, visual resources and infrastructure. The dairy farm will create both negative and beneficial long-term impacts in these categories, with mitigation measures to offset detrimental effects addressed in Section 1.4.3 and Chapter 4.0.

With the dairy in operation, during periodic seasonal storm water runoff events (about 10 times/yr) there may be additional nutrients introduced to the agricultural ditches, which ultimately drain to the nearshore ocean water. The findings of the water quality evaluations are presented in Sections 4.16, 4.17, 4.22 and 4.23. The complete studies are presented in Appendix E and Appendix F. There is also the potential for vector insects such as flies to become established at the dairy farm, controlled by Integrated Pest Management measures. The findings of the manure-related insect study are presented in Section 4.11, and the complete study is presented in Appendix B. Air quality in the immediate vicinity of the dairy farm (within 1,700 feet) may, in the worst-case conditions, be affected with odors from the effluent pond and manure in the pasture paddocks. The findings of the air quality odor model are presented in Sections 4.19 and 4.25, and the complete study is presented in Appendix I.

1.4.3 PROPOSED MITIGATION MEASURES

There are few potential long-term adverse impacts anticipated to result from the construction and implementation of Hawai‘i Dairy Farms. Relative to the agricultural, social, economic and employment benefits that are expected to result from the dairy operation, with application of the various mitigation measures described in the EIS, the potential adverse impacts are not considered significant. Potential short-term impacts due to construction activities will be limited to construction efforts such as earthwork, noise, visual and temporary air quality impacts related to dust and equipment emissions. Long-term impacts are expected to be modest and consistent with the agricultural environment in which the dairy farm is located. Potential short-term and long-term impacts, and mitigation measures are discussed in detail in Chapter 4.0 and summarized below.
Soil Erosion Mitigation. Short-term soils loss will be controlled by proper construction site management and best management practices. Pursuant to the NRCS Conservation Plan, long term soil losses will be minimized. Pasture creation and management with Hawai‘i Dairy Farms will stabilize and protect soils across nearly 500 acres at Māhā‘ulepū, reducing soil erosion and suspended sediment runoff to drainage ways and the nearshore ocean waters. Vegetated buffer zones and Best Management Practices will be employed to minimize soil erosion.

Water Quality Mitigation. To sustain pasture grasses, there will be nutrients added through the application of effluent pond water and commercial fertilizers, and some nutrients will pass through soils and enter the agricultural ditches. Nutrient loss will be minimized through vigorous pasture grass cover and thatch, and 35 ft wide vegetation buffers maintained along the agricultural ditches. Irrigation water will not be applied within 50 ft of the agricultural ditches. The vegetated buffers will also deter the movement of manure particles carried in runoff during peak storm events. These numerous mitigation actions by the dairy operations will minimize adverse effects to water quality and have minimal to no effects on nearshore marine water per Appendices F and K.

Archaeological and Cultural Resource Mitigation. An Archaeological Inventory Survey (AIS) was conducted for the project, and is being reviewed for approval by the State Historic Preservation Division (SHPD). Based on the findings of the AIS and SHPD review, there are no archaeological sites on site, only historic period agricultural features. As directed by SHPD, potential requirements for on-site archaeological monitoring of construction activities will be implemented.

Pest Insect (Flies) Mitigation. The potential for the dairy to generate new fly populations at the dairy facilities will be mitigated by diligent housekeeping to wash down active areas at the milking parlor and holding pens to minimize waste accumulation and fly populations. Best Management Practices and Integrated Pest Management measures will minimize fly populations. Introduction of dung beetles to the pasture paddocks will substantially hasten the breakdown of manure and minimize fly populations. With these mitigation measures, the dairy is not expected to increase the fly population affecting the surrounding offsite area.

Odor Mitigation. The potential for odors to be generated by the dairy facilities will be mitigated by diligent housekeeping to wash down active areas at the milking parlor and holding pens to minimize waste accumulation and subsequent odor generation. Management of the effluent ponds and effective operation of the irrigation system will further reduce the potential for odor generation. Introduction of dung beetles to the pasture paddocks will increase manure breakdown and minimize odor generation. With these mitigation measures, the dairy is not expected to generate adverse odors which would affect the surrounding offsite area.

Air Quality Mitigation. The impact of construction activity on air quality will be mitigated by conforming to dust control measures, particularly those specified in the State Department of Health’s (DOH) Ambient Air Quality Standards, Chapter 11-59, Hawai‘i Administrative Rules.

Noise Mitigation. Temporary but unavoidable noise impacts may occur during the construction activities within the area. The use of properly muffled construction equipment will help ameliorate these impacts. The incorporation of State DOH construction noise limits and curfew times, which are applicable throughout the State of Hawai‘i, is another noise mitigation measure which is normally applied to construction activities. Once construction is completed, there will be minor additional noise impacts resulting from some dairy equipment operations.
Traffic Mitigation. During the construction phase of the dairy, some inconvenience is anticipated, as the delivery of construction equipment, construction worker vehicles and materials will utilize area roadways to access the dairy site. Efforts will be made to minimize conflicts with traffic along the area roadways during construction activities. In coordination with State and County authorities, these activities will follow applicable rules and permits for transport, including routing and required additional safety escort vehicles. Traffic operations along the area roadways and intersections will not be significantly affected.

1.5 UNRESOLVED ISSUES

Below are identified issues that are being actively addressed, but which are currently unresolved.

Resolution of the Dairy Herd Size. Successful dairy farming involves the mastery of numerous elements, such as soil science, agronomy and animal husbandry. The final scaling of the milking cow herd size for the Hawai‘i Dairy Farms operations will ultimately be determined based on the results of pasture grass development at the Māhā‘ulepū site, and dairy cow milk production levels. HDF has committed to no more than 699 milking cows. Any expansion would depend on many factors that would be resolved in the future based on how the biomass and natural systems perform with 699 milking cows. Up to the committed herd size, this will be an iterative process of monitoring and testing to determine the best approaches to optimize dairy operations and foster good health in the natural systems.

It is anticipated that the HDF dairy herd can be increased well beyond 1,000 to 1,500 milking cows and be sustainable from an operational and environmental perspective. Expansion beyond the 699 milking cows level will require issuance of a CAFO/NPDES permit by the State Dept of Health. With careful monitoring of the operations and the natural systems, including the soils, pasture grasses and water quality, the dairy scaling can be accomplished with sensitivity to the various indicators of carrying capacity. The potential for HDF to reach the upper scale of 2,000 milking cows at the dairy may or may not ultimately occur, depending upon the operational sensitivities and the indicators shown by the carefully monitored natural systems.

Milk Products Processing. The scope of milk processing operations has yet to be resolved. The location for the milk processing activity has not been finalized. The opportunity to undertake value-added processing steps in milk products processing could also be conducted on-island. Completion of milk products processing on-island would create additional employment and government revenues for Kaua‘i, increase the availability of local milk products, and further bolster the local agricultural economy. If milk products processing is not undertaken on Kaua‘i, the pasteurized milk would be shipped in bulk to one of the existing processing facilities on O‘ahu or Hawai‘i Island for further process steps, packaging and marketing.

1.6 SUMMARY OF COMPATIBILITY WITH LAND USE POLICIES AND PLANS

The planned improvements and operations at Hawai‘i Dairy Farms are compatible with and supportive of State of Hawai‘i and County of Kaua‘i land use policies, plans and control related to the natural and social environment. The Proposed Project is consistent with and permitted by applicable land use designations and, as discussed in Section 5.0, will contribute a wide range of benefits to further established goals, objectives and policies. In particular, Hawai‘i Dairy Farms is consistent with the State and County initiatives for food sustainability and the long-term intended use of Important Agricultural Land on Kaua‘i. The dairy is also consistent with the provisions of the State of Hawai‘i Agricultural Functional Plan, and long-range planning for diversified agricultural use of Māhā‘ulepū lands under the County of Kaua‘i General Plan and the South Kaua‘i Community Development Plan.
1.7 SUMMARY OF ALTERNATIVES CONSIDERED TO THE PROPOSED ACTION

Hawai‘i Dairy Farms represents the current vision and intent to create a state of the art pasture-based, rotational grazing dairy. The Draft EIS evaluates alternatives that meet the project’s Purpose and Need, and considers changes to dairy operations and location. Alternatives to the Proposed Project are evaluated in Section 6.0. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200), requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. A range of potential alternative actions may be contemplated for the future, however, several alternatives which do not meet the project purpose are not advanced for detailed analysis of environmental benefits, costs, and risks. The options considered but not meeting the project purpose included: conservation condemnation, rezoning/development for urban/resort use, development of an agricultural subdivision, and a large scale agricultural park and truck crop processing center.

Those alternatives carried forward in the Alternatives Analysis for further evaluation are several alternatives to the Proposed Project which could attain the objectives of the action. EIS law calls for rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. The alternatives considered include the following:

1. The Alternative of “No Action”,
2. Conventional Feedlot Dairy Alternative,
3. Alternative Location for Pasture-Based Dairy, and
4. Milk Processing Alternative by HDF.

A summary description and evaluation is presented for each alternative in Section 1.7.1 to 1.7.4.

1.7.1 NO-ACTION ALTERNATIVE

The No-Action Alternative would continue future use of agricultural property without the establishment of the sustainable pasture-based dairy operations. With the Important Agricultural Lands designation, this land is expected to be used for either grazing or cultivation. Portions of the property would be available for cattle and sheep grazing, or other more intensive agricultural uses. The property would be available for beef cattle grazing with a herd size of several hundred animals to become re-established, potentially with the addition of sheep or other animals. Use of these lands for cattle or sheep grazing pasture could be re-established, with cattle and/or sheep grazing on the 557 acre pasture area. At the stocking rate of two to four animals per acre, common to Kaua‘i grazing lands, the total number of cattle and sheep grazing could potentially be 2,000 animals.

With a traditional grazing operation in the No-Action Alternative, no special provisions would be required for managing agricultural land use, cover crops and runoff. Soil loss and surface water quality impacts would be consistent with large animal grazing operations, as occurs commonly on large agricultural lands on Kaua‘i. With no site-specific operational controls, the grazing lease operations would be covered under the existing agricultural conservation plan applicable to the broad suite of agricultural uses on agricultural lands at Māhā‘ulepū. Surface water quality would be degraded through storm runoff of animal waste and suspended sediment.
There would be no new agricultural employment with this alternative. Further, this alternative does not meet the purpose and need of the proposed action, as it does not provide support for a unique underrepresented industry like dairy, which is overly imported in the state of Hawai‘i, and therefore was not subjected to further evaluation.

1.7.2 CONVENTIONAL FEEDLOT DAIRY ALTERNATIVE

The development and operation of a conventional feedlot dairy would potentially achieve the project purpose to increase local milk production. This alternative would utilize the conventional methods for a large-scale commercial dairy in which milking cows are confined in large all-weather barn facilities, without access to forage and without pastures. A total of either 699 or 2,000 dairy cows would be confined within several large barns. The dairy farm complex would occupy a land area of approximately 5.5 to 12.5 acres, with dairy facilities consisting of several large barns, milking parlor, storage buildings, feed storage and waste storage lagoons.

The requirement to supply imported feed would be significant, estimated at 8 to 10 tons per day for a mature milking cow herd of 699 cows, or 25 to 30 tons per day for up to 2,000 cows. All of this imported feed would need to be imported to Kaua‘i, and transported to the dairy. It is noted that history showed the decline of Hawai‘i’s dairy industry and eventual demise largely due to the escalating cost of feed imported from the mainland U.S.

There would be potential long-term impacts associated with operations of the conventional feedlot alternative. Due to the higher density of animals in the barn area and a limited pasture area, the conventional feedlot alternative has a higher concentration of manure and urine waste. The barn and milking parlor facilities would require additional potable water use for the regular wash down of the large barn areas to manage sanitary conditions. The concentration of animal waste would pose the potential for increased populations of pest insects, such as flies, occurring with the conventional feedlot alternative. In addition, there would be the potential for adverse odors to be generated by the conventional feedlot operations, due to the animal waste concentration in the barns, yards and large waste ponds. The conventional feedlot dairy would also have substantial impacts in terms of truck traffic, water use, waste disposal and energy use.

Although this alternative could potentially meet the purpose and need of the proposed action, it would also produce comparatively greater environmental impacts and public health risks than the proposed action. Section 6.0 presents an evaluation of this alternative, and a comparison of the proposed project with this alternative.

1.7.3 ALTERNATIVE LOCATION FOR THE PASTURE-BASED DAIRY

An alternative Kaua‘i location using a site other than Māhā‘ulepū would be considered under this alternative. The pasture-based dairy operation requires 500 to 600 acres of usable, gently-sloped land on agricultural zoned lands available for long-term lease. The micro-climate requires soil conditions favorable for nutrient absorption with access to a reasonably priced irrigation water source, to sustain nutritious grass pastures. Other required elements would include roadway access, potable water and irrigation water sources.
The high-level evaluation of 33,000 acres of Grove Farm holdings under the screening criteria as potential lands to locate a pasture-based dairy, as summarized below.

- Conservation District lands and Urban lands owned by Grove Farms could not be considered for the pasture-based dairy due to inappropriate zoning/land use compatibility.
- Long-term farming leases exist across major portions of the Grove Farm agricultural holdings, along with investments (e.g. crops, livestock, improvements and facilities).
- Inland mauka agricultural lands receive high annual rainfall and lower incident sunlight, with suboptimal pasture grass growing conditions.
- Agricultural lands mauka of Kuhio Highway and Kaumualii Highway generally have steep slopes, non-contiguous areas, and some rocky soils, all factors affecting animal stress.
- Irrigation water availability varies due to proximity to existing reservoirs and wells.
- Areas up-gradient of established County and private wells for drinking water supply.
- Unavailable or inadequate support infrastructure at mauka locations.

An alternative location for the pasture-based dairy was considered on approximately 972 acres of Grove Farm agricultural land at Puhi. The alternative location would potentially satisfy some of the evaluation criteria in terms of slopes, soils, micro-climate, water supply and support infrastructure. Under the comparative evaluation criteria for site screening identification, the alternative site would be less suitable than the Māhā’ulepū site due to land tenure, greater slopes, higher rainfall and less sunlight, with a perennial stream draining into a wildlife refuge.

Although this alternative could potentially meet the purpose and need of the proposed action, it would also produce comparatively greater environmental impacts than the proposed action. Section 6.0 presents an evaluation of this alternative, and a comparison of the proposed project with this alternative.

1.7.4 MILK PROCESSING ALTERNATIVE BY HDF

An alternative is for HDF to pasteurize raw milk on the island of Kaua‘i. The pasteurized milk could then be sold to a processor/bottler. Currently, Meadow Gold is the only processor/packager with operational facilities on both O‘ahu and Hawai‘i island. Any pasteurization or processing facility would be sited in an appropriately zoned industrial area with access to adequate electricity, municipal potable water and wastewater services, and with existing roadway infrastructure suitable for required truck transport. On the island of Kaua‘i, an opportunity exists to retrofit and utilize the closed processing facility in Puhi, though this alternative requires cooperation of the facility owner, Meadow Gold. Capital expenditure for the retrofit could be more than $1 million.

The processing alternative by HDF would have no significant environmental impacts. The processing facility would be sited on lands with appropriate zoning for milk processing and accessory uses without a need for obtaining additional special permits. Traffic associated with processing would add worker vehicle trips to the facility. Noise from worker vehicles and trucks would increase slightly due to the shipping. Vehicle emissions would also occur as a result of these shipments. The interisland transfers would occur as part of other freight components shipped on the existing regularly scheduled barge transits.

In-state milk production would increase agricultural revenues and jobs in Hawai‘i. With HDF processing, employment in the manufacturing industry would increase. Processing would generate substantial positive State and County revenues. The milk processing operation would require potable water from the County system. The processing operation would also generate wastewater discharged to the County sewer system. This alternative could potentially meet the purpose and need of the proposed action.
1.8 LISTING OF REQUIRED GOVERNMENT PERMITS AND APPROVALS

Table 1-3 identifies the major State and County land use permits and approvals that are anticipated to be required for the project, including site, building, construction and infrastructure approvals. Agricultural facilities and operations of HDF will require reviews and approvals from federal, state and county agencies and entities. Should HDF elect to expand the dairy beyond 699 milking cows, additional permitting is required.

2.0

PURPOSE AND NEED OF THE PROPOSED PROJECT
2.0 PURPOSE AND NEED OF THE PROPOSED PROJECT

2.1 INTRODUCTION AND BACKGROUND

Hawaii is an island state, with a total population of roughly 1.4 million people (U.S. Census Bureau, 2015). Roughly 70 percent of the state’s population is centered on the island of O‘ahu, with smaller populations on the neighbor islands of Hawaii, Maui, Moloka‘i, Lana‘i and Kaua‘i. Hawaii’s indigenous population cultivated rich agricultural lands for sustenance, using food stock brought aboard the sailing canoes with the original island settlers. Agricultural field systems were created inland, close to fresh water resources. Kalo (taro), a staple crop, was cultivated in both irrigated and dry fields. Other dry land agriculture crops included ‘uala (sweet potato), uhi (yams), mai‘a (bananas), ipu (gourds), and kō (sugar cane).

Following European contact, large tracts of land were used for monoculture crop production (notably sugarcane and pineapple). These plantation crops served as the islands’ major economic industry for over a century. Large-scale plantation farms were phased out by the late 1900s, as land and labor costs drove sugar and pineapple production to countries with lower production costs. Agricultural lands of the plantation era have largely remained fallow, with some areas converted to cultivation of a wide range of diversified agriculture products.

The majority of goods used in the state, including the daily food requirements of its residents, arrive via ocean and air shipping. Roughly 90 percent of all food products consumed in Hawaii are imported, and the current population size makes food importation an increasingly practical necessity. Today’s insulated and refrigerated ocean freight containers allow perishable goods, such as fresh produce, milk and milk products, to sustain the seven- to ten-day transit time for import from the mainland United States (U.S.) or abroad. With optimized just-in-time delivery schedules for big box retail and grocery businesses, there is limited food supply in storage. It is estimated that the on-island food storage represents less than a two-week supply. This fact highlights Hawaii’s vulnerability and its dependency on imported food. Whether a natural disaster such as a hurricane or labor dispute affects shipping, or geopolitical events such as 9-11, the islands are in jeopardy of a serious disruption to the food supply.
The State of Hawai‘i Office of Planning, in cooperation with the Department of Agriculture, issued a report in October 2012 entitled: 

**Increased Food Security and Food Self-Sufficiency Strategy.** The report sets forth policies and action to increase the amount of locally grown food consumed by Hawai‘i residents. Today, with cooperation by private landowners, actions to increase food self-sufficiency and food security are being initiated across the state. Milk and milk products represent perishable goods providing important nutrition that could be produced entirely in Hawai‘i, and interest has grown to reestablish Hawai‘i’s dairy industry.

Located at the western end of the island chain, the island of Kaua‘i is known for its remote setting, lush green landscape, soaring mountain ridges and raw natural beauty. The island is characterized by smaller towns totaling approximately 70,000 residents, supported by the visitor industry, agriculture, the military and a modest service economy. Large areas of prime agricultural lands have gone fallow since the closing of the sugar plantation era, with some used for grazing, and portions cultivated for seed crops and diversified agriculture products.

Concomitantly, Kaua‘i residents have been concerned about issues that hamper and impact the island as a community. Prominent issues include: employment and economic stability; opportunities for affordable housing; the scale and pace of real estate and urban land development; providing for renewable energy; food production on important agricultural lands; protection of water source and quality, and endangered species and habitats; and retention of Hawaiian cultural sites and cultural values. The proposed project supports Kaua‘i’s social and economic function, and focuses on improving Hawai‘i’s food sustainability.

![Image](image.png)

**Figure 2.1-1 County and State Plans Supportive of Agricultural Self-Sufficiency**
2.2 History of the Dairy Industry in Hawai‘i

Dairies have been a component of the Hawai‘i agricultural industry for over two centuries. Cattle were first brought to the islands in 1793. Records suggest that dairy cattle were introduced in the late 1800s, with the first commercial dairy in 1869; by 1880, there were five dairy operations. Many plantations across the state developed small dairy operations to support their agricultural communities. During World War II, dairy farms played an important role in the health and nutrition of the military, as milk was provided free to the injured personnel.

The island of Kaua‘i has a rich dairy history. By 1923, Kaua‘i hosted 34 dairy cattle farms operating on smaller farms across the island as plantation dairies. Many dairy operations on Kaua‘i did not persist after World War II due to increased regulations such as pasteurization, which required expensive facilities. Hawai‘i Island dairies were located in Kohala and Hamakua. Haleakala Ranch Dairy supplied the island of Maui starting in 1896. By 1955, the number of dairies in the state was somewhere between 86 and 90 farms, and the cow populations peaked in 1965 with 15,100 head. The state’s population was 711,000 residents. While each of the islands had numerous dairy operations, O‘ahu had the largest concentration of dairy cows and operations: Pacific Dairy in Wai‘anae; Waimanalo Dairy Farm; and Meadow Gold Dairy, initially in Waialae and moved to Kawailoa.

By the early 1960s, the Waimea Dairy and Sokei Dairy in Kapa‘a were the two largest dairies on Kaua‘i. Both were acquired by Meadow Gold Dairies Hawai‘i, which ran the 170-acre Moloa’a Dairy and developed a milk processing facility in Puhi (The Garden Island, 2014). Dairy operations were eventually consolidated at Moloa’a, which closed in 2000. Reasons for the closure included market competition from rapidly consolidating regional and national producers with large-scale production advantages in lower cost areas, and the advent of bulk milk importation to Hawai‘i. The smaller local operation at Moloa’a Dairy struggled with the relatively high land, labor and regulatory costs (D. Moriki; The Garden Island, 2/26/14).

By 1974 on O‘ahu, increased urbanization pushed dairy operations from pastures to dry lot operations in Wai‘anae. The lack of forage combined with drier region of high daily temperatures increased animal stress and reduced milk production. In 1980, the cow population in Hawai‘i began to decrease. While periodic growth occurred from the mid-1980s to 1990, costs of imported feed and transportation, milk prices, and aging dairy owners contributed to the industry decline. By 2008, operational expenses had skyrocketed. Combined with milk price regulations limiting price paid to the farmer, nearly all of Hawai‘i’s local dairies closed.

2.2.1 The Dairy Market in Hawai‘i

Peak milk production in the state was 160 million pounds in 1988; by 2006, production had declined by more than 64 percent to 57 million pounds (HDOA, 2013). In 1988, Hawai‘i’s dairy industry was valued in excess of $33 million, and declined 45 percent over seven years to just $18 million in 2005 (HDOA, 2013). Current production is 1.75 million gallons annually, which equates to just over 15 million pounds. The demise of Hawai‘i’s dairies stemmed from the higher cost of local milk production and loss of market presence due to competitive lower cost imported milk from the mainland U.S. To face the market forces and offset a portion of the market served by imported product, Hawai‘i dairy businesses must overcome the hurdles in production, processing, distribution and market reach.
Until 1984, 100 percent of Hawai‘i’s milk was produced by local dairies. The first milk was imported to Hawai‘i in 1985 by Safeway with the introduction of its Lucerne brand into the market (HDOA, 2013). By the mid-1990s, the two largest milk processors, Foremost Dairies and Meadow Gold Hawai‘i, began importing milk in bulk for local processing. Currently, Meadow Gold (Dean Foods) is the only company in Hawai‘i that processes and packages fluid milk, with facilities in Honolulu and Hilo. As of 2015, only 10 percent of the fluid milk sold in the islands is from local dairies.

The only two remaining dairies are located on the island of Hawai‘i (the Big Island): Big Island Dairy in O‘okala; and Clover Leaf Dairy in ‘Upolu. These dairies haul fluid milk product using their trucks and drivers to the Meadow Gold processing plant in Hilo. Big Island Dairy milk is marketed as "Mountain Apple" brand through KTA Supermarkets on the island of Hawai‘i, and as “Hawai‘i’s Fresh” on other islands. With a June, 2015 announcement that Meadow Gold will reduce the price it pays to Hawai‘i farmers by 23 percent, the Big Island dairies face serious obstacles to sustain operations (Hawai‘i News Now, 2015). A new endeavor on the Big Island to produce milk for cheese using a herd of approximately 200 cows fed on pasture and locally-grown corn anticipates beginning commercial operation in 2016 (Pacific Business News, 2014).

The majority of Hawai‘i’s milk supply is shipped in bulk containers from the U.S. West Coast. Meadow Gold’s Honolulu processing plant imports pasteurized milk in bulk insulated tanks. These bulk tanks travel unrefrigerated, with milk deemed acceptable if the temperature is below 45°F when received at the plant (HDOA, 2013). The tanks of skim milk and whole milk are re-pasteurized and blended to provide a product mix of mostly lower fat fluid milks. The Hawai‘i State Department of Agriculture estimated milk from California takes 8 to 12 days to make it to a store shelf in Hawai‘i (HDOA, 2013). With a 16 to 18-day shelf life remaining, milk purchased may be 24 to 30 days from the date of milking.

Packaged milk and milk products are brought in by various grocers and large retailers and transported directly to the retail store. Most is shipped in refrigerated containers. A smaller portion of packaged milk, including organic milk, undergoes ultra-high temperature processing (UHT) that sterilizes food by heating it above 275°F. This makes the product "shelf safe" which means it does not require refrigeration until opened. Most organic milk undergoes this process but rather than being packaged in aseptic, shelf safe cartons, it is packaged in the classic milk carton and sold in the refrigerated section of a retail store. This extends its shelf life to 90 days.

A simple analysis of current population and potential fluid milk demand in the State of Hawai‘i indicates the entire size of the market is approximately 22,000 cows (HDOA, 2013). Based on U.S. per capita consumption rates, fresh milk consumption in Hawai‘i is estimated at a potential 597,000 gallons per week. Meadow Gold currently experiences demand for approximately 400,000 gallons per week. The difference is supplied by packaged milk shipped directly by grocers and big box retailers.

Dairy operations in Hawai‘i face significant hurdles, including a monopoly milk processor, limited breeding stock, and a need to educate the consumer on benefits of truly local milk. For Hawai‘i to re-establish its dairy industry, it will require the introduction of advanced dairy farming technologies, efficient operational processes, and monitoring to ensure environmental protection standards are upheld.
More than six years ago, Grove Farm Company, Incorporated (Grove Farm) began contemplating how to restart Kaua‘i’s dairy industry. Alternatives to the conventional feedlot based dairy were considered, and a pasture-based model was determined to be a clean, cost-effective and sustainable method. Sustainable is defined in this EIS as:

_Meeting the needs of the present without compromising the ability of future generations to meet their own needs._

Grove Farm partnered with Finistere Ventures, Kamehameha Schools, Maui Land & Pineapple, and Ulupono Initiative to conduct grass trials on four islands to identify productive lands capable of growing nutritious forage for dairy cows. Māhā‘ulepū Valley was determined to provide ideal conditions and to meet criteria required to establish a successful dairy venture including dedication of the land to agriculture through Important Agricultural Lands designation, allowing for long-term lease, ample water source, and relatively flat land to avoid stress on cows.

2.2.2 IMPORTANT AGRICULTURAL LANDS

Article XI of the Constitution of the State of Hawai‘i includes conservation and protection of natural resources and lands, including agricultural lands. In a 1978 amendment to the Constitution, the concept of “important agricultural lands” (IAL) emerged in Section 3, Article XI: “The State shall conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The legislature shall provide standards and criteria to accomplish the foregoing.

Lands identified by the State as important agricultural lands needed to fulfill the purposes above shall not be reclassified by the State or rezoned by its political subdivisions without meeting the standards and criteria established by the legislature and approved by a two-thirds vote of the body responsible for the reclassification or rezoning action.”

Not until 2005 were “important agricultural lands” established in statute. After decades of debate, farmers and landowners formed a historic alliance and joined with the Department of Agriculture, State Land Use Commission, Office of Planning, and members of the legislature to pass Act 183 (HDOA, 2007). Important Agricultural Lands were defined as those:

- capable of producing sustained high agricultural yields when treated and managed according to accepted farming methods and technology;
- that contribute to the state’s economic base and produce agricultural commodities for export or local consumption; and
- needed to promote the expansion of agricultural activities and income for the future, even if currently not in production.

Eight specific criteria were provided, and lands meeting any of the criteria are eligible for consideration. Act 233 of 2008 established landowner incentives, such as tax credits and loan guarantees, to encourage voluntary designation of lands as IAL. The IAL designation makes it more difficult to utilize lands for non-agricultural purposes by the Constitutional requirement for a two-thirds vote of the governing body responsible for the reclassification or rezoning.
On the island of Kaua‘i, landowner Grove Farm was proactive in the identification and retention of Important Agricultural Lands within its holdings. In 2011, Mahaulepu Farm LLC (formed by Grove Farm), petitioned and received IAL designation for 1,533 acres in Māhā‘ulepū. The designation meets the objectives of Hawai‘i’s IAL land use law by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand income and job opportunities.

Māhā‘ulepū has been an agricultural center on Kaua‘i for centuries. Farming occupied the low slope areas in Māhā‘ulepū, and ranching used the uncultivated areas surrounding the valley for grazing. Since the demise of sugarcane in the 1990s, some acreage is cultivated for the seed industry, though most former agricultural fields have been under-utilized or vacant since. Recent efforts by Grove Farm to revitalize agriculture in the area involved an agricultural park concept in Māhā‘ulepū to make parcels appropriate for small farm operations. Operations established through the agricultural park offering include Haraguchi Taro Farms, a banana farm and beef cattle grazing.

In combination with Ulupono Initiative, Hawai‘i Dairy Farms, LLC (HDF) reflects a viable approach to apply use of Important Agricultural Lands to agricultural self-sufficiency and food production. HDF represents a continued commitment by the landowner to support farming and local food production, and to aid in the resurrection of Hawai‘i’s dairy industry.

Figure 2.2-1 State Land Use Districts and Important Agricultural Lands on Kaua‘i
2.3 PURPOSE AND NEED FOR THE HAWAI’I DAIRY FARMS PROJECT

2.3.1 PROJECT PURPOSE

The project purpose is to establish a sustainable, pastoral rotational-grazing dairy farm that will increase current local milk production, bolster Hawai‘i’s declining dairy industry, and reduce reliance on imported milk from the mainland United States. The rotational-grazing dairy system utilizes 100 percent of all manure on-site as natural fertilizer to grow grass. This cost-effective method reduces imported fertilizer and feed, and minimizes potential impacts to the environment.

2.3.2 PROJECT NEED

Currently, residents and visitors to Hawai‘i rely on air- and ship-freight for 90 percent of goods, including food. Food sustainability is of growing interest to residents, especially those who have experienced low available supplies when faced with natural disasters, labor disputes that affect shipping ports, and geopolitical events such as 9-11. With the departure of large sugar and pineapple plantations from Hawai‘i, more lands are available for diversified agricultural endeavors. A 2008 study identified the economic benefits of replacing 10 percent of imported food with locally produced food as generating an estimated Hawai‘i economy-wide impact of $188 million in indirect sales, $47 million in earnings, $6 million in state tax revenues, and more than 2,300 jobs (CTAHR, 2008). Additionally, there is a desire to retain Hawai‘i’s agricultural history and the open landscapes associated with ranging and farming.

Between 1984 and 2015, importation of milk to Hawai‘i rose from 0 to 90 percent. The local dairy industry has been reduced to just two dairies on the Big Island, and with a recent cut in price paid to those dairies of 23 percent by the processor, local milk production is in jeopardy. Conventional feedlot dairy operations face management challenges including costs of imported feed which fluctuate with grain and fuel prices, and the need to store manure in waste impoundment lagoons as a waste product. Without a need to utilize manure as a nutrient for growing crops, options for utilizing manure produced are limited to drying manure for sale, spreading on lands that can tolerate the nutrients, utilizing dried manure solids as bedding for dairy cows in confinement, or generating energy, which ultimately requires treatment and disposal. The pastoral-based dairy utilizes a system to balance needs of the forage (grass) with nutrients provided by manure produced on site.

2.3.3 PROJECT OBJECTIVES

Hawai‘i Dairy Farms set eight objectives to achieve to bolster local milk production in Hawai‘i:

1. Provide more than 1,000,000 gallons annually of fresh, nutritious milk for Hawai‘i families and revitalize the dairy industry in Hawai‘i.
2. Apply proven, sustainable pasture-based rotational grazing system and state-of-the-art technology to reduce reliance on costly imported fertilizer and feed.
3. Grow local, quality grass as a primary feedstock optimal for dairy cow nutrition and health, utilizing results of forage research conducted at five sites across four Hawaiian Islands.
4. Design facilities to provide animal comfort, including maximum time on pasture and minimal milking time.
5. Effectively integrate dairy operations within the island community setting.
6. Optimize dairy product shipping and marketing.
7. Provide local farming employment and build the agricultural economy.
8. Protect and enhance the area’s natural, cultural, social and economic environment through sound agricultural planning, preservation of open space and protection of sensitive resources, and development of economic benefit.

2.3.4 EVALUATION CRITERIA

Within the context of the HDF objectives, primary evaluation criteria have been established which must be satisfied for the project to be economically, socially and environmentally responsible. The four evaluation criteria are:

1. Secure sufficient contiguous land area under long-term lease with adequate water supply (including potable water to meet standards under milk rules), suitable soil properties, gentle slope conditions, and road accessibility.

2. Generate new long-term employment in the agricultural sector on Kaua’i in a wide range of positions including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk products processing and dairy business management.

3. Create a model for dairy operations utilizing IAL, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure to advance food self-sufficiency.

4. Utilize 100 percent of manure on site as nutrients to grow forage for dairy cows. Grow sufficient forage to provide 70 to 85 percent of feedstock required for the herd.

Hawai’i Dairy Farms has been designed to meet the guiding objectives. The project represents a directed effort to establish a pasture-based dairy in Hawai’i that will lead to improving food security for Hawai’i. The model uses a pastoral rotational-grazing system on former sugarcane plantation lands. With the demonstrated success of Hawai’i Dairy Farms, the proponents will be able to continue and expand their community leadership and social investment within Hawai’i by adapting the grazing system to other locations in the state. These objectives and criteria are the guiding parameters that ultimately define the direction for Hawai’i Dairy Farms. As discussed in Section 6.0, these evaluation criteria are applied to evaluate and compare probable impacts of the Proposed Action with alternative actions.

2.4 PLANNED DAIRY DEVELOPMENT ON MĀHĀʻULEPŪ AGRICULTURAL LANDS

A partnership of landowners and supporters throughout the state worked to determine optimal sites for Hawai’i’s first pasture-based dairy. The group sought an approach to dairy farming reliant on local forage and nutrient recycling, rather than the conventional feed lot dairies. After significant research and inquiry, New Zealand’s grass-fed model was found to be the cleanest, most cost-effective method for sustainable dairy production in Hawai’i.

From 2010 to 2011, Grove Farm partnered with Finistere Ventures, Kamehameha Schools, Maui Land & Pineapple and Ulupono Initiative to conduct grass trials statewide and determine the best
site for a rotational pasture-based dairy. Kaua‘i was found to be the optimal location. Operational needs for a pasture-based dairy include:

- Relatively flat, contiguous acres to move cows with minimal stress,
- Soils suitable to efficiently utilize applied nutrients for growth of forage,
- Adequate water for irrigation and operations,
- Suitable climate conditions for animals and grass growth,
- Agricultural-zoned land available for 20 years or more of sufficient acreage to support an economically viable dairy, preferably IAL, and
- Access to required operational support elements (trucking, pasteurization, work force, etc.).

In late 2013, Ulupono Initiative made the investment to fund Hawai‘i Dairy Farms, the first pasture-based, rotational-grazing dairy in the state. HDF was formed as a positive step toward the island state’s food security, economic diversity, and sustainability. At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually at market price. Increasing fresh milk by approximately 10 percent of current supply using cows in Hawai‘i will reduce reliance on imported milk from the mainland U.S. HDF operations will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations of Hawai‘i’s past.

HDF is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The application process for a National Pollutant Discharge Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

Chapter 3 describes details of the proposed project, known as the “Proposed Action”. Chapter 4 analyzes probable impacts to the environmental and socio-economic resources from the Proposed Action. Chapter 5 provides regulatory context relevant to the proposed land use and agricultural operations. Alternatives to the Proposed Action that were considered, and an analysis of potential impacts, are presented in Chapter 6.
Figure 2.4-1 Project Location on Māhā‘ulepū Agricultural Lands
3.0

DESCRIPTION OF THE PROPOSED ACTION
3.0 DESCRIPTION OF THE PROPOSED ACTION

The project will reinvigorate the flagging dairy industry in Hawai‘i and establish a financially and environmentally sustainable, pastoral rotational-grazing dairy to provide more than 1,000,000 gallons of fresh milk for Hawai‘i’s families. This section describes the proposed action within the agricultural context of the Māhā'ulepū site. Individual improvements composing the Hawai‘i Dairy Farms project are detailed in this chapter, with site plans where relevant.
3.1 SITE DESCRIPTION: HISTORY AND VISION

HDF leases agricultural land in Māhāʻulepū Valley on the south shore of Kaua‘i (see previous chapter, Figure 2.4-1 Project Location Map, and Figure 3.1-1). The 557-acre site consists of portions of three parcels leased from Mahaulepu Farm LLC (Figure 3.1-2 Tax Map Key). The lease area was surveyed for a metes and bounds description, which modified the acreage from an originally estimated 578-acres to the surveyed 557-acres to allow for access around the perimeter, fencing setbacks, buffers from cultural sites above the farm, and for potential future expansion of the taro farm by the lease-holder.

Māhāʻulepū Valley lies on the leeward side of the Hāʻupu mountain ridge, a prominent feature of southern Kaua‘i, where Mt. Hāʻupu forms the highest point at 2,297-feet elevation in the back of the valley. Māhāʻulepū has a long history of agricultural use. Prior to European contact, the valley was occupied by Hawaiians who cultivated traditional food crops such as kalo (taro) and kō (sugarcane). During the transition of land tenure following arrival of Europeans and the rule of King Kamehameha III, Māhāʻulepū Valley became the first place in the island chain where sugarcane was commercially grown.

As early as 1820, sugarcane was milled in Māhāʻulepū for local use; commercial-scale operation was underway in 1878 as Kōloa Plantation and occupied roughly 875 acres in Māhāʻulepū Valley (Figure 3.1-3). Cultivation continued under various entities until 1996 when the Kōloa Mill closed. In historic times, cattle occasionally foraged on the slopes above the valley. Grove Farm Company, Incorporated (Grove Farm) leased a portion of the Māhāʻulepū area to ranchers as early as 1986, with portions of the valley floor grazed by cattle from 2002 to 2013. Approximately 400 – 500 head of beef cattle were shifted off the valley floor to surrounding properties upon HDF’s lease. Taro cultivation was introduced on an adjacent parcel in 2007 when landowner Grove Farm offered small parcels with access to water to individual farmers in an effort to establish an agricultural park of varied users. The land was originally owned by Grove Farm and Visionary, LLC (Lihue Land Company) and transferred to Mahaulepu Farm LLC in 2011.

The nearest populated area to Māhāʻulepū Valley is the Kōloa town community; residences closest to the site are 2.3 miles west. Kōloa town has its roots firmly tied to the agricultural history of the region. The resort area of Po‘ipū began with oceanfront resort hotel development in the 1960s. During the 1970s and 1980s, agricultural lands in the Po‘ipū area were reclassified from State Agricultural District to Urban District, and rezoned by the County as resort. The Grand Hyatt Kaua‘i is the closest resort to the dairy site, with 1.6 miles between the property boundaries. Significant expansion along this coastline occurred from 1980 to present, with active development of hotels, timeshare condominiums, single-family resort residences, golf courses and commercial centers.

Community concern over loss of agricultural land for another proposed resort on the last stretch of undeveloped Māhāʻulepū coastline prompted the County Council and State Legislature to pass resolutions supporting future preservation of the Māhāʻulepū ahupua’a. The 2000 Kaua‘i General Plan recommended community involvement in planning for the future of Māhāʻulepū to take into consideration various interests and factors to include: the long-term need to manage lands for preservation of significant natural and cultural features; the landowner’s desire to develop revenue-producing uses that are sensitive to the area’s unique qualities; the need to secure permanent public access to the shoreline; and the potential to create a coastal park (COK, 2000). Grove Farm Company, Inc., testified in response to a State resolution for re-assertion of its rights to plan for its own lands and expressed concern that development of a park or public use of Māhāʻulepū would support a takings action for government ownership. Grove Farm has continued to allow public access and use of Māhāʻulepū lands at its expense.
Figure 3.1-1  Project Area
Figure 3.1-2  Tax Map Key for Project Area
In 2011 the landowner petitioned for, and the State Land Use Commission designated, 1,533 acres in the Māhāʻulepū region as Important Agricultural Lands (IAL) under the provision of the Hawaiʻi State Constitution (Article XI, Section 3). This constitutional requirement is for conservation and protection of agricultural lands, promotion of diversified agriculture, and increased agricultural self-sufficiency. The IAL designation assures available lands suitable to support a diversity of agricultural activities and opportunities to expand agricultural income and job opportunities. The designation includes the 557 acres leased by HDF (See previous chapter, Figure 2.2-1).

HDF will establish and operate a sustainable, pastoral rotational-grazing dairy farm in Māhāʻulepū Valley on the island of Kauaʻi to produce fresh, locally available nutritious milk for Hawaiʻi families. The rotational-grazing method utilizes 100 percent of the cows’ manure as fertilizer for pasture grass to provide the primary source of nutrition. This cost-effective method will reduce reliance on imported fertilizer and feed. Pasture grass will provide a local food source appropriate for cow health and quality milk production, and will comprise at least 70 percent of the animals’ diet.

HDF has committed to establish a herd of up to 699 mature dairy cows. As explained in Section 2.4, HDF may contemplate possible expansion of the herd following proven success of the rotational-grazing system for local milk production. While additional regulatory review and public input would be required at that time, this Environmental Impact Statement (EIS) documents potential impacts from both herd sizes for comparative purposes and full disclosure. Differences in infrastructure or operations for the two herd sizes are noted, where applicable.
3.2 CONSERVATION PRACTICES

In 1935, the U.S. Congress directed the creation of the Soil Conservation Service in response to drought and wide-scale soil erosion in the mid-western U.S. known as the “Dust Bowl”. Erosion of soil was recognized as having an impact on the Nation and rural communities. The Soil Conservation Service became the Natural Resources Conservation Service (NRCS) in 1994 to acknowledge its expanded role in watershed-scale approach using science-based tools and standards in agronomy, engineering economics, wildlife biology and other disciplines to aid landowners in implementation of conservation practices.

Conservation planning under NRCS emphasizes desired future conditions while improving the conditions of natural resources. Participation is voluntary for private projects on private lands that do not use federal funds. NRCS employees work with local conservation districts to establish objectives that reflect resource issues and priorities of the district (NRCS, 2013). The NRCS approach combines locally-led solutions with science and research, stewardship, partnerships, and proven conservation practices. Technical guidance is available through NRCS handbooks, input from NRCS conservationists, certified technical service providers (TSP), and the local soil and water conservation district.

In Hawai‘i, soil and water conservation districts are legally constituted self-governing sub-units of the Hawai‘i state government organized under the 1947 Hawai‘i Soil and Water Conservation District Law. Hawai‘i Revised Statutes Chapter 180, as amended, outlines the duties and powers of the SWCDs to administer and conduct soil and water conservation activities within the State of Hawai‘i. Since 1967, the Hawai‘i State Department of Land and Natural Resources (DLNR) has provided funding and administrative support (SWCD, 2016). The East and West Kaua‘i Soil and Water Conservation Districts were founded in 1953. As with the other districts in the state and across the nation, the districts are locally led grassroots organization guided by unpaid volunteers who contribute their time and effort, with support from conservation partners, to preserve natural resources and enhance the quality of life in their communities (E&WKSWCD, 2015).

Hawai‘i Dairy Farms has engaged with the NRCS resource conservationist to seek technical guidance, including consultation with a technical service provider (TSP). A Conservation Plan for the project, which includes a Comprehensive Nutrient Management Plan, was reviewed and accepted by West Kaua‘i Soil and Water Conservation District. Conservation planning is a process that recognizes the art and science of natural resource management will never be complete or finished. As conditions and knowledge of the resources change, the methods to achieve natural resource and agricultural goals may be modified. On-going dialogue and guidance based on observations in the field are anticipated throughout project implementation and establishment.

NRCS has set a standard for numerous conservation practices which are known as practice standards and practice codes. Planning for both HDF implementation and future operations incorporates these practice standards and codes. Where the standards and codes have been customized for Hawai‘i and other Pacific Island environments by the local NRCS Pacific Islands Area office, the ‘PI’ standard or code was followed. Table 3.2-1 documents the Practice Codes utilized in the HDF project.

Additional relevant Practice Codes may be utilized.

Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices, including but not limited to those shown above, are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads in accordance with best management practices.

3.3 DAIRY SITE REQUIREMENTS AND LAYOUT

Operational needs for a pasture-based dairy are listed in Section 2.4. Two additional operational needs - suitable climate and soil - are discussed in Chapter 4. The following section expands upon the elements of the Māhāʻulepū site that fit the following needs:

- relatively flat, contiguous acreage;
- adequate water for irrigation and operations;
- agricultural-zoned land available for 20 years or more with sufficient acreage to support an economically viable dairy (preferably utilizing Important Agricultural Lands - IAL); and
- access to support elements (trucking, pasteurization, and work force).

A pasture-based dairy requires relatively flat, contiguous acreage. Gentle slopes allow dairy cows to conserve energy moving between paddocks and the milking parlor twice each day. The Māhāʻulepū site ranges from 0-10 percent slope, with steeper areas along the agricultural ditches created for irrigation during the sugarcane plantation era. Minimal stones in the pastures and along the raceways provide for hoof comfort and protect against injury and lameness. The predominant soils are suitable for establishment of nutritious grasses and nutrient application (See Sect. 3.5 and 4.3).

The 557-acre site consists of 547 acres for paddocks, vegetated buffers (“setbacks”) along drainage ways, farm roads, and cow races. The dairy buildings and supporting infrastructure, holding yards and roads occupy the remaining 10-acre area, located on the western boundary of the site (Table 3.3-1 and Figure 3.3-1).

3.3.1 BUILDINGS

The developed area “footprint” would occupy less than two percent of the total farm area. Four buildings would be constructed to serve different functions, supported by utilities and infrastructure.

Utilities needed for the dairy facilities include a potable water distribution system from the private on-site well, one domestic individual wastewater system (IWS, a DOH-approved septic system) for the employee restroom, and utility-provided electrical power and communications. Agricultural infrastructure components are discussed in Section 3.3.2.

3.3.1.1 Milking Parlor

The largest building designed for the dairy is known as the milking parlor. Components of the building, approximately 256-feet long by 88.5-feet wide and 33-feet tall, include a covered loading area, milking area, holding pens, mechanical room and pump room, office space, veterinary space and storage, staff restrooms, and milk storage.

The milking area contains an automated 60-stall rotary, which utilizes a slowly turning platform. A dairy employee will place a milking machine on the udder; the machine disengages when no milk is detected. Cows are eager to enter the rotary where they are provided a mixture of grain and supplemental nutrients, which would initially constitute approximately 30 percent of their dietary needs. The grain mixture complements the main diet of grass and provides supplemental nutrients to support cow health and milk production. The supplemental grain feed would be stored in two 44-ton capacity, 60-degree cone silos. The milking parlor would operate 365 days a year. Typical milking time is 8 to 10 minutes; the time moving between the paddocks and milking parlor is approximately one hour per session, for a total of two hours off pasture each day.

3.3.1.2 Implement Shed

An implement shed would be used to store equipment, tools, and supplies, and to provide space for farm machinery. Sized at approximately 65-feet long by 26-feet wide by 15-feet tall, the implement shed will be an open bay steel structure on a concrete slab with a metal roof. Refer to Figure 3.3-1, Dairy Facilities Site Plan.
3.3.1.3 Calf Sheds

The calf sheds are steel-framed structures with metal roofs anchored to foundation on an underlying concrete slab. Each of the two sheds will be approximately 81-feet long by 26-feet wide, and 15-feet tall (Figure 3.3-3). To allow for the natural social behavior of calves and provide room for them to turn comfortably and lie down, 20 calves share a pen. The pens are sized to allot roughly 21 square feet per calf, and are divided into a feeding area and a bedding area. Newborn calves are kept in individual protective “crates” within the calf shed for the first 10 days to ensure successful feeding and to provide individual monitoring and attention. At approximately 10 days of age, calves are moved to pens with other calves until they are ready to transition to pasture at about 3 to 4 weeks of age. The feeding area is washed daily, with wash water routed to the effluent ponds through under surface pipes (see Agricultural Infrastructure section, following). With freedom to move about, calves typically will not soil their bedding while at rest; any manure will be removed as needed.
3.3.1.4 Holding Yard

Cows waiting to enter the milking parlor will move through the holding area as a mob, twice each day. The yard is designed to hold a mob of up to 330 cows at any one time. The committed herd size of 699 mature dairy cows will be managed in mobs of 105 to 115 cows. A mob is a group of cows that mimics the natural social order of bovines and is managed together. The yard is approximately 12,300 square feet (150-feet long by 82-feet wide); half of the area will be covered with roofing (Figure 3.3-4 Dairy Facility Detail). The maximum time off pasture for each milking – including moving from the paddock, through the holding yard and milking parlor, and back to a fresh paddock – will be one-hour per milking, two times each day.

![Figure 3.3-4 Dairy Facility Detail](image)

3.3.1.5 Effluent Ponds

Manure will be washed from the yard frequently to provide a healthy environment for the cows. Washdown water containing manure and urine will be collected and transferred to the settling pond through underground pipes. The collected effluent will be utilized as natural fertilizer to provide nutrients for pasture grass (see Section 3.5.4, Irrigation and Nutrient Balance).

3.3.1.6 Access Road and Tanker Truck Turnaround

Primary access to the dairy facility will be from the existing farm road in the center of the site, via a newly paved 20-foot wide road. Milk tanker trucks will utilize the access road to load milk and to transport milk off-site. The paved road will terminate at a truck turnaround by the covered loading area of the milking parlor, where raw, cooled milk will be pumped directly into insulated tanker trucks from the loading area for transport off-site (Figure 3.3-1 Dairy Facility Site Plan).
Utilities will be installed to provide electrical power, potable water, domestic wastewater, drainage and communications within the buildings and facilities in the area of the milking parlor, as described in this section.

**Electrical Power**

Electrical power will be provided through an overhead service connection to the existing Kaua‘i Island Utility Cooperative (KIUC) grid. An existing overhead line along the farm road mauka of the facility will feed to a new three-phase, 75-300 kVA transformer via a subgrade duct bank. Electrical lines to the dairy facilities will be run in a concrete-encased conduit routed underneath the access road. Additional power will be supplied by photovoltaic (PV) panels mounted to structure roofs, with a total generation capacity of 500 kW power.

**Potable water**

Potable water is required for milk cooling, livestock consumption, and consumption within the dairy facility, as well as to supply wash water to maintain animal health and sanitation of the milking parlor, holding yards and calf sheds. State of Hawai‘i Department of Health (DOH) Milk Rules require potable water used for milk production – in the milking parlor and for milking operations - be from an approved supply that is properly located, protected, and operated in a sanitary manner.

Potable water will be sourced from the existing Māhāʻulepū Well Battery located within the project site. The well site originally contained up to 14 wells, the first ten of which were drilled by the sugar plantation between 1897 and 1901 (TNWRE, 2016). The final four wells were drilled during a modification of the well battery in 1927 to 1928. Of the 14 wells, only 3 were deemed sufficient and available for use by HDF. One well will be used for potable water, a second will be used for groundwater monitoring, and the third will be available for backup if needed. The well water has been tested and is of acceptable quality to meet the DOH Milk Rules.

Water will be stored in lined water storage tanks with a total capacity of approximately 80,000 gallons located outside the milking parlor’s southwest corner. From the storage tanks, water will be distributed into the milking parlor and to adjacent buildings for use. Water from the tanks will be used for both milk parlor and yards, as well as delivered to the paddocks to supply water for the herd (livestock water is discussed in Section 3.3.2, Agricultural Infrastructure). Small booster pumps will be used to deliver the required flow throughout the farm.

Within the milking parlor, potable water is primarily used to cool milk and to maintain sanitation. Water is used to flush out the milking equipment, as well as to wash manure and urine into the effluent ponds from the holding areas, milking parlor, and calf sheds. Sanitation facilities for dairy employees include restroom and hand-washing facilities, including hot and cold running water dispensed through a mixing valve and faucet.

Demand for potable water in the milking parlor facility is estimated to be approximately 12,165 gallons per day (gpd) for human consumption and wash water, and 17,475 for livestock consumption (at 25 gpd per cow per day). Total demand will initially be approximately 30,000 gpd with the committed herd size of 699 mature dairy cows. The potable water demand for the contemplated possible herd expansion up to 2,000 mature dairy cows is shown in Section 3.8.1.
**Domestic Wastewater**
Wastewater from a restroom planned for dairy personnel will be serviced by an individual wastewater system (IWS). An IWS treats wastewater on-site using DOH-approved systems (e.g. septic tank). The system will be designed for a flow of 700 gpd, with a 1,500-gallon capacity septic tank certified by the International Association of Plumbing and Mechanical Officials. The IWS septic tank system will be underground, outside and just south of the milking parlor.

**Communications**
Telephone and internet service will be provided through an overhead service connection via drop pole to the same subgrade trench as the electrical power, in a separate duct conduit that feeds into a 2’-0” by 4’-0” Hawaiian Telecom pull box. Communication lines will extend from the pull box to the dairy facilities via subgrade concrete encased conduit.

**Stormwater Run-Off/Drainage**
Gutters, curbs and swales will be used within the dairy facility to direct surface sheet flow as a part of the overall site stormwater management plan. Metal roofing material on dairy buildings will be sloped to adequately sized gutters and downspouts. Roof run-off from the implement shed, milking parlor, and covered section of the holding yard will be discharged at ground level directly to grass surrounding the buildings. Run-off from a 1.75-acre area within the facility, primarily uncovered areas with potential of manure, will be routed to the storage ponds. This area includes the loading area, the uncovered part of the holding yard, and the area immediately surrounding the effluent ponds. The pond edge will be above grade to prevent run-off from outside areas from entering the ponds.

Stormwater run-off from the calving shed roofs will discharge at ground level and be collected with the potentially contaminated runoff from the uncovered areas and directed to the storage ponds.

### 3.3.2 AGRICULTURAL INFRASTRUCTURE

Agricultural infrastructure and utilities required for the dairy operations will include storage tanks and silos, effluent storage ponds, livestock water systems, and drainage improvements. The irrigation system and distribution of livestock water are discussed in Section 3.5, Pasture Management.

#### 3.3.2.1 Storage Tanks and Silos

Milk storage tanks will be erected in the “milk room” within the milking parlor. The tanks maintain milk at the regulated temperature until transferred to a tanker truck. The milk room is located just inside the covered loading bay.

Potable water will be stored in two tanks described in the previous section under Utilities. The tanks are located outside the southwest corner of the milking parlor. Feed is stored in two cone silos outside the south side of the milking parlor, as explained in Section 3.3.2. Feed is lifted from the delivery pit via a grainleg and dispensed into troughs accessible by cows in the 60-stall rotary while milking. The silos are sited on a concrete pad.

Gasoline and diesel fuels will be stored in above-ground tanks. Fuels will be used in farm equipment, and will be available if needed to power an emergency back-up generator. Storage and inventory procedures for fuels and other petroleum products utilized at the dairy are described in Chapter 4, Section 4.13 Hazardous Substances.
3.3.2.2 Livestock Water Distribution System

Availability of drinking water has an impact on animal health and milk production. The livestock water distribution system has been designed to supply a large volume of water to meet the seasonal high daily water demand of 25 gpd per cow. Potable water will be pumped from the Māhā'ulepū Well 14 and stored near the milking parlor in two covered storage tanks with combined capacity of 80,000 gallons. Small diameter water mains will deliver water to at least two troughs in each paddock. Troughs will be filled with valves that allow water flow when the water level decreases, and to stop water flow when the trough is full. The raised, concrete troughs will be placed on a stable crushed rock base at a height that allows cows to reach over and into the water, but discourages stepping into the trough.

The total potable water demand for HDF is documented in Chapter 4, Sections 4.16.2 and 4.23.1.

3.3.2.3 Drainage Improvements

Drainage improvements will consist of surface modifications to include swales (referred to as grassed waterway in NRCS Practice Codes), sediment basins, stream crossings, surface drainages, and water and sediment control basin. Much of the existing drainage infrastructure, installed and used for sugarcane irrigation, will be restored where possible and reused or improved.

3.3.2.4 Effluent Storage Ponds

The pasture-based system utilizes manure as a valuable resource. This is a fundamental difference and advantage over conventional feedlot dairy operations, which have insufficient land to recycle the nutrients for uptake by forage plants and instead rely on imported feed and large storage lagoons to hold manure. The pasture-based dairy relies on 100 percent of the nutrients from manure deposited on the pasture, with application of manure captured in the effluent ponds, to grow the majority of forage for the herd.

Collection and storage of effluent provide a tool for the dairy manager to control the schedule, timing, and mix of nutrients to be applied. Sizing of the storage facility allows flexibility in scheduling land application when weather and field conditions are suitable, and when nutrients in the effluent can best be used. The storage period is determined by the utilization schedule. The ponds for HDF will be sized to accommodate the potential maximum effluent generated from the contemplated herd size of up to 2,000 mature dairy cows. For the committed herd size of 699 mature dairy cows, the ponds will have excess capacity.

Siting, design and construction of the ponds will be in compliance with the University of Hawai‘i College of Tropical Agriculture and Human Resources (CTAHR) and technical guidance from NRCS. The Livestock Waste Management Guidelines (U.H., 2010) requires storage facilities for animal wastes should provide a minimum buffer of 1,000 feet from public drinking water resources, and 50-feet from surface water resources. At their closest points, the ponds will be sited approximately 125 feet from the nearest drainage ditch, and 3,420 feet from the nearest public drinking water well (Figure 3.3-5). Design guidance for effluent storage requires sizing of the pond to contain all wastewater, manure, clean water, solids accumulation, net surface rainfall including runoff, and the direct precipitation sized for a 25-year, 24-hour rainfall event.
Figure 3.3-5  Effluent Pond Siting
Wash water from the milking parlor will be routed to the settling pond through a pipe. Run-off from the dairy facility will be managed as described in Section 3.3.1.7 (Stormwater Run-Off/Drainage). The U.H. Waste Management Guidelines (2010) require waste lagoons to be lined with a synthetic liner if within 1,000 feet of a public drinking water source, or within 50 feet from surface water resources and/or State waters.

While the ponds’ distances from water resources exceed U.H. Waste Management Guidelines (2010) thresholds to require lining with synthetic liner, HDF has elected to line the ponds to protect against seepage into surrounding soil. The synthetic liner will meet the standards of the NRCS Conservation Practice Code, and will be underlain with a sensor system that can detect moisture and alert personnel to potential leaks. Inlets, outlets, ramps and other elements of the effluent transfer system will be installed according to NRCS practices to prevent damage to the operation of the liner. Volumes, assumptions and additional description of the pond system can be found in Appendix D, Nutrient Balance Analysis.

The two-pond system for HDF will be composed of a settling pond and a storage pond. Daily generation of effluent with wash water entering the ponds has been calculated to be 13,226 gallons per day (gpd) for the committed herd size of 699 mature dairy cows. Roughly 1 percent of the daily effluent consists of solids, with approximately 5,952 gallons of solids accumulating over a 45-day storage period (Table 3.3-2). Storage calculations for the contemplated future possible herd size of up to 2,000 mature dairy cows are shown in Section 3.8.1.

Solids are retained in the settling pond through filters. The volume of the settling pond allows space for stirring to re-suspend solids for application to pastures, which provides an additional 285,241 gallons of pond capacity (Figure 3.3-6). Solids will be cycled through the pond onto the paddocks over a period of approximately 45 days (see Section 3.5.4, Irrigation and Nutrient Balance).

The storage pond is sized to hold a volume equivalent to 30 days of effluent from the contemplated herd size of up to 2,000 mature dairy cows, plus normal precipitation and run-off for a 30-day period from the 1.75-acre, uncovered portion of the total facility area to receive manure and wash water, plus the possible rainfall from a 25-year, 24-hour storm event (Figure 3.3-6). While precipitation over these areas is directed to the storage ponds via drain inlets and piping because it
will be mixed with manure and wash water, other precipitation from remaining areas of the facility and adjacent pasture will not enter the pond, as the pond edges consist of raised berms. Grading around the facility will direct uncontaminated rainfall away from the facility.

For the committed herd size of 699 mature dairy cows, the storage pond could accommodate nearly one million gallons more than the NRCS design requirements (Figure 3.3-6). In normal operations, the storage pond provides additional spare volume at the top of the pond. In the 699-cow scenario, the spare volume is an additional 45% of the total volume design. In the 2,000-cow scenario, the spare volume represents an additional buffer of up to 12%. These spare volumes provide even greater buffer above the design capacity which includes not only the required 25-year, 24 hour storm event, but also allows volume for 30 days of storage, and normal precipitation to the surfaces surrounding the ponds.

Figure 3.3-6  Effluent Pond Plan and Section for Committed Herd of 699 Mature Dairy Cows
Nonetheless, the storage pond design incorporates an emergency spillway to direct overflow to a secondary containment area in case of a cataclysmic event. This containment is beyond the regulatory requirement, and would only be utilized during an unprecedented rain or flood event. The capacity of the secondary containment is approximately 1,125,600 gallons, which is roughly equivalent to the total wastewater volume for a 30-day period from the potential contemplated herd size of up to 2,000 mature dairy cows.

Liquid effluent will be mixed with non-potable water from the Waita Reservoir and applied to pastures through a pivot irrigation system. The typical utilization schedule for the nutrient-laden water from the storage pond is every four days, depending on field conditions. Slurry will be applied through a mobile hard-hose reel dispensed through a gun nozzle, referred to as a gun irrigation system. Slurry refers to solids from the bottom of the settling pond mixed with non-potable water that can be applied through the gun irrigation system. The frequency and quantity of effluent applied depends on a variety of conditions discussed in Section 3.5.4, Irrigation and Nutrient Balance.

### 3.4 HERD MANAGEMENT

The management practices and pasture-based rotational grazing system to be applied by HDF maximizes grass as the cows’ primary nutrition source and minimizes stress to the animals. Cows will be managed in social groups known as “mobs”, mimicking the natural social order of bovines. The committed herd size of 699 mature dairy cows will be organized in mobs of 105 to 115 cows. The pasture-based model allows cows to move about freely and to lie down and rest, which is an important part of the digestion cycle. Cows will spend 22 of each 24-hour period foraging on pasture or resting, outdoors in natural light and fresh air. The gently sloped paddocks and walkways will minimize the energy expended by the mature dairy cows as they graze or are transferred to and from the various paddocks and the milking facility; surfaces of the walkways and cow races will be topped with crushed limestone to provide a comfortable path under hoof. Cows tend to be healthier and live longer productive lives with access to fresh air, high quality feed, and exercise while they forage (NRCS, 2007).

Health of the herd is of primary importance as the success of a dairy relies on cows effectively producing quality milk. All cows will be treated with a high standard of care. Dairy managers and caretakers will be trained and competent in handling animals to minimize stress and ensure the herds’ welfare. A licensed veterinarian may prescribe use of antibiotics approved by the Food and Drug Administration (FDA) for treatment of illnesses. Adherence to guidelines that prohibit the sale of milk from cows undergoing antibiotic treatment will ensure no adulteration of milk. Routine laboratory tests of milk for traces of antibiotic residue will be conducted. HDF will not inject cows with bovine growth hormone, referred to as rBST or rBGH.

With the committed herd size, there will be approximately 150 calves on the HDF site at any one time. Approximately 50 calves would be housed within the calf sheds, with approximately 100 calves on pasture, grazing. The actual numbers will depend on the calves’ age, size and health status. Once the calves reach approximately 165 pounds or 90 days of age, they will be transferred to an offsite calf raising facility (see Sections 3.7 and 3.8.4, Offsite Herd Management).

Should animals die at the site, they will be buried at a designated area, following plans for carcass management as specified in the Waste Management Plan reviewed by DOH.
HDF will comply with the applicable State and Federal regulations related to the importation of livestock and livestock disease control. This includes importation requirements by the State of Hawai‘i Animal Industry Division pre-entry requirements such as testing for diseases such as brucellosis, and tuberculosis. The cows will also undergo approved external parasite prevention methods, and national uniform tagging or identification registration and processing.

3.5 PASTURE MANAGEMENT

The pastoral rotational-grazing dairy provides a local feedstock – grass – as the herd’s primary food source. Reducing imported feed stabilizes costs and provides a food source closer to the natural diet of cows. Pasture is defined by the Natural Resource Conservation Service (NRCS) as:

... a land use type having vegetation cover comprised primarily of introduced or enhanced native forage species that is used for livestock grazing. Pasture receives periodic renovation and cultural treatments such as tillage, fertilization, mowing, weed control, and may be irrigated. Pasture vegetation can consist of grasses, legumes, other forbs, shrubs or a mixture. Pasture differs from range in that it primarily produces vegetation that has initially been planted to provide preferred forage for grazing livestock. The majority of these forages are introduced, having originally come from areas in other continents. Most are now naturalized and are vital components of pasture based grazing systems (NRCS, 2016).

Results of grass trials initially conducted at five sites across four Hawaiian Islands were instrumental in identifying appropriate varieties of grass. Additional project-specific trials at the Māhāʻulepū site on Kaua‘i have been conducted for more than 18 months. The results have identified sufficient yield and nutrition to supply 70 percent of the cows’ diet; improvements in grass productivity are anticipated to provide up to 85 percent of cows’ diet.
Figure 3.5-1  Dairy Facility Site Plan
3.5.1 PADDOKS, FENCING AND SETBACKS

The 469.9 acres of pasture will be divided into 119 paddocks that average 3 to 5 acres in size (Figure 3.5-3 and Table 3.3-1). Smaller paddocks will be located near the dairy facility for use as temporary pasture for cows or calves being moved on or off the farm (see Section 3.7, Offsite Herd Management by Kaua'i Ranchers). To protect water quality of surface water and downstream areas, paddock fences are set 35 feet back from the top of bank of drainage ways in the site. Existing vegetation within the setbacks will be managed or restored to reduce erosion, improve stability of ditch banks, increase net carbon storage, and improve and maintain water quality.

As described in Section 3.3.2, a minimum of two concrete above-ground water troughs will be installed in each paddock for livestock drinking water.

Fencing is essential to containing cows for safety, protecting water quality, and optimizing animal and pasture health, milking output, grazing coverage, and nutrient distribution. A permanent perimeter fence will be constructed using steel t-posts installed every 10 feet, and a wooden post placed every 50 feet. The fence will include 42-inch woven wire topped with a strand of straight wire at 48-inch height, with a strand of barbed wire at ground level to deter feral pigs. Within the perimeter fence, paddock fencing will consist of two or three strands of electric wire mounted on wooden t-posts. Electric fencing is the standard material used for cows and cattle as it is effective and moved with relative ease to re-configure paddocks. T-posts are pounded into the earth using a hand-held pole pounder. Fence corners are strengthened through use of 6-inch diameter wood posts driven 2-feet into the ground using a mechanical pounder powered by a tractor hydraulics system. Gate posts made of steel pipe will be installed in holes approximately 12 inches across and 36 inches deep and set in concrete. The integrity of the fence is essential to project success, and will be diligently monitored and maintained by the dairy manager, who will be onsite daily.

3.5.2 COW WALKWAYS

Contiguous acreage is required for a pasture-based grazing system in which cows must walk to and from the milking parlor twice each day. Cow walkways are designed to conserve energy of the animals by utilizing gentle slope, and to minimize stress by allowing mobs to move at a relaxed pace. The walkways at HDF will be 16- to 20-feet wide, which allows the mob to walk as a group with their heads lowered. The walkways will be topped with crushed limestone that provides a soft surface to minimize hoof damage. The walkways will be elevated above the pasture grade, and in some areas will be parallel to farm roads. Surfaces will be slightly crowned to ensure drainage to either side of the walkway, and swales roughly 12-inches in depth will be created parallel to each road or raceway. Design and installation of roads, raceways, and swales will be in compliance with the HDF Conservation Plan and utilize standards from applicable NRCS Practice Codes.
3.5.3 FORAGE PRODUCTIVITY

Field trials of Kikuyu varieties conducted at the farm over the last 18 months are the basis for determining initial yields of pasture grass. The grass yields resulting from the field trials are anticipated to increase with full establishment of the dairy and maturation of the pastures. Cows on pasture aerate soils while foraging and deposit manure which, in turn, increases organic matter and carbon in the soil. These elements revitalize soil structure through improved microbial communities that assist with incorporation of manure nutrients into the soils, and convert them to a form readily available for plant uptake. Horticultural experts will continue to monitor grass yields during pasture establishment and as part of the ongoing dairy management. As a key piece of the overall nutrient balance, these data sets will help determine the ultimate potential carrying capacity of the farm.

Figure 3.5-2 Kikuyu Grass

Kikuyu and Guinea grasses brought in as cattle forage decades ago will be sown to transform the former sugar cane fields into pasture. The grass thatch will be built and initially maintained by frequent mowing. When the thatch is established, paddocks will be grazed for 8- to 12-hour periods during which cows leave manure behind to nourish soils and grass with a supply of natural nutrients. The dominant grass is Kikuyu (*Pennisetum clandestinum*), a high yielding species that can yield more than 20 tons (U.S.) dry matter per acre annually. In moist, tropical conditions with a year-round growing season, the grass has produced more than 35 tons of dry matter per acre per year.
Figure 3.5-3  Paddock Layout
As the cattle excrete on the Kikuyu thatch, nutrients are incorporated into what is effectively an organic net. Healthy soils contain primary decomposers such as earthworms and dung beetles that move manure into the soil profile when they burrow, aerating the soil to make organic materials accessible to secondary decomposers. Secondary decomposers include microbes (microorganisms) such as bacteria, protozoa, and fungi. The decomposition process breaks down manure into nutrient components that are readily available for uptake by the grass crop. In a healthy system, a manure pile can be removed from the soil surface within 24 hours. Even with the applied manure and effluent nutrients, the grass will need significant additional nutrients from conventional fertilizers to maintain optimum grass growth and yield goals with 699 mature dairy cows.

Kikuyu yield ranges between 4 tons (unfertilized) and 35 tons of dry matter (DM)/acre/year depending on fertilization levels. Kikuyu's response to fertilization is linear, and anticipated growth rates in Māhāʻulepū with irrigation are estimated to be some of the best in the world.

HDF coordinated the collection of Kikuyu grass samples beginning September 2, 2014. Kikuyu grass samples were collected at 18-day intervals between mowing and repeated after every fourth mowing. The intent was to simulate harvest of the grass by cows grazing on the paddock every 18 days, which allows for an 18-day rest period. A random grab sample method was used to replicate a cow grazing. Samples were collected every 5 steps while walking diagonally across the field. About 30 grabs were collected from each field and mixed to create a composite sample for the field. These samples were collected and dried at the same time as the production data samples and sent to Cumberland Valley Analytical services for wet chemistry and in vitro assay of forage quality. The trials were conducted in different locations on the farm for over a year across more than 75 acres of planted pasture.

Although the goal is for a 20-ton Kikuyu yield for mature pasture grass, the Kikuyu grass trials have averaged 16.3 tons of Dry Matter (DM) /acre/year which will initially be used as the basis for all nutrient application rates. The production of grass and realized yields is directly related to the nutrient application rates that can be utilized, as the grass relies on removal of natural or applied nutrients from the soils for growth. As the grass and pasture is established, yields are expected to increase, and removal of nutrients from the soil for uptake to the crop will increase.

Based on the Cumberland Valley Analytical results, the nutrient removal rates for Kikuyu in pounds removed per ton of Dry Matter (DM) which can be used in the nutrient mass balance analysis (see Section 3.5.4, Irrigation and Nutrient Balance) are as follows:

- **Lbs N removed per ton DM** = 64 lbs. N
- **Lbs P removed per ton DM** = 11.4 lbs. P
- **Lbs K removed per ton DM** = 90 lbs. K

While the crop growing season in Hawai‘i is year-round, trials have indicated that production of grass is lower during the winter months and higher during the summer months (16.3 tons of DM / acre/ year is an average). HDF expects to harvest, bale, and store extra grass crops during the summer months to supplement crop production and feed during the winter months to balance the availability of grass feed. Additionally, the grass yields resulting from the field trials are anticipated to increase with full establishment of the dairy and maturation of the pastures, a process which can take up to three years to reach optimal potential.
The NRCS Technical Service Provider working with HDF to develop the nutrient management plan, Red Barn Consulting, incorporated soil and agronomy information from technical consultants gathered at the Māhāʻulepū site (see Section 3.5.4, Irrigation and Nutrient Balance). The findings indicate a nutrient deficient soil regime, requiring supplemental commercial fertilizer for sustained pasture growth in addition to anticipated manure nutrients. The nutrient balance analysis shows that with the committed herd size of 699, supplemental commercial fertilizers will be needed to provide sufficient nutrients for continued soil health and grass productivity.

3.5.4 IRRIGATION AND NUTRIENT BALANCE

Irrigation is the primary method of applying natural fertilizer from the effluent ponds. This section discusses irrigation methods, setbacks, and determination of nutrient application rates.

3.5.4.1 Irrigation

The available pasture for grazing totals 469.9 acres. Of those acres, 346.5 acres will be irrigated with irrigation water and/or diluted effluent through either the pivot irrigation systems or through gun irrigators. Irrigation water supply is provided to the farm from Waita Reservoir, and will be filtered and pumped to the various irrigation components on the farm. The pivot irrigation system utilizes two central pivots that feed water to an overhead, rotating sprayer supported by trusses mounted on wheeled towers that rotate in a 1,000-foot diameter. Nozzles are suspended several feet from the ground to direct water directly onto the pasture grass; the droplet size is large enough to reach the ground effectively without aerosolizing. Irrigation is not conducted during high winds.

The irrigation system will be controlled by a software system utilizing global positioning system (GPS) receivers to allow very precise application of irrigation and/or diluted effluent on the pasture. The rate at which irrigation water and/or diluted effluent will be applied can be varied by controlling pivot speed and water volume, depending on the actual irrigation needs of the farm. A somewhat typical application rate would include a 48-hour rotation and application of up to 0.39 inches of irrigation and/or diluted effluent onto the paddocks. Pivot crossings will consist of an elevated metal track anchored on both sides of the waterway to allow the pivot wheel to traverse ditches without impact.

Approximately 26.2% of the total pasture area will not be irrigated, primarily in the mauka areas of the farm where the pivots are unable to reach. No gun irrigation system will be used in this area. See Figure 3.5-5, Irrigation Map, for irrigated and non-irrigated areas. These areas will receive nutrient application as needed to maintain optimal grass growth; nutrient application is discussed in the following section.

Gun irrigators will be used to irrigate areas not covered by the pivots. The gun irrigators utilize a hard-hose reel, which can be moved throughout the farm as needed (Figure 3.5-4, Irrigated Pasture Area). Additional information on development of an irrigation system and irrigation management plan, including application methods, rates and schedules for irrigation are presented in Appendix D.

The GPS system within the pivots turns the irrigation and/or diluted effluent spray off within 50 feet on either side of a ditch, adhering to the best practice of not applying nutrients within the setback areas of waterways and ditches (see following section). Figure 3.5-4 illustrates the irrigation pivot system.
A separate rotating, hard-hose reel gun system will be utilized for application of solids from the settling pond as slurry, and is discussed in the following section – Nutrient Balance. This system will be completely separate from the gun irrigation system in the makai areas of the farm. A mixture of suspended solids, liquid effluent, and irrigation water will form the slurry mix, which will be pumped from the settling pond via underground piping to hydrants around the farm to which the hard-hose reel gun system connects.

The actual amount of applied irrigation and schedule of irrigation days will depend on the number of rain days and amount of precipitation. Therefore, irrigation demand is further examined on a monthly basis for operational purposes, based upon historical rainfall data, the pasture grass crop evapotranspiration (ET) rates, and average monthly precipitation. Effective precipitation is assumed to be up to 0.80 inches of the daily rainfall amount at the Māhā'ulepū Rain Gauge Station 941.1, with the assumption that rainfall greater than 0.80 inches is either lost to deep percolation into the soil or runoff, thereby reducing precipitation available to the crop (TNWRE, 2016).

Based upon the effective precipitation, demand estimates and methodology described in the Nutrient Balance Analysis (Appendix D), an Irrigation Water Management Plan, which will detail specific farm operating procedures, will be developed to provide the farm operator a plan for proper management and application of irrigation water to allow efficient use of water, minimize energy consumption, and maximize crop yield.
Figure 3.5-4  Irrigated Pasture Area
3.5.4.2 Nutrient Balance

NRCS provides technical guidance on applying agricultural waste depending on the desired use of the waste. Where waste is utilized as a resource, it is being used for the constituent components that provide benefit.

Nutrient management is the practice of managing the amount, rate, source, method of application, and timing of plant nutrients and soil amendments. The NRCS Conservation Practice Standard 590 (referred to as Standard 590), Nutrient Management, is applied to commercial fertilizers, organic by-products, waste water, organic matter, and irrigation water. The timing and application of nutrients should correspond as closely as practical with plant uptake, soil properties and weather conditions. The NRCS Standard 590 purpose, as reflected in a Nutrient Management Plan, is to:

- Budget, supply and conserve nutrients for plant production;
- To minimize agricultural nonpoint source pollution of surface and groundwater resources;
- To properly utilize manure or organic by-products as a plant nutrient source;
- To protect air quality by reducing odors, nitrogen emissions, and the formation of atmospheric particulates; and
- To maintain or improve the physical, chemical, and biological condition of soil.

A Technical Service Provider knowledgeable in NRCS Conservation Practices was retained to work with HDF technical advisors in determining a nutrient balance for the Māhāʻulepū site. Application of manure can be beneficial to soils by improving organic matter, increasing infiltration of water, and improving the soils’ ability to support pasture growth and root establishment.

The Nutrient Management Plan (NMP) developed for HDF includes the following required components:

1. An inventory of nutrient sources on the farm, including manure and crop residues.
2. Nutrient analyses of each of these sources.
3. A budget to supply and conserve nutrients for plant production
4. Soil tests to determine the nutrient needs of the crops to be grown.
5. Procedures for when and how to apply the manure to maximize crop benefit and minimize the environmental impacts of the nutrients.
7. Best Management Practices that minimize agricultural sources of pollution to surface and groundwater resources.
8. Procedures to monitor and maintain or improve the physical, chemical, and biological condition of the soil.

It is important to note that the NMP is an adaptive management tool. Sometimes described as a “living, breathing document,” the nutrient conditions are constantly monitored and the NMP will be updated as conditions on the dairy mature. The results from soil testing, manure testing, and forage testing will be utilized to update and inform the nutrient management process for HDF. Tests will be performed annually at a minimum, and more frequent as needed to assist with nutrient management on the farm.

Liquid effluent, containing vital nutrients for the Kikuyu crop growth that support and feed the mature dairy cows on pasture, will be applied through either of the two center pivots, providing a total application area of 285.1 acres. This represents the pasture area under the pivots, excluding access roads, cow raceways, dairy facility, and the 50-foot setback from drains/waterways. Priority
areas for nutrient application will be recently grazed paddocks that are in a regrowth period for approximately 18 days – a “rest” period for the paddocks, as the grass will require significant nutrient during its regrowth phase.

Soil moisture and the amount of precipitation will also determine the actual amount of both irrigation water and effluent to be applied in an application. Any deficit below field capacity determines the amount that can and may be applied. The frequency and number of heavy rain days will dictate the schedule of both irrigation water and effluent application. The maximum flow rate from the pump injecting the effluent from the storage pond is 320 gallons per minute (gpm). During the 48-hour cycle, roughly 0.12 inches of effluent water is applied via injection into the irrigation water to the center pivot, as part of the 0.39 inches of total irrigation per cycle.

The following liquid effluent setbacks are incorporated into the design to prevent application of effluent within the distance specified below:

- County Well Kōloʻa F – 1,000 feet on all sides (through County DOW agreement)
- Irrigation ditch, agricultural water, and natural water resource - 50 feet from top of bank of the water resource on both sides.
- Cow walkways and races - 6 feet on both sides
- Existing taro farm - 20 feet on all sides

The setback distances from water resources are based upon requirements contained within the “Guidelines for Livestock Waste Management”, by University of Hawai‘i Mānoa, College of Tropical Agriculture and Human Resources (CTAHR). While the minimum setback distance for the application of effluent from public drinking water sources is 50 feet per the Guidelines, HDF has agreed to increase this setback to 1,000 feet following consultation with the County of Kaua‘i Department of Water.

Based upon the areas served by each pivot, 0.54 MG of effluent can be applied by Pivot #1 and 0.39 MG of effluent can be applied by Pivot #2 per run. Each run lasts for a 48-hour cycle. These quantities are well below the irrigation demand of the crop for the 48-hour cycle during the spring, summer, and fall months. The storage pond effluent level will be lowered after each application cycle, as effluent applied by just one run of either pivot is greater than the daily effluent generation of 0.038 MGD at the contemplated herd size of up to 2,000 mature dairy cows.

When soils are saturated, irrigation and effluent application will be delayed until the soil structure can take additional water. Pond levels will be maintained at an operation level that allows capacity to store - in addition to capacity for the 25-year, 24-hour rainfall event - normal precipitation for up to 30 days, suspended solids and effluent from the contemplated herd size of up to 2,000 mature dairy cows, and slurry mixing volume. At 699 mature dairy cows, less effluent is produced allowing for even greater storage capacity and operational buffer. Each application of liquid effluent will be managed by area and volume, to ensure nutrients do not exceed crop demand.

Solids (mostly soft organic matter, but also some sand and mud, etc.), mixed with liquid effluent or irrigation water into a suspension, will be applied on designated areas, at a minimum of every 5 weeks (within 45 days), and it will be applied through a rotating gun system, utilized only for slurry. The slurry gun system is separate from the irrigation gun system used at the makai side of the farm. At 699 mature dairy cows, the area where the slurry will be applied is typically in non-irrigated areas, which are outside of the liquid effluent application area from the center pivot as
well as the gun irrigation system. At 2,000 mature dairy cows, slurry can be applied to non-irrigated areas, which are outside of the liquid effluent application area from the center pivot, as well as areas under the gun irrigation system. Management of the placement of slurry helps to ensure that nutrients or irrigation water are not excessively applied in any particular area, exceeding crop demand.

HDF anticipates slurry application more frequently than the maximum 45 day time frame, to manage effluent levels within the settling pond and reduce the overall volume utilized within the storage pond. If slurry is removed more frequently from the settling pond, more liquid effluent generated by the washdown of the dairy facility would be utilized in the settling pond’s mixing volume for slurry application in lieu of being collected in the storage pond and injected into the center pivots irrigation system, as the settling pond would be more frequently empty. This allows for additional buffer capacity in the storage pond system. Each application of slurry will be managed by area and volume, to ensure nutrients do not exceed crop demand.

Each application of nutrient, whether as-excreted manure from the cows on pasture, liquid effluent from the center pivots, or slurry application, must be managed by area and volume to ensure nutrients do not exceed crop demands. Such management is summarized in a nutrient mass balance analysis. Refer to Appendix D. An overview of Hawai’i Dairy Farm’s planned nutrient mass balance for 699 mature dairy cows is shown in the following table. The mass balance for the contemplated herd size is provided in Section 3.8.3.

The nutrient mass balance approach for HDF assumes that 100 percent of the manure nutrients are 100 percent available at the time of application. This is a very conservative way of calculating nutrients that are available for crop uptake, and ultimately the stocking density and number of animals that can be supported on the pasture. Because of nitrogen dynamics, most nutrient management plans only account for 50 percent of the nitrogen to be plant available while the other 50 percent is lost to the environment through volatilization. This nutrient balance analysis does not take any volatilization into account.
Plant nutrient uptake is also inefficient with respect to phosphorous because of the extensive sorption and binding reactions of phosphorous with the soils at the HDF site, sharply reducing the amount that is plant available. This mass balance uses the full amount of manure nutrients applied to the fields, whether it is irrigated, applied as slurry, or is excreted by the cow directly onto the pasture, as available to the crop, in the management of the farm's nutrient cycle and to determine the overall stocking density. If volatilization or soil sorption were taken into account, more manure nutrients (and more cows up to 2,000) could be used to maintain a healthy pasture and soil/crop nutrient balance.

While the nutrient deficits shown in Table 3.5-1 represent the supplemental fertilizer required for the Kikuyu crop, they are not an exact accounting of the total amount of commercial nutrients that must be applied to maintain high forage productivity and soil health. Rather, these values only represent the net amount of nutrients that need to be provided to and utilized by the crop through commercial fertilization, beyond the nutrient that is available to the crop from manure sources. Fertilization, especially the application of commercial nitrogen, can be inefficient with actual requirements with respect to forage production, and fertilization needs can be as much as 25 to 50 percent greater than the arithmetical difference resulting from a mass balance calculation - due to volatilization or soil sorption (Yost & Krueger, 2016). It should be noted and planned that the commercial fertilization requirements to maintain high forage productivity and soil health can exceed the simple arithmetic difference between the nutrients applied by manure and the forage uptake.

While these two factors in nutrient availability may seem contrary to each other in nutrient management analyses, where it would appear that manure nutrients are 100 percent available to the crop but more commercial nutrients would be needed due to inefficiencies in fertilization, the manure nutrient application and availability are first and foremost, the primary factors in measuring the stocking density of the farm, as the manure is the primary source of nutrients for the kikuyu crop. The commercial nutrient application is only meant to provide the needed deficit of nutrients to the crop, beyond what is provided by the manure, to maintain high forage productivity and soil health. The inefficiencies of nutrient application from a mass balance perspective and from a commercial fertilization perspective do not have the same impacts on the pasture-based rotation grazing dairy system. By assuming 100 percent of manure nutrients are available to the crop (though it is anticipated that nutrients are lost to volatilization of nitrogen and soil sorption of phosphorous), HDF is proposing a very conservative mass balance approach that reduces the stocking density of the farm. By understanding that commercial fertilizers are inefficient due to these same dynamics, HDF is realistic in its commercial fertilizer expectations and what is needed to provide the remaining nutrients to the crop that it does not get from manure sources.

3.5.4.3 Contingency Scenario

The ponds are sized to accommodate 30 days of storage for up to 2,000 mature dairy cows and more than 85 days of storage for 699 mature dairy cows. The ponds will also provide storage for normal precipitation over 30 days and rainfall from the 25-year/24-hour event. It will be highly unlikely that the storage pond will be full at any time for the contemplated 2,000 cow dairy and nearly impossible for the committed 699 cow dairy. For the pond to become full would require a number of extremely low probability events occurring at the same time (large storm events in tandem, extended heavy rain periods, no irrigation days, and no application of the settling pond slurry). Throughout the 30-day storage period, effluent is planned for application every 4 days and the slurry application is expected at least once every 45 days, ensuring that the pond levels are kept at manageable levels.
Nonetheless, if the storage pond were full, the time to completely empty the pond is around 100 hours, if a cataclysmic storm was forecast. If warranted due to potential impact from the approaching storm event, the settling pond could also be pumped empty within an additional 36 hours. If the forecasted storm is forecast six days prior, then virtually no effluent would remain in the ponds when the storm arrives.

3.6 OFFSITE MILK PROCESSING

Under the proposed action, HDF will sell raw milk wholesale to a processor/packager. Milk processing includes pasteurization, bottling and packaging of milk. A processing facility would need refrigeration units, bulk product storage, bulk product transfers to containers, finished product packaging, and trans-shipment staging and loading.

Milk was processed by Meadow Gold at a facility in Puhi until the closure of Kaua‘i’s last dairy at Moloa‘a (Meadow Gold) in the year 2000. The Puhi, Kaua‘i facility could be retrofitted with cooperation from Meadow Gold, the state’s only current milk processor and bottler with operational facilities on O‘ahu and Hawai‘i Island. One option for retrofitting the existing facility could be to pasteurize milk on Kaua‘i, then ship the pasteurized milk to another island for processing and packaging. Another option could be to retrofit the existing facility to bring the milk to market by pasteurizing, bottling and packaging on Kaua‘i. This would be similar to the production of milk from the two existing dairies on the Big Island, where the majority of milk produced and processed is also on the Big Island. In addition to fluid milk, other milk products such as soft cheeses and yogurt could be produced as added-value products. Determination as to the best option for pasteurization and processing would be made by the processor/packager prior to the start of Hawai‘i Dairy Farms operations.

It is anticipated that agreements will be established for milk processing at the existing Meadow Gold Dairies Hawai‘i facility on O‘ahu. Under this scenario, Meadow Gold will take possession of the raw milk on Kaua‘i for shipment. Milk will be trucked in chilled containers from Kaua‘i to the interisland barge dock at Nawiliwili Harbor. Containers will be loaded aboard regularly scheduled interisland barge service, which can carry a variety of cargo including containers and vehicles. Once the barge arrives at its terminal on O‘ahu, containers will be trucked to the existing Meadow Gold processing facility in Honolulu.

Milk processing will be undertaken by the purchaser of raw milk and utilize existing process facilities, equipment, refrigeration units, bulk product storage, finished product packaging, and distribution. Milk and milk products would ultimately be sold to supermarkets and retail stores on O‘ahu, and possibly distributed to customers throughout the State.

3.7 OFFSITE HERD MANAGEMENT BY KAUA‘I RANCHERS

The milk production cycle of a cow begins after birth of a calf, when lactation begins. Newborn calves will be housed on the Māhā‘ulepū site and provided essential colostrum and nutrients for a healthy start. During the calves’ initial 90 days, they will be transitioned to pasture at HDF before transfer to ranches on Kaua‘i to be raised offsite. The permitted herd size of 699 mature dairy cows at the Māhā‘ulepū site applies to mature dairy cows. Animals in various stages of lactation and rest will be transferred between HDF and other ranches as needed for animal health and dairy productivity. This will both benefit the dairy, and infuse the beef market in Hawai‘i with a new, local source of pasture-raised calves. Male calves will become part of the beef cattle herd; heifers (female calves that haven’t given birth) will be raised until returned to the HDF herd as a birthing/milking cow.
Two ranches on Kaua‘i have initially expressed an interest in taking HDF calves and cows. Makoa Ranch near Kapa’a is an active cattle ranch run by the Farias family. The ranch will care for dry cows during an annual resting period, and raise calves until ready for return to HDF pasture. Calves suitable as beef cattle will be incorporated into the Makoa Ranch herd or sold to other ranching operations. “Close-up cows”, or those cows returning to milk production at HDF will initially be transferred to ʻOmaʻo Ranch for transition.

Annually, dairy cows are rested or “dried” for 60 days before returning to milk production. The existing ranch operations are established and require no additional facilities, permits, or improvements to have fluctuation in herd numbers, which is typical of cattle operations.

For the initial two years of operation with the committed herd size, approximately 600 cows and calves will be managed offsite. When the herd has matured, the number of animals to be managed offsite will be approximately 1,100. Section 3.8.4 shows the number of offsite animals under the contemplated herd size.

### 3.8 CONTEMPLATED HERD SIZE

#### 3.8.1 BUILDINGS AND AGRICULTURAL INFRASTRUCTURE

The building design and agricultural infrastructure is capable of accommodating both the committed Proposed Action herd size of up to 699 mature dairy cows, as well as the contemplated Proposed Action of a possible expanded herd up to 2,000 mature dairy cows. The number of animals moving through the dairy facilities would increase under the contemplated herd size. Specific differences between the committed and contemplated herd size are discussed in the following.

Potable water demand will increase with additional cows under the contemplated potential future herd size. Another 25 gpd per animal for drinking water is required, increasing the livestock water demand by approximately 12,500 gallons daily to a total of 50,000 gpd. Additional wash water of 17.4 gpd per animal would be required; this would increase demand by 22,640 gpd. The total potable water demand for up to 2,000 mature dairy cows would be 84,800 gpd, an increase of 54,800 gpd over the committed herd size.

</tr>
</tbody>
</table>
As described in Section 3.3.2, the effluent ponds have been designed in accordance with NRCS and University of Hawai‘i guidance, and were reviewed by the Department of Health in the 2014 HDF Waste Management Plan. The pond design is the same for the committed and contemplated herd sizes. The regulatory design requirement is containment for 30 days of effluent storage for the herd size, plus precipitation and run-off from the 1.75-acre, uncovered portion of the facility that will receive manure and wash water, and precipitation from the 25-year, 24 hour storm event. The HDF pond design includes excess volume equivalent to 30-days of normal precipitation to the surfaces surrounding the pond and provides an additional buffer of 12 percent for spare volume for the 2,000-cow scenario.
3.8.2 **HERD MANAGEMENT**

Under the contemplated Proposed Action of an expanded herd, cows will be managed in larger groups (300-330 cows per mob). It takes more time to milk the entire mob, corresponding to an increase in animal numbers. However, the individual milking time for each cow remains 8- to 10-minutes per cow. The number of paddocks and the acreage remains the same.

With the contemplated herd of up to 2,000 mature dairy cows, there will be approximately 500 calves at any one time, 167 of which will be housed within the calf sheds. This is an increase of 350 calves over the committed herd size model.

3.8.3 **PASTURE MANAGEMENT**

Pasture management for the contemplated herd size of up to 2,000 mature dairy cows is similar to the committed herd size. The 469.9 acres of pasture will be divided into paddocks ranging from 3 to 5 acres in size. Mobs of 300 – 330 cows will graze adjacent paddocks, and move to the milking parlor one mob at a time twice each day.

It is expected that grass yields will improve by several tons per acre with establishment of the committed herd size of 699 mature dairy cows having provided organic nutrients from manure. As explained in Section 3.5.2, the organic matter will result in improved soils and more efficient nutrient uptake by plants. Yields achieved during trials at the HDF site have averaged 16.3 Tons of Dry Matter (DM) / acre / year. With manure and cows on site, yields are anticipated to rise, and HDF anticipates a future yield of 20 tons (U.S.) of Kikuyu dry matter production per acre per year.

The contemplated herd size would produce additional manure both within paddocks and in the milking parlor, providing additional organic nutrients and reducing the requirement of supplemental commercial fertilizer. As a conservative estimate, the nutrient mass balance for the contemplated herd size assumes the grass yields do not increase. As shown in Table 3.8-2, the percentage of nitrogen provided by animals is 88.3 percent, an increase of 57.8 percent over the amount provided by the committed herd size (shown in Table 3.5-1). The percentage of phosphorus increases by 68.4 percent from the amount provided by the committed herd size.

**Table 3.8-2  Nutrient Mass Balance for Contemplated Herd Size up to 2,000 Mature Dairy Cows**

<td>(4.2)%</td>
</tr>
</tbody>
</table>
Total calculation for phosphorus provided by animals exceeds the plant demand at the dry matter yield of 16.3 Tons of DM/acre/year. With a one-ton increase, to 17.3 Tons of DM/acre/year, phosphorus will return to a deficit and require supplemental commercial fertilizer.

Nutrient management and mass balance analyses are dynamic and are influenced by the many different environmental variables that enter into nutrient cycle planning. Variables include grass yields, stocking density, manure nutrient content, soil nutrient content, and crop nutrient content. Several management options exist to keep phosphorus and other nutrients in balance, which may include and are not limited to: improved soil health from initial additions of phosphorus, reduction in contemplated herd size to approximately 1,875 mature dairy cows, or the expected increase in the grass yields from 16.3 tons of DM per acre per year to 20 tons of DM per acre per year (though an increase to 17.3 tons of DM per acre per year would be sufficient to bring phosphorus applications back into balance with crop demand and eliminate any phosphorus overage). Higher grass yields would demand additional phosphorus. Nitrogen from commercial fertilizer would be required at both 1,875 and 2,000 mature dairy cows.

3.8.4 OFFSITE HERD MANAGEMENT

As shown in Section 3.4, the cows managed offsite include cows returning to productivity at HDF, cows in rest, heifers raised until becoming productive dairy cows at HDF, and baby steers available for beef operations. Initially, the contemplated herd size of up to 2,000 mature dairy cows at HDF will provide an additional 900 cows for other ranches to manage. With the contemplated herd fully operational, approximately 2,000 cows will be managed by other ranches.

3.9 PROJECTED COSTS

Total project development costs are estimated to be between $9.5 and $11.5 million. These costs included projected construction needs as well as related equipment expenses to fully develop the project.

3.10 IMPLEMENTATION AND PERMIT SCHEDULE

The timing for implementation of the dairy development is tied to the completion of plan reviews, document reviews, permits and approvals. Table 3.10-1 provides a summary of permits required and status, and an implementation timetable.

This chapter describes the existing environmental conditions and identifies probable impacts of the proposed project. “Environmental conditions” include human and economic conditions as well as natural resources. Strategies to mitigate significant impacts are identified.

As described in Section 2.4, Hawai’i Dairy Farms (HDF) is committed to establishing a herd of up to 699 mature dairy cows to demonstrate the pasture based, rotational-grazing system is an economically and environmentally sustainable model for Hawai’i. With proven success at a herd size of 699, HDF may contemplate possible expansion of the herd in the future. A possible expansion of the herd would require additional permits that would be sought at such time as HDF may decide to pursue an expanded operation. However, to fully disclose potential impacts of both the committed herd size and the contemplated, possible expansion up to a 2,000-milking cow herd, this chapter presents possible impacts of both herd sizes where applicable.

Sections 4.1 – 4.14 present resource conditions and probable impacts that will not differ between the herd size. Impacts that may change with dairy operations at different herd sizes begin with Section 4.15, Demographic and Economic Conditions. Probable impacts and mitigation from the committed herd size of up to 699 milking cows are presented in Sections 4.15 through 4.20. Probable impacts and mitigation for the contemplated expansion of the herd potentially up to 2,000 milking cows are presented in Sections 4.21 through 4.26.
4.1 CLIMATE

Climatic conditions affect the growth of forage and the health of dairy cows. Heat stress can reduce the productivity of dairy cows, and suitable climatic conditions were an important consideration in siting the dairy. Cows in the pasture-based system are on pasture 22 hours of each day and therefore exposed to natural airflow with ample space between animals for cooling. Selecting an appropriate breed of cow for Hawai‘i’s climate was another important consideration for HDF.

4.1.1 Existing Conditions - Climate

The Po‘ipū area is generally known for its mild conditions. Temperatures range from 72 to 86°F in the summer months, and 64 to 80°F in the winter. The area’s climate is greatly influenced by its inland location and valley topography. Winds in the Po‘ipū area are generally from the east-northeast direction (tradewinds) ranging from 5 to 15 miles per hour. Wind conditions vary depending on season and weather conditions, as occasional storms can generate strong Kona winds from the south, and land breeze circulations can develop during times of weak tradewind conditions.

Meteorological data for 2014 was obtained for the project site. Depicted on a windrose, the data shows predominant winds from the northeast. The strongest winds come periodically from the southwest. Calm conditions occur just 1 percent of the time (Figure 4.1-1).

![Wind Direction and Wind Speed](image-url)
Average rainfall in Māhā'ulepū is just under 50 inches annually.

Rain gauge data for a rain gauge located near the site off Māhā'ulepū Road (“Māhā'ulepū 941.1”) was obtained from National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center. The data reveal that more than a week of consecutive rain is very unusual for Māhā'ulepū Valley. The rainfall events for 30 years were recorded (a total of 10,957 days from 1/1/1984 to 12/31/2013) and ranked based on days of consecutive rainfall (DAPR) and the corresponding multiday precipitation total (MDPR). Table 4.1-2 shows only 5 occurrences in the last 30 years with more than a week of consecutive rain. And rainfall exceeded 2 or more inches of rain during only 4 of those occurrences, with 2.6 and 3.7 inches recorded (highlighted in following table).

Solar radiation in the project area is estimated to range from a low of 155.2 watts/square meter in January to a high of 234.5 watts/square meter in June, with an annual average of 196.6 watts/square meter (Giambelluca et al., 2014). This is in comparison to the highest solar intensity for Kaua‘i in the south Po‘ipū area, estimated to range from a low of 164 watts/square meter in December to a high of 296.6 watts/square meter in June, with an annual average of 238.5 watts/square meter. The solar radiation values are estimates, as routine monitoring of solar radiation occurs at relatively few locations in Hawai‘i. University of Hawai‘i researchers have estimated values across the State by combining modeling with observations from ground stations and satellites. The effects of clouds and shading on terrain are incorporated. Information on solar radiation informs evapotranspiration which, in turn, informs understanding of the hydrologic cycle (Giambelluca et al., 2014).

Evapotranspiration is variable and influenced by climate factors, soils properties, and types of vegetation. As evapotranspiration rates are difficult to measure directly, the rates for Hawai‘i have been modeled and mapped across the state. The modeling was conducted to inform management of water resources and to plan conservation activities under agreement between the State of Hawai‘i Commission on Water Resource Management and the U.S. Army Corps of Engineers. Additional information can be found at: http://evapotranspiration.geography.hawaii.edu.

**4.1.2 Probable Impacts and Mitigation Measures - Climate**

Impacts that would be considered significant related to climate could include:

- Increase in solar radiation; and
- Changes to the evapotranspiration cycle from dairy operations.

Greenhouse gas emissions are discussed in Section 4.19.3, Greenhouse Gases.

**Short-term Impacts and Mitigation - Climate**

Changes to solar radiation and the evapotranspiration cycle large enough to affect climate would be large-scale and long-term. The scale of HDF is not large enough to influence these global cycles. Neither the committed Proposed Action (699 milking cows) nor the contemplated Proposed Action (expanded herd) will impact climate conditions in the short-term. No significant impacts are anticipated, and no mitigation would be required.

**Long-term Impacts and Mitigation - Climate**

The scale of HDF is not large enough to influence global cycles of solar radiation and the hydrologic cycle. Minimal construction and an increase in ground cover density will not affect climate processes. The Proposed Action will increase vegetative density across the pasture areas, which will hold more moisture than the current intermittent coverage of vegetation across the site. The 557-acre site is not large enough to have a regional influence on climate.

Neither the committed herd size nor the contemplated herd size will impact climate conditions in the long-term. No significant impacts are anticipated, and no mitigation would be required.
4.2 TOPOGRAPHY

4.2.1 Existing Conditions - Topography

The project site is situated in the valley of Māhā'ulepū ahupua'a on the island of Kaua'i. Māhā'ulepū Valley is located on the leeward side of the Ha'upu mountain ridge, which runs in the east-west direction. The valley is flanked by low ridges. From Mount Ha'upu at 2,297 feet above mean sea level (AMSL), the highest point along the ridge forming the back of the valley, the ground drops steeply down to the valley bottom at an elevation of about 150 feet AMSL.

The upper reach of the dairy farm property begins at the 150 feet AMSL elevation, gradually sloping to an elevation of 60 feet AMSL along Māhā'ulepū Road on the makai side of the project site. Terrain within the dairy typically slopes from 2 to 15 percent, which is the gentle slope required for the comfort of dairy cows when grazing and navigating between paddocks and the milking parlor. Isolated areas of steeper slopes associated with drainages installed by plantation era agricultural operations cross the areas proposed for pasture.

4.2.2 Probable Impacts and Mitigation Measures - Topography

Impacts that would be considered significant related to topography could include:
- Changes to drainage patterns from large-scale excavation, filling, or leveling; and
- Potential for loss of stability.

Facility design utilizes guidance from the Natural Resources Conservation Service (NRCS), National Engineering Handbook (NEH) and from the American Society of Agricultural and Biological Engineers. Conservation practices established in NRCS technical guidance are incorporated both into the design and construction, including the animal walkways (Pacific Islands Area - PI - Code 575), the access road and waterway crossing (Codes 560 and 578), and heavy use area protection (PI Code 561).

The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the HDF site: the milking parlor, calving sheds, implement shed; supporting agricultural infrastructure such as silos and stormwater controls; and the section of paved road with truck turn-around. Areas surrounding the built facilities will be graded to create drainage swales and berms, to install underground pipelines, and to modify existing farm roads and establish cow walkways.

Existing drainage ways will be protected from impacts of cows through fencing, to be installed 35-feet from the top of each bank. Within the pasture area, low lying areas, berms, and other features previously installed by former agricultural operations may be smoothed as needed to minimize hazards to cows.

Best management practices to avoid, control and capture soil erosion from grading and ground disturbance are discussed in Section 4.17, Surface Water Resources. Foundation areas for buildings will utilize cut and fill within the site to minimize disturbances to topography.
Short-term Impacts and Mitigation – Topography

Structural and management controls to limit and route drainage within the construction area are explained in Section 4.17 Surface Water Resource Impacts.

Changes to drainage on the project site in the short-term are not anticipated to be significant as a result of dairy construction. No mitigation is required.

Long-term Impacts and Mitigation - Topography

The existing major drainage ditches on the site will be maintained. Within the 10-acre dairy facility area, swales will be installed as part of the drainage design to route stormwater run-off according to best management practices for livestock operations. In the pasture area, previously installed swales for agriculture and low-lying areas may be smoothed or filled in accordance with NRCS Practice Code for Land Smoothing, to improve surface drainage and uniformity for grazing.

Existing farm roads and cow raceways will be elevated above the pasture grade. Surfaces will be slightly crowned to ensure drainage to either side of the road or raceway and swales roughly 12-inches in depth will be created parallel to each road or raceway. Design and installation of roads, raceways and swales will be in compliance with the HDF Conservation Plan and utilize standards from applicable NRCS Practice Codes.

Changes to topography, including improved drainage, are not anticipated to be significant over the long-term. No mitigation is required.

4.3 SOILS

Soil health, also referred to as soil quality, is defined as the continued capacity of soil to function as a vital living ecosystem that sustains plants, animals, and humans. Soil contains living organisms that perform functions required to grow food and fiber. Soil is an ecosystem that can be managed to provide nutrients for plant growth, to absorb and hold rainwater for use during dryer periods, to filter and buffer potential pollutants from leaving fields, to serve as a firm foundation for agricultural activities, and to provide habitat for soil microbes to flourish and diversify to keep the ecosystem running smoothly (NRCS, 2015).

Comments received during the initial scoping for this Environmental Impact Statement (EIS) included a “Custom Soils Resource Report for Island of Kaua’i, Hawai’i.” The report was generated from the United States Department of Agriculture (USDA) NRCS website, which allows any internet user to define an area of interest, customize data results, and generate a Custom Soil Resource Report. The user can select or deselect parameters based upon which data the user would like to display. These user-generated reports are not evaluated by NRCS.

4.3.1 Existing Conditions - Soils

The types of soils in Māhā’ulepū Valley and soil properties are both relevant to this EIS. The information presented is based on NRCS soils maps, supplemented with two rounds of independent soil sampling to characterize available soil nutrients and conditions. Baseline conditions and implications for long-term soil health and productivity are summarized in the following section, and recommendations for nutrient management are included in the report attached as Appendix C, Hawai‘i Dairy Farms Soils Baseline Nutrient Status.
Soil Types

NRCS has mapped and classified soils for more than 95 percent of the United States. Table 4.3-1 summarizes the soil types for the project area. The most abundant soil types occurring throughout the HDF site are Kalihi Clay and Kaʻena Clay Brown Variant. These soils underlay 32 percent and 29 percent of the dairy project area, respectively (Figure 4.3-1). The Kalihi series is described as “poorly drained” soils that developed in alluvium derived from basic igneous rock. Average annual soil temperature is 74°F. The Kaʻena series is described as a very deep soil, also as poorly drained, and is primarily located on alluvial fans and talus slopes on both Oʻahu and Kauaʻi. Elevations of this soil series vary anywhere from 50 to 150 feet.

The classification of soils as poorly drained indicates the relatively slow rate water movement within soil and to surrounding areas. Poorly drained is not an indication of low or poor infiltration. Infiltration refers to the ability of water to enter the soil surface, whereas “drainage” refers to the movement of water within or from the soil profile. Poorly drained soils typically have low hydraulic conductivity (Yost, 2016). Hydraulic conductivity is further discussed in the following section, Soil Properties.

Soils classified as poorly drained often exhibit anaerobic conditions. Anaerobic conditions typically result in higher rates of denitrification, which is the conversion of nitrate and nitrite to gaseous forms. This essentially reduces the potential for nitrate impacts on waterbodies. With reduced movement of water through the soil profile, the mobility of nutrients such as potassium and phosphorus is also reduced. Soil types at the HDF site are known to adsorb and retain large amounts of phosphorus. In this way, “poorly drained” soils may represent less risk of nitrate and nitrite leaching to associated waterbodies than “well drained” soils (Yost, 2016).

Figure 4.3-1 Soils Characterization at HDF
Soil samples were taken throughout the site in April, 2014 and February, 2015. Laboratory analysis of 2014 soil samples identified pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents. The results illustrate that the soils are depleted of nutrients, which is typical for lands formerly used for sugarcane. The soil nutrient status and fertility demands of the primary crop, Kikuyu grass, were used to identify the quantities of nutrients required for productive grass growth. The soils data provide a baseline to guide adaptive nutrient management throughout establishment and maturity of the dairy.

The second round of field sampling was conducted in 2015 by University of Hawai‘i researchers acting as technical consultants. This sampling focused on evaluation of soils characterized as “poorly drained”, and established a quantitative baseline of soil salinity and sodicity to provide for future monitoring of soil health with application of manure effluent. Laboratory analysis determined electrical conductivity and exchangeable sodium percentage, in addition to nutrient levels of nitrogen, phosphorus, calcium, magnesium, and potassium.

The NRCS Nutrient Management Standard provides a phosphorus leaching index for Hawai‘i soils. The leaching potential for each soil type at HDF is low, with an index value of 10 to 18 which is well below the upper index value of 30 still considered low. The moderate index ranges from 30 to 90, and the high index is for values above 90. Under the NRCS Nutrient Management Standard, on low risk soils, phosphorus can be applied at rates greater than crop requirements, not to exceed the nitrogen requirement for the succeeding crop, if manure or other organic materials are used to supply nutrients. Since the grass crop is not newly planted for each rotation and the growing season is constant and year-round, the phosphorus application is planned to be managed and adjusted to not exceed the crop requirement rate.

**Soil Properties**

Manure will add organic matter to the soil, which improves soil structure. Higher levels of humus and organic matter compounds can improve porosity of soils, which improves water-holding capacity, infiltration rate, and water-capture efficiency. With improved porosity, rainwater can more quickly penetrate the soil, resulting in less runoff and higher rates of water retention. Uptake of carbon dioxide from the atmosphere by plants is the process of photosynthesis. When cows eat plants, organic carbon is returned to the soils as manure. Forms of carbon that are difficult to break down become stabilized in the soil as humus, which provides stable organic material that maintains soil tilth and enhances the ability of soils to absorb water and nutrients (ATTRA, 2001).

Traditionally, soil has been the largest area of storage for carbon on earth. However, human disruption of the carbon cycle throughout periods of modern industrialization has released excess carbon into the atmosphere and into the oceans, resulting in a lack of stable carbon that was previously stored in soils. Photosynthesis is the greatest catalyst of transferring carbon from the air into soil. Once in soils, carbon feeds soil microbes that assist plants in acquiring nutrients and create stable forms of soil carbon (Center for Food Safety, 2015). Microbes such as mycorrhiza effectively transport a variety of needed nutrients effectively into plants, including nitrogen and phosphorus. High rates of synthetic fertilizers have interrupted the biological efficiency of nutrient uptake by plants; in a biologically active environment, ammonia is rapidly converted into an organic form of nitrogen that cannot be leached or volatilized (Jones, 2015).

In waste treatment, the primary functions of soil are to prevent migration of pathogens to surface water or groundwater, retard and reduce contaminants, and provide a barrier against direct human contact.
with effluent. A study prepared for the State of Hawai‘i Department of Health (DOH), Safe Drinking Water Branch identified groundwater zones most at risk from on-site disposal systems by evaluating – among other parameters - soil filtering capacity. Titled *Human Health and Environmental Risk Ranking of On-Site Sewage Disposal Systems for the Hawaiian Islands of Kauai, Molokai, Maui, and Hawaii* (Whittier and El-Kadi, 2014), the study mapped soil hydraulic conductivity state-wide. For adequate treatment to occur, the soil must be permeable enough to prevent saturated conditions, but also have a small enough pore throat diameter to filter pathogens from the effluent. Clay particles act as sorption sites for nitrate and other nutrients. Bacteria in soils can convert reactive nitrogen species into inert nitrogen gas (Whittier and El-Kadi, 2014).

Hydraulic conductivity represents the ability of soils to transport water given a hydraulic gradient, and is expressed in units of feet per day. The hydraulic conductivity of permeable flank lavas in the Hawaiian Islands ranges from hundreds to thousands of feet per day, whereas estimates for less permeable dike-intruded lavas range from 1 to 500 feet per day (Hunt, 1996, in Whittier and El-Kadi, 2014). Figure 4.3-2 depicts the hydraulic conductivity for the south Kaua‘i area. Permeable lavas, represented by a high hydraulic conductivity, increase the distance groundwater can travel before pathogens die-off or contaminants can degrade to a point of being benign (Whittier and El-Kadi, 2014). The weathered alluvium of Māhā‘ulepū Valley shows a hydraulic conductivity on the order of 10.5 – 50 feet per day, whereas the adjacent soils of the Kōloa-Po‘ipū region is on the order of 201 – 500 feet per day. Therefore, water movement through soils under the proposed dairy site is 10 times slower than the neighboring area, allowing greater time for the remedial properties of soil and associated bacteria to denitrify nitrates and render potential contaminants inert.

Implications of soil hydraulic conductivity in the Kōloa-Po‘ipū and Māhā‘ulepū regions are discussed in Section 4.16.2, Potable Water.

### 4.3.2 Probable Impacts and Mitigation Measures - Soils

Impacts that would be considered significant related to soils could include:

- Increased potential for soil loss or erosion;
- Depletion or enhancement of soil nutrients and reduction or increase in organic matter; and
- Creating imbalance of soil nutrients and minerals through application of nutrients in manure and fertilizer.

Minimizing and controlling erosion from construction is discussed in Section 4.2, Topography, and Section 4.17, Surface Water Resources and Nearshore Marine Environment.
Figure 4.3-2 Soil Hydraulic Conductivity
Short-term Impacts and Mitigation - Soils

Short-term soil impacts during establishment of the dairy farm will include earthwork for the dairy facility, creating cow raceways, paving key road areas within the dairy facility, improvements to existing drainage systems, and installation of effluent storage ponds and utility infrastructure. The dairy project has been granted an exemption under Section 22.7.6 of the County Sediment and Erosion Control Ordinance by the County of Kaua’i Department of Public Works provided that conservation practices documented in the HDF Conservation Plan are employed.

Soil conservation is a core principal of the Conservation Plan. Applicable conservation practices are listed in Chapter 3, Section 3.2, Conservation Practices. NRCS practice codes identify design and construction standards related to drainage, materials, operations and applicable engineering standards. Work to date at HDF has followed the Conservation Plan, which was been approved by the West Kaua’i Soil and Water Conservation District in December 2013.

Best management practices are described in Section 4.17, Surface Water Resources and Nearshore Marine Environment. These practices will be documented in the Stormwater Pollution Protection Plan to be submitted as part of the National Pollutant Discharge Elimination System (NPDES) – Construction Stormwater General Permit.

Soil loss during construction will be minimized through the various best management practices and controls. Soil loss is expected to be within permitted thresholds. No significant impacts will result.

Long-term Impacts and Mitigation – Soils

The soil types in HDF are classified as poorly drained, depleted of nutrients. Step one to improve soils for sufficient crop growth is to restore nutrients. Nutrients beyond the crop demand will be taken up by the soils, and will begin to build to levels that will be reflected in improved tilth. The soils are suitable for nutrient application, initially a higher percentage of commercial fertilizers followed by increasing organic nutrients from manure as the herd matures. Estimates by the groundwater engineer are two percent of the nitrogen, and one percent of the phosphorus may pass through to shallow ground water and eventually discharge to the ocean (see Section 4.17, Surface Water Resources and Nearshore Marine Environment). The poorly permeable soils allow little movement of groundwater, which provides ample time for denitrification and for biological organisms in the soil to make nutrients available for plants.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third of the annual increase in atmospheric carbon dioxide (Lal 2004, in Machmuller et al., 2015). The potential soil organic matter and carbon dioxide sequestration benefits are likely greatest in highly degraded soils in warm subtropical climates, partly due to long pasture-growing seasons (Machmuller et al., 2015).

Long-term soil impacts are anticipated to result in improvements to the physical, chemical, and biological condition of the soil.
HAWAI‘I DAIRY FARMS
Draft Environmental Impact Statement

4.4 LAND USE AND AGRICULTURAL SETTING

4.4.1 Existing Conditions - Land Use and Agricultural Setting

The project area occupies agricultural land in Māhā‘ulepū Valley, an area that has a long history of agricultural use, as it was the first place in the island chain where sugarcane was commercially grown. The property is an Agricultural District per State Land Use District designations. The property also features land classified as Prime per the State Department of Agriculture's Agricultural Lands of Importance to the State of Hawai‘i (ALISH).

In 2005, the State established Important Agricultural Lands (IAL) by statute. The purpose of IAL lands is to conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The designation process determines that the land meets physical requirements including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with high soil agricultural productivity ratings under the Land Study Bureau of University of Hawai‘i.

The State Land Use District Boundaries under the State of Hawai‘i Land Use Law classify the uses of lands within Hawai‘i to accommodate growth and development while still retaining the natural resources in the area. The dairy site is situated in the State designated Agricultural District and the County of Kaua‘i designated Agriculture District (Figure 4.4-1).

In 2011, in accordance with Hawai‘i Revised Statutes (HRS) 205-44 and -45 and Hawai‘i Administrative Rules (HAR) Chapter 15-15, Mahaulepu Farm LLC filed a petition with the State of Hawai‘i Land Use Commission (LUC) to designate 1,533 acres of agricultural lands in Māhā‘ulepū (including 557 acres that make up the Hawai‘i Dairy Farm project area) as Important Agricultural Lands (IAL) under the IAL provision of the Hawai‘i State Constitution (Article XI, Section 3). Figure 4.4-2 shows the IAL designation in the South Kaua‘i region. The IAL designation meets the objectives of HRS 205-42 by contributing to the maintenance of a strategic agricultural land resource base to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities.

The designation process determined that the land meets a number of requirements established in HRS §205-45, including contiguous, functional land units large enough to allow flexibility in agricultural production near appropriate infrastructure and water, with 88.5 percent of the area featuring an overall soil agricultural productivity rating of “B” (with ‘A’ representing the class of highest productivity soils and “E” representing the lowest) per the Land Study Bureau of U.H.
The 2000 Kaua‘i General Plan recommended community involvement in planning for the future of Māhā‘ulepū to take into consideration various interests and factors to include: the long-term need to manage lands for preservation of significant natural and cultural features; the landowner’s desire to develop revenue-producing uses that are sensitive to the area’s unique qualities; the need to secure permanent public access to the shoreline; and the potential to create a coastal park (COK, 2000). Grove Farm Company, Inc., in response to a State resolution supporting future preservation of the Māhā‘ulepū ahupua‘a, testified for re-assertion of its rights to plan for its own lands and expressed concern that development of a park or public use of Māhā‘ulepū would support a takings action for government ownership. Grove Farm has continued to allow public access and use of Māhā‘ulepū lands at its expense.

**Neighboring Areas**

Properties immediately surrounding the HDF site are in agricultural use. The south shore of Kaua‘i is home to some of the most productive farm land in the state, attributed to consistent sunshine, ample fresh water, and a large amount of Class A and B soils. The large tracts of farmland with a regional water system such as that maintained by Mahaulepu Farm and Grove Farm, allow for stability in support of farm ventures while providing local residents with a reliable source of employment (HDOA, 2016).

Several single-family farm lot dwellings are located on agricultural lands approximately one mile west of the dairy site’s southwestern corner. The closest residential communities are Kōloa and Po‘ipū, approximately 2.3 miles and 2.5 miles away from the dairy facilities, respectively. Located to
the west and southwest of the dairy property, these communities have an estimated 3,704 housing units, an increase of roughly 3.1 percent since 2000. Approximately 36.8 percent of Kōloa-Po‘ipū housing units are vacant for seasonal, recreational, or occasional use, a higher proportion compared to 14.4 percent of units for Kaua‘i County as a whole (PEP, 2016).

The Po‘ipū Beach Resort area has been developed along the coastline over the past 30 years. During the 1970s and 1980s, agricultural lands in the Po‘ipū area were reclassified from State Agricultural District to Urban District, and rezoned by the County as Resort. Significant expansion along this coastline occurred from 1980 to present, with active development of hotels, timeshare condominiums, single-family resort residences, golf courses, and commercial development. This includes the Grand Hyatt Kaua‘i, Sheraton Kaua‘i Resort and Kōloa Landing.

The largest share of visitor units on Kaua‘i is located within the Po‘ipū/Kukui‘ula area. Of the 8,492 visitor units, 3,065 units were located in Po‘ipū/Kukui‘ula. This includes 1,124 hotel units, or 41.1 percent of the total number of hotel units on the island. Hotels in the area include the Grand Hyatt Kaua‘i Resort & Spa, Koa Kea Hotel & Resort, and the Sheraton Kaua‘i Resort. The Grand Hyatt Kaua‘i Resort & Spa, the closest hotel to the proposed Hawai‘i Dairy Farms, is located approximately 2.4 miles away from the dairy facilities and provides 602 visitor units (Figure 4.4-3).

### 4.4.2 Probable Impacts and Mitigation Measures - Land Use and Agricultural Setting

Impacts that would be considered significant related to Land Use could include:

- Non-compliance with State and County land use designations; and
- Request for change of State and County land use designations

**Short-term Impacts and Mitigation – Land Use and Agriculture**

The development of Hawai‘i Dairy Farms would be in full compliance with its agricultural State Land Use District designation, and embodies the IAL designation per the Hawai‘i State Constitution by using lands in the project area for their intended purpose of diversified agriculture and agricultural self-sufficiency.

No request for change of land use will be made and no short-term impacts are anticipated. No mitigation is needed.
**Figure 4.4-2 Important Agricultural Lands in Region**

Legend:
- **Project Boundary**
- **Important Agricultural Lands (IAL)**

4.5 VISUAL AND AESTHETIC RESOURCES

4.5.1 Existing Conditions - Visual and Aesthetic Resources

The Kōloa-Po‘ipū-Kalaheo Planning District Heritage Resources shown in the Kaua‘i 2000 General Plan depict important landforms with ecological, recreational, cultural, and scenic value. The County’s intent is to preserve these scenic resources and public views, ranging from parks, to highway corridors, mountains and elevated landforms, as well as shoreline views. According to the resources map, the majority of the project area is identified as Open Space, Parks, Agriculture, and Conservation. To the southwest, the Pu‘u Hunihuni crater is identified as an important landform, and Ala Kinoiki Road is identified as a scenic roadway corridor. To the north/northeast, the Ha‘upu Mountains that surround the project area are identified as an important landform (Figure 4.5-1).

Existing views of the dairy property and adjoining agricultural lands at Māhāʻulepū Valley are shown in Figure 4.5-2. The dairy site is not visible from public vantage points along County
roadways or areas along the coastline. Access into the valley is limited to minimize conflict with existing agricultural operations. HDF lands are accessible from Māhāʻulepū Road or other agricultural roads, which are secured by farm gates. The majority of the dairy area has gentle topography, with no evident physical features standing out within this broad agricultural valley. Intervening vegetation and topography generally screen public views of the valley lowlands. From distant vantage points, portions of the HDF pasture area may be visible.

The tallest structures of the Hawaiʻi Dairy Farms facilities would include the milking parlor and associated storage tanks, all of which will be roughly 33 feet in height. These items are in keeping with the agricultural character of the area, and are expected to have minimal to no impact on public views of the Puʻu Hunihuni crater, views from the Ala Kinoiki Road corridor, or the views of the Mount Haʻupu surrounding the project. Dairy farm structures will conform to County height limits for agricultural zoned land.

Figure 4.5-1 Hawaiʻi Dairy Farms Site in Māhāʻulepū Valley, Kauaʻi

4.5.2 Probable Impacts and Mitigation Measures - Visual and Aesthetic Resources

Impacts that would be considered significant related to visual resources could include:

- Changes or obstructions to views due to construction activities and/or equipment; and
- Potential impacts on visual resources by permanent dairy structures and facilities.

Short-term Impacts and Mitigation – Visual and Aesthetic Resources

Views during the farm development phase will show pasture establishment (grazing grass crop grow-out, pasture mowing, fence installation) and facility construction (buildings, erection of silos and tanks). Views of the dairy support facilities development will be very limited, occurring more than 1,000 feet from Māhāʻulepū Road and several miles away from public roads. Construction activity will be short-term, lasting approximately four to six months. There are no public scenic views or lookouts that will be affected by construction of the dairy.
Due to the limited public access to view locations along farm roads in Māhā’ulepū Valley, there will be little or no impact to public views of the dairy property during the development of the dairy pastures and support facilities.

Figure 4.5-2 Views of Māhā’ulepū Valley and the Dairy Property
(View Key Provided in Figure 4.5-3)
Figure 4.5-3 View Key Map
Long-term Impacts and Mitigation - Visual and Aesthetic Resources

The tallest structures of the Hawai‘i Dairy Farm facilities include the milking parlor and the associated storage tanks, which will be roughly 33 feet tall. These facilities will be noticeable from offsite locations with distant views of the pastures and dairy facilities location. The proposed facilities are in keeping with the agricultural character of the area, and are expected to have minimal impact to public views.

There are no public scenic views or lookouts that will be affected by dairy development or operations. There will be no adverse effect to public views of the Pu‘u Hunihuni crater, views from the Ala Kinoiki Road corridor, or impediment to views of the Mount Ha‘upu.

4.6 NATURAL HAZARDS

Natural hazards affecting Hawai‘i include flooding, tsunamis, earthquakes, and hurricanes. According to the 2002 USGS Atlas of Natural Hazards in the Hawaiian Coastal Zone, the Po‘ipū coast has an Overall Hazard Assessment that ranges between low (3) to moderate (5). Figure 4.6-1 depicts the hazard ratings for the various natural hazards that could affect the Po‘ipū coastal area.

4.6.1 Existing Conditions - Natural Hazards

Flooding

The Māhā‘ulepū area is located within Federal Emergency Management Agency (FEMA) Zone X, based on FEMA Flood Insurance Rate Map (FIRM), which includes areas outside the 0.2% annual chance floodplain (Figure 4.6-2).

With the discontinuation of sugarcane cultivation in 1996, culverts and ditches in the valley became impacted with sediments and vegetation. During periods of high rainfall, reduced capacity caused Waiopili Ditch to be overwhelmed and stormwater was reported flowing across Māhā‘ulepū Road. Since leasing the site, HDF has worked with the landowner, Mahaulepu Farm, to remove sediments and restore capacity to the ditches. Calculations of rainfall runoff show sufficient drainage capacity in the ditches when maintained with minimal sediment build-up.

Tsunami Inundation

The proposed location for HDF lies between the 60 and 150 feet elevation, outside the tsunami evacuation zone (Figure 4.6-2). There is no threat of tsunami inundation at the project site.

Hurricanes

Historical hurricane paths over the central Pacific show a typical pattern passing to the south of the Hawaiian Islands, with a maximum hurricane occurrence during the late summer when the ocean surface is warmest. Storms that approach the Hawaiian Islands from the east have historically weakened east of Hawai‘i under the combined influence of unfavorable westerly wind conditions, resulting in large wind shear and cooler sea-surface temperatures. However, natural variability in ocean circulation and atmosphere has allowed potentially destructive storms to reach Hawai‘i from the east. Hurricanes Dot (1959), Iwa (1982), and Iniki (1992) all approached from the south and passed near Kaua‘i. This unusual track requires a breakdown of the semi-permanent ridge of high pressure to the north of the islands, which occurs when a trough of low pressure approaches the island chain from the northwest. Such troughs are generally confined to higher latitudes, except in winter.
Although they occur infrequently, Kaua‘i has received a greater amount of damage from hurricanes when compared to the other Hawaiian Islands.

![Figure 4.6-1 Natural Hazard Rating for Po‘ipū Coast](http://pubs.usgs.gov/imap/i2761/sections/2_Kaua'i.pdf)

**Seismic**

The Kaua‘i and Ni‘ihau region of the Hawaiian Islands has experienced tremors from earthquakes originating further south in the island chain, but no known seismic activity has originated among these northern islands. Per the 2006 International Building Code (IBC) Seismic Design Map (Figure 1613.5(10)), the project area could experience seismic activity between .20 and .25 of the earth's gravitational acceleration (g-force). This represents the upper limits of probable force experienced by the region during a probable seismic event. According to the USGS, seismic hazards in the Po‘ipū region are low.
Impacts that would be considered significant related to natural hazards could include:

- Damage to facilities or harm to personnel or livestock from natural hazards; and
- Failure to anticipate and plan for protection of the dairy facility and operations from a natural hazard.

Preparedness is the best protection for natural disasters. Structural design of dairy facilities will meet IBC 2006 standards with local amendments. Provisions in design will address wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation of the area recommended Seismic Site Class D under IBC standards be utilized for foundation design where the barns and agricultural infrastructure will be constructed.

A natural disaster plan has been prepared by the Hawai‘i Dairy Farms’ manager to address hurricane, fire, and potential flooding hazard scenarios. HDF is not in a tsunami inundation area, so this scenario is mentioned in the disaster plan only for HDF personnel to maintain awareness. The disaster response plan outlines safety procedures during the event, follow up actions, and emergency contacts for assistance before, during or following the event.
The disaster plan relies upon knowledge of cow behavior. Extensive guidance for livestock protection comes from NRCS, the Florida State Agricultural Response Team (SART), Pennsylvania State College of Agricultural Sciences, and Cornell University Cooperative Extension. Adapting guidance to specific natural disaster threats is the first step in preparing the HDF disaster response plan. Land managers in the Māhā'ulepū region during hurricanes that affected Kaua‘i in 1982 and 1992 observed defoliation of vegetation, and no flooding event in the period following passage of the storms (Killerman, pers. com.).

For the herd at HDF, which will not be confined within structures, the 470 acres of pasture within the valley would provide the best protection. Evacuation off the farm is not planned. Cows sense security in numbers, and prefer to remain within a group (known as a mob, described in Chapter 3). Mobs will be moved to an appropriate group of paddocks based on the threat. Each paddock is equipped with sufficient drinking water troughs for the number of livestock corresponding to paddock size. Once the threat has passed, mobs will be returned to the next scheduled paddock in the mobs’ rotation.

Ditches and culverts will be monitored for blockages or debris dams during high rainfall events. Such debris would be removed to maintain the full capacity of the ditches.

**Short-term Impacts and Mitigation – Natural Hazards**

Emergency procedures for the construction site will comply with Occupational Safety and Health Administration (OSHA), County of Kaua‘i, and State of Hawai‘i safety requirements. An emergency preparedness plan for protection of animals has been prepared for HDF internal use. Construction design will meet IBC standards with local amendments. No short-term significant impacts are anticipated related to natural hazards.

**Long-term Impacts and Mitigation – Natural Hazards**

Geologic and potential natural hazards pose no major constraints to the project. Emergency management procedures and staff training for emergency events will be in place to implement prevention and mitigation should natural hazards occur in the region that may impact the dairy herd or facilities.

There has been no storm event that would exceed the capacity of the effluent ponds since rainfall has been recorded in Māhā'ulepū Valley (see Section 4.1, Table 4.1-2). The effluent pond capacity for the committed herd size of 699 milking cows has been designed well beyond the regulatory requirements, and would provide nearly 1 million additional gallons of storage. As an additional safeguard, a secondary containment berm with an additional capacity of 1,131,000 gallons – representing more than 85 days of effluent with wash water from the 699 milking cow herd – is included in the design. So there are two stages of storage capacity beyond both the regulatory requirements and any recorded rainfall event over the past three decades.

**4.7 ARCHAEOLOGICAL AND HISTORIC RESOURCES**

The Hawai‘i Dairy Farms project is subject to a historic preservation review by the State Department of Land and Natural Resources, State Historic Preservation Division (SHPD) under HRS Chapter 6E and Chapter 13-284. An archaeological inventory survey (AIS) of the proposed site was conducted in July and August 2014 by Scientific Consultant Services, Inc. The following comes from the findings of the AIS, which is included as Appendix G.
4.7.1 Existing Conditions - Archaeological and Historic Resources

Archaeological Studies

Previous archaeological studies along the Māhā'ulepū coast have identified a number of sites including petroglyphs, human burials, fossils, cultural artifacts, and several heiau. However, despite the vast amount of archaeological information available for the coastal areas, inland studies of Māhā'ulepū — including the project site — are limited. The only site previously identified and given an official State site number was Site 3094, located at the northern end of the valley on land outside of the boundaries of the project area. This site contains a large boulder with about 20 anthropomorphic figures (petroglyphs), two pecked cups, and a long etched groove.

A total of 16 sites were identified during the AIS (Figure 4.7-1). These sites were identified through pedestrian survey of the project area and an extended survey area within 100-meters of the northern boundary. Fifteen (15) of the sites were newly identified during the current survey and one site, State Site 50-30-10-3094, had been previously identified and was again found during this survey. Of the 16 identified sites, 6 sites occur in the project area and 10 sites occur in the extended survey area. One of these newly identified sites offsite is believed to be associated with pre-Contact and/or early historic times, a rectangular rock enclosure (Site 2250) interpreted to be an agricultural heiau. Only one other pre-contact site, the petroglyph boulder, is offsite. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century, all of which are affiliated with sugarcane cultivation.

That a majority of the documented sites are related to the historic-era is not surprising, given the massive landscape modifications that occurred during intensive sugarcane cultivation on the valley floor. Survey and subsurface exploration within a cluster of land commission awards (LCAs) within the valley revealed no historic era cultural materials. LCAs represent land claims by commoners following a change of ownership from ali‘i (Hawaiians of noble descent) to those who had longevity of occupancy.

Historic Period Development

Sugarcane began to be grown and milled commercially in Māhā'ulepū Valley and around Kōloa in the 1820s. In 1835 the Kōloa Plantation, owned by Ladd and Company, was up and running, the first attempt at producing sugarcane commercially. The land was leased for a fifty-year period from Kaua‘i Governor Kaikioewa and King Kamehameha III. The lease was the first of its kind in Hawai‘i and was the first formal recognition that an individual other than a chief could control land use.

The sugar industry grew sporadically between 1845 and 1875. The Hawaiian Government benefited from a reciprocity treaty negotiated towards the end of this period, allowing all unrefined Hawaiian sugar to be admitted into the United States duty free. Kōloa Plantation commenced growing sugarcane in Māhā'ulepū Valley in 1878, a practice that continued for more than one hundred years.

The various parcels around Kōloa went through a succession of owners until 1864 when George N. Wilcox consolidated and purchased all of Māhā'ulepū Valley and coastal lands forming Grove Farm Company. Sugar cultivation in the valley continued through 1996. Since the cessation of sugarcane cultivation, Māhā'ulepū Valley has been the location of ranching (2002) and taro cultivation (2007), the latter conducted by W.T. Haraguchi under lease.
Figure 4.7-1 Archaeological Survey
4.7.2 Probable Impacts and Mitigation Measures - Archaeological and Historic Resources

Impacts that would be considered significant related to archaeological and historic resources could include:

- Disturbance or discovery of archaeologic or historic features during construction; and
- Potential future disturbances of historic sites from on-going dairy operations.

Short-term Impacts and Mitigation – Archaeological and Historic Resources

The findings of the current AIS indicate that portions of the project area were used for agriculture in the period after European contact. No pre-contact cultural sites were identified within the project site boundaries. In the unlikely event that archaeological resources are discovered during construction, appropriate procedures will be followed as required in applicable Hawaiʻi Revised Statutes and regulations, including contacting State Historic Preservation Division.

The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will contain dairy activities and related impacts within the project area. No short-term impacts are anticipated.

Long-term Impacts and Mitigation – Archaeological and Historic Resources

The sixteen historic properties were assessed for significance by the archaeological consultant. No effect from dairy facility installation or operations is anticipated, and no further archaeological work is recommended for the sites. The two sites considered significant under multiple criteria occur outside the project area. Neither site will be adversely affected by the proposed dairy project.

A majority of the identified sites within the project area were associated with Plantation-era sugarcane cultivation, and will not be adversely affected by the proposed project. Most are in fair to good condition. While representing an interesting time period in the history of the Kūloa-Māhāʻulepū area, no further work is recommended as all relevant information has been gathered from these sites. Adaptive re-use is a possibility, such as use of bridges and culverts. No long-term impacts are anticipated, and no further mitigation is recommended for the project area.

4.8 CULTURAL PRACTICES AND RESOURCES

Scientific Consultant Services, Inc. prepared a Cultural Impact Assessment (CIA) of the dairy farm and vicinity dated April, 2016. The CIA evaluation seeks to assess traditional cultural practices as well as resources pertaining to the project area within the ahupua’a. This section summarizes the types of traditional practices and cultural resources associated with the proposed project site vicinity. The full CIA is in Appendix H.

4.8.1 Existing Conditions - Cultural Practices and Historic Resources

Traditional Hawaiian Background

Early settlement and agricultural development is thought to have been first established on the windward sides of the Hawaiian Islands sometime in the A.D. 900-1000 range on Kaua‘i during what is known as the Colonization Period. Most likely arriving from east Polynesia, these early inhabitants brought with them a variety of tools, fishing gear, and household goods. Dogs, pigs and chickens were brought by these Polynesian voyagers for food.

Considering that every food crop cultivated by the Hawaiians arrived with them shows a considerable knowledge not only of the planting and harvesting of these crops but the ability to transport their seeds, cuttings, and roots. Prior to European Contact (1778), Hawaiians cultivated taro in both irrigated and dry fields. Other dry land agriculture crops included ‘uala (sweet potato), uhi (yams), mai’a (bananas), ipu (gourds), and kō (sugarcane).

Hawaiian aquaculture was extensive, with the construction and maintenance of coastal and riverine fish ponds. Their fishing ranged from shoreline to pelagic with different strategies for each. In order to maintain and benefit from all of these resource zones, Hawaiian polities were organized into ahupua’a which gave residents access to a wide array of resources extending from mountain top forests to deep sea fishing zones. Ahupua’a boundaries could expand, contract, appear, and disappear, as dependent upon political events. Given the size of Māhā‘ulepū Valley and environs, this ahupua’a was highly valued.

Initial Polynesian settlement of Kaua‘i occurred in the resource-rich regions surrounding Wailua River, on the east coast, the equally verdant Waimea River region on the southern coast, and the Hanalei region on the north coast. Pre-Contact sites have been most commonly identified in coastal or near coastal areas, locations removed from intensive sugarcane production. Initial settlement is presumed near the coastline in the A.D. 1000 to 1200 range, with expansion inland during the A.D. 1400 to 1600s, as was typical across the islands.

In early 1778 Captain James Cook and the two ships under his command, H.M.S. Resolution and H.M.S. Discovery arrived off of Kaua‘i. Finding that they could not make land fall at Wailua, Cook continued westward until reaching Waimea. This would be the beginning of contact between Europeans and Hawaiians. After the death of Cook in 1778, the journey continued, now under the command of Captain Clerke. After their departure a short time later, it would not be until 1786 that Europeans returned to the Hawaiian Islands, with Waimea (Kaua‘i) receiving her share of British and American vessels focusing on the lucrative fur trade in the Pacific Northwest.
Beginning in approximately 1790, battles between several rulers on occurred and around Maui, Moloka‘i, and Hawai‘i Island with increasing ferocity. After two unsuccessful efforts that failed in 1796 and 1804 due to storms and smallpox respectively, in 1810 King Kamehameha I used diplomacy, suggesting that he rule the eastern islands in name and deed, while the ruler of Kaua‘i, King Kaumualii, acknowledge his suzerainty but continue to rule Kaua‘i and Ni‘ihau. It was agreed that the arrangement would end with the death of Kaumualii and that rule would then pass to the heirs of Kamehameha.

This arrangement lasted between 1810 and 1822. It endured the death of Kamehameha the Great in 1819. During these 12 years, Kaumualii solidified rule of his kingdom and engaged in efforts to gain foreign weapons and support from the Russian Fur Company. Also during this time, the trade in sandalwood flourished. Harvested in the Hawaiian Islands, traded for goods to European and American captains, and sold in the Chinese trade ports of Macao and Canton, sandalwood became the first Hawaiian cash crop. The independent rule of Kaua‘i came to an end in 1824 with the death of Kaumualii. This same year, the heir of Kamehameha, Li‘iholii Kamehameha II also died. The kingdom of Hawai‘i would now be ruled by Queen Ka‘ahumanu. Ka‘ahumanu ruled as Regent until her death in 1831.

A daughter of Kamehameha, Kīna‘u, took over as regent until 1834 at which time Kauikeaouli Kamehameha III took the throne. He had lived on Kaua‘i as a boy but had spent the majority of his youth on O‘ahu. Ruling until his own early death in 1854, his reign was admirable for its civil rights, efficiency, and the creation of the Great Mahele, by which land awards to commoners and granting ownership to the disenfranchised was achieved. In Māhā‘ulepū, there were many Land Commission Awards, but the majority of the acreage was retained by the government. In 1831, the heir of Kamehameha, Liholiho Kamehameha II also died. The kingdom of Hawai‘i would now be ruled by Queen Ka‘ahumanu. Ka‘ahumanu ruled as Regent until her death in 1831.

Traditional and Historic Land Tenure and Use

The Māhele was a drastic change in the lives of Hawaiians. Commoners, also known as maka‘ainana, had for centuries been allowed use, but denied ownership, of the lands they worked. This changed in the late 1840s when private ownership of lands was made into law. Certainly ali‘i, or nobles, had the better of the deal, but commoners were allowed to claim, through right of labor and longevity of occupancy, LCA. Many of LCAs for Māhā‘ulepū are tightly clustered within the ‘ili of Kawailoa, which is within the current project area. There is a cluster east of Māhā‘ulepū Ditch near the center of the valley. The remainder of the valley was deemed government land. Thus, no LCAs occur elsewhere in the project area or the extended survey area.

The Governor of Kaua‘i in 1842 was Keakaono, the granddaughter of Kamehameha. During her governorship she partook in land exchanges, consolidating her grants in Māhā‘ulepū and Kōloa. These consolidated lands would become the basis for the next cash crop, one that could be rejuvenated and continued, unlike sandalwood. From the 1830s until the 1990s, sugar would be the economic focus of Māhā‘ulepū. Remnants of industrial-level sugarcane cultivation in the area represent the greatest number of historic properties documented during the current AIS study.

That the entire valley (including the project area) was under intensive sugarcane cultivation is evidenced by the infrastructure put into the valley through time. Early 20th century maps also document the extent of the fields throughout the Kōloa area, showing the entirety of the current project area consisted of sugarcane lands.
4.8.2 Probable Impacts and Mitigation Measures - Cultural Practices and Historic Resources

Impacts that would be considered significant related to cultural practices and resources could include:

- Isolation of cultural resources from their setting; and
- Introduction of elements that may alter the setting in which cultural practices take place.

Short-term Impacts and Mitigation – Cultural Practices and Resources

The cultural assessment examined the potential effect of the project on cultural resources, practices or beliefs. Information received from the community indicates the Māhā‘ulepū ahupua‘a has been and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. Gathering of plants and marine resources, and two known State sites are outside the project area: State Site 50-30-10-2250, the agricultural heiau; and State Site 50-30-10-3094, a carved petroglyph boulder. No significant cultural sites occur within the HDF site.

No change to current cultural practices within the Māhā‘ulepū ahupua‘a will occur from dairy establishment or operations.

Long-term Impacts and Mitigation – Cultural Practices and Resources

The perception of most community members interviewed was that the dairy may have indirect and direct negative impacts on the environment in the area. This EIS analyzes potential environmental impacts, which are summarized in Section 4.27.

The findings of research related to preparation of the Cultural Impact Assessment for the dairy site, including interviews of community members, states that it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.

4.9 FLORA

A botanical survey of the dairy property was conducted by Eric Guinther (August 2014) to assess the existing plant species. The survey also investigated for the presence of plants currently listed as endangered, threatened or proposed for listing under Federal or the State of Hawai‘i’s endangered species programs, located onsite or within the immediate vicinity of the dairy site. The findings of the assessment are included in Appendix A.

4.9.1 Existing Conditions - Flora

The Hawai‘i Dairy Farms project site is proposed for an area currently in pasture. The pastures vary between recently cultivated and various states of weedy regrowth. No active grazing was observed at the time of the survey (July 2014). A small herd of cows (*Bos taurus*) were seen within a paddock beyond the east side of the property. Consequently, while many of the pastures are a mix of open ground and weedy growth, others are densely overgrown with grasses and other herbaceous plants. Trees are few and scattered, mostly along waterways on the property. Along the edges of the survey area, on the east, north, and west, the sloping land is forested. Since nearly all of the forest is out of the survey area, it was visited at numerous points along the margin but not entered for any significant distance (generally only as far as the old plantation ditch which extended around the valley edge). The vegetation within the project area is herbaceous and typical of regularly disturbed land (i.e., agricultural).
In all, 115 species of plants were identified from various parts of the survey area. Only five of these (or 4.3 percent) are species native to Hawai‘i, and all of those are considered indigenous (found in Hawai‘i and other Pacific Islands, as opposed to endemic species that are unique to the Hawaiian Islands). All of the remainder (110 species) are introduced plants that have become naturalized, with the exception of one introduction that is regarded as an ornamental plant.

A somewhat unusual aspect of the flora is the abundance of a number of weedy herbaceous dicots in the fields. Species, such as false ragweed (*Parthenium hysterophorus*), kikāna (*Xanthium strumarium*), little bell (*Ipomoea triloba*), fuzzy rattlepod (*Crotalaria incana*), sensitive plant (*Mimosa pudica*), and prickly sida (*Sida spinosa*), are especially abundant covering large areas of relatively recently disturbed pastureland. Guinea grass (*Urochloa maxima*) and California grass (*Urochloa mutica*) are dominant in areas where the pasture has not been disturbed recently by tilling or ungulate browsing, and are abundant mixed with the dicot herbs just mentioned. There are also pasture areas where other species of grass predominate.

Five indigenous species were identified in the botanical survey. These include the ‘ilima (*Sida fallax*), a common short-stature shrub, moa (*psilotum nudum*), a ground cover fern, ‘uhala (Waltheria indica), a short-stature shrub, hala (*Pandanus textorius*) a medium to large size shade tree, *Cyperus polystachyos*, a short-stature shrub, and *Fimbristylis dichotoma*, a grass-like plant that grows in/around water features.

The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur on this land. The results of the survey substantiate this prediction. Only four percent of all plants recorded during the survey were native, indicating that only species adapted of constant disturbances can survive. With but a few exceptions, these adapted species are non-natives in the lowlands of the Hawaiian Islands.

A search of Bernice P. Bishop Museum Herbarium records conducted by Anita Manning, yielded 91 entries for “Māhā’ulepū”. The majority of the natives in the listing were collected along the coast or “Hāʻupu Ridge” or “Pu‘u Pihakapu”. The list of rare native species is impressive, and though the locations are associated with Māhā’ulepū Valley, the habitats represented are vastly different from those of the valley floor where the dairy would be located. Indeed, all of the plants of interest were collected in either coastal dunes, exposed coastal sites, or the steep, rocky cliffs at elevations well above the site. All species in the collection with locations likely to be similar to, if not in, the project pasture lands, are non-native species.

An endangered native plant, ‘ōhai (*Sesbania tomentosa*, a shrub in the pea family), is typically found in dry, coastal areas below 2,500 feet elevation. Destruction of its natural habitats has greatly reduced natural occurrence Statewide. According to the National Park Service Māhāʻulepū, Island of Kaua‘i Reconnaissance Survey (2008), the U.S. Fish and Wildlife Service has designated Critical Habitat along the entire Māhāʻulepū shoreline for the endangered ‘ōhai. No suitable habitat for the ‘ōhai plant exists on the dairy site.
4.9.2 Probable Impacts and Mitigation Measures - Flora

Impacts that could be considered significant related to flora could include:

- Disturbance or displacement of native vegetation and native habitats, or flora with State or Federal status as threatened or endangered; and
- Long-term degradation of native habitat or flora on site as part of on-going dairy operations.

Short-term Impacts and Mitigation – Flora

Native plants with potential to stabilize banks will be encouraged and supplemented if needed to enhance the planned buffer strips along drainages (Section 4.17.2, Surface Water Quality). No threatened or endangered plants occur on the project property. Only 5 of the 115 plant species recorded during the survey were native, and no intact native habitat exists. Construction of the dairy farm is not expected to result in adverse impacts to native plants.

Long-term Impacts and Mitigation – Flora

Vegetated buffer strips along the drainageways are part of the Conservation Plan to reduce erosion and stabilize slopes. Where native plants occur or could survive if planted, native plants will be used in the stabilization. No long-term impacts to native plant habitats or endangered or threatened plants species will occur as a result of the dairy.

4.10 FAUNA

Avian and mammalian surveys were conducted by Rana Biological Consulting, Inc. (August 2014). This survey was conducted to assess the potential presence of avian or mammalian species currently listed as endangered, threatened or proposed for listing under either Federal or State endangered species lists. The survey covered the dairy site area and immediate vicinity. The results of the survey are included in Appendix A.

4.10.1 Existing Conditions - Fauna

A total of 1,070 individual birds of 31 species, representing 23 separate families, were recorded during station counts. Of the 31 species detected during station counts, seven were native species. Four of the native species are listed as endangered under both Federal and State of Hawai‘i: Nēnē (Branta sandvicensis), Hawaiian Duck (Anas wyvilliana), the Hawaiian sub-species of the Common Gallinule (Gallinula galeata sandvicensis) and Black-necked Stilt (Himantopus mexicanus knudseni). The remaining three native species detected during point counts, Black-crowned Night-Heron (Nycticorax nycticorax hoactli), Pacific Golden-Plover (Pluvialis fulva), and Wandering Tattler (Tringa incana) are indigenous species. The heron is an indigenous resident breeding species and the plover and tattler are indigenous migratory shorebird species. An additional endangered endemic species, Hawaiian Coot (Fulica alai) was recorded as an incidental observation while transiting from one count station to another. The remaining 27 avian species detected are alien to the Hawaiian Islands.

Avian diversity and densities were in keeping with the location of the property and the habitats presently on the site. Four alien species, Zebra Dove (Geopelia striata), Cattle Egret (Bulbucus ibis), Common Myna (Acridotheres tritis) and Japanese White-eye (Zosterops japonicus) accounted for 52 percent of all birds recorded during station counts. The most commonly recorded species was Zebra Dove, which accounted for 18 percent of the total number of individual birds recorded. An average of 38 individual birds was recorded per station count, a number that is relatively high for a lowland site on Kaua‘i.
Six terrestrial mammalian species were recorded on the site. A small herd of cows (*Bos taurus*) were seen within a paddock just beyond the east side of the property. Flocks of recently shorn sheep were present within the taro farm, which is located within the dairy property, but is not part of the dairy farm. All other species identified in the survey are listed in Appendix A. No mammalian species proposed for listing, or listed as endangered or threatened under either Federal or State of Hawai‘i endangered species statutes, was recorded during the course of this survey (DLNR 1998; USFWS 2014).

### 4.10.2 Probable Impacts and Mitigation Measures - Fauna

Impacts that would be considered significant related to fauna could include:

- Disturbance or displacement of endangered species habitat during construction; and
- Long-term disruption of fauna on site and nearby as part of on-going dairy operations.

**Short-term Impacts and Mitigation – Fauna**

There is no critical habitat for endangered species in the upper Māhā‘ulepū Valley. Four species of endangered waterbirds have been recorded on the site, though the area does not provide critical habitat. Seabirds that nest in upland areas of Kaua‘i may overfly the site; outside lights used at night will utilize shades to protect against uplighting to prevent possible disorientation of the birds.

Short-term impacts for waterbirds and seabirds could be posed by construction activities, such as clearing and grubbing, which have the potential to disturb nesting waterbirds, nests, eggs and young. There also is the potential for interactions between endangered waterbirds and construction equipment, vehicles and construction personnel. Waterbirds disturbed when nesting may abandon their nest, eggs and to a lesser degree chicks. Nēnē nest in the general Kōloa area, and the habitat present on parts of the site is suitable for nēnē nesting. Potential impacts to this species are similar to those discussed for waterbirds, though nēnē may utilize areas far from water to nest, if adequate shrubbery exists. Increased vehicular traffic associated with construction activities also increases the risk of birds being run over or hit by vehicles, within the dairy site.

Measures will be adopted to avoid potential seabird and nēnē goose collisions with fences and structures. Potential measures include lowering construction cranes at night, using conservation fencing to protect specified areas, marking tall structures and fencing with white visibility polytape, limiting nighttime lighting, and shading any outside lights used at night.
During the construction phase and throughout day-to-day operation of the dairy farm, the following measures and training are recommended to ensure that construction activities do not result in deleterious impacts to the birds that may be encountered during construction.

- Develop an endangered species awareness training module
- Provide endangered species awareness training to construction and other workers prior to starting work
- Prepare Endangered Species Identification references with photographs, description of habits, and likely areas on the property where they are most likely to occur and/or to nest
- Have qualified biologist survey for nesting waterbirds and nēnē immediately prior to construction activities. Halt activity if nesting activity is identified within 100 feet of construction until nesting activity has ended. Alternately, consult with State or Federal wildlife regulators to determine the best course of action
- Post 15 mile per hour speed limit signs and enforce on all roads within the project
- No pets allowed on property – especially dogs and cats
- Provide closed trash receptacles for all personnel and visitor food and provide for disposal
- Enforce no feeding of any birds
- Designate construction personnel parking areas
- Survey and delineate construction materials and equipment parking and maintenance areas
- Include the above as contract provisions and in construction best management practices
• If nighttime construction activity or equipment maintenance is proposed during the construction phases of the dairy farm, all associated lights should be shielded, and when large flood/work lights are used, they should be placed on poles that are high enough to allow the lights to be pointed directly at the ground.
• All outdoor lights installed as part of the project will be shielded to reduce the potential for interactions of nocturnally flying seabirds with external lights and man-made structures (Reed et al., 1985; Telfer et al., 1987).
• Maintain traps with or without baits to capture feral cats or rats that may harm waterbirds or nēnē transiting or using the HDF site.

Long-term Impacts and Mitigation – Fauna

The impacts described for the dairy construction period for the four waterbird species and seabirds potentially overflying the area would be similar for long-term dairy operations. Additionally, operation of the dairy may attract higher densities of mammalian predators such as cats, dogs and rats. On many dairy farms the increased number of rodents drawn to feed, silage and waste treatment areas is usually alleviated by encouraging cats within the facility to assist in the control of rodents. The increase in either or both of these predators would pose heightened risks to nesting Nēnē and protected waterbirds, nests, eggs and their young.

It is likely that Hawaiian hoary bats overfly the project area on a seasonal basis. The principal potential impact that the development of the proposed dairy farms poses to bats is during the clearing and grubbing phases of construction as vegetation is removed. The removal of vegetation within the project site may temporarily displace individual bats, which may use the vegetation as a roosting location. There are very few mature trees on the dairy farm site, which is the habitat preferred by hoary bats as roosting locations. As bats use multiple roosts within their home territories, the potential disturbance resulting from the removal of the vegetation is likely to be minimal. During the pupping season (June to September), females carrying their pups may be less able to rapidly vacate a roost site as the vegetation is cleared. Additionally, adult female bats sometimes leave their pups in the roost tree while they forage. There are almost no suitable roost trees within the dairy site; therefore, no effect to bats is expected from that the dairy farm.

Following build-out and the start of Dairy operations, the following mitigation strategies will be implemented:

• Develop an Avian Species Protection Plan; the plan would include all of the topics outlined above. The material would be presented in more detail and with the rationale for why following those best management practices is necessary to ensure that dairy operations would not result in deleterious impacts to protected wildlife. The Plan would also include these additional topics:
  • Prepare Endangered Species Identification references with photographs, description of habits, and areas on the property where they are most likely to occur and/or to nest
  • Employee endangered species training, provided both in writing and as a PowerPoint presentation for use in training new personnel and annual updates of training
  • Predator control program
  • Downed seabird, and injured waterbird response protocols
4.11 INVERTEBRATE SPECIES AND PEST INSECTS

A study of invertebrate species and pest insects was conducted by Steven Lee Montgomery, PhD, Consulting Biologist (January 2016). The study summarizes the presence or absence of native species or pest species associated with cattle manure in the general Māhāʻulepū area, as well as the parasites and predators on site that control those species. Fieldwork was conducted September 15-16, 2014. The full report is in Appendix B.

4.11.1 Existing Conditions – Invertebrate Species and Pest Insects

Beneficial insects include primary decomposers such as earthworms and dung beetles, and pollinators including bees. Pest insects are those that can negatively impact livestock health and production, such as flies. An invertebrate study of manure-associated insects was conducted for the EIS. The study included a field survey that used manure from an adjacent beef cattle herd as a lure, and determined flies and other manure-related insects currently present at the HDF site. Two common flies, the stable fly and the horn fly, were identified. Both of these flies are widespread throughout the Hawaiian Islands. The greenbottle fly was reared from manure taken back to a laboratory following the field survey. Additionally, flies known to exist on Kauaʻi but not seen at the HDF site during the survey are identified and include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations.

The stable fly is so named due to its association with the manure of horses and cattle, but it can breed in rotting vegetation including beach seaweeds. The adult stable fly prefers to land on animals’ legs, causing annoyance as they feed on the blood of livestock. As with most insect pests associated with livestock, this annoyance causes stress and loss of operational productivity. The stable fly may bite humans nearby. The horn fly has been widespread in the Hawaiian Islands since 1898; Kauaʻi herds have benefitted from control by parasitic micro-wasps and introduced dung beetles that reduce larvae breeding in dung. The horn fly causes pain and annoyance to cattle, but rarely bites man. The greenbottle fly was not observed on site but did hatch from manure brought back to a laboratory setting following the survey. This fly cannot bite or sting (Montgomery, 2016).

Twenty species of predators and competitors to the horn fly were successfully established in Hawaiʻi between 1898 and 1985. Research shows that 95 percent fewer horn flies emerged from dung patties containing a beetle species that has been identified at the HDF site. Proven control methods for the stable fly include parasitic micro-wasps and spreading out manure (DuPonte and Larish in Montgomery, 2016). Among the invertebrates introduced to combat livestock-related flies are extremely tiny parasitic wasps that prey on various fly species. The adult wasps could be described as the size of gnat. Using an ovipositor – described by lay people as a “stinger” – the female lays eggs in the larvae or pupa of flies. The male wasp has no such “stinger”. See Figure 4.11-1 a – c.

![Figure 4.11-1 Parasitic Wasp Introduced to Hawaiʻi](image)
No native invertebrates of any species are attracted to manure of large herbivores. As deer, goats, cattle, pigs, and horses were not present in pre-human Hawai‘i, native invertebrates did not evolve to use large, wet manure piles as habitat or food (Montgomery, 2016). No Federally or State listed endangered or threatened invertebrate species were noted in a survey (Montgomery, 2016). The project location does not provide any habitat for *Drosophila musaphilia*, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened (USFWS 2008). Native *Drosophila* habitat is located many miles away in the high elevation koa-‘ōhi’a forests.

Bees are an essential part of the agricultural ecosystem. Honey bees (*Apis mellifera*) were observed at the watering trough for the Māhā‘ulepū Cattle Co. stock and on the dairy farm overhead pivot irrigation system. It is to be expected that honey bees will visit any water source set up for the dairy herd. Recent declines in honey bee populations in the wild on O‘ahu and Hawai‘i Island are due to accidental Varroa mite introductions and a souring beetle that ferments its nectar in bee hives (Montgomery, 2016). While neither has been reported on Kaua‘i, State quarantines are currently in place to minimize spread of the mites and help protect local bee populations.

Sheep are kept near the Haraguchi Farm kalo ponds to graze for weed control. The pellet-sized manure of sheep is structurally quite different from that of cattle and does not support the same invertebrate species.

Some illegal dumping of household trash is known to occur in the area. The anonymity provided by locations such as the country roadsides in the vicinity of the dairy farm make it a convenient place to drop trash. Bags of trash containing food remains may be dumped, and this household trash sitting in the open is a recognized fly breeding habitat (Ikeda et al. 1973).

Kōloa Lava Tube System. There are no known caves or lava tubes found on or adjacent to the dairy farm property. The known caves in the vicinity are approximately 0.75 mile from the closest point to the dairy farm. Several miles away from the dairy farm property is the Kōloa Lava Tube System, which provides habitat for two endemic cave species, the Kaua‘i Cave Wolf Spider and the Kaua‘i Cave amphipod. Both invertebrates are listed as endangered under the U.S. Endangered Species Act. Not all caves in the Kōloa area contain these animals. Per the 2006 U.S. Fish and Wildlife Service (USFWS) Draft Recovery Plan for Kaua‘i Cave Species, most caves in the Kōloa District do not contain the optimal climatological conditions required by these organisms. Continued development for housing and tourism is described by the USFWS (2006) as potentially leading to the destruction of remaining cave habitats in the area.

### 4.11.2 Probable Impacts and Mitigation Measures

Impacts that would be considered significant related to invertebrate insects and pest species could include:

- Disturbance or displacement of protected or endangered insects; and
- Inadvertent introduction of non-native species not known to Hawai‘i, or an increase in pest populations.

**Short-term Impacts and Mitigation – Invertebrate Species and Pest Insects**

There are no native, protected or endangered insect species within the HDF site. Construction will not impact any endangered invertebrate populations. It is possible that flies known from elsewhere on the island, associated with areas containing high pet populations, could be inadvertently transferred the HDF site and possibly utilize cow manure as a food source.
To minimize potential establishment of pest flies or other insects, food waste generated during the construction phase will be bagged, covered, contained and disposed of in order to limit possible breeding habitat for flies. Inspections of building materials for ants or other insects will be conducted to prevent introduction of new pests to the HDF site.

Long-term management for pests (explained in the following) relies on a natural food web cycle that will expand as the habitat (manure) is increased. In the short-term, supplemental pest control using mechanical and chemical methods may be used to prevent any spike in pest populations. Mechanical methods include sticky tapes or ribbons that could be used in the milking parlor or covered areas of the dairy facility. Traps will be used as needed for both monitoring and removal of flies. Traps can use attractants or not; versions designed for use outdoors could be used in paddocks from which cows are excluded (those not being actively grazed). Chemical methods may be used to prevent short-term spikes in pest populations. Insecticides and herbicides are non-discriminatory and kill beneficial as well as pest insects. Such control would only be used when needed by those qualified to apply chemicals, and in accordance with authorized procedures and regulatory labeling requirements.

Long-term Impacts and Mitigation – Invertebrate Species and Pest Insects

Integrated pest management utilizes knowledge of the ancient food web among species. Disrupting reproduction of potential pests with appropriate means at key points in the life cycle has been used in Hawai‘i for decades (Figure 4.11-2). Extensive introduction of dung beetle species between 1898 and 1985 in response to cattle-related insect pests resulted in 14 dung beetle species becoming established on Kaua‘i. Cattle egrets, a bird species introduced to Hawai‘i in the late 1950s to control cattle-associated insects, break up dung patties while searching for prey (Figure 4.11-3).

Dung beetles speed incorporation of the manure into the soil by breaking up bovine manure pats and transporting the organic material into the soil. A healthy population of dung beetles can bury a dung pat in one to three days. Breaking up and burying the dung patty destroys the habitat for insects such as flies to complete their life cycle. The stable fly requires approximately 21 days within the dung patty for the immature life stage (egg to pupa) to survive. The house fly takes 7 to 10 days from egg to fly, and can use a number of damp, decaying material as habitat. The horn fly takes 10 to 20 days from egg to adult.
The behavioral diversity among dung beetle species working together can bury dung pats in one to three days. Some beetle species fly at night and some during the day; some prefer older manure over fresh. HDF and other ranchers on Kaua‘i may choose to engage with the State Department of Agriculture to translocate dung beetle species already introduced on Kaua‘i to Māhā’ulepū and other areas if manure-related flies become a problem (Figure 4.11-2).

HDF will not maintain any populations of dogs, cats or chickens at the dairy, and will discourage feral pigs and the island’s wild jungle fowl. These domesticated or feral animal populations could provide dung that facilitates breeding of several species of flies not currently established on site. Proper disposal of dog and cat feces is important. Chicken feces can accumulate in sufficient amount to provide a location for fly breeding. While feral chickens are common throughout Kaua‘i, HDF will diligently clean any spilled feed or other potential attractants to keep chickens away from the dairy facility.

Good housekeeping is an important tool in controlling establishment of most flies. Human food waste from on-site workers’ meals would be disposed of in a covered, lined container and removed from the site often. Any spilled or waste supplement foods for the cattle should not be allowed to become wet and stay exposed. Rotting food waste can provide attractive habitat for fly breeding, therefore food waste must be disposed of properly. HDF personnel would be alert for bags along the roads around the property and remove them if practical. If left, the trash bags could breed flies that would then migrate to the nearest habitat of interest – the cattle manure.

Haraguchi Farm must also maintain the health of its sheep, as cows and sheep can share health issues. Of special concern should be the sheep bot fly (Oestrus ovis) that rarely can pass to cattle. This pest attacks by laying eggs that produce maggots in eyes and nasal passages.

Bees are an essential part of any agricultural ecosystem. It is expected that honey bees will visit water sources set up for the HDF herd. A ‘ramp’ will be built into any open water source to allow bees some chance of swimming to an escape rather than drowning. A struggling bee, floating in the tank, lapped up by a drinking cow could sting by reflex. A scoop or sieve will be used to remove bees before stock access the drinking area. The bees should be disposed of safely as the stingers of even a dead bee will function if pressure is exerted. Also, safe application practices for any unavoidable herbicide or pesticide will be utilized to narrowly target the correct pest species without harming other insects and animals in the area. Anyone using herbicides or pesticides will be properly trained and informed, and if a honey bee colony location appears to be a danger to workers or cattle, or to be in danger itself, a local beekeeper will be contacted for advice and removal (Montgomery, 2016).

Neither the botanical and faunal survey nor the invertebrate survey revealed any evidence of lava tubes or caves on the property, and no such features have been reported for the area in the near surrounds of the HDF site. Thus no cave invertebrate species will be affected by the dairy farm. The known habitat in the Kōloa region for the endangered cave spider and amphipod is several miles away, with no reported connection to the dairy farm site. Integrated pest management measures employed to reduce cattle-associated pest fly species at this site will not affect native flies (Drosophila), as the habitat for this species is high elevation koa-ōhi’a forests located miles away.

The dairy operation is not expected to impact any endangered invertebrate populations. HDF will minimize populations of any pest insects such as flies, which already exist on the island of Kaua‘i.
4.12 NOISE

Acoustic conditions (noise) in the area of the dairy farm and surroundings are evaluated in this section. The anticipated short-term and long-term noise conditions associated with the dairy farm and planned mitigation actions are discussed.

4.12.1 Existing Conditions - Noise

Noise can be defined as unwanted sound, a sound that is considered loud or unpleasant, and/or sound that causes disturbance. Research related to noise and livestock focuses on noise levels and minimization of unexpected sounds that caused stress to cows. Noise stress results in loss of livestock productivity and thereby financial loss to farmers and ranchers. Little research exists on the sound levels from livestock.

Sound is measured in decibels (dB). The State of Hawai‘i Department of Health rules use the A-weighting sound network (dBA) in the HAR §11-46, Community Noise Control. Sound through the air is similar to ripples on a pond of water. In open space without reflection, ripples spread uniformly in all directions and decrease in amplitude further from the source. In free field conditions such as outdoors, amplitude drops by half as distance doubles (OSHA, 2016). When sound passes close to absorbing ground cover such as grassland and fields, the "soft ground" absorbs extra sound as it passes.

Typical dBA of conversational speech is 60 dBA; the sound of a shower or vacuum cleaner is roughly 70 to 75 dBA. The OSHA standard for protection against the effects of noise exposure allows an 8-hour duration at 90 dBA before a hearing conservation program is required for employees.

The HDF site in Māhā‘ulepū Valley is 1.5 to 2.5 miles from resort and residential areas on land zoned for agricultural use. Typical noise currently generated near the HDF site is truck ingress/egress along private farm roads, agricultural equipment, and cattle and sheep.

4.12.2 Probable Impacts and Mitigation Measures

Impacts that would be considered significant related to noise could include:

- Increased noise levels during construction; and
- Noise levels that interfere with human activities at home, work or in schools, or that is injurious to people's health and well-being.

Short-term Impacts and Mitigation – Noise

Construction work at the project site will involve activities that may generate an increase in noise levels. Noise related to construction will be a short-term condition, occurring during daylight hours.

Construction vehicles and activities must comply with HAR §11-46. A permit is required for construction activities that emit noise in excess of 78 decibels or that cost a total of more than $250,000 (based on the value on the building permit).

Construction noise is anticipated to be short-term, and will be minimized through application of best management practices to include the use of mufflers to suppress loud equipment and limitations on the hours of heavy equipment operation.
Long-term Impacts and Mitigation – Noise

The dairy farm will utilize milking equipment contained in the milking parlor, and will use field equipment such as tractors. Equipment will typically be used during daylight hours. Dairy operations will comply with applicable noise control ordinances. Under HAR §11-46, agriculture is classified as Zoning District Class C, which specifies maximum permissible sound levels of 70 dBA in the daytime and 70 dBA at nighttime. Maximum permissible sound levels apply to any point at or beyond the property line, and are not to be exceeded more than 10 percent of the time within any 20 minute period.

Dairy operations will generate noise in keeping with agricultural zoning of the parcel. The primary noise receptors in the area would be farmers working nearby parcels. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.

4.13 HAZARDOUS SUBSTANCES

This section summarizes a search of State and Federal public records for known hazardous waste on the dairy property. The use and storage of regulated materials for dairy operations is also documented.

4.13.1 Existing Conditions – Hazardous Substances

State of Hawai‘i. The State DOH Solid and Hazardous Waste Branch regulates the generation, treatment, storage, and disposal of hazardous waste. Underground storage tanks (UST) that store petroleum or pesticides are commonly found on agricultural lands. A search of the State’s UST list, last updated September 4, 2015, show no USTs on the dairy parcels (DOH, 2015).

The DOH Hazard Evaluation and Emergency Response (HEER) office provides leadership, support and partnership in preventing, planning for, responding to, and enforcing environmental laws relating to the release or threats of releases of hazardous substances. Former agricultural operations resulted in soil contamination on sites across the island of Kaua‘i. Site-specific facilities, sites or areas in which HEER has investigated or may investigate are tracked in the public records accessed through the HEER website. The HEER Emergency Response Lookup Spreadsheet (updated 12/2/2014) revealed no sites within the HDF site.

Review of the historical sources for the property site – topographic maps and aerial photos - show no pesticide mixing or storage facilities on the HDF site or surrounding areas.

Federal Database. None of the dairy farm parcels are listed for action in the Federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) information systems database. CERCLA is commonly referred to as the “Superfund” program. The database tracks the location of identified abandoned hazardous waste sites. No such sites exist within or adjacent to the dairy parcels.

According to the database provided by HEER, no Brownfield sites have been identified within or adjacent to the parcel by Federal, State or County agencies. A Brownfield property is any real property that may be contaminated and is not being used to its full potential. The State’s HEER office works with prospective purchasers and developers to clean up properties under available CERCLA programs.

Review of State and Federal public records for the island of Kaua‘i show no reports of petroleum, hazardous substances, pollutants or contaminant releases at the dairy farm site.
4.13.2 Probable Impacts and Mitigation Measures – Hazardous Substances

Impacts that would be considered significant related to hazardous substances could include:

- Production or run-off of hazardous substances during construction; and
- Long-term purposeful or inadvertent introduction or seepage of hazardous substances to soils or waters from on-going dairy operations.

**Short-term Impacts and Mitigation – Hazardous Substances**

Construction equipment operations at the dairy farm will involve the use of fuels and lubricants. Construction operators will conduct operations in compliance with State and Federal laws to properly manage the use and storage of fuels, lubricants and cleaning to avoid the release of hazardous materials.

No significant short-term impacts related to hazardous substances will occur.

**Long-term Impacts and Mitigation – Hazardous Substances**

Establishment of pasture and on-going cultivation of the robust grass that will provide dairy cows with the majority of their food source will include use of commercial fertilizer to support sufficient grass yields. Herbicides will be used judiciously where needed to control pasture weeds. Flies inhibit productivity on a dairy farm. An integrated pest management program will be employed, with primary control focused on eliminating breeding sites and maintaining a natural predator-prey cycle among invertebrates (see Section 4.11, Invertebrate Species and Pest Insects.).

Healthy cows are a priority for HDF, and antibiotics as prescribed by a licensed veterinarian may be used from time to time, to ensure cows remain healthy and are treated humanely. Guidelines set by Food and Drug Administration (FDA) will be followed to avoid any antibiotic adulteration of milk. Additionally, HDF will routinely conduct laboratory tests on milk for any trace of antibiotic residue. HDF will not treat cows with bovine growth hormones (rBST or rBGH).

Equipment operations at the dairy farm require fuels and lubricants. An emergency power generator with associated fuel storage will be available to power the milking parlor and other critical operations in the event of an electrical outage. Off-road diesel fuel and unleaded gasoline for use in farm vehicles will be stored in two above-ground exterior tanks. Hydraulic fluid and motor oil, to be delivered from a local fuel supplier, will be retained in 55-gallon drums. Brake and transmission fluids and all-purpose grease, will be maintained in the original containers. All containers and drums will be stored within appropriately designed secondary containment areas.

Pesticides, herbicides, fuels and lubricants will be stored according to regulations. Products will be locked within the implement shed when not in use, and segregated by type and per regulations. Fertilizers will be stored in original packaging as delivered by the supplier. Herbicides, pesticides and veterinarian-prescribed medicines will be stored in a separate, locked area under the direct control of the dairy manager or delegate.

No significant long-term impacts will occur from hazardous substances related to dairy operations, due to minimization of risk, secondary containment, and compliance with best management practices.
4.14 PUBLIC SERVICES

4.14.1 Fire Department

Existing Conditions - Fire Department

The County of Kaua‘i Fire Department services the entire island of Kaua‘i. The closest fire station to the dairy is located in Kōloa, approximately 4.5 miles to the west.

Probable Impacts and Mitigation Measures - Fire Department

The dairy farm facilities will be built in compliance with County building and fire codes. Dairy facilities and dairy operations are not anticipated to place a significant demand on fire protection services. Fire suppression and fire safety training requirements for the facilities will be satisfied in consultation with the Kaua‘i Fire Department. There will be no significant short-term or long-term impacts anticipated on fire department services as a result of this project.

4.14.2 Medical

Existing Conditions - Medical

The nearest medical facility is located at Wilcox Memorial Hospital in Līhu‘e, 16.5 miles northeast of the dairy farm location.

Probable Impacts and Mitigation Measures - Medical

Dairy employees may infrequently require service at the local medical facility. Such use is not anticipated to adversely affect the service capacity of Wilcox Memorial Hospital. There are no significant short-term or long-term impacts anticipated on medical services as a result of this project.

4.14.3 Police

Existing Conditions - Police

The County of Kaua‘i Police Department provides police services for the entire island. The closest police substation to the dairy is located in Kōloa, approximately 3.5 miles away.

Probable Impacts and Mitigation Measures - Police

The dairy operations will not impact police service in the area. There are no significant short-term or long-term impacts anticipated to police services as a result of this project. Therefore, no mitigation will be required.

4.14.4 Educational Facilities

Existing Conditions - Educational Facilities

A number of public and private elementary, middle schools, high schools, and a community college are located throughout the neighboring Kōloa and Līhu‘e regions. These schools include Kalaeo
Elementary, Kōloa Elementary, Holy Cross School, 'Ele'ele Elementary School, Kamehameha Schools, Island School, Olelo Christian Academy, Chiefess Kamakahelei Middle School, Kawaihē Public Charter School, Kaua'i High School, and Kaua'i Community College.

Probable Impacts and Mitigation Measures - Educational Facilities

The dairy farm operations will not impact local educational facilities. Employees of the farm may have children attending local schools. Education programs will be established for local schools to learn about the pasture-based dairy operation and food sustainability. No mitigation measures will be required. There are no significant short-term or long-term impacts anticipated to educational facilities as a result of this project.

4.14.5 Libraries

Existing Conditions - Libraries

Public libraries located in proximity to Hawai‘i Dairy Farms include the Kōloa Public and School Library and the Līhu‘e Public Library.

Probable Impacts and Mitigation Measures - Libraries

The dairy will not affect the local public library system. There are no significant short-term or long-term impacts anticipated to libraries as a result of this project. No mitigation will be required.

4.15 DEMOGRAPHIC AND ECONOMIC CONDITIONS

Analysis of impacts examine the ways in which the existing physical environment of the community can be altered by land developments, and how these changes may affect the area’s demographics and economy.

Potential impacts and mitigation for a herd size of 699 milking cows are presented in this section; for a contemplated herd size of up to 2,000 milking cows, impacts and mitigation are presented in Section 4.21.

4.15.1 Existing Conditions - Demographic and Economic Conditions

Demographic Characteristics of Po‘ipū Residents

The project area of Māhā‘ulepū is located in the Po‘ipū area on the south shore of Kaua‘i. In 2010, the population of the Kōloa-Po‘ipū Census tract was 2,544, with a median age of 44.8 years old. This represents nearly 4 percent of the island’s total 67,100 residents.

Between 2009 and 2013, white residents comprised a slightly higher proportion of the Kōloa-Po‘ipū population compared to the County as a whole: 42.1 percent of residents were white compared to 33.4 percent of residents in the County. A slightly lower proportion of the Kōloa-Po‘ipū population was born in the State of Hawai‘i; an estimated 51.6 percent of the region’s population was native born to the State, compared to 55.9 percent for the County as a whole.
The resident profile of the Kōloa-Po’ipū Census tract is slightly older than that of Kaua’i County. The median age in Kōloa-Po’ipū was 44.8 years old between 2009 and 2013, compared to 41.6 years old in the County. The Kōloa-Po’ipū region is characterized by a higher proportion of retirement age residents (65 years and older) and a lower proportion of school age children. Of the residents living in the Kōloa-Po’ipū Census tract, 66.7 percent attended some college or received a higher education degree, compared to 61.1 percent throughout the County (PEP, 2016).

Po’ipū has been known as one of the two major tourist and luxury home destinations on the island, with the largest inventory of hotel rooms, transient vacation rentals, and luxury vacation homes on the island. The north shore is the second major tourist and luxury home region. The median sales price for a single-family home in Kōloa-Po’ipū was $1,210,000 in May, 2015, nearly double the county-wide median price of $645,000 (PEP, 2016).

**Economic Characteristics**

The median household income for Kaua’i County during the period 2009 to 2013 is estimated at $62,052, an increase of 37.8 percent since the year 2000. Approximately 11.2 percent of the County's population was living below the poverty line. Census data for the Kōloa-Po’ipū area shows the median household income level the same as that of the County as a whole ($62,052), though Kōloa-Po’ipū has a higher per capita income and a lower proportion of residents living in poverty (7.5 percent compared to 11.2 percent at poverty for the County).

Tourism is one of the largest industries in Hawai’i. Statewide, the top three industries are educational, health and social services (20.3 percent); arts, entertainment, recreation, and accommodation (15.7 percent); and retail trade (11.6 percent). At the County level on Kaua’i, the employment trends are very similar to the State’s, except with an even greater proportion of the workforce in the tourism-related industries of arts, entertainment, recreation, and accommodation (21.8 percent) as well as retail trade (13.5 percent). Po’ipū area trends mirror trends of the island, further highlighting the strong influence of the visitor industry.

Conversely, the agriculture, forestry, fishing, and hunting industry is one of the smallest in the State at 1.6 percent. On Kaua’i, this percentage is slightly higher at 2.9 percent. The Po’ipū census tract, however, is more similar to the State trend, with agriculture accounting for just 1.5 percent of the employed population.

Despite the changing character of the Po’ipū area towards a resort town, Māhāʻulepū has a long history of agricultural use, as it was one of the first places in the island chain where sugarcane was commercially grown. In 2011, the State of Hawai’i Land Use Commission designated 1,533 acres of land (including 557 acres that make up the Hawai’i Dairy Farms project area) as "Important Agricultural Lands" under HRS Chapter 205 – Hawai’i’s land use law. Per HRS Chapter 205, both State and County governments are responsible for promoting the long-term viability of agricultural use of conserved/protected Important Agricultural Lands. This designation is intended to increase the viability of agriculture through the expansion of the agriculture industry, increase job opportunities, and increase in food security for current and future generations.
Property Values

Economic impacts of nuisance issues that could affect property values were examined. With a long history of agriculture, most of Kaua‘i has a rural ambiance. Most homes and visitor units on the island are within one mile of some agricultural activity; the rural character adds to the appeal of the island. The site of the Grand Hyatt Kaua‘i was rezoned from agriculture to resort; the resort opened in 1992 while sugarcane was still grown just mauka of the hotel property.

Sugarcane fields bordered Kōloa on three sides, and bordered parts of Po‘ipū. Sugarcane fields were burned prior to harvest, creating smoke; dust and soil runoff followed field disturbance; and large canehaul trucks created considerable noise, dust and cane litter. The Kōloa Sugar Mill emitted odors, smoke and noise. The distance of the mill to the nearest homes in Kōloa is approximately 0.8 mile; proposed dairy activities would be 2.5 miles from the nearest home in Kōloa. An agricultural transition to seed crops utilized land adjacent to the Po‘ipū Bay Resort Golf Course. Dust from disturbed, open lands was an issue, and concern of herbicide use drifting offsite dominated community conversations. Dust from proposed HDF operations would be minimal with grass as the cover crop.

With the demise of sugar and seed crops in Kōloa and Po‘ipū, the cattle grazing for the beef market is now the dominant use of agricultural land in the region. Grazing lands to the east, north and west of Kōloa total over 2,900 acres, which is reduced from over 3,300 acres before Māhāulepū Valley was leased by HDF. In the near term, grazing is likely to expand onto most of the lands used recently for seed crops. In Kōloa and Po‘ipū, grazing occurs less than 200 feet from some homes, less than 1 mile from some visitor units, less than one-third of mile to the east and west of the main commercial area of Kōloa, and less than 200 feet from a golf course.

Many of the homes in the region that are near cattle operations are in the northeast and eastern sections of Kōloa; most of the homes were built before 1980 and are of modest size (less than 1,200 square feet). For these homes, the 2016 median assessed values ranged from $406,100 to $567,500. At the western end of Po‘ipū is Kukui‘ula—a luxury residential community that abuts grazing land. Most of the homes are newer, built after 2012, and most are large at over 2,100 square feet. For 2016, median assessed values of these residential lots and homes ranged from $1,297,150 for a lot, to $2,893,100 for a lot with home.

4.15.2 Probable Impacts and Mitigation Measures - Demographic and Economic Conditions

Impacts that would be considered significant related to demographic and economic conditions could include:

- Impact of construction labor and materials on local economy and businesses; and
- Long-term impacts from the dairy operation on nearby property values and the agricultural industry locally and Statewide.
Short-term Impacts and Mitigation – Demographic and Economic Conditions

The Hawai‘i Dairy Farms project would create short-term benefits through jobs for local construction personnel and local material suppliers. Construction employment would be expected to average about 12 jobs per year during the development period. Such jobs would include equipment operators, cement workers to lay foundations, metal workers, carpenters, plumbers, electricians, roofers, supervisors, painters, etc. Based on State employment multipliers, indirect employment related to Dairy construction would be expected to average about 16 jobs on Kaua‘i, and 8 on O‘ahu. Thus direct-plus-indirect employment associated with Dairy development would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i (PEP, 2016).

Construction of the facilities at HDF would contribute approximately $9.1 million per year during the development phase. This includes direct equipment and construction expenditures, and indirect sales related to construction.

In addition to the creation of an average of 12 construction worker jobs during the estimated construction period, the State of Hawai‘i and County of Kaua‘i will receive excise tax revenues on finished development and building materials, conveyance taxes, and income taxes on wages. Revenues from development activities to the State is estimated at $650,000, with revenue offset by a tax credit for improvements on lands designated IAL. County revenue derived from development will be negligible.

Long-term Impacts and Mitigation – Demographic and Economic Conditions

Hawai‘i Dairy Farms would contribute to diversification of Kaua‘i’s economy, which is heavily based on the visitor industry. With only two dairies remaining in the State (both on the Big Island), less than 10 percent of Hawai‘i’s milk is locally supplied. The Hawai‘i Dairy Farms project, with an established herd of up to 699 milking cows, will increase the supply of local fluid milk by approximately 1.5 million gallons of milk annually, a 50 percent increase in statewide milk production. Once the facility is established and dairy operations have reached the committed herd size, approximately 11 direct and indirect full-time equivalent jobs would be sustained on Kaua‘i, including 5 farm jobs and about 6 indirect jobs. An additional 3 indirect jobs would be created on O‘ahu. For the contemplated herd size direct and indirect employment will roughly double.

Once fully operational with a herd of 699 mature dairy cows, annual direct-plus-indirect sales are estimated annually at $8.1 million on Kaua‘i, with an additional $2 million on O‘ahu.

When the dairy has matured to full production for the 699-cow dairy, net income to the State is calculated to exceed $60,000 annually. Net income to the County from HDF is anticipated to generate $51,000 (PEP, 2016)

Employment and sales and tax revenue for the contemplated herd size of up to 2,000 milking cows is discussed in Section 4.21.
Results of technical study on economic impacts included an evaluation of property values adjacent to grazed areas within Kōloa and Poʻipū. New, larger homes being built adjacent to grazing lands in developments with amenities, the 2016 median assessed values ranges from $1,297,150 for a lot, to $2,893,100 for a lot with home. Clearly, beef cattle operations are compatible with nearby homes, commercial areas, resorts and recreational areas. Although stocking densities are lower for beef cattle on unirrigated pastures than they are for the proposed dairy on irrigated pastures, the operations are similar: cattle are rotated among pastures as limited by the carrying capacity of the land.

Results of technical studies and the findings of the EIS show no unmitigated nuisances that would affect property values as a result of dairy implementation or operations. No noticeable odors, flies, noise, waste or water discharges will reach resort or residential areas. As such, the dairy will not adversely affect residents, nearby recreational activities, guests in nearby resorts, or diminish property sales or property values in the area. The dairy will help maintain the existing rural character and ambience of the Kōloa-Poʻipū region. (PEP, 2016).

4.16 GROUNDWATER RESOURCES

Water is essential for life. As an island state, Hawai‘i has limited access to natural fresh water supplies. Competition for fresh water from increasing resident and visitor populations, as well as potential impacts of global climate change, require that Hawai‘i become as efficient as possible in its use of limited fresh water supplies. More than 90 percent of the State’s drinking water comes from groundwater sources, while much of the water used for agricultural irrigation comes from surface water sources (CH2MHill, 2013).

Groundwater is defined by the State Water Code as “water found beneath the surface of the earth, whether in perched supply, dike-confined, flowing, or percolating in underground channels or streams, under artesian pressure or not, or otherwise.” Groundwater is protected through regulation at the Federal, State and County level. The Commission on Water Resource Management (CWRM), under the State Department of Land and Natural Resources, is the primary steward of the water resources public trust and has broad powers and responsibilities to protect and manage Hawai‘i’s water resources.

CWRM administers the State Water Code, codified in Hawai‘i Revised Statutes Chapter 174C (2008 amendment) and associated administrative rules. Other State agencies continue to have responsibilities for water quality (Department of Health) and coastal zone management (Department of Business, Economic Development and Tourism). Four types of water resource and development plans are referred to as the “Hawai‘i Water Plan”: a water resource protection plan prepared by CWRM; water use and development plans prepared by and for each county; a State water project plan; and a water quality plan prepared by the Department of Health.

This section of the EIS presents existing conditions of groundwater resources of the Māhā‘ulepū area, and assesses probable impacts from dairy farm operations with the committed herd size of 699 milking cows. Probable impacts and recommended mitigation for groundwater related to the contemplated herd size of up to 2,000 milking cows are presented in Section 4.22.
4.16.1 Hydrology

Existing Conditions - Hydrology

The Kōloa area was formed by lavas of the Napali formation of the Waimea volcanic series. Surface lavas of the Napali formation exhibit extensive weathering which may extend to considerable depths – as great as 400 feet below sea level. Weathered lava in the area is typically Saprolite, a soft, thoroughly decomposed rock. The Māhā‘ulepū valley floor is filled with alluvium, which generally extends about 60 feet under the surface and is underlain by highly weathered lava at a shallow depth by secondary eruptions of the Kōloa series (COK DOW, 2001).

Groundwater units have been established by CWRM (2008) to manage groundwater resources. Primarily determined by subsurface conditions, each island is divided into regions that reflect hydrogeological similarities within hydrographic, topographic and historical boundaries. The hydrologic unit encompassing Māhā‘ulepū Valley is the 51-square mile Kōloa Aquifer System Area (code 20101). The sustainable yield of the aquifer is 30 million gallons per day (MGD). For the Kōloa aquifer in general, CWRM (2008) notes that the nature and extent of the basal ground water lens is not well understood due to the presence of a discontinuous, unmapped confining layer.

An analysis of groundwater and surface water was conducted for this EIS that identified two groundwater bodies within the valley: (1) a deep aquifer system within unweathered volcanic material, which is buried beneath thick alluvium that covers the valley floor; and (2) shallow groundwater in the thick alluvium. The alluvial material is highly weathered lava composed of dark brown to black silty clay and clayey silt. The aquifer of highest value and use resides deep within the unweathered volcanic material. The alluvial material blanketing the valley floor is less permeable than the unweathered volcanics by orders of magnitude. Groundwater wells developed for access to potable water are described in the following section 4.16.2, Potable Water.

Four wells to access groundwater in the alluvium were installed within the HDF site to facilitate the groundwater and surface water analysis. Water quality samples were taken to determine general conditions and to document baseline conditions, and the alluvial waterbody was monitored in response to pumping within the deep aquifer wells located in the volcanics to determine hydrologic connectivity. The proposed water quality monitoring program is presented in Section 4.16.3, Probable Impacts and Recommended Mitigation.

Hydrologic Connectivity of Waterbodies within Māhā‘ulepū

The groundwater and surface water analysis for this EIS examined whether the two waterbodies within Māhā‘ulepū may be connected. Four studies were conducted to determine whether the groundwater in the alluvial material might discharge into the lower aquifer confined in the unweathered volcanic material at depth. Additionally, the study quantified the current water quality within the alluvial waterbodies. Methods and results of the examination are summarized here and the full report is included in Appendix E.

The following studies were conducted to determine any relationship between groundwater bodies, as part of the groundwater analysis:

1. Review of drilling logs for the last four wells developed in the Well 14 Battery, which ascertained the wells fully penetrated the alluvium and tap into groundwater within the unweathered volcanics;
2. Measurements of salinity and temperature of groundwater from two water bodies – one in the unweathered volcanics, and another in the deep alluvium on the valley floor;
3. Pump testing of a well in the Māhā'ulepū Well 14 Battery while monitoring response of groundwater in the alluvium; and
4. Response of groundwater in the alluvium to operation of the Kōloa Well F pump.

Driller’s logs for installation of the final four wells developed in the Māhā'ulepū Well 14 Battery were published in the 1960 Bulletin 13 of the Hawai‘i Division of Hydrography. The logs record sticky red, brown, and purple clay layers from 75- to 300-foot depth. These layers are essentially impermeable and function as an aquiclude to separate the groundwater in the alluvium from the confined groundwater in the underlying volcanics (TNWRE, 2016).

Measurements of salinity and temperature in the deep, confined aquifer accessed through one of the three Māhā'ulepū 14 wells showed a uniform conductivity and temperature, at 335 μS/cm and 72.0° F, respectively. Measurements of the groundwater within the alluvium show significantly higher salinity in three of the monitoring wells (HDF-1, HDF-3 and HDF-4), and significantly lower salinity (fresher) water in HDF-2. Water in the four monitoring wells was 2 to 6 degrees warmer than the temperatures recorded in the deep aquifer. Percolation of rainfall directly on the ground and surface runoff from upland provides recharge to the groundwater in the alluvium; the significant salinity and temperature differences measured between the aquifers suggests discharge of water from the alluvium into the deep volcanic aquifer is not occurring (TNWRE, 2016).

The pump test utilized water level recorders within wells HDF-1 and HDF-2, as well as two wells in the Well 14 Battery, to measure drawdown of water within a well while pumping water out of the Māhā'ulepū 14 well. The test was conducted on March 17, 2015; water levels were recorded at 30-second intervals throughout the 10-hour pumping period. By the end of the pumping period, water levels were drawn down 17.1 feet (at a pumping rate of 825 gallons per minute [gpm]) in the Māhā'ulepū 14 well. Water response in the other two wells within the Well 14 battery was instantaneous; one located 96 feet east showed drawdown of 5.3 feet, and the other located 67 feet west of the Māhā'ulepū 14 well showed drawdown of 3.7 feet.

Response of water levels within the two monitoring wells was also recorded. HDF-1 is 190 feet east of the pumped well. The water level actually showed a build-up of 0.05 feet during the pump test. This was attributed to the weight of the pumped water deposited on the ground surface. Otherwise, there was no response to the well water level. HDF-2 is 1,300 feet east of the pumped well, and showed no response to pumping. Graphs of the results can be found in Appendix E.

Finally, water level recorders were installed in each of the four HDF monitor wells and in the County Department of Water (DOW) Kōloa Well F for a seven-day period from May 13 to 20, 2015. The objective was to determine any identifiable response in the nearest monitoring well, HDF-4, which is 630 feet from Kōloa Well F. The most likely response was anticipated to be a pressure pulse arriving at HDF-4 several minutes following the starting or stopping of the pump at Kōloa F well. No such response occurred.

The groundwater and surface water study provides insight to the depth of the groundwater in the alluvial layer. Toward the inland end of the property (wells HDF-1 and 2), groundwater levels are about 80 feet AMSL. The level drops rapidly going makai, to 68 feet AMSL at HDF-4, and to 49 feet at HDF-3. In general, the movement of groundwater in the alluvium is from mauka to makai with ultimate discharge into the marine environment. Seasonally, modest amounts of groundwater may
discharge to the agricultural ditch during wet conditions in the vicinity of the HDF-1 and HDF-2 monitoring wells. Because the groundwater level drops substantially at the makai end of the site (near the HDF-3 monitoring well), no groundwater discharge to the ditches occurs in this area (TNWRE, 2016).

Overall, groundwater levels in the alluvial layer are 30-feet to more than 50-feet higher than the piezometric head of groundwater in the confined underlying volcanic series. The results of the four examinations demonstrate that there is complete hydrologic separation of the two groundwater bodies in Māhāʻulepū (TNWRE, 2016).

4.16.2 Potable Water

Existing Conditions – Potable Water

Wells in Māhāʻulepū Vicinity

HDF will utilize an onsite well for potable water that was established a century ago to serve the sugarcane plantation. The last of the 14 field wells developed between 1897 and 1928, it is the deepest of the wells drilled through alluvial material to reach the aquifer deep within the volcanic series (Table 4.16-1 Information on Wells In and Near to Māhāʻulepū, Kauaʻi). The battery of wells produced 3 MGD during use for sugarcane irrigation (TNWRE, 2016).

Figure 4.16-1  Wells in Māhā‘ulepū Vicinity
In 1928, the original 10 wells were abandoned when the well battery was modified with four new wells and above-ground line shaft turbine pumps. Of the four well drilled in 1927 to 1928, only three functional wells were relocated during the groundwater and surface water analysis conducted for this EIS. One well will provide potable water to be used by HDF for dairy operations, a second well will be maintained as a back-up for potable water, and the third well will be utilized for deep groundwater monitoring.

The County of Kaua‘i developed three potable water wells in 1977, 1981, and 1998 to meet the demand for the growing Poʻipū resort community (Figure 4.16-1, Wells in the Māhāʻulepū Area). Well depths range from 198-feet to 247-feet below sea level and lie in the water-bearing, unweathered Waimea volcanic series. The Kōloa F well, developed in 1998, is the closest public water source to the proposed dairy with a distance of 580-feet from the closest boundary of the HDF leased area, and approximately 0.6 mile from the dairy facilities (Figure 3.3-4). Geotechnical investigations at the Kōloa F well site determined that residual and alluvial soils underlie the surface to a depth of at least 15 feet, much shallower than the estimated 60-foot depth of alluvium on the valley floor of deep (COK DOW, 2001).

A report prepared in June 1999 on development of Kōloa F well noted barometric responses in the County Kōloa wells indicated confined aquifers or compartments (COK DOW, 2001).

Groundwater Source Protection

To assess the susceptibility of public water systems to contamination, the State of Hawai‘i Department of Health Clean Water Branch (CWB) initiated a source water assessment program (SWAP) consistent with Federal requirements established by the U.S. Environmental Protection Agency (EPA) and with existing assessment and protection efforts in Hawai‘i (Whittier et al., 2010). The SWAP process involved: (1) delineation of the area around a drinking water source through which contaminants may travel to the water supply; (2) inventory for potential activities that may release microbiological or chemical contaminants within the delineated area; and (3) determination of the drinking water source susceptibility to surrounding potential contamination activities (Spengler, 2014).

The SWAP delineated three zones of contribution referred to as capture zone delineations (CZD) for all public drinking water sources in the State of Hawai‘i based on groundwater time-of-travel (TOT) criteria (Whittier and El-Kadi, 2014). The initial zone, Zone A, is the “well control site” zone and consists of a 50-meter diameter around each well. The second CZD, Zone B, delineates the 2-year TOT, which relates to conservative survival times for bacteria and viruses in soil and groundwater. The third CZD, Zone C, delineates the 10-year TOT, which would allow sufficient time to implement management and remedial measures to mitigate contamination from accidental contamination spills or other causes (Whittier, 2010).

Figure 4.16-2 depicts the modeled capture zones for the Kōloa F well, and displays the groundwater flow pathlines from the west- north-west. The modeling depicts Zone C, the 10-year TOT, overlapping the southwest corner of the HDF site indicating a potential for leachate. However, results of the hydrologic assessment demonstrate the complete hydrologic separation of the two groundwater bodies in Māhāʻulepū: the aquifer in the deep unweathered volcanic series and the source of the Kōloa F well, from the groundwater in alluvial layers on the valley floor. Additionally, the groundwater flow pathlines depict the majority of water captured is from the west- north-west (CWB, 2016).
A discussion of the ability of soils to mediate bacteriological and chemical contaminants is introduced in Section 4.3.1, Soils. As shown in Figure 4.3-2, the hydraulic conductivity of the soils in Māhā'ulepū range from 10.5 – 50 feet per day. The hydrologic assessment conducted for this EIS estimates the permeability coefficient as almost certainly less than 1.0 feet per day (TNWRE, 2016).

Findings for the Po'ipū - Kōloa region are included in the following section.

Figure 4.16-2  County Well Head Capture Zone Delineation

*Department of Health Clean Water Branch Sanitary Survey*

Public complaints of contamination of Waiopili Ditch spurred an investigation by the Hawai'i Department of Health CWB into all possible sources that may contribute to high bacteria levels or other potential contamination sources in a watershed. The CWB research utilized a methodology known as a “Sanitary Survey.”

The Sanitary Survey completed by the CWB (2016) documents the existing inventory of wastewater injection wells, stormwater injection wells, and individual wastewater systems including cesspools in the highly urbanized Waikomo Watershed. The Waikomo Watershed includes the developed areas of Kōloa and Po'ipū. Approximately 120 injection wells discharge an estimated 1.4 MGD per day. Cesspools discharge raw sewage into the ground without treatment at the estimated rate of 1.6 MGD per day and represent 76 percent of the 2,238 on-site disposal systems (OSDS) in the area. There are no wastewater injection wells within the Māhā'ulepū sub-watershed or upgradient of the dairy property.
The Kōloa karst topography and lava tube systems that straddles the Waikomo Watershed may provide transport of injection well and cesspool effluent to the Makauwahi Cave/sinkhole lava tube system in the Māhāʻulepū sub-watershed. The fate of these discharges is eventual release into the nearshore waters at various points at reef shelf depths offshore. The Sanitary Survey estimates groundwater and coastal waters of south-east Kaua'i are being contaminated with roughly 3 MGD of wastewater daily (CWB, 2016).

**Groundwater Monitoring Wells**

As described earlier in this section, four wells to access groundwater in the alluvium were installed within the HDF site to facilitate the hydrologic assessment. Analysis of water quality samples were conducted to serve as a baseline for the nutrient composition of the shallow waterbody within the alluvium. Future water quality samples can then be compared to these samples, collected prior to dairy implementation. Periodic assessments can identify any change in nutrient content that may identify seepage of nutrients into this waterbody. While the waterbody in the alluvial material is hydrologically disconnected from the deeper aquifer in volcanic basalt, any significant increases could inform nutrient management of HDF and allow for management changes to minimize nutrients not being effectively utilized by the grass crop.

Results from the baseline water quality samples collected in May and July of 2015, show that water within the alluvial ground waterbody is fresh (salinities on the order of 0.18 to 0.47 parts per thousand). Results also reveal that the nitrogen and silica levels are much lower than typical for groundwater in Hawaiian basalt. Typical nitrogen levels in basalt aquifer wells throughout the State are 70 to 80 μM, per the hydrologist’s experience over decades of sampling. Typical silica levels are 700 μM. For the groundwater in the alluvium sampled from the monitor wells, nitrogen and silica are about half the typical levels found in wells tapping aquifers in basalt. The complete results of the groundwater monitoring are contained in both Appendix E (Estimates of the Potential Impact on Groundwater and Surface Water by Hawaii Dairy Farms in Mahaulepu, Kauai) and Appendix F (Baseline Conditions and An Assessment of the Effect of the Proposed Hawaii Dairy Farm on Surface Water and Marine Water Chemistry, Mahaulepu, Kauai, Hawaii).

One of the three usable wells in the Māhāʻulepū 14 battery will be utilized as needed for deep water quality monitoring.

### 4.16.3 Probable Impacts and Mitigation Measures - Groundwater Resources

Impacts that would be considered significant related to groundwater supply and groundwater quality could include:

- Depleting the groundwater supply or interfering with groundwater recharge for aquifers in the project area; and
- Degradation of groundwater quality below State or Federal standards.

**Short-term Impacts and Mitigation – Groundwater Resources**

Water supply required for construction is anticipated to be nominal in comparison to previous agricultural water demand. The major water demand during construction will be for fugitive dust control in compliance with Hawai‘i Air Quality rules (see Section 4.19). Water will come from a non-municipal source: either the on-site deep wells; or from the HDF allocation of water from Waita Reservoir (see following Section 4.17, Surface Water).
Construction of Hawai‘i Dairy Farms facilities is not anticipated to deplete the groundwater source or interfere with groundwater recharge in the short-term. There will be no significant effect on the groundwater supply in the short-term.

**Long-term Impacts and Mitigation – Groundwater Resources**

Long-term groundwater supply impacts are not anticipated to be significant. Total potable water demand is approximately 30,000 gpd (0.03 MGD) for the committed proposed action herd size of up to 699 milking cows (Table 4.16-2). Groundwater use for the contemplated herd size of up to 2,000 milking cows is shown in Section 4.22, Table 4.22-1. The demand of approximately 30,000 gallons per day (0.03 MGD) the committed herd size is a small fraction of the 3 MGD produced by the on-site, existing Māhāʻulepū 14 well during the sugarcane plantation era (TNWRE, 2016).

*The majority of water used will be captured and re-used to irrigate pasture grass.*

A majority of the potable water will be used as wash water. Chapter 3, Section 3.3.1.7 notes that the DOH Milk Rules require potable water for milk production including that used as wash water in the milk house and milking operations. The pasture-based dairy system utilizes all manure produced on site, capturing effluent washed from the milking parlor and holding yards though floor drains via pipes into the effluent ponds. The water and associated nutrients from cow effluent are then reused on pastures as irrigation water. All potable water used as wash water will be re-applied to pasture and thus remain a part of the hydrologic cycle.

The buildings with related infrastructure and paved area of the dairy facility will constitute less than two percent of the total site acreage. Therefore, minimal impermeable area will be created. Stormwater runoff will either be directed to areas of grass, or be routed via curbing to the effluent ponds for runoff that potentially contains manure.

The groundwater and surface water analysis determined that the modest potable water use rate for dairy operations, and the 4,500-foot distance between the Māhāʻulepū 14 well and the nearest County potable water well (Kōloa Well F), will result in no adverse impacts to ongoing use of groundwater in the unweathered volcanic series, which is the source of potable water (TNWRE, 2016). Further, the assessment determined there is no hydrologic connection between the aquifer in the unweathered volcanic series, the source of potable water, and the shallow groundwater body in the alluvium. Thus nutrients added by the dairy operation will have no impacts to the County drinking water well, the source of potable water within the deep volcanics.

A calculation of applied nutrients that may pass-through grass and soils was estimated based on the mass nutrient balance for HDF (TNWRE, 2016). The estimate assumed that of the nutrients applied or excreted at the HDF site, two percent of total nitrogen and one percent of phosphorus could...
potentially pass through the turf and soil: to shallow groundwater and eventual release to surface water. Surface water is estimated to carry three times more nutrients than groundwater moving through the alluvium on the valley floor (see following discussion, Surface Water). The nutrient contributions from the dairy pastures would not occur as chronic daily releases, rather, the runoff contributions would be limited to periods of major rainfall and storm water events. Per best practices, no effluent application would be conducted during such weather events.

Though the waterbody in which the County wells occur (the deep volcanics) is confined and hydrologically separated from shallow waterbodies in the Māhāʻulepū Valley alluvial material, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing. Chapter 3, Figure 3.5-2, Paddock Layout, shows the area within the HDF site that will be excluded from grazing and nutrient application. This is greater than the 50-meter well control zone, and is significantly greater than the 50-foot setback for application of livestock effluent identified in the Livestock Waste Management Guidelines (UH, 2010).

Four water monitoring wells installed by HDF into the shallow water aquifer within the alluvium will allow long-term water quality monitoring. Monitoring and analysis of nutrient and chemical constituent levels over time will identify any change in composition of shallow groundwater in the alluvium. Results from the monitoring program will be shared with DOH, dairy neighbors and the local Kauaʻi community.

4.17 SURFACE WATER RESOURCES & NEARSHORE MARINE ENVIRONMENT

The State DLNR Commission on Water Resource Management has established surface water hydrologic units for managing surface water resources. The project area is located within the Māhāʻulepū Surface Water Hydrologic Unit, which features relatively high precipitation with relatively low stream discharge.

This section of the EIS presents existing conditions of surface water resources and the nearshore marine environment of the Māhāʻulepū area, and assesses probable impacts from dairy farm operations with the committed herd size of 699 milking cows. Probable impacts and recommended mitigation for surface water resources and nearshore marine related to the contemplated herd size of up to 2,000 milking cows are presented in Section 4.23.

4.17.1 Intermittent Streams and Agricultural Ditches of Māhāʻulepū Valley

Existing Conditions – Surface Waters and Ditches

The project area is located on the bottom-land of the upper Māhāʻulepū Valley, which is fed by several intermittent streams coming off of the south slope of the Haʻupu Ridge. These normally dry streams converge into man-made channels running through the project site across the valley floor; and meet a concrete ditch that parallels lower Māhāʻulepū Road. This ditch, named Waipōli Ditch, is joined by a reach from the west that originates at a small unnamed reservoir, and continues off site towards the south. Older agricultural ʻauwai (ditch) that run in and around the project area appear abandoned and no longer functional.
The main surface water course which crosses the HDF site is not named on the U.S. Geologic Survey quadrangle map. At its mauka end above the HDF property, it is a relatively steep, naturally occurring water course with several small tributaries. Across the HDF property and for some distance further makai, the channel is manmade and was created to facilitate former sugarcane irrigation. The groundwater and surface water analysis conducted for this EIS (see Section 4.16.1, Hydrology) observed that groundwater from the alluvium discharges into the channels on a seasonal basis in the vicinity of the HDF-1 and HDF-2 monitoring wells. In the lower elevations of the site no such discharge occurs as the groundwater level in the alluvium is substantially lower.

There are a number of other drainage channels that convey surface water runoff which originates offsite and cross or border the HDF property. Historically the Waita Reservoir Ditch circumnavigated the Māhā'ulepū Valley floor, bringing water to both the Māhā'ulepū Reservoir (outside the HDF site) and to provide for sugarcane furrow irrigation. This ditch apparently fell out of use when the irrigation method was converted from furrow to drip (TNWRE, 2016). From that time forward, water from the Well 14 battery was apparently the sole source of irrigation for sugarcane in the valley. In the post-plantation period (from about 1999), water from Waita Reservoir has been delivered to Māhā'ulepū via a 12-inch pipeline. The pipeline supplies an actively cultivated taro farm within Māhā'ulepū Valley, banana cultivation near DOW's Kōloa Well F, a quarry on the east side of the valley, and agricultural crops makai of the HDF property. HDF is utilizing the non-potable water source to irrigate approximately 70 acres of grass at the mauka end of the site.

Many of the aquatic features just described are shown on the USFWS National Wetlands Inventory (NWI) and assigned codes that describe the habitat type presumed by the Inventory (most information in the NWI was derived from aerial photographs and maps, not field investigations; USFWS, 2014). All of the water ditches on the property (and the ‘auwai around the margin of the valley floor) are coded “R4SBCx”, which represents: intermittent (seasonally flooded) flowing water, in an excavated channel. An exception is the ditch (and channel upslope) directing stream flow off Kāmaulele (Figure 4.4-2), which is coded R3RBH: an upper perennial stream with a rock bottom. However, this characterization is unlikely (Rana Biological and AECOS, 2016). According to CWRM (2005, 2008), there are no perennial streams in the Māhā'ulepū watershed.

4.17.2 Surface Water Quality

Hawai‘i’s Department of Health Clean Water Branch (CWB) administers and enforces Statewide water pollution laws and rules. CWB oversees permits for point-source discharge, monitors permit compliance, investigates complaints, and conducts water quality sampling. The CWB Monitoring and Analysis Section is responsible for sampling and analysis in support of Federal Clean Water Act (CWA) §303(d) assessments, §305(b) integrated reports, and §319 non-point source management grants. A major activity of CWB is water quality monitoring of beaches as initiated under the Beaches Environmental Assessment and Coastal Health Act of 2000 (BEACH), an amendment to the Federal CWA. Additionally, coastal chemistry monitoring of nearshore and offshore waters is conducted for select indicators of water quality; however, offshore sampling has been suspended due to manpower and funding constraints (CWB, 2012).
Water quality standards are established relative to designation of the waterbody (e.g. inland freshwater, open ocean, embayment, estuaries). Classification of State waters (inland or marine) and water uses are documented in Hawai‘i Administrative Rules (HAR) HAR §11-54. Narrative and numeric criteria are specific to waterbody classification, and provide the basis for evaluating water quality data. The U.S. Environmental Protection Agency (EPA) recommended new water quality criteria for recreational waters to protect health of beaches and waters. Priority for Hawai‘i’s nearshore water quality monitoring goes to public beaches where the general public recreates in numbers; areas accessed across private lands are typically not included due to limited funding.

The Kaua‘i Chapter of the Surfrider Foundation began collecting water samples in Waiopili Ditch near the bridge accessing Makauwahi Cave Reserve in April of 2014. Its “Blue Water Task Force” typically collects water samples from the ocean environment, and some streams not tested by DOH. The group reported high levels of enterococcus to the State DOH and provided its data. However, for DOH to utilize water quality data provided by a third party, the party must furnish its Quality Assurance Project Plan, chain of custody, and laboratory reports. Evaluation of the third-party data by DOH CWB determined it did not meet CWB quality assurance/quality control requirements, and it could not be used for regulatory purposes.

CWB had not conducted water quality sampling for either nearshore recreation waters at the terminus of Waiopili Ditch, or of surface waters in the Māhā’ulepū Surface Water Hydrologic Unit as the remote areas are on private lands. Complaints from the public citing the high levels of enterococcus in Waiopili Ditch and concerns about the proposed dairy prompted CWB to conduct a “Sanitary Survey” of the Māhā’ulepū and adjacent watersheds. DOH conducted water sampling within the Waiopili Ditch and areas upstream, and initiated a series of investigations into water quality issues. Following EPA standards for a Sanitary Survey, DOH has completed Part I of its report: Waiopili Ditch Sanitary Survey, Kauai, Part I (CWB, 2016).

The findings of the Sanitary Survey indicate that high levels of enterococcus and Clostridium perfringens occur in sediment of Waiopili Ditch. Soil has been identified as a primary source of fecal indicator bacteria in the environment, and can be transported by precipitation into even pristine streams and rivers (Hardina and Fujioka, 1991, in CWB, unpublished). The agricultural ditch and intermittent streams showed degraded water quality parameters for nutrients and pathogens. Elevated levels in these water courses is due to the low flow conditions and varied inputs from the agricultural lands and natural contributions from the watershed. Water inputs to the agricultural ditches come from a watershed area surrounding the Māhā’ulepū Valley, including the sloped areas from Ha’upu Ridge (CWB, 2016).

The Sanitary Survey found no significant impact to the Waiopili Ditch from any activity that can be attributed to the dairy. Feral animal waste, decaying organic debris and inputs from existing agricultural operations may all be contributing factors in the indicator levels found in ditches running through Māhā’ulepū Valley. The dense canopy along the makai end of Waiopili ditch blocks ultraviolet rays that could help reduce bacteria levels. CWB notes that Waiopili Ditch is a man-made drainage on private property, and is not an inviting recreational body of water utilized by people. The predicted risk of illness from recreation exposure to a cattle-impacted waterbody is 25- to 150-times lower than the risk of illness associated with human sources of contamination (EPA, 2010 in CWB, 2016).
Marine Research Consultants, Inc. (MRCI) conducted water quality surveys of the intermittent streams and agricultural ditches feeding into and including the Waiopili Ditch for this EIS (see Figure 4.17-1). Counts of indicator bacteria (enterococcus and *C. perfringens*) in surface water samples and nearshore marine samples showed no repetitive pattern: counts were high and variable between sampling sites, and showed variation among periods sampled. As no dairy activities existed during the sampling, the high levels of indicator bacteria appear to be the result of naturally occurring sources, as well as other ongoing land uses (MRCI, 2016). These sources may include feral animals, or domesticated animals (pigs, sheep) that are being raised near the dairy property. No dairy cattle were present on the site during any of the sampling events, so the observed counts of indicator bacteria are not a result of dairy operations.

### 4.17.3 Nearshore Marine Waters

Water quality constituents including nutrients and bacteria were measured in the nearshore waters off Waiopili Ditch and the coastline along Māhāʻulepū and Poʻipū to establish baseline conditions for this EIS (see Figure 4.17-1). Ocean waters along this shoreline are considered high quality ocean waters due to the active wave, winds and currents which provides mixing energy. This stretch of open coastal waters is classified as class A under State Water Quality Standards, as no embayments, marine waters, or open coastal waters in the vicinity are listed in HAR §11-54 for special protection. Use of class A waters in the standards state: “the objective of class A [marine] waters that their use for recreational purposes and aesthetic enjoyment be protected. Any other use shall be permitted as long as it is compatible with the protection and propagation of fish, shellfish, and wildlife, and with the recreation in and on these waters. These waters shall not act as receiving waters for any discharge which has not received the best degree of treatment or control compatible with the criteria established for this class” (DOH, 2014).

Comparing the surface water samples to those taken in nearshore ocean water revealed that indicator bacteria were substantially lower in the ocean than in the ditch. The rapid decrease is likely a result of both physical mixing of water masses and toxicity from saline water. In any event, the elevated levels of indicator bacteria do not extend beyond the shoreline (MRCI, 2016).

Analyses of water chemistry samples from the marine environment indicate two major patterns. Small elevations of inorganic nutrients (Si, NO₃-, PO₄³-, TN, TP) at the shoreline, along with corresponding decreases in salinity indicate only a small input of groundwater at the shoreline. Groundwater input is mixed to background oceanic values within meters of the shoreline. Along the marine sampling station originating at the juncture of Waiopili Ditch and the ocean, steep gradients of nutrients, salinity, Chloryphyll *a* and turbidity were observed. These gradients are the result of a narrow zone of mixing between ditch water and ocean water in the intertidal region of the reef flat. Typical oceanographic conditions of tradewind generated seas and long-period swells breaking on the reef platform result in rapid mixing and dilution of ditch water constituents within a narrow zone that only extends several meters from the shoreline. As a result, input from ditch water is highly restricted in terms of effects to the marine environment.

The MRCI report is included as Appendix F.
Figure 4.17-1  Surface and Marine Water Sampling Sites
4.17.4 Probable Impacts and Mitigation Measures

Impacts that would be considered significant related to surface water could include:

- Cows depositing manure into on-site surface water and damaging the banks of the drainageway causing erosion;
- Introducing sedimentation into the on-site drainage ways; and
- Stormwater run-off carrying manure or nutrients into surface waters.

The probable impacts to surface waters and the nearshore marine environment are discussed in this section. The *Surface Water Quality and Marine Assessment* report prepared by MRCI includes an analysis of potential impacts from dairy operations, including nutrient run-off from the dairy site. Proposed minimization and mitigation measures to reduce HDF impacts to surface waters and the nearshore marine environment are included.

**Short-term Impacts and Mitigation Measures – Surface Water Resources & Marine Environment**

As discussed in Chapter 3.0, Description of the Proposed Action and Section 4.2, Topography, there will be site work required for pasture establishment and dairy facilities development. These developments will be designed to employ NRCS standards per the HDF Conservation Plan. Best management practices will be utilized during construction and pasture establishment.

A Stormwater Pollution Prevention Plan (SWPPP) has been developed for the site to document controls and best management practices to avoid, control, and trap potential erosion associated with construction activities. The SWPPP is required as part of the application for the NPDES – Construction Stormwater General Permit, and describes any discharge in compliance with relevant regulations.

In compliance with Federal and State Clean Water regulations, HDF will institute appropriate controls and procedures to retain stormwater impacted by construction, and to prevent hazardous materials such as petroleum products from construction vehicles from coming into contact with stormwater run-off. Both management controls and structural controls will be implemented in the short-term. Management controls will include: minimizing exposure of disturbed surfaces; monitoring and repair of structural controls; prohibiting leaking or poorly-maintained construction equipment and machinery; and keeping adjacent public, paved streets free of dirt and mud. Structural controls to be utilized during construction will include: silt fence installed in key locations; sand bags barriers in swales; and geotextile filter fabric and sediment logs around drain inlets.

Normal ongoing farming and ranching activities are exempt from the Clean Water Act Section 404. HDF received confirmation of exemption for maintenance of existing drainage ditches from the Honolulu District, U.S. Army Corps of Engineers (USACE) in 2013. Additional practices are anticipated to fall under the exemption for construction or maintenance of existing or new animal walkways, stream crossings, and farm roads with application of best management practices.

Short-term adverse impacts to surface waters from construction are anticipated to be within NPDES permitted levels. No short-term adverse effects are anticipated to the quality of nearshore ocean waters and the nearshore marine environment.
Long-term Impacts and Mitigation Measures – Surface Water Resources & Marine Environment

Long-term impacts will improve surface water quality in agricultural ditches and the downstream Waiopili Ditch.

Soil Erosion and Suspended Sediments. Over the long-term, the surface water quality in the agricultural ditches and Waiopili Ditch will be improved by active management of the dairy site. Cultivation of a grass thatch for complete vegetative cover throughout the dairy paddocks will minimize currently exposed soils within the site.

Vegetation and stream flow in the areas downstream of the dairy site are beyond the control of the dairy operation. Mahaulepu Farm’s agricultural tenants have responsibilities to maintain farm lands and vegetation growth along ditches to allow channel flow during peak stormwater runoff events. Suspended soil inputs from natural sources and offsite ranching and agricultural uses in the watershed will continue to enter the agricultural ditches, which drain downstream into Waiopili Ditch and the nearshore ocean waters.

Waiopili Ditch receives runoff from the larger 2,700-acre Māhā’ulepū Valley sub-watershed, including the lands mauka and makai of the dairy facilities and pasture paddocks. The dairy site represents roughly 20 percent of the sub-watershed, and soil erosion within the dairy will be reduced by establishment of the thick grass ground cover for pasture and filter strips along drainageways (Section 4.3.2, Soils).

Nutrients from Effluent Irrigation and Commercial Fertilizer Application. The Conservation Plan and best management practices include setbacks to minimize impacts to waterways. For effluent application, the setback is 50 feet from drainageways. Irrigation and nutrients application will maintain sufficient pasture grazing grasses for the herd. Non-potable irrigation water from Waita Reservoir will be applied through the central pivot system, and can be mixed with nutrient-enriched water from the effluent ponds as fertilizer. Refer to Section 3.5.3 and Appendix D, Nutrient Balance Analysis (Group 70 and Red Barn, 2016).

The natural fertilizer from manure deposited directly to pasture and effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop with the committed herd size of 699 milking cows. Therefore, supplemental commercial fertilizer will be required to provide sufficient nutrients to sustain the pasture grass at the committed herd size. In keeping with the NRCS Nutrient Management Practice Code, monitoring and analysis of soil, manure, and tissue samples will be used to amend the nutrient budget analysis prepared for the site (Appendix D).

Surface water is estimated to carry three times more nutrients than groundwater moving through the alluvium on the valley floor (see previous discussion, Groundwater). The groundwater and surface water analysis (Appendix E) estimates two percent of total nitrogen and one percent of phosphorus could potentially pass through the turf and soil. Given the poor permeability of the alluvium, groundwater flow would be modest. However, the groundwater level in the alluvium is approximately 80 feet above mean sea level near the HDF monitoring wells 1 and 2. The groundwater can rise in wetter periods and intersect the deep drainage ditches. Episodic, seasonal events will result in a modest amount of discharge from groundwater into the surface channel.

Using NRCS curve number method to compute runoff for the sites’ B and D class soils and irrigated pasture in good condition, it is estimated that actual runoff into drainageways from HDF pasture will only occur when rainfall exceeds 0.8 inches. Based on the 30-year daily rainfall record for the
area, such rainfall events are estimated to occur approximately three percent of days, or an average of 10 days annually (TNWRE, 2016). Applying the estimates of nutrient pass-through to the HDF operational nutrient mass balance, two percent of nitrogen pass through would total 10,000 pounds per year, and one percent of phosphorus pass through would total 900 pounds per year. Note that nutrient release from the dairy site would not occur as chronic daily release, rather, the runoff contributions would be limited to periods of the major rainfall and storm water events. Per best practices, no effluent application would be conducted during such weather events.

Section 4.20.1, Interrelationships and Cumulative Environmental Impacts, compares the nutrient input from the adjacent Kōloa- Poʻipū region. Nitrogen additions to the near-term marine environment along the Poʻipū coastline are estimated at 38,510 pounds per year from domestic wastewater and landscape fertilization, equating to 3.5 times greater than the potential contribution from HDF; phosphorus of 1,260 pounds per year is calculated and is 1.4 times greater than the potential contribution from HDF.

**Nutrients from Manure in Pastures.** Utilizing nutrients from the manure’s organic matter is key to the pasture-based rotational grazing system. As described in Section 4.3, Soils, microbes within the soils effectively transport nutrients from manure and effluent to plants. Cow manure deposited in the pastures will break down naturally into organic matter and release nutrients in the process. The soluble nutrients from the manure will enter the pasture grass, underlying thatch and soil profile, and be utilized as part of the nutrient requirement of pasture grasses. Montgomery (2016) notes that high populations of dung beetles at this location will effectively bury dung pats into the soil profile in one to three days. Yost (2016) anticipates the manure nutrients will largely be utilized by the pasture grass.

**NRCS Practice Standards and the U.H. Guidebook** have established various setbacks to minimize impacts to waterways. Fences will be erected along 35-foot setbacks to exclude cows from drainageways. The 35-foot setbacks (totaling 70 feet, as setbacks are on both sides of the drainageways) will be vegetated to act as filter strips and trap soil particles and organic debris from stormwater runoff. Manure particles that do not settle out in to the buffer area could be carried into ditch waters and downstream with stormwater flows. During runoff events, ditch waters will also contain substantial organic debris, suspended sediment and nutrients from natural and other man-made sources in the watershed. The relative contribution of manure particles in the stormwater flows within agricultural ditches will be a small fraction of the total from the watershed.

**Impacts to the Nearshore Marine Environment.** During the rainfall and runoff events, the dairy’s nutrient contributions would be further diluted by additional volume of surface runoff and ditch flows. The terminus of Waiopili Ditch is a deep, muddy basin that joins the ocean through a channel cut through beach sand. Water chemistry measurements made by MRCI identified mixing of ditch water occurs rapidly and within a short distance of the shoreline. MRCI concluded there will be no substantial effects to marine water quality from the HDF dairy (Appendix F).

**Mitigation –Buffers.** Vegetative buffers totaling 70 feet in width – 35 feet on either side measured from the top of the agricultural ditches – will be established in keeping with the *Livestock Waste Management Guidelines* (U.H., 2010) to improve and maintain water quality and reduce erosion. Fences will be erected along the 35-foot setbacks to exclude cows from the buffer areas; vegetation along the buffer will trap soil particles and organic debris in order to minimize inputs to stormwater runoff. Vegetation in and adjacent to the ditches will be maintained to control overgrowth and minimize ditch bank soil erosion.
Additional effluent application setbacks totaling 100 feet in width – 50 feet from the top of either side of a waterway – will keep nutrient applications away from waterways.

**Mitigation - Surface Water Quality Monitoring.** A long-term water quality monitoring program has been instituted to regularly sample and analyze nutrient and chemical constituent levels of the surface waters (agricultural ditches and Waipio Pli Ditch). The monitoring program and methods will be established to meet the CWB quality assurance/quality control requirements. The ongoing testing program will provide feedback to the dairy management team regarding changes in water quality. Data from the surface water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

Increases in nutrients as a result of dairy establishment or operations can inform modification of the operation's nutrient management. Modifications to the timing and placement of effluent can be made; the rate of application can changed; different crops can be utilized to increase uptake by plants; and the number of cows can be changed. Nutrient management is a dynamic process that is informed by monitoring a number of parameters; the ability to monitor nearby water bodies for changes in nutrients is an additional check that provides data to be publically shared.

**Mitigation - Ocean Water Quality Monitoring.** A long-term ocean water quality monitoring has been instituted in conjunction with the surface water quality monitoring, to regularly sample and analyze nutrient and chemical constituent levels in the nearshore marine waters. The ongoing testing program will provide feedback to the dairy management team regarding changes in water quality. Data from the nearshore water monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

### 4.18 ROADWAYS AND TRAFFIC

In this section, analysis for the committed herd size of 699 milking cows is presented. Refer to Section 4.24.1 for the traffic-related conditions related to the future contemplated herd size of up to 2,000 milking cows.

**Existing Conditions – Roadways and Traffic**

Primary access to the site is via Māhā‘ulepū Road, a two-way, two-lane road, which is accessible from Kōloa Road (Highway 530) via Ala Kinoiki Road, a two-way, two-lane County bypass road that provides mauka-makai access from Māhā‘ulepū Road to Po‘ipū Road. Secondary access would be provided southeast of the project site from Po‘ipū Road, a two-way, two-lane County collector road, which connects to Māhā‘ulepū Road. Kōloa Road is a two-way, two-lane County road that runs from Kaumuali‘i Highway to the west to Maluhia Road to the east (Figure 4.18-1). Traffic for 2009-2010 was measured along Ala Kinoiki Road at 8,000 vehicles per day, and along Kōloa Road at 6,500 vehicles per day (Fehr & Peers in COK, 2015a).

The HDF site is accessed from Māhā‘ulepū Road via a network of unimproved private agriculture haul roads. The agricultural roads are utilized by trucks accessing quarry operations and agricultural properties in the vicinity of the HDF site. Privately owned and rental vehicles travel the rough, unpaved roads to access beaches east of the HDF site. The private landowner, Mahaulepu Farm, allows access during daylight hours and locks gates across the access points at night. Typically these vehicles follow a dirt road that begins at the terminus of Po‘ipū Road near the Grand Hyatt Kaua‘i.
4.18.1 Probable Impacts and Mitigation Measures - Roadways and Traffic

Impacts that would be considered significant related to traffic could include:

- A significant increase in traffic on Ala Kinoiki or Po’ipū roads; significant traffic delays for a substantial number of motorists; or
- Changes to traffic patterns or road infrastructure that affect pedestrian, bicyclist or motorist safety.

**Short-term Impacts and Mitigation Measures – Roadways and Traffic**

The proposed project is not expected to significantly increase traffic in the project vicinity. The construction-related traffic will end after project completion.

There will be no significant change to traffic patterns or infrastructure related to the public roads.

**Long-term Impacts and Mitigation Measures – Roadways and Traffic**

Traffic operations along Māhā’ulepū Road and the surrounding County roads are expected to continue to operate at acceptable levels of service during peak hours of traffic. The projected increase in vehicle movements related to HDF operations is shown in Table 4.18-1, and includes daily employees accessing the site, milk tanker and supply trucks every two days, and truck with stock trailer, for a total of 12 additional vehicle trips per day. These additional trips would have a minimal effect on traffic conditions at County roadways in the surrounding area.

There will be no significant change to traffic patterns or infrastructure related to the public roads. Construction equipment mobilization will comply with Hawai‘i Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

The potential traffic impact based on the contemplated herd size is discussed in Section 4.24.
Figure 4.18-1  Major Roads in Vicinity
4.19 AIR QUALITY, ODOR, AND GREENHOUSE GAS

Potential odors and emission levels for air pollutants relevant to dairy operations were modeled, as currently there are no cows on site. Odors, greenhouse gas (GHG) emission rates, and potential fugitive dust for the proposed dairy operations were estimated based on published research values and local weather data. The full report, Hawai‘i Dairy Farms Air Emissions and Odor Evaluation Technical Report, is included as Appendix I of this EIS.

Under the Clean Air Act of 1970 (CAA), amended November 1990, the U.S. Environmental Protection Agency (EPA) regulates both large and small sources of air pollutants by establishing National Ambient Air Quality Standards (NAAQS) for six criteria pollutants:

1. Particle Pollution (often referred to as particulate matter, PM_{10} and PM_{2.5}),
2. Sulfur Dioxide (SO_{2}),
3. Nitrogen Dioxide (NO_{2}),
4. Ground-level Ozone (O_{3}),
5. Carbon Monoxide (CO), and

The State of Hawai‘i has established its own State Ambient Air Quality Standards (SAAQS) as provided for under HAR 11-59 that are as strict or, in some cases, more strict than the NAAQS. In addition to the six criteria pollutants, the State established a SAAQS that includes hydrogen sulfide (H_{2}S) (resulting from volcanic gases). The State has also established standards for air pollution control such as fugitive dust emissions emanating from construction activities (Hawai‘i Administrative Rules [HAR] Chapter 11 Title 60.1 [11-60.1]). These standards prohibit any visible emissions of fugitive dust from construction activities at the property line. The State standards are administered by the Hawai‘i Department of Health (DOH), Clean Air Branch (CAB).

No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist.

Emissions relevant to livestock operation include particulate matter and fugitive dust. Greenhouse gases related to dairy cows include methane (CH_{4}) from enteric fermentation, and both methane and nitrous oxide (N_{2}O) emissions from manure application.

In the following sections, analysis for the committed herd size 699 milking cows is presented. Refer to Section 4.25 for the air quality, odor and greenhouse gas analysis for the future contemplated herd size of up to 2,000 milking cows.

### 4.19.1 Air Quality

**Existing Conditions – Air Quality**

Emissions associated with animal livestock operations include fugitive dust. GHG emissions are discussed separately in Section 4.19.3.

Dust will be generated as cows move along soft limestone walkways that connect the paddocks and lead to and from the milking parlor. Potential emission rates were estimated from published literature, where particulate matter (PM) is measurable from the “drylots” of confined dairy operations where animals walk over dirt and dried manure throughout the day. Applying the
emission rates from this available literature to HDF, therefore, greatly overestimates potential emission, as cows in the rotational-grazing system will be on pasture 22 hours each day and will spend two hours – in two separate milking cycles – moving to and from the barn for the 10- to 15-minute milking sessions.

Methodology – Air Quality Modeling

Natural sources of air pollution emissions that could affect the project area at times but cannot be quantified accurately include the ocean (sea spray), plants (aero-allergens), wind-blown dust, and perhaps distant volcanoes on Hawai‘i Island.

Fugitive dust concentrations were modeled for HDF by applying the PM rates from available literature, which measured PM from a “dry lot” used for traditional confinement dairies. Using these dust rates in the model, therefore, over-estimate the potential quantity of PM, because HDF will utilize a pasture-based system. The HDF system will have cows off pasture just two hours each day.

Using atmospheric dispersion modeling system (AERMOD), the rates were scaled to the size of the non-pasture areas used by cows at HDF. Results were added to the background concentration of particulate matter (both PM$_{10}$ and PM$_{2.5}$) measured on the island of O‘ahu. This was considered the total impact and is compared to the State ambient air quality standards in Table 4.19-1. Only the contemplated herd size of up to 2,000 milking cows was modeled, as at the lower threshold of 699 cows the potential fugitive dust impact would be negligible.

Probable Impacts and Mitigation Measures - Air Quality

Impacts that would be considered significant related to air quality could include:

- Dust and debris generated during construction of the dairy facilities; and
- On-going dairy operations increasing odor, GHG, and air pollutants in the region.

Short-term Impacts and Mitigation – Air Quality

Short-term impacts may consist of exhaust emissions from construction equipment and increased vehicular activity during the construction phase, and fugitive dust emissions during soil excavation. Exhaust emissions from vehicle and heavy equipment may be perceptible along public roads, however, emissions from on-site work will dissipate before reaching public access areas due to the remote dairy location. Vehicular access to the site during construction will include limited delivery of construction materials and heavy equipment for site work, and daily vehicle access to the site by construction workers.
In accordance with Title 11, Hawai‘i Administrative Rules Chapter §11-60.1 “Air Pollution Control”, control measures are required to prevent or minimize any fugitive dust emissions caused by construction work from affecting the surrounding areas. Short-term construction dust can be reduced through implementation of dust control measures as recommended by DOH Clean Air Branch. Relevant control measures include:

- Using water to control dust on disturbed surfaces and haul roads;
- Limiting the disturbed area at any given time, and/or mulching or stabilizing inactive areas that have been worked; and
- Establish and monitor speed limits for trucks on-site.

Moving construction equipment and workers to and from the project site during off-peak traffic hours will help to mitigate exhaust emissions. Equipment and materials requiring heavy truck transport will be moved during periods of low traffic volume. Daytime work hours for construction will be set to avoid peak traffic hours in the project vicinity. Details of construction plans and contractor coordination will be determined in conjunction with contractor selection. Construction activities will comply with the State Air Pollution Control rules.

**Long-term Impacts and Mitigation – Air Quality**

Long-term impacts from dairy operations may occur from particulate matter in the form of dust. Utilizing published fugitive dust rates to the model overestimates potential particulate matter from cows at HDF moving along dairy raceways and paved areas. Only the contemplated herd size of up to 2,000 milking cows was modeled, as at the lower threshold of 699 cows the potential fugitive dust impact would be negligible. The estimated concentration for PM$_{10}$ is 2.01 µg/m$^3$ per 24-hour period, well below the State standard of 150 µg/m$^3$. The estimated concentration for PM$_{2.5}$ is 0.23 µg/m$^3$ per 24-hour period, well below the Federal standard of 35 µg/m$^3$ (Table 4-19.2). Dust control (e.g. watering walkways and washing down the holding yards) will be utilized as needed to keep any particulate matter on site.

The total annual particulate matter emissions were also estimated for PM and greenhouse gases (GHGs). Total annual emissions (in tons per year) are typically estimated for potential permitting applicability. Results of the estimate for a herd size of 699 mature dairy cows for PM was 0.6 tons per year. The project will not require any permits under the Clean Air Act, or State of Hawai‘i counterpart.

Potential impacts related to the potential contemplated herd size can be found in Section 4.25.1.

**4.19.2 Odor Assessment**

Odor refers to the combined effects of a mixture of gases on the sense of smell. Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. No animals or dairy facilities currently exist in the area leased by HDF, so air dispersion models were used to determine potential odor levels based on dairy facility design and established modeling methods. Local weather data was used in conjunction with the AERMOD (version 1) modeling system to evaluate odors documented for dairy heifers and effluent ponds.

**Existing Conditions - Odor**

The project area and surrounding acreage have been leased to various tenants for ranching and diversified agricultural operations since the late 1990s, when wide-scale sugar cultivation ceased.
and the Kōloa Mill closed. W.T. Haraguchi Taro Farm utilizes 38 acres for the cultivation of taro, surrounded on three sides by the HDF project. The taro farm also maintains a herd of sheep to keep weedy plants in check surrounding the lo‘i kalo (taro ponds).

Predominant winds blow towards the southwest with an average wind speed of 10 miles per hour (Figure 4-1.1). The developed area nearest HDF is an agricultural subdivision east of Ala Kinoiki Road, currently with two homes. The Grand Hyatt Kaua‘i and the Weliweli residential area west of Ala Kinoiki are both 1.6 miles from the south-westernmost corner of the HDF pastures, and 2.5 miles from the dairy facilities, which includes the milking parlor and effluent storage pond (Figure 4.4-3). Two private recreational facilities – the easternmost edge of the Po‘ipu Bay Golf Course and CJM Country Stables – lie 1.6 miles from the facilities of the proposed dairy.

**Methodology – Odor Assessment**

Odor is perceived when one or more chemical substances in the air come in contact with various human sensory systems. A human’s sense of smell is derived from the olfactory receptors in the top, back of the nasal cavity. Scientific methods to measure odor have been developed for use in sensory evaluation related to the trade industry (for perfumes, coffee, wine, etc.) and for regulatory monitoring and compliance. International standards dictate the scientific methods and practices of odor measurement which are objective, quantitative, dependable and reproducible. The perception threshold of an “odor unit” is defined by the point at which 50 percent of panelists, in laboratory conditions, cannot smell the odor but 50 percent of the panelists can detect the odor (Arcadis, 2016).

No regulatory threshold exists for dairy farm odors, and determining an odor threshold is complicated by lack of suitable data on odor levels associated with annoyance and complaint. A 2004 study suggested 6.5 OU/m³, 1-hour averaging and the 99.5th percentile at the receptor as appropriate criteria (Wang & Feitz, 2004). The 6.5 OU/m³ is described as the point at which 50 percent of a population can successfully detect an odor. The 1-hour averaging and 99.5th percentile describes the time over which the 6.5 OU/m³ may be detected. With 8,760 hours in a year, 0.5 percent of the year equates to 44 hours. Therefore, the 6.5 OU/m³, 1-hour averaging at the 99.5th percentile means that 50 percent of the population may detect an odor during just 44 hours during a one-year period. The modeling considers the worst-case meteorological conditions, so it is likely odor detection beyond the HDF boundaries will be even less frequent (Arcadis, 2016).

Odor emission sources identified for modeling at HDF were manure in the pasture fields, irrigation water containing diluted nutrients from effluent, the effluent storage ponds, and the dairy buildings. The odor model assumed the total pasture area was 563 acres, which overestimates the actual area used as pasture. Farm roads, cow walk/raceways, and vegetated buffers along drainages total nearly 70 acres of areas utilized for transit or excluded by fencing. The dairy facility will occupy less than 10 acres of the total project area.

Measures of odors for the evaluation conducted for HDF utilized data relevant to the odor emission source. Odor rates for the effluent storage ponds were published in Dairy Australia in 2008, based on analysis of 30 ponds over 12 months in Australia. Odor emission rates for manure of dairy heifers were determined in a trial conducted at the Pennsylvania State University (Topper et al., 2008). Emission rates for the dairy buildings were based on Jacobson et al. (2001).
Probable Impacts and Mitigation Measures - Odor

Odor isopleths (a line used to map all points having the same numerical value) were created using the results of AERMOD computer modeling that utilized four types of input data: emission source information, receptor locations, meteorology, and model specific control options (site and project specific data options).

Short-term Impacts and Mitigation – Odor

As the herd is established at HDF, odor will be below the modeled quantity as fewer animals will be on site. In the short-term, there will be no odor impacts.
Long-term Impacts and Mitigation – Odor

Unlike a traditional confinement dairy facility, the majority of manure will be deposited directly on the pasture where it will break down and be incorporated into the soil within a one- to three-day period. Manure collected from barns and paved areas will be washed into a settling pond for re-use on the pastures. Manure is cycled through the ponds on a regular basis guided by irrigation needs; over a period of roughly 45 days, effluent is completely utilized and replaced.

Figure 4-19.2 displays results of modeling the annual extent of the 6.5 OU/m³ odor level for the herd size of 699 milking cows. The colored area depicts the 99.5th percentile threshold of 6.5 OU/m³. Within the detection area (Figure 4.19-1 odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year. The odor isopleth does not extend beyond the dairy farm boundary more than approximately 1,670-feet (within one-third of a mile), and does not reach recreational or residential areas.

Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site (Figure 4.19-1).

Windbreaks, also known as shelterbelts, are used for a variety of purposes including reduction and interception of airborne odors. As a best management practice, Casuarina cunninghamiana will be planted along the east south-east boundary of the dairy site. Locally known as ironwood, this tree was introduced to Hawai‘i from its native Australia in the late 1800s.

Potential impacts related to the potential contemplated herd size can be found in Section 4.25.2.

4.19.3 Greenhouse Gases

No State or Federal regulations for greenhouse gas emissions from farm operations or small businesses currently exist. However, livestock and agriculture as an industry contributes to greenhouse gas emissions. During the public scoping period, inquiries about the project’s potential contribution to greenhouse gas were received. As the dairy has not been established, published scientific models were applied to calculate probable emissions from the pasture-based dairy operations. Results are presented here, and the probable impacts assessed.

When sunlight reaches Earth’s surface, it can either be reflected back into space or absorbed by Earth. Once absorbed, the planet releases some of the energy back into the atmosphere as heat (also called infrared radiation). Greenhouse gases (GHGs) like water vapor (H₂O), carbon dioxide (CO₂), and methane (CH₄) absorb energy, slowing or preventing the loss of heat to space. In this way, GHGs act like a blanket, making Earth warmer than it would otherwise be. This process is commonly known as the “greenhouse effect”. Human activities have contributed substantially to climate change by adding CO₂ and other heat-trapping gases to the atmosphere. Human activities, such as the burning of fossil fuels and changes in land use, release large amounts of CO₂, causing concentrations in the atmosphere to rise.

GHG emissions or the “carbon footprint” related to transporting fluid milk are not considered as part of this EIS. Carbon footprint is a term used to measure the amount of net carbon dioxide or other carbon compounds emitted into the atmosphere by the activities of an individual, company, country, etc. Carbon emission calculators have been developed to measure the carbon footprint of
various activities, and rely on assumptions which vary greatly. Carbon calculators have been found
to differ by an order of magnitude (Peck, 2010). Most carbon calculators identify direct greenhouse
consumption, such as household energy use, transportation distances and methods. Indirect carbon
emissions relate to food choices, recycling habits, leisure activities and shopping habits (Fry, 2008).

The primary sources of GHG gases in the United States are: electricity production (41 percent);
transportation (27 percent); industry (21 percent); commercial and residential (12 percent);
agriculture, including livestock (9 percent) and land use and forestry (13 percent) (EPA, 2015).
Methane from enteric fermentation, and both methane and nitrous (N\textsubscript{2}O) emission from manure
application are gases that can contribute to greenhouse gas (GHG) emissions. The Kaua‘i Island
Utility Cooperative published its CO\textsubscript{2} emission for energy generation between 2010 and 2013. The
range is from more than 302,000 tons of CO\textsubscript{2} in 2010, to less than 294,000 tons in 2013.

Removing carbon dioxide from the atmosphere is known as “sequestration”. Natural sequestration
is a biological process that occurs during photosynthesis of plants.

**Existing Conditions – Greenhouse Gases**

Prior to HDF’s lease of the property, the land was used for a herd of approximately 250 beef cattle.
Currently, the site consists of agricultural equipment in operation necessary to grow an area of
grass in the northeast corner of the farm. With the current minimal equipment and no cows
currently present, GHG emission rates are negligible.

**Methodology – Greenhouse Gases**

Estimates of GHG emission rates from a pasture-based dairy were calculated using the
Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas
Inventories (2006). Parameters for dairy cattle in Oceanic (warm) climates were selected as most
applicable to conditions at HDF. Estimated emissions of methane and nitrous were converted to
carbon dioxide equivalents (CO\textsubscript{2}e) using the IPCC’s AR3 global warming potential (GWP) that
relates the GHG to CO\textsubscript{2} (Arcadis, 2016).

**Probable Impacts and Mitigation Measures - Greenhouse Gases**

The EPA issued the Final Mandatory Reporting of Greenhouse Gases Rule (GHG Reporting Rule), which
became effective on January 1, 2010. The GHG Reporting Rule requires annual reporting of GHG
emissions from large sources in the United States, including suppliers of fossil fuels or industrial GHGs;
manufacturers of vehicles and engines; and facilities that emit greater than 25,000 metric tons per year
(mtpy) each of CO\textsubscript{2} and other GHGs. Permits and reporting for the stationary source emitters with the
potential to emit 25,000 metric tons per year or greater of GHGs are required under the Clean Air Act.
Small businesses and farms are not included or required to report.

**Short-term Impacts and Mitigation – Greenhouse Gases**

Short-term impacts that could contribute to greenhouse gases are those identified related to
construction in Section 4.19.1, Air Quality. Mitigation measures to reduce emissions are outlined in the
Air Quality section. Contributions to GHG from implementation of the dairy over the short-term will not
be significant.
Long-term Impacts and Mitigation – Greenhouse Gases

Long-term operational impacts were modeled using the IPCC guidelines and conversions, and estimated the emissions potential for GHG at the dairy at the committed herd size of 699 milking cows to be 2,693 CO₂e metric tons per year (2,969 US tons). This is equivalent to the GHG generated by 170 4-person households, including home energy consumption, transportation and waste (https://www3.epa.gov/carbon-footprint-calculator).

Operational practices to protect air quality by reducing nitrogen emissions will come from guidance in NRCS Conservation Practice Standard 590, Nutrient Management. Application of nutrients must be adjusted to minimize negative impacts of GHG release to the environment through adjustments to the source, timing, amounts, and placement of nutrients. Specific practices to be utilized at HDF include: slow release fertilizers; nutrient enhancement technologies; and stabilized nitrogen fertilizers.

To reduce use of fossil fuels at the dairy, HDF will install solar photovoltaic power generation to provide onsite power. A roof-top mounted system using solar panels will be designed to produce 500 kilowatt hours.

While the presence of cows may increase GHG, a long-term beneficial impact of the grazing fields is the sequestration of carbon as CO₂ captured by the process of from photosynthesis by the grass. According to recent studies in the Soil Science Society of America Journal, converting formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, which enhances soil quality, grass production, and has the potential to offset up to one-third the annual increase in CO₂ production of an area (Machmuller, 2015).

Estimated GHG related to the potential contemplated herd size can be found in Section 4.25.3.

4.20 SUMMARY OF PROBABLE IMPACTS AND CONTEXTUAL ISSUES (COMMITTED HERD SIZE)

This section discusses the dairy farm’s potential secondary effects and the cumulative impacts on the environment at the committed herd size of 699 milking cows.

4.20.1 Interrelationships and Cumulative Environmental Impacts

Hawai’i Dairy Farms is being implemented to make productive use of lands designated as Important Agricultural Land with food production and a dairy to produce fresh milk and milk products. The dairy farm is an agricultural use planned within the existing Māhāʻulepū agricultural area. Other known uses underway or planned in the region, with the dairy farm in operation, will contribute to the contextual setting of interrelationship and cumulative effects.

Agricultural and Commercial Uses in Māhāʻulepū Valley

Surrounding agricultural operations and activities within the Māhāʻulepū sub-watershed include:

- Vasconcellos Cattle – cow-calf operation (adjacent, northwest)
- Palama / Māhāʻulepū Cattle – head beef cattle (adjacent, east)
- CJM Country Stables – commercial guided horseback riding (not adjacent, south)
- Māhāʻulepū Quarry, Jas. W. Glover, Ltd – sand and limestone aggregate (not adjacent, east)
- W.T. Haraguchi Taro Farm – taro cultivation; approx. 80 sheep (within HDF site)
- Pioneer Parent Seed Co. – recently vacated; land no longer in cultivation (adjacent, south)
- Banana Farm – approximately 10 acres (not adjacent, southeast)

**Planned Development in the Kōloa - Po'ipū Region**

Currently, there are several new agricultural enterprises planned in the vicinity, along with other public and private development and redevelopment efforts in the Kōloa Town and Po'ipū area. The South Kaua'i Community Plan (County of Kaua'i Planning Department, July 2015) summarizes planned developments in the region. Some may be on hold pending finances or funding:

- The Kōloa - Po’ipū Regional Wastewater Reclamation Facility is a privately-owned (HOH Utilities, LLC) and operated regional wastewater reclamation facility and wastewater collection system.
- The County of Kaua'i Department of Water: water system improvements to support residents and businesses for planned growth in the Kōloa Town and Po'ipū communities
- Kōloa Landing Resort: adding 200 new residential units in Po'ipū by 2016
- Sheraton Kaua'i Resort Expansion: 394 units on 10.7 acres; planned conversion to timeshare
- Kukui’ula master planned resort residential community: 1,000 acres in development phases, including golf course, clubhouse, spa, commercial centers, and residential units
- Kukui’ula Affordable Housing project: 60 affordable units
- Kōloa Marketplace: 71,000 square-feet (sf) mixed-use commercial center
- Waihohonu: 50-unit residential development at the old Kōloa Camp area
- Village at Kōloa Town: 34 residences and 45,000 sf retail office
- Kōloa Creekside: 72-unit multi-family residential project in Kōloa
- Paanau Village, Phase 2: 50-unit multi-family residential project in Kōloa Town
- Wainani at Po'ipū: 69 single-family homes by DR Horton
- Kahuna at Po'ipū Golf Resort: new phase build-out
- Pili Mai Community in Po'ipū: 191 luxury condominiums by Brookfield Homes Hawai‘i
- Royal Palms at Po’ipū Beach: 100-unit resort condominium development
- Po’ipū Gateway Mixed-use Village: 1,100 new residential units and mixed use commercial
- Koa’e Workforce Housing Development: 130 to 150 multifamily affordable housing residential units (County of Kaua‘i, 2015)

**Probable Cumulative Impacts**

Existing commercial and agricultural uses within the Māhāʻulepū sub-watershed have the potential to impact natural resources, notably use of potable water, and to contribute to environmental impacts in the region, notably nutrient inputs to groundwater and the nearshore marine environment from on-site sewage disposal systems. Nearly 2,500 new residences or room units are listed in the South Kaua'i Community Plan, ranging from high-end single family resort homes to affordable housing, and including commercial and retail development. Recognizing the number of development projects planned and probable impacts, alongside potential impacts from the dairy farm, combine to provide insight to probable cumulative impacts. Qualitative or quantitative analyses were conducted in this EIS for pest insects, demographic and economic conditions, groundwater resources, surface water and nearshore marine resources, roadways and traffic, and air quality, odors and greenhouse gases.
Pest Insects

There are no native, protected or endangered insect species within the HDF site. Flies identified on the HDF site using manure from neighboring livestock as bait for invertebrates include two flies associated with livestock (the stable fly and the horn fly), and the greenbottle fly, often confused with the house fly. Flies known to exist on Kaua‘i but not seen at the HDF site include the house fly, the dog dung fly, and the chicken dung fly. These pests are common in areas with high pet populations. It is possible these fly species could be brought inadvertently to the dairy and could transfer to manure as a food source.

Fly populations at HDF will be minimized through a process known as Integrated Pest Management (IPM). IPM disrupts reproduction with appropriate means at key points in the pest's life cycle. Used in Hawai‘i for decades, dozens of invertebrates and a bird (the cattle egret) were introduced between 1898 and 1985 to reduce livestock-related insects. IPM utilizes knowledge of the ancient food web among species. An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which can bury manure in one to three days and thereby incorporate it into the
soil. This interrupts the egg to fly lifecycle, which ranges from 7 to 20 days depending on the species. Populations of dung beetles found on Kaua‘i and those species already in Māhā‘ulepū Valley, will expand with the growing manure food source, thus increasing and speeding breakdown of manure.

Area ranchers may work together with the State Department of Agriculture to request translocation of dung beetle species already on Kaua‘i. This would supplement beetles on the HDF site and at other ranches with additional beetle species to more quickly and effectively bury manure. Different species are active at different times (day versus night), and perform different roles (burying deep versus shallow) to integrate manure into soils.

In the Kōloa- Poʻipū region, pest fly populations are dependent upon food and breeding sources nearby such as dog, cat, and chicken dung. Beef cattle graze in the region on agriculturally-zoned lands along Ala Kinoiki Road between Kōloa and Poʻipū, and it is likely that livestock-related flies are found in this region, which is more than 1.5 miles from HDF. Localized controls are needed in the Kōloa- Poʻipū area to address breeding sites in and amongst the food and animals wastes within the region to reduce pest populations.

**Demographic and Economic Conditions**

Implementation of the dairy farm will provide approximately 11 direct and indirect full-time equivalent jobs, including 5 farm jobs and 6 indirect jobs on Kaua‘i, with 3 additional indirect jobs on O‘ahu at the committed herd of 699 milking cows. The economic impacts are summarized in Section 4.15, and the complete study is provided in Appendix J. The increase in agricultural employment will add to local economic activity. Once fully operational with a herd of 699 mature dairy cows, annual direct-plus-indirect sales are estimated annually at $8.1 million on Kaua‘i, with an additional $2 million on O‘ahu. These sales would generate $60,000 annually in net income to the State, mostly from excise taxes on sales. The dairy farm will add agricultural industry employment, provide net revenues to the County and State, and bring fresh milk and milk products to advance local food sustainability.

**Groundwater Resources**

**Demand - HDF:**
The dairy farm would use 30,000 gpd of potable water for the committed herd size of 699 milking cows. This includes 25 gpd per cow for drinking water, and less than 18 gpd per cow for wash water in the milking parlor. The existing, on-site agricultural well will be re-activated and utilized; its yield during the sugarcane planation era was 3 million gallons per day. The demand is well within the aquifer yield.

Nearly all of the potable water used will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Potable water used in the milking parlor and dairy facilities will be captured and recycled in irrigation water, and some percentage of the livestock drinking water will be returned as effluent and ultimately utilized by the pasture grass. The modest potable water use rate for dairy operations, and the 4,500-foot distance between the Māhā‘ulepū 14 well and the nearest County potable water well (Kōloa Well F), will result in no adverse impacts to ongoing use of groundwater in the unweathered volcanic series, which is the source of potable water (TNWRE, 2016).
Demand - Kōloa-Po’ipū:
Total demand for municipal potable water in the Kōloa-Po’ipū region was 2.3 MGD (CWRM, 2008). Documented use rates for residential and resort units were last published for Kaua‘i in the Department of Water’s long-range plan, Water Plan 2020 (COK, 2001). For planning purposes, single-family demand assumed was 500 gpd per residential unit, and 350 gpd per resort unit. Golf course irrigation rates are estimated to average 51,000 gpd per golf course statewide (CH2MHill, 2013). Municipal water demand for the three golf courses in the Kōloa-Po’ipū region is therefore estimated at 153,000 gpd.

The adjacent, developed Kōloa-Po’ipū region shows large and increasing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase from the year 2010 population of 67,100 residents to 84,400 in 2030, an increase of 17,300 residents over the 20-year period. The South Kaua‘i population is estimated to reach 16,855 in 2035. Compared to the remainder of the island, population growth for this region is projected to increase to encompass 19.2 percent of the County population; in 2010 the region contained roughly 17.4 percent of the County population (COK, 2015a).

Water resources must therefore be carefully managed to accommodate the projected growth and water demand in the region through 2035.

Groundwater Quality – HDF:
The groundwater assessment determined there is no hydrologic connection between the shallow groundwater body in the alluvium and the source of potable water in the unweathered volcanic series. The poor permeability of the alluvium means that groundwater flow would be modest. Surface water is estimated to carry three times the nutrients than groundwater moving through the alluvium on the valley floor (see following section, Surface Water and Nearshore Marine). Nutrients added by the dairy operation will have no impacts to the County drinking water well, the source of potable water within the deep volcanics.

Groundwater Quality – Kōloa-Po’ipū:
The Kōloa karst topography and lava tube systems that straddles the Waikomo Watershed may provide transport of injection well and cesspool effluent to the Makauwahi Cave/sinkhole lava tube system in the Māhā‘ulepū sub-watershed. The CWB Sanitary Survey estimates groundwater and coastal waters of south-east Kaua‘i are being contaminated with roughly 3 MGD of wastewater daily (CWB, 2016).

Effluent Production – HDF:
The total generation of effluent captured by the settling and storage ponds for re-use on pastures is estimated at 10.9 gpd per cow. Including minimal input from calves within the calf sheds, the total wastewater volume to be collected from dairy facilities is 13,225 gpd (0.013 MGD) for the committed herd size. This includes required wash water of 17.4 gpd per cow (see Demand – HDF, preceding). The wastewater from dairy facilities will be re-applied to grow pasture grass, a locally available food source which will provide 70 percent or more of the herd’s nutritional requirements.

Effluent Production – Kōloa-Po’ipū:
An estimated at 1.17 MGD of wastewater disposal was processed at treatment plants in 2010 (SSFM, 2016). This is in addition to estimates of wastewater disposed of through on-site systems; see Groundwater Quality - Kōloa-Po’ipū, preceding. An evaluation of Kaua‘i’s infrastructure through the
year 2035 predicts the island will face inadequate wastewater treatment and solid waste capacity (SSFM, 2016). For the year 2035, wastewater volume for the region is projected to more than double to 2.42 MGD.

Reclaimed wastewater from sewage treatment plants is used to both treat wastewater and provide nutrients to landscaping and golf courses. The 2013 Update of the Hawaii Water Reuse Survey and Report (CWRM, 2013) reports that the key factor for reclaimed water use at most Kaua‘i County water reuse projects is primarily wastewater disposal. Reclaimed wastewater is derived from sewage that undergoes preliminary treatment (removal of large debris), then primary and secondary treatment to settle out solids and organic materials and manages microorganisms like bacteria, protozoa, ciliates and worms that eat the organic material. Advanced treatment, also known as tertiary treatment, can include additional filtration and disinfection such as ultra-violet light or chlorine, to reduce pathogen levels. Additional nutrient removal through uptake by flora in treatment lagoons or constructed wetlands, though often the benefit of retaining nitrogen and phosphorus in reclaimed water makes it useful for irrigation. The extent of disinfection is reflected in whether the effluent water is characterized as R-2 or R-1 reclaimed water. Most reclaimed water projects blend the treated water with surface or brackish water for golf course and landscape irrigation.

The Po‘ipū Bay Resort Golf Course, located 1.6 miles southwest of the proposed HDF facilities, averaged 100,000 gpd (0.1 MGD) use of R-2 reclaimed water in 2013. The wastewater source used is from the Grand Hyatt Kaua‘i wastewater treatment facility. Reclaimed water is mixed with Waita Reservoir and stream water for irrigation. The percentage of recycled water varies throughout the year depending on rainfall volumes. An on-site injection well operated by golf course maintenance personnel is used to dispose of excess recycled water during extended rainy conditions when irrigation is not required (CWRM, 2013).

Kiahuna Golf Course is located in the Waikomo watershed in Po‘ipū, to the west of Māhā‘ulepū Valley. R-2 water from the Po‘ipū Water Reclamation Facility (WRF) has been used since 1984 for irrigation, blended at 40 to 60 percent with water from Waikomo Stream. DOH guidelines require a 500-foot buffer between the point of application and nearby properties, however, R-2 water has been used via spray irrigation along fairways lined with single-family homes as this use was approved and initiated prior to passage of the DOH guidelines. The reclaimed water used at the course has been upgraded to R-1. On-site injection wells are available for disposal of wastewater when effluent does not meet R-1 water standards, or if the golf course does not require irrigation due to heavy rain events (CWRM, 2013).

The golf course is considered a convenient effluent disposal option of the Po‘ipū WRF as it can typically utilize the entire daily flow from the facility. In 2013, Kiahuna Golf Course used 360,000 gpd (0.36 MGD) of reclaimed water to partially meet irrigation demand. Waikomo Stream has partially satisfied demand with 0.3 MGD for irrigation, but peak summer irrigation demand for reaches 0.7 MGD, which can only be met with reclaimed water supply. The R-1 water from the Po‘ipū WRF is also provided though the golf course system to the nearby commercial properties. Kōloa Landing receives 70,000 gpd (0.07 MGD) for landscape irrigation.

Surface Water and Nearshore Marine Resources

The surface waters crossing the dairy farm site include some input from an intermittent stream above the site and drainage collected in agricultural ditches developed during the sugarcane
plantation era. These surface waters are not a recreational resource and are not used by the public, even near the ditch terminus at the ocean. With an on-site manager for the new agricultural endeavor utilizing best management practices to protect water quality through nutrient and soil management, current run-off would be reduced. HDF will follow its NRCS reviewed Conservation Plan to minimize sediment, nutrient and pathogen inputs to the surface waters in these drainages.

The groundwater body in the alluvium is hydrologically disconnected from the County well water in deep unweathered volcanics. Episodic, seasonal rainfall events cause groundwater in the alluvium to rise and intersect with the deep agricultural ditches in the vicinity of HDF monitoring wells 1 and 2. Such episodes are calculated to average 10 days annually, which would result in a modest amount of groundwater containing nutrients to discharge into the surface ditches. The amount of nutrients estimated from HDF operations released to surface water is calculated at 10,000 pounds of nitrogen and 900 pounds of phosphorus annually.

An estimate of nitrogen input to the marine environment from resort landscaping fertilization and domestic wastewater in the Po’ipū region is calculated to be 38,510 pounds of nitrogen annually. This is 3.8 times greater than the estimate from dairy operations. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. Significantly different soils mean that nutrient inputs from the Po’ipū region are constant throughout the year, and no mitigation is applied to reduce the quantities.

Working closely with DOH and NRCS, dairy farm staff are helping to improve understanding of factors that affect local water quality. Adherence to strict measures to protect water quality through proper irrigation management practices and re-analysis of nutrient inputs and outtake, the dairy farm will balance nutrient needs of pasture grass as well as improve the water-holding capacity of soils. Occasional nutrient run-off may allow some diluted nutrients to bypass mitigation measures to be employed, but will have no significant deleterious effect on the area’s surface water quality. Nearshore water quality at the Waiopili Ditch outlet and along this coastline will not be significantly degraded by inputs from HDF.

Roadways and Traffic

The development of the dairy farm facilities and future operations is not expected to have a significant impact on traffic operations in the area roadways. The projected increase in vehicle movements related to HDF operations for the committed herd size of 699 milking cows is approximately 12 additional vehicle trips per day. Traffic data in 2009 to 2010 on Ala Kinoiki Road was 8,000 trips per day, and on Kōloa Road, 6,500 daily trips, for a total of 14,500 vehicle trips in the vicinity. An additional 12 trips daily would have a minimal effect on traffic conditions at County roadways in the area.

Air Quality/Odors/Greenhouse Gases

Results from the air quality odor model indicate that any long-term impacts on air quality in the project area due to dairy farm operations would be negligible. Under the worst-case meteorological conditions, concentrations of odor are limited to within 800 feet of the dairy farm boundary and do not reach residential or resort areas. With active management of the dairy operations, there will be no noticeable odors or reduction of air quality in the surrounding area. The limited number of worker vehicles and trucks will create nominal increase in air emissions, not significantly contributing to the air emissions generated by vehicles in the region. Contributions to greenhouse gas will not be significant.
According to the 2013 Update of the Hawaii Water Reuse Survey and Report (CWRM, 2013), effluent from sewage treatment plants, referred to as reclaimed water, is blended into the Po‘ipū Bay Resort Golf Course lake at a concentration of 20 to 40 percent with Waita Reservoir water. Irrigation of the first three holes on the golf course uses up to 60 percent reclaimed water, as maintenance personnel have observed the benefit of added nutrients. A slight odor is noted when the reclaimed water is spray-irrigated, and is reported to be more noticeable at the first three holes where the higher concentration is used (CWRM, 2013). The irrigation of effluent located within the recreational area, creates an odor source in close proximity to the resort.

4.20.2 Potential Secondary Effects

Local Milk Production and Food Sustainability. The creation of Hawai‘i Dairy Farms will produce substantial secondary effects in terms of local milk production and increased food sustainability. When the dairy matures to full capacity with a committed herd size of 699 milking cows, it will produce approximately 1.5 million gallons of fresh, local milk each year for the residents of Hawai‘i. The 1.5 million gallons of locally produced milk will reduce Hawai‘i’s 90 percent dependence on milk shipments from the U.S. mainland. Potential future processing of fluid milk into soft cheeses and yogurt could provide value-added products for HDF or procurers of the fluid milk.

Indirect Employment. For the development period of the dairy, indirect employment during the construction period based on state employment multipliers is expected to average 16 jobs on Kaua‘i and an additional 8 indirect jobs on O‘ahu. When the dairy is operational at the committed herd size, approximately 6 additional indirect jobs will be created on Kaua‘i and another 3 indirect jobs created on O‘ahu. These full-time equivalent jobs are in addition to the direct HDF job creation included in Section 4.15.

Source of Calves for the Local Ranching Industry. Over the long-term, dairy operations will provide a source of calves for the local ranching industry and expand the market for ranch-related additional goods and services from local vendors.

Offsite Herd Management. The committed herd size of 699 milking cows at the Māhāʻulepū site relates to a permitting threshold that references the count of mature milking cows. Animals in various stages of lactation and rest will be transferred between HDF and existing Kaua‘i ranches as needed for animal health and dairy productivity. Makoa Ranch and ‘Oma‘o Ranch are existing ranch operations, which require no additional facilities, permits, or improvements. The fluctuation in herd numbers is typical of cattle operations, and poses no impact to the Makoa or ‘Oma‘o ranches, or areas outside the project area.

The Hawai‘i Dairy Farms’ operation will produce calves, as discussed in Chapter 3.0, Section 3.4. Newborn calves will initially be housed at the Māhāʻulepū site and transitioned to pasture at about three to four weeks of age. At approximately 90 days of age (or at 165 pounds), the calves will be transferred to existing working ranches on Kaua‘i and raised offsite. Two ranches on Kaua‘i have initially agreed to take calves from HDF. Makoa Ranch near Kapa’a is an active cattle ranch run by the Farias family. The ranch will raise heifers until ready for return to HDF pasture. Calves to be raised for beef will be incorporated into the Makoa Ranch herd, or sold to other ranching operations. ‘Oma‘o Ranch will care for dry cows during an annual resting period.

Offsite Transportation. Employees working at HDF will create five offsite vehicle trips each day. Transport of cows for herd management will involve one or two truck trips per day between HDF and the offsite ranches. Fluid milk will be trucked offsite once every two days. Sand and feed
delivery would generate three truck trips per week. Fertilizer would be delivered once every other month. Milk transport from Kaua‘i would be once or twice each week via regularly scheduled ocean barges departing from Nawiliwili Harbor. Offsite transportation associated with HDF operations is not anticipated to generate significant secondary effects.

4.20.3 Relationship between Local Short-term Uses of the Environment and the Maintenance and Enhancement of Long-term Productivity

Narrowing of the range of beneficial uses of the environment

The area in which HDF will operate a dairy farm has been used for commercial agricultural for nearly two decades. The dairy farm does not propose a change in land use or a narrowing of the range of beneficial uses of the environment. Instead, it proposes a revitalization of farming on this area designated as Important Agricultural Land and introduction of a sustainable food production. After the end of the lease term – initially 20-years with an additional 10-year option – the land could be used for other purposes. This term could possibly be extended.

Long-term risks to health and safety

Hawai‘i Dairy Farms will not create long-term risk to health and safety. Evaluation of operations and probable impacts to drinking water quality and surface waters demonstrates risks to be minimal. Water quality monitoring will be established to demonstrate no loss of water quality from operations. Pest insects and odors will be minimized by dairy management and is without potential nuisance or health effects to area residents, workers and visitors.

Foreclosure of future options

The dairy farm maintains the existing and reasonable uses of the property for agriculture, and does not foreclose future options.

Trade-offs among short-term and long-term gains and losses

The short-term inconveniences caused by construction activity include increased noise and dust, and increased traffic due to construction vehicles. Once construction is completed, the dairy farm will become a producer of local fresh milk and milk products without the delay and added costs of shipping from the mainland. Along with gains to local food security, the long-term benefits outweigh the relatively short-term losses anticipated during construction.

4.20.4 Irreversible and Irretrievable Commitments of Resources

The construction of the dairy facilities will occupy less than 10 acres, totaling less than 2 percent of the 557-acre site. The site could be modified for other uses in the future. Soil conditions and fertility will be improved through the addition of manure and organic matter, resulting in better growing conditions for future agricultural endeavors.

An irretrievable commitment of private fiscal resources, labor, construction materials and energy will be expended to implement the dairy. There will be a permanent commitment of private funds and resources to plan, design, construct and operate the facilities.

Use of the site for dairy operations does not preclude future conservation use of the wider region, such as examined by the U.S. National Park Service in its 2006 to 2007 reconnaissance study.
4.20.5 Potential for Environmental Accidents

The potential for environmental accidents at the dairy farm has been minimized through exceedance of design requirements and redundancies. The effluent ponds are scaled beyond required capacity. For the extremely remote possibility that the ponds would overflow, a secondary containment system has been designed as an additional safeguard. Risks to surface water quality are minimized with application of best practices including vegetated filter strips and 35-foot setbacks to exclude cows from drainageways. Fuels and chemicals utilized at the dairy facilities will be stored following established protocols and be utilized by qualified applicators in compliance with labeling to safeguard the environment. Secondary containment systems will be utilized in keeping with requirements and best management practices.

4.20.6 Adverse Environmental Effects that Cannot Be Avoided

Implementation of the project will produce unavoidable affects in the short and long-term. Short-term effects are generally associated with construction, and will prevail only for the duration of the construction period. Long-term effects would generally arise after construction. Effects that can be considered both adverse and unavoidable are discussed below.

Unavoidable Adverse Short-Term Effects

- Temporary increases in soil erosion may result from construction, consistent with possible levels after application of best management practices. Small amounts of soil and dust may be carried beyond construction sites in surface runoff water.
- Temporary increases in noise impacts may occur during the construction activities within the HDF site, particularly during excavation activities.
- Temporary impacts to air quality, primarily from fugitive dust emissions, are anticipated during construction activities. Impacts will be within permitted thresholds.
- Short-term traffic impacts from construction activities would be expected to occur as the result of the following types of activities:
  - Increases in truck traffic associated with construction, equipment staging, and delivery of construction materials;
  - Increases in automobile traffic associated with construction workers traveling to and from the dairy farm site.

Unavoidable Adverse Long-Term Effects

- Vegetation will be replaced with non-permeable surfaces where facilities are constructed, totaling 0.1 percent of the site.
- Dairy farm operations will increase potable water consumption for the dairy herd and milking, and non-potable water for pasture irrigation.
- Dairy cows will produce manure and urine in the paddocks to be managed as part of the overall pasture grass nutrient demand, with a small percentage of nutrients passing to surface water and the nearshore marine environment where it will have no impact.
- There will be increased demand on existing utilities and infrastructure. Sustainable design practices and technology will be utilized to reduce demand requirements, including solar power generation.
- There will be an insignificant increase in traffic in the area due to the agricultural industry worker vehicles and local supplier deliveries to and from the dairy.
4.21 DEMOGRAPHIC AND ECONOMIC CONDITIONS (CONTEMPLATED HERD SIZE)

4.21.1 Existing Conditions - Demographic and Economic Conditions

The existing conditions are as described in Section 4.15.

4.21.2 Probable Impacts and Mitigation Measures - Demographic and Economic Conditions

As described in Section 4.15, the production of HDF with an established herd of up to 699 milking cows would increase the supply of local fluid milk by approximately 1.5 million gallons annually. With a herd up to 2,000 milking cows, approximately 4.4 million gallons of milk would be produced. This would double local milk production currently supplied by operational dairies on the Island of Hawai‘i.

Additional employment generated by a possible expansion to accommodate the contemplated 2,000 milking cow herd is estimated at approximately double that of the committed herd size (see Section 4.15). Five additional farm jobs and another 6 indirect jobs would increase the total of direct and indirect full-time equivalent jobs on Kaua‘i to 11, with an additional 3 indirect jobs created on Oʻahu, bringing the total Oʻahu indirect jobs to 6. This would total 22 direct-indirect jobs on Kaua‘i, and 6 indirect jobs on Oʻahu.

At full operations, HDF would generate a net income to the County of $51,000 per year, derived from property taxes on improvements. The State would derive approximately $170,000 annually in revenues, primarily from excise tax on sales for the contemplated herd sizes of 2,000 mature dairy cows.

With a long history of agriculture, most of Kaua‘i has a rural ambiance. Most homes and visitor units on the island are within one mile of some agricultural activity; the rural character adds to the appeal of the island. The review of property values adjacent to beef cattle operations in the region reveals newer homes with large square footage in a luxury residential community with 2016 assessed values of $1,297,150 for a lot, to $2,893,100 for a lot with home. Clearly, beef cattle operations are compatible with nearby homes, commercial areas, resorts and recreational areas. The ranching and rural ambience adds to the value.

4.22 GROUNDWATER RESOURCES (CONTEMPLATED HERD SIZE)

4.22.1 Existing Conditions – Groundwater Resources

The existing conditions are as described in Section 4.16.

4.22.2 Probable Impacts and Mitigation Measures – Groundwater Resources

Impacts that would be considered significant related to groundwater supply and groundwater quality could include:

- Depleting the groundwater supply or interfering with groundwater recharge for aquifers in the project area; and
- Degradation of groundwater quality below State or Federal standards.
Short-term Impacts and Mitigation – Groundwater Resources

Short-term impacts are similar to those described in Section 4.16.3 for the committed herd size. Construction of Hawai‘i Dairy Farms facilities is not anticipated to deplete the groundwater source or interfere with groundwater recharge in the short-term.

Long-term Impacts and Mitigation – Groundwater Resources

Long-term impacts on groundwater resources at the committed herd size as shown in Section 4.16.3 are not significant. For the contemplated herd size of up to 2,000 milking cows, the potable water demand will be approximately 54,800 gpd more than the committed herd size. Water demand would increase by 25 gallons per cow per day, and additional potable water would be needed for milk cooling and sanitation within the milking parlor. An estimated 84,800 gpd would be required for the future contemplated herd size (Table 4.22-1). As with the committed herd size, all potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. The potable water well located on the HDF site provided 3 MGD during the sugarcane plantation era; the demand of approximately 84,800 gallons per day (0.085 MGD) is well within the capacity of Māhā'ulepū 14 well.

<table>

<tr>
<td></td>
<td>Total Potable Demand 84,800 gpd</td>
</tr>
</tbody>
</table>

†The majority of water used will be captured and re-used to irrigate pasture grass.

The water use rate for a potential future herd size of up to 2,000 milking cows will not significantly impact the aquifer capacity. The potable water demand for the contemplated herd size is relatively modest compared to the 3 MGD capacity of the aquifer deep in the weathered volcanics. The 4,500-foot distance between the HDF Māhā'ulepū 14 well source and the nearest County potable water well (Kōloa Well F), coupled with the modest demand, means that no adverse impacts to ongoing use of groundwater in the volcanics will occur as a result of this use (TNWRE, 2016). Long-term groundwater supply impacts at the future contemplated herd size are not anticipated to be significant.

The groundwater and surface water analysis determined there is no hydrologic connection between the aquifer in the unweathered volcanic series and the shallow groundwater body in the alluvium. Thus nutrients added by the dairy operation will have no impacts to the County drinking water well, the source of potable water within the deep volcanics.

Four water monitoring wells have been installed by HDF into the shallow groundwater within the alluvium to allow monitoring of water quality. Results from the monitoring program will be shared with the DOH CWB, dairy neighbors and the local Kaua‘i community.

4.23 SURFACE WATER RESOURCES & NEARSHORE MARINE ENVIRONMENT (CONTEMPLATED HERD SIZE)

4.23.1 Existing Conditions - Surface Water Resources

The existing conditions are as described in Section 4.17.
4.23.2 Probable Impacts and Mitigation Measures

Impacts that would be considered significant related to surface water could include:

- Cows depositing manure into on-site surface water and damaging the banks of the drainageway causing erosion;
- Introducing sedimentation into the on-site drainage ways; and
- Stormwater run-off carrying manure or nutrients into surface waters.

Probable Impacts and Mitigation – Surface Water Resources & Nearshore Marine Environment

Short-term Impacts and Mitigation – Surface Water Resources & Nearshore Marine Environment (Contemplated Herd Size)

Short-term impacts are similar to those described in Section 4.17.4 for the committed herd size. A Stormwater Pollution Prevention Plan (SWPPP) has been developed for the site to document controls and best management practices to avoid, control, and trap potential erosion associated with construction activities. The SWPPP is required as part of the application for the NPDES – Construction Stormwater General Permit, and describes any discharge in compliance with relevant regulations. Pasture establishment and setbacks of 35-feet from the top of each drainageway will act as filter strips to reduce sediments contributing to surface water turbidity downstream of the dairy site. No short-term adverse effects are anticipated to the quality of nearshore ocean waters and the nearshore marine environment.

Long-term Impacts and Mitigation – Surface Water Resources & Nearshore Marine Environment (Contemplated Herd Size)

Section 4.17 describes how nutrients applied for dairy operations could potentially move to surface waters. The groundwater level of the alluvium is approximately 80 feet above mean sea level near the HDF monitoring wells 1 and 2. This groundwater fluctuates with seasonal high rainfall. In wetter periods, the level rises above the invert elevation of the manmade channels, and a modest amount of discharge from groundwater enters the ditch (TNWRE, 2016). These amounts could possibly be discharged when rainfall exceeds 0.8 inches; according to the 30-year rainfall record, such rainfall has occurred at about three percent of days or about ten day per year on average. These runoff-producing events would be the primary mode of conveyance of nitrogen and phosphorus into surface waters and ultimately to the marine environment. With the estimate of two percent of nitrogen and one percent of phosphorus from HDF operations passing through the pasture turf into shallow groundwater, an estimated 10,000 pounds per year of nitrogen and 900 pounds per year of phosphorus could enter surface water (Appendix E).

Nutrients required to sustain the 470 acres of pasture are the same for the committed and the future contemplated herd size. What changes is the amount supplied as natural fertilizer (manure and effluent) and supplemental chemical fertilizer. The Nutrient Balance Analysis prepared for HDF shows that natural fertilizer from manure deposited directly to pasture and the effluent collected from the milking parlor for the contemplated herd size at 2,000 milking cows will result in an excess of phosphorus from manure and effluent. Nutrient values relevant to the HDF site were used to create the existing mass balance for the site; only through monitoring actual field conditions can the true nutrient balance be known and maintained.
Several management options exist to keep phosphorus and other nutrients in balance. Higher grass yields would demand additional phosphorus. With an increase from the current 16.3 tons of dry matter (DM) per acre per year to a yield of 17.3 tons DM per acre per year, phosphorus demand by the pasture will eliminate any phosphorus overage. Based on research by consultants to HDF, yields of 20 tons DM per acre per year are anticipated following establishment of the committed herd of 699 milking cows and several years of pasture maturation. Should yields not increase as planned, carrying capacity of the site would be 1,875 mature milking cows. With reduced manure, phosphorus levels would require commercial supplementation to maintain the pasture. Nitrogen from commercial fertilizer would be required at both 1,875 and 2,000 milking cows. Adherence to the Conservation Plan and NRCS Nutrient Management Practice Code requires monitoring and analysis of soil, manure, and tissue samples which can be used to amend the nutrient budget prepared for the site.

Setbacks established in adherence to the Conservation Plan and best management practices to reduce impacts to waterways are detailed in Chapter 3, Section 3.5. The setback for effluent application is 50 feet from each side of surface waters. Perimeter fencing to exclude cows from surface waters provides a 35-foot buffer on either side of the drainageways. Vegetative buffers will be maintained within the 35-foot setback from the drainageways.

A long-term water quality monitoring program will be instituted to regularly evaluate surface water quality in the agricultural ditches and Waiopili Ditch, along with nearshore ocean waters. The ongoing monitoring will inform the dairy management team of changes in water quality to gauge whether nutrients and pathogens are reaching a level of environmental concern.

### 4.24 ROADWAYS AND TRAFFIC (CONTEMPLATED HERD SIZE)

#### 4.24.1 Existing Conditions – Roadways and Traffic

The existing conditions are as described in Section 4.18.

The South Kaua‘i Community Plan projects daily vehicle counts along Ala Kinoiki Road at 7,200 trips per day by the year 2035, and 9,500 daily trips on Kōloa Road (COK, 2015a).

#### 4.24.2 Probable Impacts and Mitigation Measures – Roadways and Traffic

Impacts that would be considered significant related to traffic could include:

- A significant increase in traffic on Ala Kinoiki or Poʻipū roads; significant traffic delays for a substantial number of motorists; or
- Changes to traffic patterns or road infrastructure that affects pedestrian, bicyclist or motorist safety.

**Short-term Impacts and Mitigation – Roadways and Traffic (Contemplated Herd Size)**

The anticipated impacts from construction are the same as for the committed herd size, as described in Section 4.18.1. Additional traffic will be generated during construction, but will return to normal levels after project completion during day-to-day operations.

There will be no significant change to traffic patterns or infrastructure related to the public roads.
Traffic operations along Māhāʻulepū Road and associated public roads will continue to operate at acceptable levels of service during peak hours of traffic. The larger potential contemplated herd size would result in a total of 23 vehicles daily, to include employees and delivery vehicles. This is an increase of 11 vehicles daily over the committed herd size.

The South Kauaʻi Community Plan estimates a slight decrease in daily vehicle movements along Ala Kinoiki Road by 2035, from the 2010 level of 8,000 to 7,200 daily vehicles. Daily vehicles along Kōloa Road, however, are expected to increase from 7,200 vehicles per day to 9,500 daily vehicles. An increase of 23 vehicles daily from HDF operations would result in 0.14 percent increase in total vehicle trips in the area. An additional 23 trips daily would have a minimal effect on traffic conditions at County roadways in the area over the long-term.

Construction equipment mobilization will comply with Hawaiʻi Department of Transportation and County requirements. Delivery trucks and milk tanker trucks will be in compliance with State and County size and weight limits; no oversized vehicles will be used for ongoing operations.

There will be no change to traffic patterns or infrastructure related to the public roads.

4.25 AIR QUALITY, ODOR, AND GREENHOUSE GASES (CONTEMPLATED HERD SIZE)

As described in Section 4.19, the potential odor and emission levels relevant to dairy operations were modeled and estimated for the proposed dairy. The full report, Hawai‘i Dairy Farms Air Emissions and Odor Evaluation Technical Report, is included in Appendix I.

4.25.1 Air Quality (Contemplated Herd Size)

Existing Conditions – Air Quality

The existing conditions are as described in Section 4.19.1.
Probable Impacts and Mitigation Measures - Air Quality

Impacts that would be considered significant related to air quality could include:

- Dust and debris generated during construction of the dairy facilities; and
- On-going dairy operations increasing odor, GHG, and air pollutants in the region.

Short-term Impacts and Mitigation – Air Quality (Contemplated Herd Size)

Short-term impacts from construction are the same as for the committed herd size, described in Section 4.19.1. Exhaust emissions from construction equipment and increased vehicular activity may occur during the construction phase. Fugitive dust emissions are probable during soil excavation, though control measures are required to prevent or minimize fugitive dust emissions from affecting surrounding areas. Due to the remote dairy location, emissions from on-site work will dissipate before reaching public access areas.

Long-term Impacts and Mitigation – Air Quality (Contemplated Herd Size)

Particulate matter in the form of dust will be created by cows when walking along unpaved raceways to the barn area, and, in theory, when walking on dried manure in the paved holding yard. In reality, the paved holding yard is hosed off regularly, and wash water and manure is collected in the effluent ponds for re-application as fertilizer on the pastures. But as explained in Section 4.19.1, the methodology overestimates potential fugitive dust as the model is based on measurements from dry lots (not paved) covered with dry manure where cows are confined.

Impacts are explained in Section 4.19.1 for the committed herd size of 699 milking cows. The following estimate is for a model threshold of 2,000 milking cows based on the dry lot model (Table 4-26.2).

Probable Impacts and Mitigation Measures – Air Quality (Contemplated Herd Size)

Modeling for HDF at both the 699 herd size and the contemplated herd size of up to 2,000 milking cows used a high fugitive dust rate which is considered beyond conditions for HDF but rely on the available published literature (see Section 4.19.1). Only the contemplated herd size of up to 2,000 milking cows was modeled, as at the lower threshold of 699 cows the potential fugitive dust impact would be negligible. The estimated concentration for PM_{10} is 2.01 \mu g/m^3 per 24-hour period, well below the State standard of 150 \mu g/m^3. The estimated concentration for PM_{2.5} is 0.23 \mu g/m^3 per 24-hour period, well below the Federal standard of 35 \mu g/m^3 (Table 4.26-1). Dust control (e.g. watering walkways and washing down the holding yards) will be utilized as needed to keep any particulate matter on site.

Table 4.26-1 Fugitive Dust Analysis

The highest estimated concentrations do not come close to the State standard (Table 4-26.2). Dust control (e.g. watering walkways and washing down the holding yards) will be utilized as needed to keep any particulate matter on site.

The total annual particulate matter emissions were also estimated for PM and greenhouse gases (GHGs). Total annual emissions (in tons per year) are typically estimated for potential permitting applicability. The estimate for a potential future contemplated herd size of up to 2,000 mature dairy cows was 3.3 tons per year. The project will not require any permits under the Clean Air Act, or State of Hawai‘i counterpart.

4.25.2 Odor Assessment (Contemplated Herd Size)

An explanation of the odor assessment methodology can be found in Section 4.19.2.

Existing Conditions - Odor

The existing conditions are as described in Section 4.19.2.

Probable Impacts and Mitigation Measures – Odor (Contemplated Herd Size)

Odor isopleths (a line used to map all points having the same numerical value) were created using the results of AERMOD computer modeling that utilizes four types of input data: emission source information, receptor locations, meteorology, and model specific control options (site and project specific data options). For the contemplated herd size, Figure 4.25-1 displays the results of modelling for the annual extent of the 6.5 OU/m³ odor level. The colored area depicts the 99.5th percentile threshold of 6.5 OU/m³. Within the colored area, odors may be detectable by 50 percent of the sensitive population once per 200 hours, or 44 hours per year.

The odor isopleth shows potential odor beyond the dairy farm boundary does not extend more than 2,780 feet (just over one-half mile), and does not reach recreational or residential areas (Figure 4.25-1).

Short-term Impacts and Mitigation – Odor

The short-term odor extent for the committed herd size is assumed to possibly be detectible by 50 percent of the sensitive population within 1,670 feet past the southern boundary, 44 hours out of every year (see Section 4.19.2). Should HDF decide to expand the herd beyond 699 milking cows, the short-term odor extent may increase correspondingly.

Long-term Impacts and Mitigation – Odor

The odor modeling analysis and isopleths for the larger contemplated herd size is shown in Figure 4.26-3. The odor threshold – defined as the 99.5th percentile of 6.5 OU/m³ odor – is the area in which odors may be detectable by 50 percent of the population at a frequency of once every 200 hours, or roughly 44 hours per year.

The odor isopleth extends beyond the dairy farm boundary approximately 2,780-feet (just over one-half mile), which would not reach recreational or residential areas (Figure 4.25-1). As explained in Section 4.19.2, the parameters used in the analysis were intentionally conservative, and the impacts shown assume an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location. Actual offsite odor impacts are likely to be much lower and/or less frequent than shown (Arcadis, 2015).
Generally, tradewinds will disperse odors to less than detectable levels beyond the HDF site; in periods of no wind, odor may not be dispersed creating the “worst case” scenario. In these periods without normal tradewind flow, the odor plume would extend to the south of the HDF site (Figure 4.25-1).

![Figure 4.25-1 Odor Detection Limits for 2,000 Herd Size](image)

4.25.3 Greenhouse Gases (Contemplated Herd Size)

See Section 4.19.3 for an overview of Greenhouse Gas (GHG).

Existing Conditions and Methodology – Greenhouse Gases

See Section 4.19.3 for existing conditions and methodology of GHG estimates for HDF. Under the Federal 2010 greenhouse gas reporting rule by the EPA, small businesses and farms are exempted from permitting requirements.
Probable Impacts and Mitigation Measures – Greenhouse Gases (Contemplated Herd Size)

Short-term Impacts and Mitigation – Greenhouse Gases
For the committed herd size, contributions to GHG in the short-term will not be significant. See Section 4.19.3. With establishment of the contemplated herd size, GHG emissions at HDF may reach the estimated 2,693 CO\textsubscript{2}e tons (2,969 US tons) per year as modeled for the committed herd size. This is equivalent to the GHG generated by 170 4-person households annually, including home energy consumption, transportation and waste.

Long-term Impacts and Mitigation – Greenhouse Gases
Potential GHG emissions for HDF at the contemplated herd size of up to 2,000 mature dairy cows was modeled as described in Section 4.19.3 using the IPCC guidelines and conversions. The estimated total of 7,705 CO\textsubscript{2}e metric tons per year (8,493 US tons) was 5,012 CO\textsubscript{2}e metric tons (5,525 tons) more than the committed herd size of 699 milking cows. This would be equivalent to the GHG generated by 485 4-person households, including home energy consumption, transportation and waste (https://www3.epa.gov/carbon-footprint-calculator).

Recent research demonstrates an increased carbon accumulation in soils used for management-intensive grazing practices. Soils with accumulated carbon increase cation exchange and water holding capacity, thus improving soil quality and providing for climate mitigation by sequestering carbon from the atmosphere (Machmuller et al., 2014).

Operational practices to protect air quality by reducing nitrogen emissions will come from guidance in NRCS Conservation Practice Standard 590, Nutrient Management. Application of nutrients will be adjusted through adjustments to the source, timing, amounts, and placement of nutrients. Specific practices to be utilized at HDF include: slow release fertilizers; nutrient enhancement technologies; and stabilized nitrogen fertilizers. Monitoring of soil nutrient levels and manure nutrient levels will be conducted and used to evaluate agronomic needs for the grass and assess potential changes to nutrient uptake.

4.26 SUMMARY OF PROBABLE IMPACTS AND CONTEXTUAL ISSUES (CONTEMPLATED HERD SIZE)
This section discusses the dairy farm’s potential secondary effects and the cumulative impacts on the environment under the contemplated herd size of up to 2,000 milking cows. This summary addresses anticipated potential effects, in addition to effects from the committed dairy herd size.

4.26.1 Interrelationships and Cumulative Environmental Impacts (Contemplated Herd Size)
The contemplated dairy farm would be within the active Māhā’ulepū agricultural area. Other known land uses underway or planned in the region, with the dairy farm in operation, will contribute to the contextual setting of interrelationship and cumulative effects. These known include uses listed in Section 4.20.1, including Agricultural and Commercial Uses and Planned Development in the Kōloa-Po’ipū Region. There are several new agricultural enterprises planned in the vicinity, along with other public and private development and redevelopment efforts in Kōloa Town and Po’ipū area, as referenced under the South Kaua’i Community Plan (COK, 2015a).
Probable Cumulative Impacts (Contemplated Herd Size)

Recognizing the number of development projects planned, the potential impacts of the dairy farm (contemplated herd size) combined with other projects in the region provide insight to probable cumulative impacts. Qualitative or quantitative analyses were conducted in this EIS for pest insects, demographic and economic conditions, groundwater resources, surface water and nearshore marine resources, roadways and traffic, and air quality, odors and greenhouse gases. Of note, nearly all construction activities will have been completed earlier for the establishment of the committed dairy herd.

Pest Insects (Contemplated Herd Size)

There are no native, protected or endangered insect species within the HDF site. For potential manure-related flies, integrated pest management will be utilized to control fly populations around dairy operations, and best practices will be applied to minimize standing manure within the dairy facilities. An especially important insect to minimize fly breeding habitat in manure is the dung beetle, which can bury manure in one to three days and thereby incorporate it into the soil thus interrupting the egg to fly lifecycle which ranges from 7 to 20 days depending on the species. Populations of dung beetles found on Kaua‘i and those species already in Māhāʻulepū Valley, will expand with the growing manure food source, thus increasing and speeding breakdown of manure.

With the establishment of the committed herd size of 699 milking cows, dung beetle populations will have had time to expand. With the natural systems established by the dairy operations, the pest insect populations are not anticipated to increase significantly with the dairy at the contemplated herd size.

Demographic and Economic Conditions (Contemplated Herd Size)

Implementation of the dairy farm at the contemplated herd size will provide approximately 11 direct and indirect full-time equivalent jobs on Kaua‘i, including 10 farm jobs. On O‘ahu, 6 indirect jobs would be created at the contemplated herd of up to 2,000 milking cows. The economic impacts are summarized in Section 4.21, and the complete study is provided in Appendix J. The increase in agricultural employment will add to local economic activity, generating $170,000 in net revenues annually to the State, and net income to the County of $51,000 per year. The dairy farm at the contemplated herd size will add more agricultural industry employment, provide greater net revenues to the County and State, and bring additional fresh milk and milk products to advance local food sustainability.

With a long history of agriculture, most of Kaua‘i has a rural ambiance. Most homes and visitor units on the island are within one mile of some agricultural activity; the rural character adds to the appeal of the island. The review of property values adjacent to beef cattle operations in the region reveals newer homes with large square footage in a luxury residential community with 2016 assessed values of $1,297,150 for a lot, to $2,893,100 for a lot with home. Clearly, beef cattle operations are compatible with nearby homes, commercial areas, resorts and recreational areas. The ranching and rural ambience adds to the value.
Groundwater Resources (Contemplated Herd Size)

**Demand - HDF:**
With an increase in cows for the contemplated potential future herd size, another 25 gpd per animal for drinking water is required, as well as additional wash water of 17.4 gpd per animal. This would increase demand for potable water to 84,800 gpd for up to 2,000 milking cows, or 54,800 gpd over the committed herd size. The existing, on-site agricultural well had an estimated yield of 3 MGD during the sugarcane plantation era; the increased demand of 84,800 gallons (0.85 million gallons) is well within the aquifer yield.

Nearly all of the potable water used will be re-applied to pasture and thus remain a part of the evapotranspiration cycle. Potable water used in the milking parlor and dairy facilities will be captured and recycled with nutrients as irrigation water. Some percentage of the livestock drinking water is returned as effluent and ultimately utilized by the pasture grass. The potable water use rate for the potential contemplated herd size of up to 2,000 milking cows, and the lack of connection plus the 4,500 foot distance between the on-site well and the nearest County potable water well (Kōloa Well F) will result in no adverse impacts to ongoing use of groundwater in the volcanic aquifer layer.

**Demand - Kōloa-Poʻipū:**
Per Section 4.20.1, the adjacent developed Kōloa-Poʻipū region shows large and growing demand for potable water for community and resort development. The State Department of Economic Development and Tourism (DBEDT) projects the population of Kaua‘i will increase from the year 2010 population of 67,100 residents to 84,400 in 2030, a change of 17,300 residents over the 20-year period. The South Kaua‘i population is estimated to reach 16,855 in 2035. Compared to the remainder of the island, population growth for this region is projected to increase to encompass 19.2 percent of the County population; in 2010 the region contained roughly 17.4 percent of the County population (COK, 2015a).

Water use reported from the Kōloa aquifer in 2004 was approximately 2.3 MGD, approximately 8 percent of the estimated 30 MGD sustainable yield for the aquifer (CWRM, 2008). For the South Kaua‘i region (the Kōloa - Poʻipū - Kalaheo districts), water use in 2035 is projected to be 3.24 MGD, an increase of nearly 1 million gallons per day (SSFM, unpublished). An evaluation of the island’s infrastructure capacity for projected growth in population (both residents and visitors) through the year 2035 predicts the island will be facing a shortage of well water (SSFM, unpublished). Water resources must therefore be carefully managed to accommodate the projected growth and water demand anticipated in the region through 2035.

With the contemplated herd size of up to 2,000 mature dairy cows, conservative calculations of potential nitrogen and phosphorus inputs to groundwater from HDF operations are the same as for the committed herd size. The addition of these nutrient levels will represent a fraction of the nutrient inputs from the Koloa-Poipu region.

Nitrogen input to the marine environment from resort landscaping and golf course fertilization, and domestic wastewater, in the Poʻipū region is 38,510 pounds of nitrogen annually. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually. This is 3.8 times greater than the estimate from dairy operations. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. Significantly different soils mean that nutrient inputs from the Poʻipū region are constant throughout the year, and no mitigation is applied to reduce the quantities.
Surface Water and Nearshore Marine Resources (Contemplated Herd Size)

With an on-site manager for the new agricultural endeavor utilizing best management practices to protect water quality through nutrient and soil management, current run-off would be reduced. Under the contemplated herd size of up to 2,000 milking cows, the NRCS-reviewed Conservation Plan will minimize sediment, nutrient and pathogen inputs to the surface waters in these drainages.

At contemplated herd size, HDF will continue to balance nutrient needs of pasture grass as well as improve the water-holding capacity of soils. Working closely with DOH and NRCS, dairy farm staff are helping to improve understanding of factors that affect local water quality. Adherence to strict measures to protect water quality through proper irrigation management practices and re-analysis of nutrient inputs and outtake, the dairy farm will balance nutrient needs of pasture grass as well as improve the water-holding capacity of soils. Occasional nutrient run-off may allow some diluted nutrients to bypass mitigation measures to be employed, but will have no significant deleterious effect on the area's surface water quality. Nearshore water quality at the Waiopili Ditch outlet and along this coastline will not be significantly degraded by inputs from HDF.

Roadways and Traffic (Contemplated Herd Size)

The development of the dairy farm facilities and future operations is not expected to have a significant impact on traffic operations in the area roadways. The projected increase in vehicle movements related to HDF operations for the future contemplated herd size of 2,000 milking cows is approximately 23 additional vehicle trips per day. Projected daily vehicle counts for the year 2030 on Ala Kinoiki Road are 7,200 trips per day, with an additional 9,500 daily trips projected for Kōloa Road, totaling 16,700 vehicle trips in the vicinity. An increase of 23 vehicles daily from HDF operations would result in 0.14 percent increase in total vehicle trips in the area. HDF will contribute no significant impacts to traffic conditions on County roadways.

Air Quality/Odors/Greenhouse Gases (Contemplated Herd Size)

Results from the air quality odor model indicate that any long-term impacts on air quality in the project area due to contemplated dairy farm operations would be negligible. Under the worst-case meteorological conditions, concentrations of odor are limited to within 2,780-feet of the dairy farm boundary and do not reach residential or resort areas. With active management of the dairy operations, there will be no noticeable odors or reduction of air quality in the surrounding area. The limited number of worker vehicles and trucks will create nominal increase in air emissions, not significantly contributing to the air emissions generated by vehicles in the region. Contributions to greenhouse gas will not be significant.

4.26.2 Potential Secondary Effects (Contemplated Herd Size)

Local Milk Production and Food Sustainability. At the contemplated herd size of up to 2,000 milking cows, Hawai’i Dairy Farms will produce substantial secondary effects in terms of local milk production, local milk products production and increased food sustainability. When the dairy matures to full capacity with a contemplated herd size of 2,000 milking cows, it will produce approximately 4.4 million gallons of fresh, local milk each year for the residents of Hawai’i. This equates to over 25 million pounds of milk, which exceeds the level for food sustainability for the island of Kaua‘i (see Section 4.21, Demographic and Economic Conditions). The 3.0 million gallons of locally produced milk will reduce Hawai’i’s 90 percent dependence on milk shipments from the
US mainland. Potential future processing of fluid milk into soft cheeses and yogurt could provide value-added products for HDF or procurers of the fluid milk.

**Indirect Employment.** For the estimated development period of the dairy, indirect employment will be generated and is expected to average 44 jobs on Kaua‘i and an additional 13 jobs on O‘ahu. For on-going dairy operations with the contemplated herd size, it is estimated that about 15 additional indirect jobs will be created on Kaua‘i and another 8 indirect jobs created on O‘ahu, in addition to the direct HDF jobs.

**Source of Calves for the Local Ranching Industry.** Over the long-term, dairy operations will provide a source of calves for the local ranching industry and expand the market for ranch-related additional goods and services from local vendors. This source of calves will increase with the contemplated herd size.

**Offsite Herd Management.** The contemplated herd size of up to 2,000 milking cows at the Māhā‘ulepū site relates to a permitting threshold that references the count of mature milking cows. As discussed in Chapter 3.0 and Section 4.20.2, animals in various stages of lactation and rest will be transferred between HDF and existing Kaua‘i ranches as needed for animal health and dairy productivity. Makoa Ranch and ‘Oma‘o Ranch on Kaua‘i are existing ranch operations, which require no additional facilities, permits, or improvements to have fluctuation in herd numbers, which is typical of cattle operations. No impact to the Makoa or ‘Oma‘o ranches, or areas outside the project area, will occur as a result of the offsite herd management.

With the contemplated herd size of up to 2,000 milking cows at the Māhā‘ulepū site, more animals will be transferred between HDF and existing Kaua‘i ranches.

**Offsite Transportation.** With the contemplated herd size of up to 2,000 milking cows, employees working at HDF will generate an estimated 10 offsite vehicle trips each day. Transport of cows for herd management will involve two truck trips per day between HDF and the offsite ranches. Fluid milk will be delivered to the milk processing site twice each day. Sand and feed delivery would generate four to five truck trips per week. Fertilizer would be delivered once every other month. Milk transport from Kaua‘i would be twice each week via regularly scheduled ocean barges departing from Nawiliwili Harbor. Offsite transportation associated with HDF operations is not anticipated to generate significant secondary effects.

**4.26.3 Relationship between Local Short-term Uses of the Environment and the Maintenance and Enhancement of Long-term Productivity (Contemplated Herd Size)**

**Narrowing of the range of beneficial uses of the environment (Contemplated Herd Size)**

The area in which HDF will operate a dairy farm has been used for commercial agricultural for nearly two decades. The dairy farm does not propose a change in land use or a narrowing of the range of beneficial uses of the environment. Instead, it proposes a revitalization of farming on this area designated as Important Agricultural Land and introduction of a sustainable food production. After the end of the lease term – initially 20-years with an additional 10-year option – the land could be used for other purposes. This term could possibly be extended. Further, additions of organic matter from manure will improve soil tilth - the physical condition of the soil - over the long-term.
**Long-term risks to health and safety (Contemplated Herd Size)**

Hawaiʻi Dairy Farms at the contemplated herd size is not anticipated to create long-term risk to health and safety. The groundwater and surface water analysis confirmed no connection between groundwater in the alluvium on the valley floor and the deeper aquifer within unweathered volcanic series containing the County drinking water source. Regardless, HDF has installed monitoring wells to assess any increased nutrients within the waterbodies in the alluvium. Measures are to be taken to protect drinking water quality and surface waters. Pest insect populations will be managed through an integrated pest management system focused on the natural food web of invertebrates to disrupt breeding. Under worse-case meteorological conditions, odors may be detected by 50 percent of people just 44 hours of each year, however, the worst-case range is within one-half mile of the site and would not reach recreational or residential areas.

**Foreclosure of future options (Contemplated Herd Size)**

The dairy farm at the contemplated herd size maintains the existing and reasonable uses of the property for agriculture, and does not foreclose future options.

**Trade-offs among short-term and long-term gains and losses (Contemplated Herd Size)**

Although construction activities will have largely been completed earlier for the establishment of the committed dairy herd, there will be short-term inconveniences caused by construction activity at the contemplated herd size. This will include some incremental increase in noise and dust, and increase in traffic due to construction vehicles. Once construction is completed, the dairy farm at the contemplated herd size will become an even larger producer of local fresh milk and milk products without the delay and added costs of shipping from the mainland. Along with gains to local food security, the long-term benefits outweigh the relatively short-term losses anticipated during construction.

**4.26.4 Irreversible and Irretrievable Commitments of Resources (Contemplated Herd Size)**

The construction of the dairy facilities will occupy less than 10 acres, totaling less than 2 percent of the 557-acre site. The site could be modified for other uses in the future. Soil conditions and fertility will be improved through the addition of manure as organic matter, resulting in better growing conditions for future agricultural endeavors.

Use of the site for dairy operations does not preclude future conservation use of the wider region, such as examined by the U.S. National Park Service in its 2006 to 2007 reconnaissance study.

**4.26.5 Potential for Environmental Accidents (Contemplated Herd Size)**

At the contemplated herd size, the potential for environmental accidents at the dairy farm will remain minimal. Standards and regulatory requirements must be met; reviews and approvals are required from the State Department of Health for the waste management facilities. Capacity beyond that required has been built into the design and scaling of the effluent ponds. For the extremely remote possibility that the ponds would overflow, a secondary containment system has been designed as an additional safeguard. Risks to surface water quality are minimized with application of best practices including vegetated filter strips and 35-foot setbacks to exclude cows from drainage ways. Fuels and chemicals utilized at the dairy facilities will be stored following established regulations and applied by qualified applicators in compliance with labeling to safeguard the environment.
4.26.6 Adverse Environmental Effects that Cannot be Avoided (Contemplated Herd Size)

Implementation of the dairy farm at the contemplated herd size will produce unavoidable affects in the short term and long term. Short-term effects are generally associated with construction, and will prevail only for the duration of the construction period, mostly completed under the committed herd size. Long-term effects would generally arise after construction. Effects that can be considered both adverse and unavoidable at the contemplated herd size are discussed below.

Unavoidable Adverse Short-Term Effects (Contemplated Herd Size)

- Existing ground cover vegetation and landscaping will be displaced by built facilities, covering approximately 2 percent of the site, will be completed at the committed dairy herd level.
- Temporary increases in soil erosion may result from dairy establishment as noted in Section 4.20.6 limited to the construction period.
- Potential short-term air quality impacts, primarily from fugitive dust emissions related to construction, are noted in Section 4.20.6 limited to the construction period.
- Short-term traffic impacts from construction activities, largely completed for the committed dairy herd, would be expected to occur as the result of the following types of activities:
  - Increases in truck traffic associated with removal and redistribution of excavation fill materials and delivery of construction materials.
  - Increases in automobile traffic associated with construction workers traveling to and from the dairy farm site.

Unavoidable Adverse Long-Term Effects (Contemplated Herd Size)

- Dairy farm operations will increase potable water consumption for the dairy herd and milking, and non-potable water for pasture irrigation.
- Dairy cows will produce manure and urine in the pasture paddocks in the contemplated herd size dairy farm operations. This will continue to be managed as part of the overall pasture grass nutrient demand, with a small percentage of nutrients passing to surface water and shallow groundwater.
- There will be increased demand on existing utilities and infrastructure in the contemplated herd size dairy farm operations. Sustainable design practices and technology will be utilized to reduce demand requirements, including solar power generation.
- There will be an insignificant increase in traffic in the area in the contemplated herd size dairy farm operations, due to the agricultural industry worker vehicles and local supplier deliveries to and from the dairy.

4.27 SUMMARY OF PROBABLE IMPACTS FOR BOTH HERD SIZES

Table 4.27-1 summarizes the impacts described in this chapter.
### Table 4.27-1 Summary of Impacts from the Committed and Contemplated Herd Size

<table>
<thead>
<tr>
<th>SUMMARY OF PROBABLE IMPACTS</th>
<th>Proposed Action - Committed Herd Size: 699 milking cows</th>
<th>Proposed Action - Contemplated Herd Size: 2,000 milking cows</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CLIMATE</strong></td>
<td>The scale of HDF is not large enough to influence global climate cycles related to solar radiation or evapotranspiration. No significant impacts are anticipated, and no mitigation would be required.</td>
<td>No change.</td>
</tr>
<tr>
<td><strong>TOPOGRAPHY</strong></td>
<td>The dairy facility and associated infrastructure will be constructed in a 10-acre area located along the site’s western boundary. Built facilities within this area will total less than 2 percent of the site. Within the pasture area, swales previously installed for agriculture and low-lying areas may be smoothed or filled to improve surface drainage and uniformity for grazing. Existing farm road will be slightly elevated, with cow raceways constructed in parallel above grade; swales will be created to direct run-off where needed.</td>
<td>No change.</td>
</tr>
<tr>
<td><strong>SOILS</strong></td>
<td>Short-term soil disturbance for construction of roadways and dairy facilities will be minimized through the adherence to the Conservation Plan, best management practices, and controls per an NPDES Construction Stormwater General Permit. Soil loss is expected to be within permitted thresholds and to not be significant Long-term soil impacts are anticipated to result in improvements to the physical, chemical, and biological condition of the soil.</td>
<td>Increased benefit to soil conditions long-term.</td>
</tr>
<tr>
<td><strong>LAND USE &amp; AGRICULTURAL SETTING</strong></td>
<td>The development of Hawai’i Dairy Farms will be in full compliance with its agricultural State Land Use District designation and embodies the IAL designation per the Hawai’i State Constitution by using the protected lands in the project area for their intended purpose of diversified agriculture and agricultural self-sufficiency. No request for change of land use will be made, and no mitigation is needed.</td>
<td>No change.</td>
</tr>
<tr>
<td><strong>VISUAL &amp; AESTHETIC RESOURCES</strong></td>
<td>No public scenic views or lookouts will be affected by dairy development or operations. There will be no adverse effect to public views of the Pu’u Huluhulu crater, views from the Ala Kinoiki Road corridor, or impediment to views of the Hā’upu Mountains from the HDF site.</td>
<td>No change.</td>
</tr>
<tr>
<td>NATURAL HAZARDS</td>
<td>No change.</td>
<td></td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td></td>
</tr>
<tr>
<td>Structural design of dairy facilities will meet International Building Code (IBC) 2006 standards with local amendments. Design incorporates wind loading (including hurricane gusts), rain and flood loading, and earthquake loading. A geotechnical evaluation recommended Seismic Site Class D under IBC standards for the area where the barns and agricultural infrastructure will be constructed. A natural disaster plan has been prepared by the Hawai‘i Dairy Farms’ manager to address hurricane, fire, and potential flooding hazard scenarios. HDF is not in a flood zone or tsunami inundation area, so this scenario is mentioned in the disaster plan only for HDF personnel to maintain awareness. The disaster response plan outlines safety procedures during the event, follow up actions, and emergency contacts for assistance before, during or following the event.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ARCHAEOLOGICAL &amp; HISTORIC RESOURCES</th>
<th>No change.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will contain dairy activities and related impacts within the project area. Ten post-European contact era sites associated with Plantation-era sugarcane cultivation were identified on site. No further work regarding these sites is recommended. Dairy operations will adapt some sites for utilization, such as bridges and culverts. In the unlikely event that resources are discovered during construction, appropriate procedures will be followed as required in applicable HRS regulations. In an extended survey area up to 1,000 meters outside the HDF northern boundary, two sites were identified that are considered significant under multiple criteria occur. Neither site, both of which are outside the project area, will be adversely affected by the proposed dairy project.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CULTURAL PRACTICES &amp; RESOURCES</th>
<th>No change.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information received from the community indicates the Māhā‘ulepū ahupua‘a has been, and is currently used for traditional cultural purposes. However, the dairy project area has not been included in these activities. Based on the research and comments received from the community, it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be adversely impacted by establishment of the dairy.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FLORA &amp; FAUNA</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>No threatened or endangered plants occur on the project property, and no intact native plant habitat exists within or surrounding the site. No critical habitat for endangered flora or fauna species is defined in or immediately surrounding the site; no impacts are anticipated from the dairy. Native plants with potential to stabilize banks will be encouraged and supplemented if needed to enhance the planned buffer strips along drainages.</td>
<td>No change.</td>
</tr>
<tr>
<td>Potential use of paddocks by native, endangered waterbirds may occur. In keeping with best practices related to protected species, any outside lighting at night will be shielded to prevent attraction to overflying seabirds. There are almost no suitable roost trees within the dairy site; therefore, no effect to bats is expected from the dairy farm. HDF will develop an Avian Species Protection Plan and train employees to detect endangered waterbirds and nēnē and prevent harmful impacts from dairy operations.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>INVERTEBRATE SPECIES &amp; PEST INSECTS</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>There are no native, protected or endangered insect species within the HDF site. Construction of the dairy facilities will not impact any native or endangered invertebrate populations. Integrated pest management will be used disrupt the fly lifecycle and minimize populations of manure-related flies. Use of mechanical insect controls, including traps (outdoors) in paddocks where cows are excluded, and sticky tapes (indoors) will be used as needed for both monitoring and removal of flies. Water troughs will incorporate “ramps” for honey bee to protect bees that come to water.</td>
<td>No change.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NOISE</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Construction work at the project site will involve activities that may generate an increase in noise levels. Noise related to construction will be a short-term condition, occurring during daylight hours. Milking equipment will be contained in the milking parlor structure, and field equipment such as tractors will typically be used during daylight hours. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.</td>
<td>No change.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HAZARDOUS SUBSTANCES</th>

A review of historic aerial photos and topographic maps show there were no pesticide mixing or storage operations on the HDF site.

**PUBLIC SERVICES**

Dairy facilities and dairy operations are not anticipated to place a significant demand on fire protection, police, or medical services. The dairy will help to support these services through contributions to County real property tax.

**DEMOGRAPHIC & ECONOMICS**

The dairy will create construction jobs and 36 direct and indirect full-time jobs during construction. Construction will provide revenues to businesses on both Kaua‘i and O‘ahu. The dairy will generate substantial positive State and County revenues. In-state milk production will expand agricultural revenues and jobs in Hawai‘i.

Approximately 11 direct and indirect full-time equivalent jobs would be sustained on Kaua‘i, including 5 farm jobs and about 6 indirect jobs. An additional 3 indirect jobs would be created on O‘ahu.

Annual direct-plus-indirect sales are estimated annually at $8.1 million on Kaua‘i, with an additional $2 million on O‘ahu.

Net income to the State is calculated to exceed $60,000 annually. Net income to the County from HDF is anticipated to generate $51,000.

With the contemplated herd size, milk production would be 4.4 million gallons annually at steady-state. This would double current local milk production of operational dairies in Hawai‘i.

Employment for ongoing operations at the contemplated herd size would be double that of the committed herd size: total 22 direct-indirect jobs on Kaua‘i, and 6 indirect jobs on O‘ahu.

Net income to the County of $51,000 per year, derived from property taxes on improvements. The State would derive approximately $170,000 annually in revenues, primarily from excise tax on sales.

The review of property values adjacent to beef cattle operations in the region reveals newer homes with large square footage in a luxury residential community with 2016 assessed values of $1,297,150 for a lot, to $2,893,100 for a lot with home. Clearly, beef cattle operations are compatible with nearby homes, commercial areas, resorts and recreational areas. The ranching and rural ambience adds to the value.

**GROUNDWATER RESOURCES**

Construction of Hawai‘i Dairy Farms facilities is not anticipated to deplete the groundwater source or interfere with groundwater recharge.

Short-term water supply demand during the construction period is anticipated to be nominal. The major water demand during construction will be for fugitive dust control. Water will come from a non-municipal source: either the on-site deep wells; or from the HDF allocation of water from Waita Reservoir.

The dairy will utilize 30,000 gallons per day of groundwater from on-site wells for potable uses: livestock water; and sanitation in the milking parlor. The demand of approximately 30,000 gallons per day (0.03 MGD) for potable water is well within the capacity of the existing

An additional 54,800 gallons per day of potable water will be used for the contemplated herd size, for a total of 84,800 gallons per day.

Setbacks are the same for both herd sizes.
Māhāʻulepū 14 well which produced 3 MGD during the sugarcane plantation era. All potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle.

The groundwater and surface water assessment determined there is no hydrologic connection between the aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Thus nutrients added by the dairy operation will have no impacts to the County drinking water well and potable water within the deep volcanics, the source of potable water. Further, the assessment concluded that the modest potable water use rate for dairy operations, and the 4,500-foot distance between the onsite potable water well and the nearest County potable water well (Kōloa Well F), mean that no adverse impacts to ongoing use of groundwater in the unweathered volcanics will occur as a result of this use.

Though the waterbody in which the County wells occur is confined and hydrologically separated from shallow waterbodies in the Māhāʻulepū Valley alluvial material, HDF established a 1,000-foot setback surrounding the Kōloa F well in agreement with the County Department of Water. Within this setback, no effluent will be applied and no animals will deposit manure as the area will not be used for grazing.

### SURFACE WATER RESOURCES

Controls and best management practices to avoid, control, and trap potential erosion associated with construction activities will be implemented. Any stormwater discharge associated with construction in the short-term will be in compliance with relevant regulations. Over the long-term, adherence to the Conservation Plan and best management practices establishes setbacks to minimize impacts to waterways. The setback for effluent application is 50 feet from each side of surface waters. Perimeter fencing to exclude cows from surface waters provides a 35-foot buffer on either side of the drainageways. Vegetative buffers will be maintained within the 35-foot setback from the drainageways.

The natural fertilizer from manure deposited directly to pasture and the effluent collected from the milking parlor is insufficient to meet the agronomic need of the pasture grass crop. Supplemental commercial fertilizer will be required to provide sufficient nutrients to sustain the pasture grass at the committed herd size.

Episodic, seasonal rainfall events cause groundwater in the alluvium to rise and intersect with the deep agricultural ditches in the vicinity of HDF monitoring wells 1 and 2. Such episodes are calculated to average 10 days annually. Setbacks and NRCS standard practices remain the same between the committed and contemplated herd sizes.

Nutrients required to sustain the 470 acres of pasture are the same for the committed and the future contemplated herd size. What changes is the amount supplied as natural fertilizer (manure and effluent) and supplemental chemical fertilizer. The Nutrient Balance Analysis prepared for HDF shows that natural fertilizer from manure deposited directly to pasture and the effluent collected from the milking parlor for the contemplated herd size at 2,000 milking cows will result in an excess of phosphorus from manure and effluent with current grass yields of 16.3 tons of dry matter per acre. Nutrient values relevant to the HDF site were used to create the existing mass balance for the site; only through monitoring actual field conditions can the true nutrient balance be known and maintained.

Several management options exist to keep phosphorus and other nutrients in balance. A herd of 1,875 mature milking cows would provide less ma-
ally, which would result in a modest amount of groundwater containing nutrients to discharge into the surface ditches. The amount of nutrients estimated from HDF operations released to surface water is calculated at 10,000 pounds of nitrogen and 900 pounds of phosphorus annually.

The minor contributions of nutrients from episodic rainfall anticipated to occur just 10 days annually from dairy operations will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs within several meters from shore.

There are over 120 wastewater treatment injection wells serving resort development in Po’ipū. Nitrogen input to the marine environment in the Po’ipū region is calculated to be 38,510 pounds annually, or 3.5 times more than the estimate of potential nutrient throughput from HDF. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. The nutrient inputs from domestic uses in the Po’ipū region are constant throughout the year and no mitigation is applied to reduce the quantities.

State DOH surveys and environmental sampling/testing programs have identified high levels of enterococci bacteria in the agricultural ditches, particularly near the terminus of the ditch near the ocean. State standards apply to recreational waters, and the ditch is not utilized recreationally by bathers.

Over the long-term, the surface water quality in the agricultural ditches and Waiopili Ditch will be improved by active management of the dairy site. The dairy site represents roughly 20 percent of the 2,700-acre Māhā‘ulepū Valley sub-watershed, and soil erosion from the HDF site will be reduced by establishment of thick grass ground cover and maintenance of vegetative buffers totaling 70 feet in width – 35 feet on either side of the agricultural drainageways.

### ROADWAYS & TRAFFIC

<table>
<thead>
<tr>
<th>Short-term construction traffic will occur during the development of the dairy facilities. For the long-term, worker vehicles and delivery and supply trucks will access the dairy on a weekly basis. The number of vehicles associated with the dairy at the committed herd size will increase by approximately 12 vehicles per day, and will not represent a significant amount of the total traffic on local roadways. Traffic conditions on roadways in Po‘ipū and Kōloa will not deteriorate as a result of the dairy operations.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traffic operations along Māhā‘ulepū Road and associated public roads will continue to operate at acceptable levels of service during peak hours of traffic. The larger potential contemplated herd size would result in a total of 23 vehicles daily, to include employees and delivery vehicles. This is an increase of 11 vehicles daily over the committed herd size. Based on known and planned developments for the South Kaua‘i region, estimated travel on Ala Kinoiki Road for the year 2035 is anticipated to be 7,200 vehicles daily. For the same year, daily vehicle travel on</td>
</tr>
</tbody>
</table>

Adherence to the Conservation Plan and NRCS Nutrient Management Practice Code requires monitoring and analysis of soil, manure, and tissue samples which can be used to amend the nutrient budget prepared for the site.

A long-term water quality monitoring program will be instituted to regularly evaluate surface water quality in the agricultural ditches and Waiopili Ditch, along with nearshore ocean waters. The ongoing monitoring will inform the dairy management team of changes in water quality to gauge whether nutrients and pathogens are reaching a level of environmental concern.
Koloa Road is anticipated to be 9,500. An increase of 23 vehicles daily from HDF operations would result in 0.14 percent increase in total vehicle trips in the area. This is less than one percent, and will not have a significant impact on traffic in the area.

<table>
<thead>
<tr>
<th>AIR QUALITY, ODOR &amp; GREENHOUSE GASES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Construction effects on air quality including dust and construction vehicle emissions will be temporary and reduced by best management practices and short-term mitigation measures.</td>
</tr>
<tr>
<td>Odor conditions at the pasture-based dairy will be limited within the dairy project area and immediate vicinity. In the worst-case meteorological conditions, odor may reach approximately 1,670 feet south of the HDF southern boundary. The odors will not reach resort or residential communities. For the area within the modeled odor isopleth, odor may be detectable by 50 percent of the population at a frequency of once every 200 hours, or roughly 44 hours per year.</td>
</tr>
<tr>
<td>No air quality impacts are anticipated during construction as a result of either herd size. For the contemplated herd size, odor may reach approximately 2,780 feet south of the HDF southern boundary in the worst-case meteorological conditions. The odors will not reach resort or residential communities. For the area within the modeled odor isopleth, odor may be detectable by 50 percent of the population at a frequency of once every 200 hours, or roughly 44 hours per year. Greenhouse gas emissions will not be significant, and in fact may be negated by the ability of soils to sequester carbon from the atmosphere and improve soil structure and function.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CUMULATIVE IMPACTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>The development and operation of the pasture-based dairy may be combined with impacts associated with anticipated future developments in the Po'ipu and Koloa region. With mitigation, there may be limited short-term impacts such as soil erosion, dust, and vehicle emissions. Long-term cumulative effects may include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors will be contained within the dairy and adjacent farms. In addition to injected wastewater nutrients entering the nearshore ocean waters generated by the Po'ipu resorts and residential areas, there will be minor amounts of nutrients contributed from the pasture-based dairy. The dairy will provide net economic benefits, adding to the agricultural economy of Kaua'i.</td>
</tr>
<tr>
<td>Quantification of probable impacts from the contemplated herd size are shown in the specific resource section. Otherwise, cumulative impacts from both the committed herd size and contemplated herd size are not significant.</td>
</tr>
</tbody>
</table>
4.28 UNRESOLVED ISSUES

Resolution of Milk Products Processing by HDF

The scope of milk processing operations has yet to be resolved. The location for the milk processing activity has not been finalized. The opportunity to undertake value-added processing steps in milk products processing could be conducted on-island. Completion of milk products processing on-island would create additional employment and government revenues for Kaua‘i, increase the availability of local milk products, and further bolster the local agricultural economy. If milk products processing is not undertaken on Kaua‘i, the milk would be shipped in bulk to one of the existing processing facilities on O‘ahu or Hawai‘i Island for further process steps, packaging and marketing.

Resolution of the Final Dairy Farm Herd Size

Successful dairy farming involves the mastery of numerous elements, such as soil science, agronomy and animal husbandry. The final scaling of the milking cow herd size for the Hawaii Dairy Farm operations will ultimately be determined based on the results of pasture grass development at the Māhā‘ulepū site, and dairy cow milk production levels. Up to the committed herd size, this will be an iterative process of monitoring and testing to determine the best approaches to optimize dairy operations and foster good health in the natural systems. It is anticipated that the HDF dairy herd can be increased well beyond 1,000 to 1,500 milking cows and be sustainable from an operational and environmental perspective. With careful monitoring of the operations and the natural systems, including the soils, pasture grasses and water quality, the dairy scaling can be accomplished with sensitivity to the various indicators of carrying capacity. The potential for HDF to reach the upper scale of 2,000 milking cows at the dairy may or may not ultimately occur, depending upon the operational sensitivities and the indicators shown by the carefully monitored natural systems.

This section addresses the Hawai‘i Dairy Farms consistency with applicable policies and plans set forth in the relevant Federal acts, laws and plans of the State of Hawai‘i, and the plans and ordinances of the County of Kaua‘i. The discussion presents the Proposed Project’s consistency with the Hawai‘i State Plan, Hawai‘i Functional Plans, Hawai‘i 2050 Sustainability Plan, State of Hawai‘i Water Policies, Hawai‘i Land Use Districts, and Hawai‘i Coastal Zone Management Act. This section also addresses the Proposed Project's consistency with County of Kaua‘i plans and policies, including the County General Plan, South Kaua‘i Community Plan, and Comprehensive Zoning Ordinance.
FEDERAL

This section assesses the relationship of the project with primary and applicable Federal regulatory controls, which includes the Coastal Zone Management Act (CZMA).

5.1 COASTAL ZONE MANAGEMENT ACT

In 1972, the Federal government enacted the CZMA to effectively manage, use, protect, and develop coastal areas in the U.S. The CZMA was a government response to increasing and competing demands upon habitats and resources of coastal lands and waters. Such demands often resulted in a loss of living marine resources and wildlife; depleted nutrient-rich areas; shoreline erosion; diminished open space for public use; and permanent and adverse changes to ecological systems. Under the CZMA, States are authorized to work in a unified manner with Federal and local governments to develop programs, policies, evaluation criteria, development standards that lend to the effective protection and prudent use of coastal lands and waters. The enforcement authority for the Federal Coastal Management Program (Public Law 104-150, as amended in 1996) has been delegated to the State of Hawai‘i under Hawai‘i Revised Statutes (HRS) Chapter 205A, Coastal Zone Management (CZM) Program.

In 1990, congress enacted the Coastal Zone Act Reauthorization Amendments (CZARA) by adding a new Section 6217 “Protecting Coastal Waters,” which requires that each State with an approved coastal zone management program must develop a Coastal Nonpoint Pollution Control Program (CNPCP) to U.S. Environmental Protection Agency (EPA) and National Oceanic and Atmospheric Administration (NOAA) for approval. The purpose of the program “shall be to develop and implement management measures for nonpoint source pollution to restore and protect coastal waters, working in close conjunction with other State and local authorities”. The Hawai‘i CNPCP follows a Watershed Approach, and activities are coordinated through Hawai‘i’s Implementation Plan for Polluted Runoff Control and considerations for Stormwater Management.

Discussion: The Hawai‘i Dairy Farms is located within the CZMA, which is defined by the State of Hawai‘i as encompassing the entire state. The project improvements are designed to conform to the goals, policies, and objectives of Hawai‘i’s CZM Program. The Proposed Project’s consistency with CZMA programs and policies to protect coastal lands and waters is documented in Sections 3 and 4 of this EIS, including significant measures to minimize or mitigate potential non-point source pollution impacts to the aquatic resources and nearshore coastal waters.
STATE OF HAWAIʻI

5.2 HAWAIʻI STATE CONSTITUTION

The Hawaiʻi Constitution was framed by a Constitutional Convention under Act 334, Session Laws of Hawaiʻi 1949. It was adopted by the people at the election held on November 7, 1950, and was deemed amended when three propositions submitted to the people in accordance with the Act of Congress approved March 18, 1959, 73 Stat 4, Public Law 86-3, were adopted by the people at the election held on June 27, 1959. As so amended, it was accepted, ratified, and confirmed by Congress by the Act of March 18, 1959. It went into effect on August 21, 1959, upon the issuance of a presidential proclamation admitting the state of Hawaiʻi into the Union.

Article XI of the Constitution, “Conservation, Control and Development of Resources,” includes conservation and protection of agricultural lands under Section 3. Following the 1978 Constitutional Convention, Section 3 was amended to require two-thirds vote by the body responsible for reclassification or rezoning to other uses, for lands identified by the State as important agricultural lands.

The State shall conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency and assure the availability of agriculturally suitable lands. The legislature shall provide standards and criteria to accomplish the foregoing. Lands identified by the State as important agricultural lands needed to fulfill the purposes above shall not be reclassified by the State or rezoned by its political subdivisions without meeting the standards and criteria established by the legislature and approved by a two-thirds vote of the body responsible for the reclassification or rezoning action.

5.2.1 ACT 183 (SLH) RELATING TO IMPORTANT AGRICULTURAL LANDS

Article XI of the State Constitution stipulates that the State shall conserve and protect agricultural lands, promote diversified agriculture, increase agricultural self-sufficiency, and assure the availability of agricultural lands through standards and criteria provided by the legislature. The criteria were developed over several decades and have just recently been operationalized on Kauaʻi through the County of Kauaʻi’s own Important Agricultural Lands (IAL) study of the island’s agriculturally zoned lands.

Community concern over loss of agricultural land for another proposed resort on the last stretch of undeveloped Māhāʻulepū coastline prompted protection of 1,533 acres of agricultural lands under the IAL provision of the Hawaiʻi State Constitution (Article XI, Section 3). This constitutional requirement is for conservation and protection of agricultural lands, promotion of diversified agriculture, and increased agricultural self-sufficiency. The IAL designation assures available agriculturally suitable lands to support a diversity of agricultural activities and opportunities that expand agricultural income and job opportunities. In 2011, approximately 1,533 acres of land in Māhāʻulepū were classified by the State Land Use Commission as IAL. This IAL area includes the 557 acres leased by Hawaiʻi Dairy Farms, LLC (HDF), which will be used to fulfill the goals of the important agricultural lands designation, including conservation, diversifying the types of agriculture industries in the state, and providing an opportunity for the state to grow its milk production industry to be more self-sufficient.
5.3 HAWAIʻI STATE PLAN

The Hawaiʻi State Plan establishes a statewide planning system that provides the goals, objectives, and policies that prioritize the directions and concerns of the State of Hawaiʻi. These will be discussed as they relate to the proposed project.

Table 5-1 assesses and evaluates how Hawaiʻi Dairy Farms supports the objectives for Important Agricultural Lands, as promulgated under HRS Chapter 205 Part III. State plan goals are not applicable to this project where noted.

| Table 5-1 Hawaiʻi State Plan, HRS Chapter 205 Part III |
|-----------------|---|---|---|
| S = Supportive, N/S = Not Supportive, N/A = Not Applicable | S | N/S | N/A |
| Section 205-41: Declaration of Policy. |
| It is declared that the people of Hawaiʻi have a substantial interest in the health and sustainability of agriculture as an industry in the State. There is a compelling state interest in conserving the State’s agricultural land resource base and assuring the long-term availability of agricultural lands for agricultural use to achieve the purposes of: |
| (1) Conserving and protecting agricultural lands | X |
| (2) Promoting diversified agriculture | X |
| (3) Increasing agricultural self-sufficiency | X |
| (4) Assuring the availability of agriculturally suitable lands | X |

**Discussion:** The project supports the goals of the State of Hawai‘i to promote sustainability in agriculture as an industry, and protecting the long term availability of lands for agriculture use, described further in EIS Sections 2.3 and 4.4.

**Section 205-43: Important agricultural lands; policies.**
State and county agricultural policies, tax policies, land use plans, ordinances, and rules shall promote the long-term viability of agricultural use of important agricultural lands and shall be consistent with and implement the following policies:

1. Promote the retention of important agricultural lands in blocks of contiguous, intact, and functional land units large enough to allow flexibility in agricultural production and management
   - X
2. Discourage the fragmentation of important agricultural lands and the conversion of these lands to nonagricultural uses
   - X
3. Direct nonagricultural uses and activities from important agricultural lands to other areas and ensure that uses on important agricultural lands are actually agricultural uses
   - X
4. Limit physical improvements on agricultural lands to maintain affordability of these lands for agricultural purposes
   - X
5. Provide a basic level of infrastructure and services on important agricultural lands limited to the minimum necessary to support agricultural uses and activities
   - X
6. Facilitate the long-term dedication of important agricultural lands for future agricultural use through the use of incentives
   - X
7. Facilitate the access of farmers to important agricultural lands for long-term viable agricultural use
   - X
8. Promote the maintenance of essential agricultural infrastructure systems, including irrigation systems
   - X

**Discussion:** The project retains and protects existing Important Agricultural Lands, and also provides a basic level of infrastructure necessary to support the agricultural uses and activities of the dairy, as described in EIS Section 4.4.

Table 5-2 assesses and evaluates how Hawai‘i Dairy Farms supports the Hawai‘i State Plan, as promulgated under HRS Chapter 226. State plan goals are not applicable to this project where noted.

**Section 226-4: State Goals.**
In order to guarantee, for the present and future generations, those elements of choice and mobility that insure that individuals and groups may approach their desired levels of self-reliance and self-determination, it shall be the goal of the State to achieve:

1. A strong, viable economy, characterized by stability, diversity, and growth, that enables the fulfillment of the needs and expectations of Hawai‘i’s present and future generations
   - X
2. A desired physical environment, characterized by beauty, cleanliness, quiet, stable natural systems, and uniqueness, that enhances the mental and physical well-being of the people.
   - X
3. Physical, social and economic well-being, for individuals and families in Hawai‘i, that nourishes a sense of community responsibility, of caring, and of participation in community life.
   - X

**Discussion:** The project supports the goals of the State of Hawai‘i to achieve a strong, viable economy, Hawai‘i Dairy Farms’ purpose is to provide sustainable financial and food security for the island of Kaua‘i and the State of Hawai‘i as a whole, further described in EIS Section 2.3.

**Section 226-5: Objective and Policies for Population.**
(A) It shall be the objective in planning for the State’s population to guide population growth to be consistent with the achievement of physical, economic, and social objectives contained in this chapter.
(B) To achieve the population objective, it shall be the policy of this State to:
### Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

</tbody>
</table>

**Discussion:** The project will not significantly add to Hawai‘i’s residential population growth. Implementation of the project will positively stimulate Hawai‘i’s tax base, and create new jobs both in the short-term construction phase and long-term dairy commerce operations. The project’s development is a coordinated effort to utilize available land and infrastructure, and will ensure valuable resources are utilized in a prudent and efficient manner.

### Section 226-6: Objectives and Policies for the Economy in General.

**A** Planning for the State’s economy in general shall be directed toward achievement of the following objectives:

1. Increased and diversified employment opportunities to achieve full employment, increased income and job choice, and improved living standards for Hawai‘i’s people. | X |
2. A steadily growing and diversified economic base that is not overly dependent on a few industries, and includes the development and expansion of industries on the neighbor islands. | X |

**B** To achieve the general economic objectives, it shall be the policy of this State to:

1. Expand Hawai‘i’s national and international marketing, communication, and organizational ties, to increase the State’s capacity to adjust to and capitalize upon economic changes and opportunities occurring outside the State. | X |
2. Promote Hawai‘i as an attractive market for environmentally and socially sound investment activities that benefit Hawai‘i’s people. | X |
3. Seek broader outlets for new or expanded Hawai‘i business investments. | X |
4. Expand existing markets and penetrate new markets for Hawai‘i’s products and services. | X |
5. Assure that the basic economic needs of Hawai‘i’s people are maintained in the event of disruptions in overseas transportation. | X |
6. Strive to achieve a level of construction activity responsive to, and consistent with, state growth objectives. | X |
7. Encourage the formation of cooperatives and other favorable marketing arrangements at the local or regional level to assist Hawai‘i’s small scale producers, manufacturers, and distributors. | X |
8. Encourage labor-intensive activities that are economically satisfying and which offer opportunities for upward mobility. | X |
9. Foster greater cooperation and coordination between the government and private sectors in developing Hawai‘i’s employment and economic growth opportunities. | X |
10. Stimulate the development and expansion of economic activities which will benefit areas with substantial or expected employment problems. | X |
11. Maintain acceptable working conditions and standards for Hawai‘i’s workers. | X |
12. Provide equal employment opportunities for all segments of Hawai‘i’s population through affirmative action and nondiscrimination measures. | X |
13. Encourage businesses that have favorable financial multiplier effects within Hawai‘i’s economy. | X |
Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<tr>
<td>(15) Increase effective communication between the educational community and the private sector to develop relevant curricula and training programs to meet future employment needs in general, and requirements of new, potential growth industries in particular.</td>
<td></td>
</tr>
<tr>
<td>(16) Foster a business climate in Hawai‘i - including attitudes, tax and regulatory policies, and financial and technical assistance programs – that is conducive to the expansion of existing enterprises and the creation and attraction of new business and industry.</td>
<td></td>
</tr>
</tbody>
</table>

Discussion: Implementation at the contemplated herd size will more than double the existing local milk production in the State of Hawai‘i, developing and revitalizing the State’s dairy industry to provide more fresh milk for local families, while also providing employment opportunities for local communities. The planned improvements will help to stabilize Hawai‘i’s economy and encourage self-sufficiency in the agriculture and dairy industries. HDF will create educational opportunities and will foster an environment for economic expansion.

Section 226-7 Objectives and Policies for the Economy – Agriculture.

(A) Planning for the State’s economy with regard to agriculture shall be directed towards achievement of the following objectives:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to economy and federal expenditures, they are not directly applicable to the Proposed Project.

**Section 226-8 Objective and Policies for the Economy - Visitor Industry.**

(A) Planning for the State’s economy with regard to the visitor industry shall be directed towards the achievement of the objective of the visitor industry that constitutes a major component of steady growth for Hawai‘i’s economy.

(B) To achieve the visitor industry objective, it shall be the policy of this State to:

1. Support and assist in the promotion of Hawai‘i’s visitor attractions and facilities.
2. Ensure that visitor industry activities are in keeping with the social, economic, and physical needs and aspirations of Hawai‘i’s people.
3. Improve the quality of existing visitor destination areas.
4. Encourage cooperation and coordination between the government and private sectors in developing and maintaining well-designed, adequately serviced visitor industry and related developments which are sensitive to neighboring communities and activities.
5. Develop the industry in a manner that will continue to provide new job opportunities and steady employment for Hawai‘i’s people.
6. Provide opportunities for Hawai‘i’s people to obtain job training and education that will allow for upward mobility within the visitor industry.
7. Foster a recognition of the contribution of the visitor industry to Hawai‘i’s economy and the need to perpetuate the aloha spirit.
8. Foster an understanding by visitors of the aloha spirit and of the unique and sensitive character of Hawai‘i’s cultures and values.

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s visitor industry, they are not directly applicable to the Proposed Project.

**Section 226-9 Objective and Policies for the Economy - Federal Expenditures.**

(A) Planning for the State’s economy with regard to federal expenditures shall be directed towards achievement of the objective of a stable federal investment base as an integral component of Hawai‘i’s economy.

(B) To achieve the federal expenditures objective, it shall be the policy of this State to:

1. Encourage the sustained flow of federal expenditures in Hawai‘i that generates long-term government civilian employment.
2. Promote Hawai‘i’s supportive role in national defense.
3. Promote the development of federally supported activities in Hawai‘i that respect state-wide economic concerns, are sensitive to community needs, and minimize adverse impacts on Hawai‘i’s environment.
4. Increase opportunities for entry and advancement of Hawai‘i’s people into federal government service.
5. Promote federal use of local commodities, services, and facilities available in Hawai‘i.
6. Strengthen federal-state-county communication and coordination in all federal activities that affect Hawai‘i.
7. Pursue the return of federally controlled lands in Hawai‘i that are not required for either the defense of the nation or for other purposes of national importance, and promote the mutually beneficial exchanges of land between federal agencies, the State, and the counties.

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to economy and federal expenditures, they are not directly applicable to the Proposed Project.

**Section 226-10 Objective and Policies for the Economy - Potential Growth Activities.**

(A) Planning for the State’s economy with regard to potential growth activities shall be directed towards achievement of the objective of development and expansion of potential growth activities that serve to increase and diversify Hawai‘i’s economic base.

(B) To achieve the potential growth activity objective, it shall be the policy of this State to:

1. Facilitate investment and employment in economic activities that have the potential for growth such as diversified agriculture, aquaculture, apparel and textile manufacturing, film and television production, and energy and marine-related industries.

**Discussion:** Hawai‘i Dairy Farms supports the State’s policies by diversifying and enhancing the local agriculture industry in developing dairy, which diversifies the State economy as a whole by providing more economic options to lessen our dependency on tourism, as described in EIS Section 4.15.

**Section 226-10.5 Objectives and Policies for the Economy - Information Industry.**

(A) Planning for the State’s economy with regard to the information industry shall be directed toward the achievement of the objective of positioning Hawai‘i as the leading dealer in information businesses and services in the Pacific Rim.

(B) To achieve the information industry objective, it shall be the policy of this State to:

1. Encourage the continued development and expansion of the telecommunications infrastructure serving Hawai‘i to accommodate future growth in the information industry;  
2. Facilitate the development of new business and service ventures in the information industry which will provide employment opportunities for the people of Hawai‘i;  
3. Encourage greater cooperation between the public and private sectors in developing and maintaining a well-designed information industry;  
4. Ensure that the development of new businesses and services in the industry are in keeping with the social, economic, and physical needs and aspirations of Hawai‘i’s people;  
5. Provide opportunities for Hawai‘i’s people to obtain job training and education that will allow for upward mobility within the information industry;  
6. Foster a recognition of the contribution of the information industry to Hawai‘i’s economy; and  
7. Assist in the promotion of Hawai‘i as a broker, creator, and processor of information in the Pacific.

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s information industry, the Proposed Project will not directly impact these policies.

**Section 226-11 Objectives and Policies for the Physical Environment - Land-based, Shoreline, and Marine Resources.**

(A) Planning for the State’s physical environment with regard to land-based, shoreline and marine resources shall be directed towards achievement of the following objectives:

1. Prudent use of Hawai‘i’s land-based, shoreline, and marine resources.  
2. Effective protection of Hawai‘i’s unique and fragile environmental resources.  

(B) To achieve the land-based, shoreline, and marine resources objectives, it shall be the policy of this State to:

1. Exercise an overall conservation ethic in the use of Hawai‘i’s natural resources.  
2. Ensure compatibility between land-based and water-based activities and natural resources and ecological systems.
Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

</tr>
<tr>
<td>Promote increased accessibility and prudent use of inland and shoreline areas for public recreational, educational and scientific purposes.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Discussion: The project is a balanced development proposal that is compatible to existing uses and relationships in the Māhā’ulepū agricultural region, and measures to protect water resources and water quality are presented in EIS Sections 4.16, 4.17, 4.23 and 4.24. While the project supports the County’s initiatives for shoreline and marine environment protection and conservation, the project is located over one mile inland of the coastline, and does not have any shoreline or marine features.

Section 226-12 Objective and Policies for the Physical Environment - Scenic, Natural Beauty, and Historic Resources.

(A) Planning for the State’s physical environment shall be directed towards achievement of the objective of enhancement of Hawai‘i’s scenic assets, natural beauty, and multi-cultural/historical resources.

(B) To achieve the scenic, natural beauty, and historic resources objective, it shall be the policy of this State to:

1. Promote the preservation and restoration of significant natural and historic resources. X
2. Provide incentives to maintain and enhance historic, cultural, and scenic amenities. X
3. Promote the preservation of views and vistas to enhance the visual and aesthetic enjoyment of mountains, ocean, scenic landscapes, and other natural features. X
4. Protect those special areas, structures, and elements that are an integral and functional part of Hawai‘i’s ethnic and cultural heritage. X
5. Encourage the design of developments and activities that complement the natural beauty of the islands. X

Discussion: The project will not impact scenic natural resources or historical and cultural resources found in and around the project site. The proposed facilities are in keeping with the agricultural character of the area, and are expected to have minimal impact to public views.

There are no public scenic views or lookouts that will be affected by dairy development or operations. There will be no adverse effect to public views of the Pu‘u Hunihuni crater, views from the Ala Kinoiki Road corridor, or impediment to views of the Mount Ha‘upu.

(A) Planning for the State’s physical environment with regard to land, air, and water quality shall be directed towards achievement of the following objectives:

1. Maintenance and pursuit of improved quality in Hawai‘i’s land, air, and water resources. X
2. Greater public awareness and appreciation of Hawai‘i’s environmental resources. X

(B) To achieve the land, air, and water quality objectives, it shall be the policy of this State to:

1. Foster educational activities that promote a better understanding of Hawai‘i’s limited environmental resources. X
2. Promote the proper management of Hawai‘i’s land and water resources. X
3. Promote effective measures to achieve desired quality in Hawai‘i’s surface, ground and coastal waters. X
4. Encourage actions to maintain or improve aural and air quality levels to enhance the health and well-being of Hawai‘i’s people. X
5. Reduce the threat to life and property from erosion, flooding, tsunamis, hurricanes, earthquakes, volcanic eruptions, and other natural or man-induced hazards and disasters. X
6. Encourage design and construction practices that enhance the physical qualities of Hawai‘i’s communities. X
7. Encourage urban developments in close proximity to existing services and facilities. X
Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<tr>
<td>(8) Foster recognition of the importance and value of the land, air, and water resources to Hawai‘i’s people, their cultures and visitors.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Best management practices and regulatory controls will ensure air and water quality are within acceptable regulatory limits on-site and within the immediate area.

Section 226-14 Objective and Policies for Facility Systems - In General.

(A) Planning for the State’s facility systems in general shall be directed towards achievement of the objective of water, transportation, waste disposal, and energy and telecommunication systems that support statewide social, economic, and physical objectives.

(B) To achieve the general facility systems objective, it shall be the policy of this State to:

1. Accommodate the needs of Hawai‘i’s people through coordination of facility systems and capital improvement priorities in consonance with state and county plans.
2. Encourage flexibility in the design and development of facility systems to promote prudent use of resources and accommodate changing public demands and priorities.
3. Ensure that required facility systems can be supported within resource capacities and at reasonable cost to the user.
4. Pursue alternative methods of financing programs and projects and cost-saving techniques in the planning, construction, and maintenance of facility systems.

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s facility systems policies, they are not directly applicable to the Proposed Project.

(A) Planning for the State’s facility systems with regard to solid and liquid wastes shall be directed towards the achievement of the following objectives:

1. Maintenance of basic public health and sanitation standards relating to treatment and disposal of solid and liquid wastes.
2. Provision of adequate sewerage facilities for physical and economic activities that alleviate problems in housing, employment, mobility, and other areas.

(B) To achieve solid and liquid waste objectives, it shall be the policy of this State to:

1. Encourage the adequate development of sewerage facilities that complement planned growth.
2. Promote re-use and recycling to reduce solid and liquid wastes and employ a conservation ethic.
3. Promote research to develop more efficient and economical treatment and disposal of solid and liquid wastes.

**Discussion:** Hawai‘i Dairy Farms does not address domestic waste, the dairy operation is centrally based upon the recycling non-domestic waste as fertilizer to produce locally available feedstock in a pasture-based rotational grazing method, which supports Objective (B)(2).

226-16 Objective and Policies for Facility Systems - Water.

(A) Planning for the State’s facility systems with regard to water shall be directed towards achievement of the objective of the provision of water to adequately accommodate domestic, agricultural, commercial, industrial, recreational, and other needs within resource capacities.

(B) To achieve the facility systems water objective, it shall be the policy of this State to:

1. Coordinate development of land use activities with existing and potential water supply.
2. Support research and development of alternative methods to meet future water requirements well in advance of anticipated needs.
3. Reclaim and encourage the productive use of runoff water and wastewater discharges.
4. Assist in improving the quality, efficiency, service, and storage capabilities of water systems for domestic and agricultural use.
5. Support water supply services to areas experiencing critical water problems.
6. Promote water conservation programs and practices in government, private industry, and the general public to help ensure adequate water to meet long-term needs.
Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>
<th></th>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
</tr>
</thead>
</table>

**Discussion:** Hawai‘i Dairy Farms nutrient management plan is designed to collect, treat, and reuse all livestock waste and wastewater generated from the facility. Fundamentally, this pasture-based dairy will effectively recycle 100% of animal wastes, as presented in EIS Section 3.3. The project is consistent with objectives and policies for water supply and water management, as discussed in EIS Section 4.1.6.

226-17 Objectives and Policies for Facility Systems - Transportation.
(A) Planning for the State’s facility systems with regard to transportation shall be directed towards the achievement of the following objectives:

1. An integrated multi-modal transportation system that services statewide needs and promotes the efficient, economical, safe, and convenient movement of people and goods.  
2. A statewide transportation system that is consistent with and will accommodate planned growth objectives throughout the State.
(B) To achieve the transportation objectives, it shall be the policy of this State to:

1. Design, program, and develop a multi-modal system in conformance with desired growth and physical development as stated in this chapter;  
2. Coordinate state, county, federal, and private transportation activities and programs toward the achievement of statewide objectives;  
3. Encourage a reasonable distribution of financial responsibilities for transportation among participating governmental and private parties;  
4. Provide for improved accessibility to shipping, docking, and storage facilities;  
5. Promote a reasonable level and variety of mass transportation services that adequately meet statewide and community needs;  
6. Encourage transportation systems that serve to accommodate present and future development needs of communities;  
7. Encourage a variety of carriers to offer increased opportunities and advantages to inter-island movement of people and goods;  
8. Increase the capacities of airport and harbor systems and support facilities to effectively accommodate transshipment and storage needs;  
9. Encourage the development of transportation systems and programs which would assist statewide economic growth and diversification;  
10. Encourage the design and development of transportation systems sensitive to the needs of affected communities and the quality of Hawai‘i’s natural environment;  
11. Encourage safe and convenient use of low-cost, energy-efficient, non-polluting means of transportation;  
12. Coordinate intergovernmental land use and transportation planning activities to ensure the timely delivery of supporting transportation infrastructure in order to accommodate planned growth objectives; and  
13. Encourage diversification of transportation modes and infrastructure to promote alternate fuels and energy efficiency.

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s transportation systems and practices, they are not directly applicable to the Proposed Project.

(A) Planning for the State’s facility systems with regard to energy shall be directed toward the achievement of the following objectives, giving due consideration to all:

1. Dependable, efficient, and economical statewide energy systems capable of supporting the needs of the people;  
2. Increased energy self-sufficiency where the ratio of indigenous to imported energy use is increased;  
3. Greater energy security in the face of threats to Hawai‘i’s energy supplies and systems; and  
4. Reduction, avoidance, or sequestration of greenhouse gas emissions from energy supply and use.
(B) To achieve the energy objectives, it shall be the policy of this State to ensure the provision of adequate, reasonably priced, and dependable energy services to accommodate demand.
(C) To further achieve the energy objectives, it shall be the policy of this State to:

1. Support research and development as well as promote the use of renewable energy sources;
Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>
<th></th>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
</tr>
</thead>
<tbody>
<tr>
<td>(2)</td>
<td>Ensure that the combination of energy supplies and energy-saving systems is sufficient to support the demands of growth;</td>
</tr>
<tr>
<td>(3)</td>
<td>Base decisions of least-cost supply-side and demand-side energy resource options on a comparison of their total costs and benefits when a least-cost is determined by a reasonably comprehensive, quantitative, and qualitative accounting of their long-term, direct and indirect economic, environmental, social, cultural, and public health costs and benefits;</td>
</tr>
<tr>
<td>(4)</td>
<td>Promote all cost-effective conservation of power and fuel supplies through measures including: (A) Development of cost-effective demand-side management programs; (B) Education; and (C) Adoption of energy-efficient practices and technologies;</td>
</tr>
<tr>
<td>(5)</td>
<td>Ensure to the extent that new supply-side resources are needed, the development or expansion of energy systems utilizes the least-cost energy supply option and maximizes efficient technologies;</td>
</tr>
<tr>
<td>(6)</td>
<td>Support research, development, and demonstration of energy efficiency, load management, and other demand-side management programs, practices, and technologies;</td>
</tr>
<tr>
<td>(7)</td>
<td>Promote alternate fuels and energy efficiency by encouraging diversification of transportation modes and infrastructure;</td>
</tr>
<tr>
<td>(8)</td>
<td>Support actions that reduce, avoid, or sequester greenhouse gases in utility, transportation, and industrial sector applications; and</td>
</tr>
<tr>
<td>(9)</td>
<td>Support actions that reduce, avoid, or sequester Hawai‘i’s greenhouse gas emissions through agriculture and forestry initiatives.</td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports several of the State’s policies related to improving Hawai‘i’s facilities systems in regards to energy usage and conservation. Hawai‘i Dairy Farms environmental commitments, such as energy efficiency and sustainable building operations. The use of solar photovoltaic energy and other energy-efficient technologies are integrated into the dairy farm, refer to EIS Section 3.2. Greenhouse gas emissions are avoided through on-site power generation and on-site waste management.

The dairy’s focus on robust and healthy grass growth will build organic matter in soils through use of manure as a natural fertilizer. Soil can incorporate carbon from the atmosphere, which benefits soil health. According to recent studies in the Soil Science Society of America Journal, the conversion of formerly tilled cropland to grazed pasture can drive substantial accumulation of organic carbons in soil, with a potential to offset up to one-third the annual increase in atmospheric carbon dioxide.

### 226-18.5 Objectives and Policies for Facility Systems - Telecommunications.

(A) Planning for the State's telecommunications facility systems shall be directed towards the achievement of dependable, efficient, and economical statewide telecommunications systems capable of supporting the needs of the people.

(B) To achieve the telecommunications objective, it shall be the policy of this State to ensure the provision of adequate, reasonably priced, and dependable telecommunications services to accommodate demand.

(C) To further achieve the telecommunications objective, it shall be the policy of this State to:

(1) Facilitate research and development of telecommunications systems and resources; X

(2) Encourage public and private sector efforts to develop means for adequate, ongoing telecommunications planning; X

(3) Promote efficient management and use of existing telecommunications systems and services; and X

(4) Facilitate the development of education and training of telecommunications personnel. X

**Discussion:** While these policies apply more directly to government, Hawai‘i Dairy Farms will continue to incorporate current and efficient telecommunication technologies.

### 226-19 Objectives and Policies for Socio-Cultural Advancement - Housing.

(A) Planning for the State’s socio-cultural advancement with regard to housing shall be directed toward the achievement of the following objectives:

(1) Greater opportunities for Hawai‘i’s people to secure reasonably priced, safe, sanitary, and livable homes, located in suitable environments that satisfactorily accommodate the needs and desires of families and individuals, through collaboration and cooperation between government and nonprofit and for-profit developers to ensure that more affordable housing is made available to very low-, low- and moderate-income segments of Hawai‘i’s population. X
Table 5-2 Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>(2) The orderly development of residential areas sensitive to community needs and other land uses.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3) The development and provision of affordable rental housing by the State to meet the housing needs of Hawai‘i’s people.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(B) To achieve the housing objectives, it shall be the policy of this State to:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(1) Effectively accommodate the housing needs of Hawai‘i’s people.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(2) Stimulate and promote feasible approaches that increase housing choices for low-income, moderate-income, and gap-group households.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(3) Increase homeownership and rental opportunities and choices in terms of quality, location, cost, densities, style, and size of housing.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(4) Promote appropriate improvement, rehabilitation, and maintenance of existing housing units and residential areas.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(5) Promote design and location of housing developments taking into account the physical setting, accessibility to public facilities and services, and other concerns of existing communities and surrounding areas.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(6) Facilitate the use of available vacant, developable, and underutilized urban lands for housing.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(7) Foster a variety of lifestyles traditional to Hawai‘i through the design and maintenance of neighborhoods that reflect the culture and values of the community.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>(8) Promote research and development of methods to reduce the cost of housing construction in Hawai‘i.</td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

**Discussion:** There is no residential development planned as part of Hawai‘i Dairy Farms.

### 226-20 Objectives and Policies for Socio-Cultural Advancement - Health.

(A) Planning for the State’s socio-cultural advancement with regard to health shall be directed towards achievement of the following objectives:

<table>
<thead>
<tr>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Fulfillment of basic individual health needs of the general public.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2) Maintenance of sanitary and environmentally healthful conditions in Hawai‘i’s communities.</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

(B) To achieve the health objectives, it shall be the policy of this State to:

<table>
<thead>
<tr>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Provide adequate and accessible services and facilities for prevention and treatment of physical and mental health problems, including substance abuse.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2) Encourage improved cooperation among public and private sectors in the provision of health care to accommodate the total health needs of individuals throughout the State.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3) Encourage public and private efforts to develop and promote statewide and local strategies to reduce health care and related insurance costs.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(4) Foster an awareness of the need for personal health maintenance and preventive health care through education and other measures.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(5) Provide programs, services, and activities that ensure environmentally healthful and sanitary conditions.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(6) Improve the State’s capabilities in preventing contamination by pesticides and other potentially hazardous substances through increased coordination, education, monitoring, and enforcement.</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms’ goals of providing fresh, healthy, locally produced milk to the State of Hawai‘i supports the HRS objectives and policies for health’s role in socio-cultural advancement. By containing and reusing waste and runoff, it also supports the maintenance of sanitary and environmentally healthy conditions in Hawai‘i. Fuels, agricultural chemicals, lubricants, cleaners or potentially hazardous substances will be utilized in compliance with applicable State and Federal requirements.

### 226-21 Objective and Policies for Socio-Cultural Advancement - Education.

(A) Planning for the State's socio-cultural advancement with regard to education shall be directed towards achievement of the objective of the provision of a variety of educational opportunities to enable individuals to fulfill their needs, responsibilities, and aspirations.

(B) To achieve the education objective, it shall be the policy of this State to:

<table>
<thead>
<tr>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Support educational programs and activities that enhance personal development, physical fitness, recreation, and cultural pursuits of all groups.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2) Ensure the provision of adequate and accessible educational services and facilities that are designed to meet individual and community needs.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3) Provide appropriate educational opportunities for groups with special needs.</td>
<td>X</td>
<td></td>

</table>

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s educational opportunities, they are not directly applicable to the Proposed Project.

226-22 Objective and Policies for Socio-Cultural Advancement - Social Services.
(A) Planning for the State’s socio-cultural advancement with regard to social services shall be directed towards the achievement of the objective of improved public and private social services and activities that enable individuals, families, and groups to become more self-reliant and confident to improve their well-being.
(B) To achieve the social service objective, it shall be the policy of the State to:

| (1) Assist individuals, especially those in need of attaining a minimally adequate standard of living and those confronted by social and economic hardship conditions, through social services and activities within the State’s fiscal capacities. | X |
| (2) Promote coordination and integrative approaches among public and private agencies and programs to jointly address social problems that will enable individuals, families, and groups to deal effectively with social problems and to enhance their participation in society. | X |
| (3) Facilitate the adjustment of new residents, especially recently arrived immigrants, into Hawai‘i’s communities. | X |
| (4) Promote alternatives to institutional care in the provision of long-term care for elder and disabled populations. | X |
| (5) Support public and private efforts to prevent domestic abuse and child molestation, and assist victims of abuse and neglect. | X |
| (6) Promote programs which assist people in need of family planning services to enable them to meet their needs. | X |

**Discussion:** Hawai‘i Dairy Farms supports the policies for government actions for socio-cultural advancement in regards to social services. However, it is not applicable to the Proposed Project.

(A) Planning for the State’s socio-cultural advancement with regard to leisure shall be directed towards the achievement of the objective of the adequate provision of resources to accommodate diverse cultural, artistic, and recreational needs for present and future generations.
(B) To achieve the leisure objective, it shall be the policy of this State to:

| (1) Foster and preserve Hawai‘i’s multi-cultural heritage through supportive cultural, artistic, recreational, and humanities-oriented programs and activities. | X |
| (2) Provide a wide range of activities and facilities to fulfill the cultural, artistic, and recreational needs of all diverse and special groups effectively and efficiently. | X |
| (3) Enhance the enjoyment of recreational experiences through safety and security measures, educational opportunities, and improved facility design and maintenance. | X |
| (4) Promote the recreational and educational potential of natural resources having scenic, open space, cultural, historical, geological, or biological values while ensuring that their inherent values are preserved. | X |
| (5) Ensure opportunities for everyone to use and enjoy Hawai‘i’s recreational resources. | X |
| (6) Assure the availability of sufficient resources to provide for future cultural, artistic, and recreational needs. | X |
| (7) Provide adequate and accessible physical fitness programs to promote the physical and mental well-being of Hawai‘i’s people. | X |

<tbody>
<tr>
<td>(8) Increase opportunities for appreciation and participation in the creative arts, including the literary, theatrical, visual, musical, folk, and traditional art forms.</td>
<td>X</td>
</tr>
<tr>
<td>(9) Encourage the development of creative expression in the artistic disciplines to enable all segments of Hawai‘i’s population to participate in the creative arts.</td>
<td>X</td>
</tr>
<tr>
<td>(10) Assure adequate access to significant natural and cultural resources in public ownership.</td>
<td>X</td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms will not restrict access via Grove Farm / Māhā‘ulepū Farm to historical and culturally significant sites located near the project site to promote and preserve cultural features, traditions and historical properties in the region. Refer to EIS Sections 4.7 and 4.8.

**226-24 Objective and Policies for Socio-Cultural Advancement - Individual Rights and Personal Well-Being.**

(A) Planning for the State’s socio-cultural advancement with regard to individual rights and personal well-being shall be directed towards achievement of the objective of increased opportunities and protection of individual rights to enable individuals to fulfill their socio-economic needs and aspirations.

(B) To achieve the individual rights and personal well-being objective, it shall be the policy of this State to:

1. Provide effective services and activities that protect individuals from criminal acts and unfair practices and that alleviate the consequences of criminal acts in order to foster a safe and secure environment.  
2. Uphold and protect the national and state constitutional rights of every individual.  
3. Assure access to, and availability of, legal assistance, consumer protection, and other public services which strive to attain social justice.  
4. Ensure equal opportunities for individual participation in society.

**Discussion:** Hawai‘i Dairy Farms supports the individual rights and personal well-being of employees through compliance with State and Federal employee rights laws.

**226-25 Objective and Policies for Socio-Cultural Advancement - Culture.**

(A) Planning for the State’s socio-cultural advancement with regard to culture shall be directed toward the achievement of the objective of enhancement of cultural identities, traditions, values, customs, and arts of Hawai‘i’s people.

(B) To achieve the culture objective, it shall be the policy of this State to:

1. Foster increased knowledge and understanding of Hawai‘i’s ethnic and cultural heritages and the history of Hawai‘i.  
2. Support activities and conditions that promote cultural values, customs, and arts that enrich the lifestyles of Hawai‘i’s people and which are sensitive and responsive to family and community needs.  
3. Encourage increased awareness of the effects of proposed public and private actions on the integrity and quality of cultural and community lifestyles in Hawai‘i.  
4. Encourage the essence of the aloha spirit in people’s daily activities to promote harmonious relationships among Hawai‘i’s people and visitors.

**Discussion:** Hawai‘i Dairy Farms supports the policies for government actions for socio-cultural advancement in regards to cultural values and cultural education.

**226-26 Objectives and Policies for Socio-Cultural Advancement - Public Safety.**

(A) Planning for the State’s socio-cultural advancement with regard to public safety shall be directed towards the achievement of the following objectives:

1. Assurance of public safety and adequate protection of life and property for all people.  
2. Optimum organizational readiness and capability in all phases of emergency management to maintain the strength, resources, and social and economic well-being of the community in the event of civil disruptions, wars, natural disasters, and other major disturbances.  
3. Promotion of a sense of community responsibility for the welfare and safety of Hawai‘i’s people.

(B) To achieve the public safety objectives, it shall be the policy of this State to:

1. Ensure that public safety programs are effective and responsive to community needs.  
2. Encourage increased community awareness and participation in public safety programs.  
3. To further achieve public safety objectives related to criminal justice, it shall be the policy of this State to:

1. Support criminal justice programs aimed at preventing and curtailing criminal activities.

</table>

**Discussion:** Hawaiʻi Dairy Farms takes the responsibility of the wellness and safety of its employees, livestock, and facilities very seriously. Buildings will be designed to appropriate natural disaster and emergency code standards, and staff will be trained to address a range of situations that require immediate response to emergencies or unlawful activity on-site. Response plans are also in place in the event of natural disaster events, further described in EIS Section 4.6.

### 226-27 Objectives and Policies for Socio-Cultural Advancement - Government.

**(A)** Planning the State’s socio-cultural advancement with regard to government shall be directed towards the achievement of the following objectives:

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td></td>
<td>X</td>

<td></td>
</tr>
</tbody>
</table>

**Discussion:** Policies related to the operation of State government are the responsibility of the State of Hawaiʻi and are not directly applicable to Hawaiʻi Dairy Farms.

---

**226-101 Purpose.**

The purpose of this part is to establish overall priority guidelines to address areas of statewide concern.

**226-102 Overall Direction.**

The State shall strive to improve the quality of life for Hawaiʻi’s present and future population through the pursuit of desirable courses of action in five major areas of statewide concern which merit priority attention: economic development, population growth and land resource management, affordable housing, crime and criminal justice, and quality education.

**226-103 Economic Priority Guidelines.**

**(A)** Priority guidelines to stimulate economic growth and encourage business expansion and development to provide needed jobs for Hawaiʻi’s people and achieve a stable and diversified economy:

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>

</tbody>
</table>
### Table 5-2  Hawaiʻi State Plan, Hawaiʻi Revised Statutes, Chapter 226

| (vi) Demonstrate a commitment to provide management opportunities to Hawaiʻi residents. | X |
| (2) Encourage the expansion of technological research to assist industry development and support the development and commercialization of technological advancements. | X |
| (3) Improve the quality, accessibility, and range of services provided by government to business, including data and reference services and assistance in complying with governmental regulations. | X |
| (4) Seek to ensure that state business tax, labor laws, and administrative policies are equitable, rational, and predictable. | X |
| (5) Streamline the building and development permit and review process, and eliminate or consolidate other burdensome or duplicative governmental requirements imposed on business, where public health, safety and welfare would not be adversely affected. | X |
| (6) Encourage the formation of cooperatives and other favorable marketing or distribution arrangements at the regional or local level to assist Hawaiʻi's small-scale producers, manufacturers, and distributors. | X |
| (7) Continue to seek legislation to protect Hawaiʻi from transportation interruptions between Hawaiʻi and the continental United States. | X |
| (8) Provide public incentives and encourage private initiative to develop and attract industries which promise long-term growth potentials and which have the following characteristics: | |
| (a) An industry that can take advantage of Hawaiʻi’s unique location and available physical and human resources. | X |
| (b) A clean industry that would have minimal adverse effects on Hawaiʻi’s environment. | X |
| (c) An industry that is willing to hire and train Hawaiʻi’s people to meet the industry’s labor needs at all levels of employment. | X |
| (d) An industry that would provide reasonable income and steady employment. | X |
| (9) Support and encourage, through educational and technical assistance programs and other means, expanded opportunities for employee ownership and participation in Hawaiʻi business. | X |
| (10) Enhance the quality of Hawaiʻi’s labor force and develop and maintain career opportunities for Hawaiʻi’s people through the following actions: | |
| (A) Expand vocational training in diversified agriculture, aquaculture, information industry, and other areas where growth is desired and feasible. | X |
| (B) Encourage more effective career counseling and guidance in high schools and post-secondary institutions to inform students of present and future career opportunities. | X |
| (C) Allocate educational resources to career areas where high employment is expected and where growth of new industries is desired. | X |
| (D) Promote career opportunities in all industries for Hawaiʻi’s people by encouraging firms doing business in the State to hire residents. | X |
| (E) Promote greater public and private sector cooperation in determining industrial training needs and in developing relevant curricula and on-the-job training opportunities. | X |
| (F) Provide retraining programs and other support services to assist entry of displaced workers into alternative employment. | X |

(8) Priority guidelines to promote the economic health and quality of the visitor industry:

| (1) Promote visitor satisfaction by fostering an environment which enhances the Aloha Spirit and minimizes inconveniences to Hawaiʻi’s residents and visitors. | X |
| (2) Encourage the development and maintenance of well-designed, adequately serviced hotels and resort destination areas which are sensitive to neighboring communities and activities and which provide for adequate shoreline setbacks and beach access. | X |
| (3) Support appropriate capital improvements to enhance the quality of existing resort destination areas and provide incentives to encourage investment in upgrading, repair, and maintenance of visitor facilities. | X |
| (4) Encourage visitor industry practices and activities which respect, preserve, and enhance Hawaiʻi’s significant natural, scenic, historic, and cultural resources. | X |
| (5) Develop and maintain career opportunities in the visitor industry for Hawaiʻi’s people, with emphasis on managerial positions. | X |
| (6) Support and coordinate tourism promotion abroad to enhance Hawaiʻi’s share of existing and potential visitor markets. | X |
### Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>
<th></th>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>Maintain and encourage a more favorable resort investment climate consistent with the objectives of this chapter.</td>
</tr>
<tr>
<td>8</td>
<td>Support law enforcement activities that provide a safer environment for both visitors and residents alike.</td>
</tr>
<tr>
<td>9</td>
<td>Coordinate visitor industry activities and promotions to business visitors through the state network of advanced data communication techniques.</td>
</tr>
<tr>
<td>C</td>
<td>Priority guidelines to promote the continued viability of the sugar and pineapple industries:</td>
</tr>
<tr>
<td>1</td>
<td>Provide adequate agricultural lands to support the economic viability of the sugar and pineapple industries.</td>
</tr>
<tr>
<td>2</td>
<td>Continue efforts to maintain federal support to provide stable sugar prices high enough to allow profitable operations in Hawai‘i.</td>
</tr>
<tr>
<td>3</td>
<td>Support research and development, as appropriate, to improve the quality and production of sugar and pineapple crops.</td>
</tr>
<tr>
<td>D</td>
<td>Priority guidelines to promote the growth and development of diversified agriculture and aquaculture:</td>
</tr>
<tr>
<td>1</td>
<td>Identify, conserve, and protect agricultural and aquacultural lands of importance and initiate affirmative and comprehensive programs to promote economically productive agricultural and aquacultural uses of such lands.</td>
</tr>
<tr>
<td>2</td>
<td>Assist in providing adequate, reasonably priced water for agricultural activities.</td>
</tr>
<tr>
<td>3</td>
<td>Encourage public and private investment to increase water supply and to improve transmission, storage, and irrigation facilities in support of diversified agriculture and aquaculture.</td>
</tr>
<tr>
<td>4</td>
<td>Assist in the formation and operation of production and marketing associations and cooperatives to reduce production and marketing costs.</td>
</tr>
<tr>
<td>5</td>
<td>Encourage and assist with the development of a waterborne and airborne freight and cargo system capable of meeting the needs of Hawai‘i’s agricultural community.</td>
</tr>
<tr>
<td>6</td>
<td>Seek favorable freight rates for Hawai‘i’s agricultural products from inter-island and overseas transportation operators.</td>
</tr>
<tr>
<td>7</td>
<td>Encourage the development and expansion of agricultural and aquacultural activities which offer long-term economic growth potential and employment opportunities.</td>
</tr>
<tr>
<td>8</td>
<td>Continue the development of agricultural parks and other programs to assist small independent farmers in securing agricultural lands and loans.</td>
</tr>
<tr>
<td>9</td>
<td>Require agricultural uses in agricultural subdivisions and closely monitor the uses in these subdivisions.</td>
</tr>
<tr>
<td>10</td>
<td>Support the continuation of land currently in use for diversified agriculture.</td>
</tr>
<tr>
<td>E</td>
<td>Priority guidelines for water use and development:</td>
</tr>
<tr>
<td>1</td>
<td>Maintain and improve water conservation programs to reduce the overall water consumption rate.</td>
</tr>
<tr>
<td>2</td>
<td>Encourage the improvement of irrigation technology and promote the use of non-potable water for agricultural and landscaping purposes.</td>
</tr>
<tr>
<td>3</td>
<td>Increase the support for research and development of economically feasible alternative water sources.</td>
</tr>
<tr>
<td>4</td>
<td>Explore alternative funding sources and approaches to support future water development programs and water system improvements.</td>
</tr>
<tr>
<td>F</td>
<td>Priority guidelines for energy use and development:</td>
</tr>
<tr>
<td>1</td>
<td>Encourage the development, demonstration, and commercialization of renewable energy sources.</td>
</tr>
<tr>
<td>2</td>
<td>Initiate, maintain, and improve energy conservation programs aimed at reducing energy waste and increasing public awareness of the need to conserve energy.</td>
</tr>
<tr>
<td>3</td>
<td>Provide incentives to encourage the use of energy conserving technology in residential, industrial, and other buildings.</td>
</tr>
<tr>
<td>4</td>
<td>Encourage the development and use of energy conserving and cost-efficient transportation systems.</td>
</tr>
<tr>
<td>G</td>
<td>Priority guidelines to promote the development of the information industry:</td>
</tr>
<tr>
<td>1</td>
<td>Establish an information network that will serve as the catalyst for establishing a viable information industry in Hawai‘i.</td>
</tr>
<tr>
<td>2</td>
<td>Encourage the development of services such as financial data processing, products and services exchange, foreign language translations, telemarketing, teleconferencing, a twenty-four-hour international stock exchange, international banking, and a Pacific Rim management center.</td>
</tr>
<tr>
<td>3</td>
<td>Encourage the development of small businesses in the information field such as software development, the development of new information systems and peripherals, data conversion and data entry services, and home or cottage services such as computer programming, secretarial, and accounting services.</td>
</tr>
</tbody>
</table>
### Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(4) Encourage the development or expansion of educational and training opportunities for residents in the information and telecommunications fields.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(5) Encourage research activities, including legal research in the information and telecommunications fields.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(6) Support promotional activities to market Hawai‘i’s information industry services.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports the HRS objectives to diversify and improve the state economy by revitalizing and developing the local dairy industry in the State, providing more job opportunities for residents while also providing a clean facility that reuses waste, and promotes water and energy reuse and conservation.

### 226-104 Population Growth and Land Resources Priority Guidelines.

**A** Priority guidelines to effect desired statewide growth and distribution:

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Encourage planning and resource management to insure that population growth rates throughout the State are consistent with available and planned resource capacities and reflect the needs and desires of Hawai‘i’s people.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2) Manage a growth rate for Hawai‘i’s economy that will parallel future employment needs for Hawai‘i’s people.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3) Ensure that adequate support services and facilities are provided to accommodate the desired distribution of future growth throughout the State.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(4) Encourage major state and federal investments and services to promote economic development and private investment to the neighbor islands, as appropriate.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(5) Explore the possibility of making available urban land, low-interest loans, and housing subsidies to encourage the provision of housing to support selective economic and population growth on the neighbor islands.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(6) Seek federal funds and other funding sources outside the State for research, program development, and training to provide future employment opportunities on the neighbor islands.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(7) Support the development of high technology parks on the neighbor islands.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

**B** Priority guidelines for regional growth distribution and land resource utilization:

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Encourage urban growth primarily to existing urban areas where adequate public facilities are already available or can be provided with reasonable public expenditures, and away from areas where other important benefits are present, such as protection of important agricultural land or preservation of lifestyles.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2) Make available marginal or nonessential agricultural lands for appropriate urban uses while maintaining agricultural lands of importance in the agricultural district.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3) Restrict development when drafting of water would result in exceeding the sustainable yield or in significantly diminishing the recharge capacity of any groundwater area.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(4) Encourage restriction of new urban development in areas where water is insufficient from any source for both agricultural and domestic use.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(5) In order to preserve green belts, give priority to state capital-improvement funds which encourage location of urban development within existing urban areas except where compelling public interest dictates development of a noncontiguous new urban core.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(6) Seek participation from the private sector for the cost of building infrastructure and utilities, and maintaining open spaces.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(7) Pursue rehabilitation of appropriate urban areas.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(8) Support the redevelopment of Kaka‘ako into a viable residential, industrial, and commercial community.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(9) Direct future urban development away from critical environmental areas or impose mitigating measures so that negative impacts on the environment would be minimized.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(10) Identify critical environmental areas in Hawai‘i to include but not be limited to the following: watershed and recharge areas; wildlife habitats (on land and in the ocean); areas with endangered species of plants and wildlife; natural streams and water bodies; scenic and recreational shoreline resources; open space and natural areas; historic and cultural sites; areas particularly sensitive to reduction in water and air quality; and scenic resources.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(11) Identify all areas where priority should be given to preserving rural character and lifestyle.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>
### Table 5-2  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>12</strong></td>
<td>Utilize Hawai‘i’s limited land resources wisely, providing adequate land to accommodate projected population and economic growth needs while ensuring the protection of the environment and the availability of the shoreline, conservation lands, and other limited resources for future generations.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td><strong>13</strong></td>
<td>Protect and enhance Hawai‘i’s shoreline, open spaces, and scenic resources.</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms is an agricultural project in an agriculture district, with agriculturally zoned land, which supports the priority guidelines relating to land resources by keeping agricultural land in active agricultural use (as opposed to residential or resort development). In support of these HRS objectives, Hawai‘i Dairy Farms will finance the cost for building infrastructure and utilities with private funds. Hawai‘i Dairy Farms recognizes its environmental responsibility, and supports the promotion of sustainable business practices through its commitment with its sustainable dairy farm model.

---

**226-105 Crime and Criminal Justice Priority Guidelines.**

(A) Priority Guidelines in the Area of Crime and Criminal Justice:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>1</strong></td>
<td>Support law enforcement activities and other criminal justice efforts that are directed to provide a safer environment.</td>
<td>X</td>
</tr>
<tr>
<td><strong>2</strong></td>
<td>Target state and local resources on efforts to reduce the incidence of violent crime and on programs relating to the apprehension and prosecution of repeat offenders.</td>
<td>X</td>
</tr>
<tr>
<td><strong>3</strong></td>
<td>Support community and neighborhood program initiatives that enable residents to assist law enforcement agencies in preventing criminal activities.</td>
<td>X</td>
</tr>
<tr>
<td><strong>4</strong></td>
<td>Reduce overcrowding or substandard conditions in correctional facilities through a comprehensive approach among all criminal justice agencies which may include sentencing law revisions and use of alternative sanctions other than incarceration for persons who pose no danger to their community.</td>
<td>X</td>
</tr>
<tr>
<td><strong>5</strong></td>
<td>Provide a range of appropriate sanctions for juvenile offenders, including community-based programs and other alternative sanctions.</td>
<td>X</td>
</tr>
<tr>
<td><strong>6</strong></td>
<td>Increase public and private efforts to assist witnesses and victims of crimes and to minimize the costs of victimization.</td>
<td>X</td>
</tr>
</tbody>
</table>

**Discussion:** Policies related to public safety are primarily the responsibility of government agencies and are not directly applicable to the Proposed Project. However, Hawai‘i Dairy Farms will institute a program for the safety of its employees with security and emergency response plans, procedures, and training in-place.

---

**226-106 Affordable Housing Priority Guidelines.**

(A) Priority guidelines for the provision of affordable housing:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>1</strong></td>
<td>Seek to use marginal or nonessential agricultural land and public land to meet housing needs of low- and moderate-income and gap-group households.</td>
<td>X</td>
</tr>
<tr>
<td><strong>2</strong></td>
<td>Encourage the use of alternative construction and development methods as a means of reducing production costs.</td>
<td>X</td>
</tr>
<tr>
<td><strong>3</strong></td>
<td>Improve information and analysis relative to land availability and suitability for housing.</td>
<td>X</td>
</tr>
<tr>
<td><strong>4</strong></td>
<td>Create incentives for development which would increase home ownership and rental opportunities for Hawai‘i’s low- and moderate-income households, gap-group households, and residents with special needs.</td>
<td>X</td>
</tr>
<tr>
<td><strong>5</strong></td>
<td>Encourage continued support for government or private housing programs that provide low interest mortgages to Hawai‘i’s people for the purchase of initial owner-occupied housing.</td>
<td>X</td>
</tr>
<tr>
<td><strong>6</strong></td>
<td>Encourage public and private sector cooperation in the development of rental housing alternatives.</td>
<td>X</td>
</tr>
<tr>
<td><strong>7</strong></td>
<td>Encourage improved coordination between various agencies and levels of government to deal with housing policies and regulations.</td>
<td>X</td>
</tr>
<tr>
<td><strong>8</strong></td>
<td>Give higher priority to the provision of quality housing that is affordable for Hawai‘i’s residents and less priority to development of housing intended primarily for individuals outside of Hawai‘i.</td>
<td>X</td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports the Hawai‘i State Plan Priority Guideline Policy of affordable housing; however, this policy is directed toward government, and does not apply to the Proposed Project.

---

**226-107 Quality Education Priority Guidelines.**

(A) Priority guidelines to promote quality education:
**Table 5-2**  Hawai‘i State Plan, Hawai‘i Revised Statutes, Chapter 226  

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>Pursue effective programs which reflect the varied district, school, and student needs to strengthen basic skills achievement.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(2)</td>
<td>Continue emphasis on general education &quot;core&quot; requirements to provide common background to students and essential support to other university programs.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(3)</td>
<td>Initiate efforts to improve the quality of education by improving the capabilities of the education workforce.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(4)</td>
<td>Promote increased opportunities for greater autonomy and flexibility of educational institutions in their decision-making responsibilities.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(5)</td>

<tr>
<td>(b)</td>
<td>Statewide electronic mail.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>(c)</td>
<td>Access to the Internet.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports the Hawai‘i State Plan Priority Guideline Policy regarding quality education; however, this policy is directed primarily toward government, and does not apply to the Proposed Project beyond the opportunities the project provides through career development.

226-107 Sustainability Priority Guidelines.

<table>
<thead>
<tr>
<th>(A)</th>
<th>Priority guidelines to promote sustainability:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1)</td>
<td>Encourage balanced economic, social, community, and environmental priorities</td>
</tr>
<tr>
<td>(2)</td>
<td>Encourage planning that respects and promotes living within the natural resources and limits of the State.</td>
</tr>
<tr>
<td>(3)</td>
<td>Promote a diversified and dynamic economy.</td>
</tr>
<tr>
<td>(4)</td>
<td>Encourage respect for the host culture.</td>
</tr>
<tr>
<td>(5)</td>
<td>Promote decisions based on meeting the needs of the present without compromising the needs of future generations.</td>
</tr>
<tr>
<td>(6)</td>
<td>Consider the principles of the ahupua’a system.</td>
</tr>
<tr>
<td>(7)</td>
<td>Emphasize that everyone, including individuals, families, communities, businesses, and government, has the responsibility for achieving a sustainable Hawai‘i.</td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports the Hawai‘i State Plan Priority Guideline Policy regarding the promotion of sustainability through its project goals to establish a wastewater reuse, pasture-based dairy in Hawai‘i. HDF will utilize a sustainable, pasture-based rotational grazing system to produce fresh, locally-available milk for the State of Hawai‘i that reduces reliance on imported goods and diversifies the local economy.

226-109 Climate Change Adaptation Priority Guidelines.

<table>
<thead>
<tr>
<th>(A)</th>
<th>Priority guidelines to adapt to climate change:</th>

<td></td>
<td></td>
</tr>
<tr>
<td>(9) Use management and implementation approaches that encourage the continual collection, evaluation, and integration of new information and strategies into new and existing practices, policies, and plans.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(10) Encourage planning and management of the natural and built environments that effectively integrate climate change policy.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to prioritizing climate change impacts, they are not directly applicable to the Proposed Project.

## 5.4 HAWAI‘I STATE FUNCTIONAL PLANS

The State Functional Plans implement the goals, objectives, policies and priority guidelines of the Hawai‘i State Plan. The Functional Plans provide the connection between State programs and State policy. Twelve functional plans have been adopted by the State Legislature, including in the areas of agriculture, conservation lands, education, energy, health, higher education, historic preservation, housing, recreation, tourism, transportation and Water Resources. These plans contain multiple objectives and specific action items to be implemented by specific state or county agencies in partnership with named entities such as academic institutions and/or community organizations. The dairy supports the following objectives of the Agriculture Functional Plan:

B. Achievement of an orderly agricultural marketing system through product promotion and industry organization.

E. Achievement of adequate capital, and knowledge of its proper management, for agricultural development

H. Achievement of productive agricultural use of lands most suitable and needed for agriculture

J. Achievement of maximum degree of public understanding and support of agriculture in Hawai‘i.

M. Achievement of adequate support services and infrastructure to meet agricultural needs.

**Discussion:** Hawai‘i Dairy Farms will promote the Functional Plan’s goal of self-sustainability in Hawai‘i, and provide positive marketing for sustainable, locally produced agriculture products that increase public understanding and support of the agriculture industry in the State.

Act 183 of 2005 was enacted to establish Important Agricultural Lands in HRS Chapter 205, Section 205-42. Hawai‘i Dairy Farms will be one of the first commercial food production operations to establish operations using IAL on Kaua‘i.
5.5 HAWAIʻI 2050 SUSTAINABILITY PLAN

The Hawaiʻi 2050 Sustainability Plan was developed in 2008 by the State of Hawaiʻi Sustainability Task Force as follow up to the State Plan and as a long-term strategy in respect to the culture, character, beauty, and history of Hawaiʻi’s island communities; balance among economic, community, and environmental priorities; and an effort to meet the needs of the present without compromising the ability to future generations to meet their own needs.

The 2050 Plan includes five goals toward a more sustainable Hawaiʻi, accompanied by strategic actions for implementation and evaluation. The goals and strategic actions that relate to the Hawaiʻi Dairy Farms project are as follows:

Goal One: Living sustainably is part of our daily practice in Hawaiʻi:

Strategic Actions:

- Develop a sustainability ethic.
- Conduct ongoing forums and cross-sector dialogue to promote collaboration and progress on achieving Hawaiʻi’s sustainability goals.

Discussion: In producing more local milk for Hawaiʻi residents, the project will promote more sustainable consumption practices. In the long-term this will not only promote the ethic of “buying local,” but will also help to alleviate the current amount of fossil fuels consumed to import milk from mainland farms. The pasture-based model used at the dairy, wherein 100 percent of the cows’ manure remains on the farm to enrich the land as fertilizer, will also set the precedent for more sustainable dairy methods in Hawaiʻi, reducing reliance on imports and renewing local soils for future generations.

Goal Two: Our diversified and globally competitive economy enables us to meaningfully live, work, and play in Hawaiʻi.

Strategic Actions:

- Develop a more diverse and resilient economy.

Discussion: Hawaiʻi Dairy Farms aims to further expand Hawaiʻi’s dairy industry by potentially doubling the current production of local milk. In addition to about 10-15 operational jobs, the project will create local supplier opportunities to support the farm operations on Kauaʻi, as well as provide herd management and opportunities for local ranchers. The project also aims to work with Kōloa Elementary School, 4-H and Future Farmers of America to educate local youth about Science Technology Engineering and Mathematics-based agricultural jobs and animal husbandry. Table 5-3 provides an evaluation summary of the project's compatibility with Hawaiʻi 2050’s goals and strategic actions.
Table 5-3  Hawai’i 2050 Sustainability Plan (SB2532 HD1, 2010 Legislative Session)

<table>
<thead>
<tr>
<th>The State’s first definition of sustainability:</th>
<th>( S )</th>
<th>( N/S )</th>
<th>( N/A )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( A. ) Hawai’i that achieves the following:</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2.0 Respects the culture, character, beauty and history of our state’s island communities</td>
<td>( S )</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3.0 Strikes a balance among economic, social and community, and environmental priorities</td>
<td>( S )</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4.0 Meets the needs of the present without compromising the ability of future generations to meet their own needs</td>
<td>( S )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

GOAL 1: Living sustainably is part of our daily practice in Hawai’i.

Develop a sustainability ethic.

- Integrate sustainability principles and practices into public and private school curricula. \( X \)
- Develop a statewide marketing and public awareness campaign on sustainability principles and practices. \( X \)
- Conduct ongoing forums and cross-sector dialogue to promote collaboration and progress on achieving Hawai’i’s sustainability goals. \( X \)
- Continually monitor trends and conditions in Hawai’i’s economy, society and natural systems. \( X \)

Discussion: Hawai’i Dairy Farms was founded as a sustainable dairy facility, with sustainable practices such as utilizing nutrients in manure to grow the grass as a primary food source for the dairy cows, and a pasture rotational-grazing system to distribute nutrients through the fields.

GOAL 2: Our diversified and globally competitive economy enables us to meaningfully live, work and play in Hawai’i.

Develop a more diverse and resilient economy.

- Provide incentives that foster sustainability-related industries, which include, but aren’t limited to renewable energy, innovation and science-based industries, and environmental technologies. \( X \)
- Increase production and consumption of local foods and products, particularly agricultural products. \( X \)
- Increase commercialization and technology transfer between post-secondary institutions and the business sector. \( X \)

Support the building blocks for economic stability and sustainability.

- Recognize and support established industries such as the visitor industry, military, construction and agriculture as strong components of the Hawai’i economy. \( X \)
- Provide incentives for industries to operate in more sustainable ways. \( X \)
- Attract local and outside capital and investments in Hawai’i’s economic activities. \( X \)
- Reduce regulations and lower the cost of running a business. \( X \)

Increase the competitiveness of Hawai’i’s workforce.

- Invest in and improve our public education system to provide for a skilled workforce. \( X \)
- Create incentives and opportunities for workforce skills upgrade training programs, including the availability of remedial education programs. \( X \)
- Increase student enrollment in post-secondary educational programs. \( X \)
- Adopt living wage guidelines and measurements. \( X \)
- Identify, prioritize and fund infrastructure “crisis points” that need fixing. \( X \)

Discussion: A goal of Hawai’i Dairy Farms is to reinvestigate the island’s dairy industry, allowing for more locally produced food creating local jobs in traditional agriculture product industries, increasing the production of local goods, and decreasing our reliance on mainland and international imports. Hawai’i Dairy Farms also aims to work with local educational institutions to help provide agricultural educational opportunities for future generations.

GOAL 3: Our natural resources are responsibly and respectfully used, replenished and preserved for future generations.

Reduce reliance on fossil (carbon-based) fuels.

- Expand renewable energy opportunities. \( X \)
- Increase energy efficiency in private and public buildings, including retrofitting existing buildings. \( X \)
- Improve energy efficiencies and options in transportation. \( X \)
- Encourage the production and use of locally produced bio-fuels. \( X \)
- Adopt building codes that encourage “green building” technology. \( X \)
- Encourage all government agencies to adopt sustainable practices, including purchasing hybrid cars, buying biodegradable products, and mandating recycling. \( X \)

Conserve water and ensure adequate water supply.

- Reduce water consumption by means of education and incentives. \( X \)
Table 5-3  Hawai‘i 2050 Sustainability Plan (SB2532 HD1, 2010 Legislative Session)

<table>
<thead>
<tr>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encourage greater production and use of recycled water.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Continually review water-conserving technologies for possible incorporation in county building codes.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Encourage price structures for water use that furthers conservation.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Require water conservation plans from large private users.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Increase recycling, reuse and waste reduction strategies.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Provide greater protection for air, and land-, fresh water- and ocean-based habitats.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Strengthen enforcement of habitat management.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Encourage “smart growth” concepts in land use and community planning.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Conserve agricultural, open space and conservation lands and resources.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Improve management of protected watersheds areas.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Incorporate the values and philosophy of the ahupua’a resource management system, as appropriate.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Establish funding for invasive species control and native ecosystems protection.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Create compact patterns of urban development.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Research and strengthen management initiatives to respond to rising sea levels, coastal hazards, erosion and other natural hazards.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Develop a comprehensive environmental mapping and measurement system to evaluate the overall health and status of Hawai‘i’s natural ecosystems.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms is dedicated to sustainable business operations, as the core operations of the project are based upon creating a sustainable dairy operation that conserves through water reuse that encourages reduction in water use. Using agriculturally zoned land for an agricultural use allows for the conservation of open space and rural land without moving towards larger patterns of urban development.

GOAL 4: Our community is strong, healthy, vibrant and nurturing, providing safety nets for those in need.

Strength social safety nets.

- Increase affordable housing opportunities for households up to 140% of median income. | X |
- Ensure access to affordable health care for all residents. | X |
- Reduce crime and violence. | X |
- Provide access to elderly housing, care-giving and other long-term care services. | X |
- Invest in greater prevention and treatment of those suffering from substance abuse and mental illness. | X |
- Increase awareness of and competency in financial literacy and asset building. | X |
- Strengthen the nonprofit sector, philanthropy and volunteerism. | X |
- Ensure that persons with disabilities are afforded equal opportunity to participate & excel in all aspects of community life. | X |
- Provide after-school and extra-curricular programs to enable Hawai‘i’s youth to broaden their life experiences. | X |

**Improve public transportation infrastructure and alternatives.**

- Reduce traffic congestion. | X |
- Encourage and provide incentives for telecommuting. | X |
- Increase and improve bicycle and pedestrian facilities, including multi-use pathways. | X |

**Strengthen public education.**

- Support parenting, educational and financial literacy initiatives that span early childhood through lifelong learning. | X |
- Increase high school graduation rates. | X |
- Strengthen career pathways for technical and trade schools that enhance Hawai‘i’s workforce. | X |
- Support post-secondary and distance learning programs that broaden personal and professional learning opportunities. | X |
- Provide access to diverse recreational facilities and opportunities. | X |

**Discussion:** While Hawai‘i Dairy Farms supports the State’s policies related to improving Hawai‘i’s social and economic benefit programs for those in need, they are not directly applicable to the Proposed Project.

GOAL 5: Our Kanaka Maoli and island cultures and values are thriving and perpetuated.
Table 5-3  Hawai‘i 2050 Sustainability Plan (SB2532 HD1, 2010 Legislative Session)

<table>
<thead>
<tr>
<th>Honor Kanaka Maoli culture and heritage.</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure the existence of and support for public and private entities that further the betterment of Kanaka Maoli.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Increase fluency in Kanaka Maoli language. It is one of the official languages of Hawai‘i.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sponsor cross-sector dialogue on Kanaka Maoli culture and island values.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Protect Kanaka Maoli intellectual property and related traditional knowledge.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Provide Kanaka Maoli cultural education for residents, visitors and the general public.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Celebrate our cultural diversity and island way of life.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Identify and protect the places, features and sacred spaces that give Hawai‘i its unique character and cultural significance.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Increase the number of educators who teach cultural and historic education.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Enable Kanaka Maoli and others to pursue traditional Kanaka Maoli lifestyles and practices.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Provide Kanaka Maoli mentors with opportunities to pass on Hawaiian culture and knowledge to the next generation of Kanaka Maoli and others. The power of wisdom comes from communication.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Perpetuate Kanaka Maoli food production associated with land and ocean traditions and practices.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Provide support for subsistence-based businesses and economies.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Discussion: Hawai‘i Dairy Farms supports and honors the state’s Kanaka Maoli heritage through identifying all historical and cultural resources found in and around the project site area.

5.6  HAWAI‘I STATE LAND USE DISTRICT BOUNDARIES

The State of Hawai‘i Land Use Law regulates the classification and uses of lands in the State to accommodate growth and development, and to retain the natural resources in the area. All State lands are classified by the State Land Use Commission as Urban, Rural, Agricultural, or Conservation, with consideration given to the General Plan of the County.

Table 5-4 provides an evaluation and summary of the project’s compatibility with Hawai‘i State Land Use District Boundaries.

Table 5-4  Hawai‘i State Land Use District Boundaries

<table>
<thead>
<tr>
<th>Chapter 205-2 (d) HRS, states that Agricultural districts shall include:</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Activities or uses as characterized by the cultivation of crops, crops for bioenergy, orchards, forage, and forestry;</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2) Farming activities or uses related to animal husbandry and game and fish propagation...</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Discussion: Hawai‘i Dairy Farms was founded with a core purpose of developing dairy as a farming activity to produce milk in an economically and environmentally sustainable way for the island of Kaua‘i and the State of Hawai‘i as a whole.
5.7 STATE OF HAWAIʻI DEPARTMENT OF AGRICULTURE

The State Department of Agricultural (DOA) is the lead state agency supporting agriculture within the State of Hawaiʻi. Pursuant to HRS §26-16(c), the DOA is tasked with:

- promoting the conservation, development, and utilization of agricultural resources in the State;
- assisting the farmers of the State and any others engaged in agriculture by research projects, dissemination of information, crop and livestock reporting service, market news service, and any other means of improving the well-being of those engaged in agriculture and increasing the productivity of the lands;
- administering the programs of the State relating to animal husbandry, entomology, farm credit, development and promotion of agricultural products and markets, and
- establishing and enforcing rules on the grading and labeling of agricultural products; and
- administering the aquaculture program under HRS §141-2.5.

Additional duties of the DOA include the formulation and implementation of general and special plans, administering HRS Chapter 166 relating to the agricultural park program, and also administering HRS Chapter 167 relating to the irrigation water development program.

**Discussion:** Hawaiʻi Dairy Farms supports the Department of Agriculture’s goals of promoting the conservation and utilization of agricultural resources in the State, improving the productivity of the Māhāʻulepū farm lands, and promoting dairy products and the dairy industry as a whole.

5.8 STATE OF HAWAIʻI WATER POLICIES

Table 5-5 provides an evaluation and summary of the project’s compatibility with State of Hawaiʻi Water Policies.

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Class II: It is the objective of this class of waters to be protected for their uses including fish, shellfish, and wildlife propagation, and for recreational purposes. The uses to be protected in this class are all uses compatible with the protection and propagation of fish, shellfish, and wildlife, and with recreation. Any action which may permanently or completely modify, alter, consume, or degrade marine bottoms, such as structural flood control channelization, (dams); landfill and reclamation; navigational structures (harbors, ramps); structural shore protection (seawalls, revetments); and wastewater effluent outfall structures may be allowed upon securing approval in writing from the director, considering the environmental impact and the public interest.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Discussion: During the rainfall and runoff events, the dairy’s nutrient contributions would be further diluted by additional volume of surface runoff and ditch flows. The terminus of Waiopili Ditch is a deep, muddy basin that joins the ocean through a channel cut through beach sand. Water chemistry measurements identified mixing of ditch water occurring rapidly and within a short distance of the shoreline. There will be no substantial effects to marine water quality from the HDF dairy.

5.9  HAWAI‘I COASTAL ZONE MANAGEMENT PROGRAM

The Hawai‘i State Coastal Zone Management Program (CZMP) was enacted by Hawai‘i Revised Statutes 205A – Hawai‘i Coastal Zone Management Act (CZMA), as a requirement of the National Coastal Zone Management Program of 1972. The program provides policy guidance for development activities as they relate to coastal land and water resources. The entire land area of the State of Hawai‘i has been determined to be within the Coastal Zone as defined by the CZMA. The primary objectives and policies of the CZM program that apply to the project include the following:

Table 5-6 discusses how the project addresses the applicable objectives and policies of the CZMA

**Discussion:** The site is outside the SMA as delineated by the County of Kaua‘i. An archaeological survey was performed for the project area in compliance with Chapter 6E of the Hawai‘i Revised Statutes, supporting the CZMP’s objective to protect and preserve historic resources. Water quality management practices are promoted by Hawai‘i Dairy Farms through soils conservation, nutrient management, and water monitoring.
COUNTY OF KAUAʻI

5.10 COUNTY OF KAUAʻI GENERAL PLAN

Fulfilling State law mandates and the Charter of the County of Kauaʻi, Kauaʻi’s General Plan provides guidance for the land use regulations, designations, and character of new development and facilities, and planning for County and State facilities and services. The objectives and policies pertaining to the project are as follows:

Table 5-7 discusses how the Proposed Project addresses the applicable objectives and policies of the County of Kauaʻi.

</tr>
<tr>
<td><strong>2.2 Vision for Kauaʻi 2020</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Caring for Land, Waters and Culture - Through planning and land use regulations, the County of Kauaʻi carefully safeguards its heritage of ecologically- and culturally-important lands, waters and sites.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B. A Strong, Diverse Economy - Preservation of Kauaʻi’s special environment and culture, Expanding local markets for local products and reducing imports, resulting in more money remaining in the local economy, More jobs with higher wages, reflecting a variety of profitable businesses seeking qualified employees, A strong education system which prepares Kauaʻi’s children, teens, college students and adults to work in the diversified economy.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Table 5-7  (Elements of the) County of Kauaʻi General Plan

<table>
<thead>
<tr>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>C. Agriculture and Aquaculture - Agricultural enterprise helps to keep Kauaʻi green and economically healthy through a variety of crops sold locally and exported. Kauaʻi residents support the farmers by buying locally-grown fruits, vegetables, taro and other basic foods. The market for organically-grown crops is increasing. In place of imported meat, Kauaʻi residents enjoy grass-fed beef from cattle raised in Kauaʻi’s pasturelands and prepared in local processing facilities. Kauaʻi now produces 50 percent of its own food, reducing food imports and keeping more money within the community.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D. High Technology - Kauaʻi’s high quality of life attracts knowledge-based businesses working in high technology enterprises. These businesses are linked with the college and the high schools, providing internship and training opportunities for Kauaʻi students. After attending college, students are able to find well-paying high-technology jobs on Kauaʻi. All parts of the island are served with fiber optic cable, allowing high-speed communications.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E. Business Health and Diversity - Small business is the foundation of Kauaʻi’s economy, employing the largest percentage of the population. There is a wide variety of business opportunities, including outdoor recreation, with environmental tourism and sports facilities; support facilities for movies and television; healing, health care, wellness and retreat centers both in alternative health and traditional medicine; assisted living facilities for retirees; innovative power generation; light manufacturing and food processing; authentic Hawaiʻian cultural businesses and cultural education; and home-based cottage businesses networked with electronic marketing.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>F. Opportunities and Prosperity - An attitude of government and community responsibility translates into effective programs that improve employment, housing and educational opportunities for Kauaʻi’s less advantaged citizens. The County, through its Offices of Community Assistance and its Office of Economic Development, works with federal and State programs, business, and the non-profit sector to develop employment opportunities for Kauaʻi’s less advantaged citizens.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>G. A Vibrant, Stable Visitor Industry - The people of Kauaʻi appreciate the many benefits the visitor industry brings to the island. They, in turn, give the gift of aloha, encouraging guests to return and to stay longer. Residents support the industry’s role in strengthening the economy, preserving the culture, and protecting the environment. In general, residents agree that a healthy, well-managed visitor industry is a major contributor to the quality of life on Kauaʻi.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>H. A Rural Place - The Island of Kauaʻi is a rural place. “Rural” describes many aspects of Kauaʻi that people value: green, open lands; raising crops for food; small communities where people know each other; the absence of city noise and lights; not feeling crowded. Kauaʻi’s rural character lies not just in those lands classified as “rural” or “agriculture”. Rather, it lies in how the whole island fits together – the relationship of urban settlements to open lands, how the built-up areas relate to the natural features of the landscape, how people get around.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>I. Urban Areas - Expansion of urban areas, particularly new shopping centers and other retail developments which attract a large amount of vehicular traffic, are controlled to avoid urban sprawl and strip development along the highway. Town edges are clearly defined, and scenic corridors are maintained along the highways and major roads between towns.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>J. Agricultural Lands - Agricultural areas are characterized by broad expanses of open space – a mixture of pastures and large-scale agricultural plantations, small farms, and clusters of residences. Land use regulations specifically provide for agricultural communities, with design standards for subdivisions to preserve open space and landscape features. Land use regulations and tax incentives are structured to promote legitimate agriculture enterprises and to increase opportunities for small farmers.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>K. Rural Roads and Highways - Our rural roads retain their “country character.” They are limited to two lanes, bordered with natural vegetation. Speed limits are kept low for safety reasons. The right-of-way may include grassed drainage swales, but there are no sidewalks, curbs or gutters. One-lane bridges have been preserved in the Hanalei-Hāʻena region, both for their historic value and because they slow traffic. Some historic bridges have also been retained in other communities, where traffic volumes are low. Traffic signage is minimal. Safe bicycle and pedestrian routes are provided.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>L. Coastal Development - In new resort developments and subdivisions along the coast, buildings are setback from the shoreline in order to serve the following purposes: to avoid potential tsunami or hurricane damage; to preserve dunes, coastal bluffs, and other important physical features; to allow space for coastal erosion, so that there is no need for a seawall and dry beach area is preserved; and to preserve views. Setbacks are based on historic coastal erosion trends, damages during past hurricane and tsunami events, the nature of the topography, and scenic values.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Table 5-7 (Elements of the) County of Kaua‘i General Plan

<table>
<thead>
<tr>
<th>Element</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>M. Parks and Access to Mountains and Ocean - Visitors share Kaua‘i’s parks, natural areas, and waters in harmony with residents and the environment. The County is implementing a long-range park master plan which is regularly updated and sets priorities for park operations and capital improvements. Each of the major State parks also has an up-to-date master plan, prepared in collaboration with the community.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>N. Towns and Commercial Development - Under the General Plan, new commercial development has been focused on meeting community shopping needs while supporting local small businesses and older business areas. With strategic decisions about highway development and new commercial zoning, the County has avoided strip development and urban sprawl.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>O. Public Facilities and Services - The County of Kaua‘i leads the state in having the lowest per capita rate of waste generation and the highest rate of reuse and recycling. The County is a leader in adopting and applying “best management practices” for land use, site development and construction. Because of careful management and regulation, Kaua‘i is free of concrete-lined drainage channels.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>P. Electrical Power - Residents of Kaua‘i County are dedicated to the efficient use of energy and to minimizing the deleterious health, safety and aesthetic impacts of power installations. In particular, the county seeks opportunities and economic methods to render facilities (including transmission lines) inconspicuous in order to enhance a “parklike” appearance throughout the island.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>Q. Airports and Harbors - Līhu‘e Airport is continually upgraded in order to support the desired level of visitor industry development and the export of agricultural products to the mainland. The commercial harbors at Nāwiliwili and Port Allen are continually upgraded to accommodate the latest cargo shipping systems.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>R. Community Participation - Kaua‘i citizens enjoy a rich civic life because of their individual and collective commitment to each other’s well-being and respect for the place. Key values are trust, mutual respect, and a determination to maintain open dialogue. Citizens of all ages, ethnic heritages, and income levels actively participate in community life at many levels and through a variety of activities. Community organizations inform citizens and mobilize them to participate in dialogue. Government agencies and public officials provide fair and equal access to information and assistance for all citizens; give adequate notice of proposed actions; conduct open meetings; and make public records accessible.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

Discussion: Hawai‘i Dairy Farms embodies the Kaua‘i Vision for 2020 through preserving Kaua‘i’s rural character through non cluster non-urban development, while keeping Kaua‘i green and economically healthy through a sustainable and progressive dairy model that expands local markets and reduces imports.

3.0 Caring for Land, Water and Culture

3.1.1 Heritage Resources Maps

<table>
<thead>
<tr>
<th>Element</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. The Heritage Resources Map depicts natural, cultural and scenic resources that are important to the County of Kaua‘i and that are intended to be conserved. The mapping of important landforms, streams and other physical elements represents the general location of the resource.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

3.1.2 State Responsibility

<table>
<thead>
<tr>
<th>Element</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. The State of Hawai‘i plays the preeminent role in managing natural resources. The Department of Land and Natural Resources (DLNR) controls and manages the forest reserves, natural area reserves, and state parks. In addition to their value as forested watershed, these lands also harbor rare and endangered plant and animal species and areas where the native ecosystem remains relatively intact. In regulating land use on urban and agricultural lands, the County seeks expert advice from DLNR on aquatic and marine resources, streams, rare and endangered species, and historic and archaeological resources.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

3.2 Scenic Views

<table>
<thead>
<tr>
<th>Element</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. In developing public facilities and in administering land use regulations, the County shall seek to preserve scenic resources and public views. Public views are those from a public place, such as a park, highway, or along the shoreline. In maintaining scenic resources, Preserve the scenic qualities of mountains, hills and other elevated landforms, qualities such as the silhouette against the horizon and the mass and shape of the landform.</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

3.3 Historic and Archaeological Resources

3.3.1 Overview and 3.3.2 Policy

<table>
<thead>
<tr>
<th>Element</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. As stated in the Vision, the people of Kaua‘i value their cultural and historic places and traditions. Many individuals and organizations care for these resources on a daily basis. Here are some examples: taking care of a heiau; organizing a Bon dance; cultivating taro in ancient taro lo‘i; interpreting historic sites to visitors;</td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>
Table 5-7  (Elements of the) County of Kauaʻi General Plan

<table>
<thead>
<tr>
<th>S = Supportive, N/S = Not Supportive, N/A = Not Applicable</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>restoring historic buildings; attending an exhibit of Kauaʻi artists at the Kauaʻi Museum. Historic and cultural resources help to give Kauaʻi its unique identity – to establish a “sense of place.” Preserve important archaeological and historic sites and provide: (1) a buffer area between the site and adjacent uses; and (2) public pedestrian access, as appropriate to the site.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

3.4 Watersheds, Streams and Water Quality

A. As stated in the Vision, the modern concept of watershed management mirrors the Native Hawaiʻian land use principles and practices under the ahupuaʻa land divisions. Like the modern concept of “watershed,” the ahupuaʻa recognizes the integral connection among land-based, stream-based, and ocean-based resources and activities. X

B. Watersheds are affected by natural events and human activities that cause changes in land and in the flow of water from the high mountains to the ocean. Current Federal and State clean water programs are targeting “nonpoint source pollution control,” with specific emphasis on protecting coastal waters from polluted runoff. County agencies fulfill particular functions in a network of regulations and agencies that control polluted runoff X

3.5 Coastal Lands

A. As mandated under the State CZM Act, the County has delineated the boundaries of the coastal Special Management Area on Kauaʻi and has adopted regulations to manage development within the SMA. The SMA regulations have been effective in mitigating the effects of new development, particularly in preserving natural and cultural resources and providing permanent public access to the beach. The SMA regulations, however, do not supersede zoning; the SMA regulations state that development must be “consistent” with the General Plan and zoning. Since SMA permits must be consistent with zoning, it is important that coastal lands be zoned based on a policy of preserving natural, cultural and scenic resources and preventing hazards to structures and the coastal environment. X

3.6 Native Hawaiian Rights

A. Under the State Constitution and the County Charter, the County of Kauaʻi is empowered to promote the health, safety and welfare of all inhabitants without discrimination as to ethnic origin. As part of carrying out its responsibilities under the Constitution and the Charter, the County recognizes the rights of native Hawaiians and the laws concerning lands and waters that have been established through the State Constitution, State and Federal laws, and State and Federal court decisions. No County ordinance or rule shall modify or diminish these rights. X

Discussion: Hawaiʻi Dairy Farms facilities are expected to have minimal to no impact on views of the Puʻu Hunihuni crater, views from the Ala Kinoiki Road corridor, or the views of the Haupu Mountains surrounding the project. There are no public scenic views or lookouts that would be affected by this project. Construction of the Hawaiʻi Dairy Farms and associated facility improvements is expected to have minimal effects on the existing groundwater systems and local watersheds. The project area is not a source of groundwater recharge, such as a forest reserve or conservation area.

4.0 Developing Jobs and Businesses

4.1 Diversifying the Economy

A. Diversifying the economy is a major theme of Kauaʻi Vision 2020 (Chapter 2). The objective is to strengthen various sectors of Kauaʻi’s economy, so that Kauaʻi is less dependent on a single industry – i.e., the visitor industry. Through the Kauaʻi General Plan Update process, the Citizens Advisory Committee (CAC) has identified three developing industries as having the greatest promise for the future: agriculture, aquaculture, and high technology. These are addressed in Sections 4.3 and 4.4 below (in this plan, aquaculture is discussed as a subset of agriculture). X

4.2 Visitor Industry

A. The visitor industry is the most significant economic force on Kauaʻi, as it is in the state as a whole. It is estimated that about 40 percent of Kauaʻi’s jobs are dependent on the visitor industry. Therefore, the economy of Kauaʻi is to a large extent determined by the number of visitors drawn to the island, how long they stay, and how much they spend. Given the existing supply of Resort-designated land, there is no cause to make major redesignations through the General Plan Update. The addition of the two West Side sites provides a potential for visitor industry development not previously available in that region. X
### Table 5-7 (Elements of the) County of Kaua‘i General Plan

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>4.3 Agriculture</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Diversified agriculture, defined as products other than sugar and pineapple, is an industry that has strong potential to be a major force in the pursuit of the 2020 Vision for economic diversification. It is a particularly important time to encourage further development of the industry since the closure of Amfac’s Līhu’e and Kekaha sugar plantations is not a matter of “if” but a matter of “when”. Further development of this industry is highly desirable because it keeps valuable agricultural lands in productive use. It also has the added benefit of preserving rural lands from development.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.4 High Technology</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Further development of the island’s high technology sector would not only create new jobs, but would also provide Kaua‘i residents with, on average, higher paying jobs. Kaua‘i’s high cost of living and dependence on the relatively low-paying service sector, increases the attractiveness of developing a strong high technology industry.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.5 Supporting Businesses and Jobs for Kaua‘i Residents</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Support and encourage the development of a wide range of small businesses, including home-based businesses.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B. Eliminate unnecessary land use and other regulations, clarify regulatory requirements, and reduce the time for processing permit applications wherever possible.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C. Support small business by providing needed infrastructure to towns and urban centers.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D. Develop and support business and technical assistance programs.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E. Strengthen the public education system in order to equip Kaua‘i’s children, teens, college students, and adults with the knowledge and skills needed to obtain a wellpaying job or start a business.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>F. Work with employers to provide career opportunities and training for local youth. Seek commitments from new or expanding businesses that they will actively recruit and train Kaua‘i residents for new jobs.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.6 Land Supply for Commercial &amp; Industrial Uses</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. The County supports commercial and industrial development on appropriately zoned lands by providing the necessary infrastructure and services. Develop vacant lands with existing commercial and industrial zoning, to the extent feasible, before approving new commercial and industrial zoning.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B. Concentrate commercial and industrial development, particularly new shopping centers which attract a large amount of vehicular traffic, in Kaua‘i’s major towns and job centers in order to minimize highway traffic and avoid urban sprawl and strip development. Concentrate commercial development in Līhu’e, other urban centers, and in town centers. The County shall strive for a balance between meeting community shopping needs with new commercial development and supporting local small businesses in older business areas.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.7 Airports</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. The State Department of Transportation, Airports Division, operates two facilities on Kaua‘i: Līhu’e Airport, the primary air terminal for the island; and Pt. Allen Airport, a general aviation airport with minimal facilities. Policies are to support improvements to Līhu’e Airport as necessary to provide for the desired level of visitor industry development and the export of agricultural products to the mainland and to support centralization of State-owned helicopter facilities and operations at Līhu’e Airport.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.8 Commercial Harbors</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Kaua‘i’s two commercial harbors, Nāwiliwili Harbor and Port Allen, are owned by the State of Hawai‘i and operated by the State Department of Transportation (DOT), Harbors Division. Policies are to develop capital improvements to Nāwiliwili Harbor to support the future needs of cruise ships and cargo vessels, develop ground transportation facilities, pedestrian circulation improvements, and terminal facilities at Nāwiliwili Harbor that will accommodate 2,000-passenger cruise ships, develop shuttle and other transportation improvements to move people out of the Nāwiliwili Harbor area to various recreation, shopping and cultural attractions, and to integrate planning for commercial facilities and Nāwiliwili Beach Park with the harbor master plan.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>4.9 Harbor Facilities</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Support improvements to Kīkīaola Harbor, in order to serve local fishing and recreation needs, to develop ocean-oriented businesses, and to serve as a cruise ship drop-off site. Encourage the development of parking and other facilities to expand the capacity of Port Allen Harbor and provide improved service. Support facilities expansion at Kukui‘ula Small Boat Harbor.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

</tr>
</thead>
</table>

Discussion: Agriculture is one of the three developing industries identified by the CAC as having the greatest promise for future diversification of the Kaua‘i economy. Hawai‘i Dairy Farms will keep valuable agricultural lands in productive use, and preserve the rural qualities of the region from undesirable urban development.

5.0 Preserving Kaua‘i’s Rural Character

5.1.1  Basic Policy

A. Enhance Urban Centers and Towns and maintain their identity by defining the Town Center and the edges of each Town. Concentrate shopping and other commercial uses in Town Centers. Encourage residential development within Urban and Town Centers and in Residential Communities contiguous to them. X

B. Promote compact urban settlements in order to limit public service costs and to preserve open space. X

C. Define and conserve Scenic Roadway Corridors along the roadways that connect Towns, Resort areas, and Residential Communities. These corridors are intended to conserve the open space between towns and to prevent sprawl and commercial strip development. X

5.2 Agricultural Lands

A. Lands included within the Agriculture designation shall be predominantly used for or held in reserve to be used in the future for agricultural activities. These activities include the breeding, planting, nourishing and caring for, gathering, and processing of any animal or plant organism, including aquatic animals and plants, for the purpose of producing food or material for non-food products; the commercial growing of flowers or other ornamental plants; the commercial growing of forest products; and the commercial breeding and caring for domestic animals and pets. X

B. The primary intent of the Agriculture designation is to conserve land and water resources in order to:
   (1) insure an excellent resource base for existing and potential agricultural uses;
   (2) assure a sufficient supply of land available for sale or lease at a cost that is economically feasible for agricultural enterprise; and
   (3) promote and preserve open agricultural lands as a key element of Kaua‘i’s rural character and lifestyle, essential to its image as “The Garden Island” and to the continued viability and development of Kaua‘i’s visitor industry. X

C. In administering zoning and subdivision regulations, the County shall seek to preserve important agricultural lands. Important agricultural lands include those designated “A” or “B” by the Land Study Bureau evaluation or “Prime” or “Unique” by the Agricultural Lands of Importance State of Hawai‘i evaluation; provided that these ratings shall be superseded at such time as the State of Hawai‘i officially maps and designates Important Agricultural Lands, as mandated in the State Constitution. X

D. Lands designated Agriculture shall include: important agricultural lands; lands in active agricultural use; lands with potential for agriculture, silviculture or aquaculture; and other lands not suited for urban development because of location, topography, economy of public services, or other purpose related to general health, safety and welfare. X

E. The secondary intent of the Agriculture designation is to provide an opportunity for Kaua‘i citizens to reside in an agricultural community. An “agricultural community” is an area that has both agricultural uses and residences. Typically, an agricultural community is established through subdivision of land and provision of roads and potable water service. Agricultural communities are generally located in outlying areas, do not have convenient access to County facilities, and may not receive the full range or highest level of County services such as are available to residential communities, towns, and urban centers. X

F. The primary intent of the Agriculture designation shall take precedence over the secondary intent. X

G. To implement the Agriculture designation, specific controls on the subdivision and alteration of designated lands shall be formulated to prevent the dissipation of agricultural potential, the loss of rural character, and the dispersal of residential and other urban uses. X

H. The following principles shall be applied in the development of an agricultural community:
   (1) maintain irrigation works and easements where feasible and beneficial to existing or potential agricultural uses within the site or downstream; and
   (2) preserve wetlands and streams and provide a riparian buffer area to prevent land disturbance and to filter runoff. X
### Table 5-7  (Elements of the) County of Kaua‘i General Plan

<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>5.3 Open Lands</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| A. The intent of the Open designation is to preserve, maintain or improve the natural characteristics of non-urban land and water areas that: &nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&n

| **5.4 Urban Land Uses** |   |     |     |
| A. One of the key policies in the Framework for preserving Kaua‘i’s rural character is to promote growth and development in compact urban areas. Urban lands comprise only four to five percent of Kaua‘i’s land area, leaving 55 percent in conservation and 40 percent in agriculture. This section sets policy for the following urban land use designations: Urban Center, Resort, Residential Community, Transportation, Military and Parks. | X |

| **5.5 Scenic Roadway Corridors** |   |     |     |
| A. The purpose of designating Scenic Roadway Corridors is to conserve open space, scenic features, and views within and along Kaua‘i’s most heavily-traveled routes. The policy of conservation recognizes the vital function of these roadways in meeting the public need for transportation. It also recognizes the legitimate desire of private landowners to make economic use of their lands. The intent of this policy is to establish basic principles for roadway design and land use within these scenic corridors and to provide a basis for County action to establish programs and regulations to implement them. | X |

| B. Scenic Roadway Corridors are primarily designated in areas between towns where the surrounding lands are primarily designated Agriculture and Open. Where a Scenic Roadway Corridor is designated within a town or adjoins an area planned for urban use, the primary intent is to promote setbacks, landscaping, and views of scenic features. Scenic Roadway Corridors are intended to provide design guidance but not to restrict the principal land uses of urban areas. | X |

**Discussion:** The goals of the Hawai‘i Dairy Farms are in accordance with the ideals set forth by the Kaua‘i General Plan (2000), as it insures a resource base for agricultural uses, promotes and preserves open agricultural lands as a key element of Kaua‘i’s rural character and lifestyle, and preserves Important Agricultural Lands and "Prime" agricultural lands for the agricultural uses of the dairy farm.

### 6.0 Enhancing Towns & Communities and Providing for Growth

#### 6.4 Kōloa-Po‘ipū-Kalāheo

| A. Located on the sunny south shore, the Kōloa-Po‘ipū-Kalāheo Planning District is home to Kaua‘i’s largest resort destination as well as some of the most active agricultural businesses. Hotels and resort condominiums are centered around the beaches and golf courses of Po‘ipū. Visitors are drawn to bicycling and ocean recreation activities, as well as attractions such as the Allerton Gardens at Lāwa‘i Kai, the historic towns. Large- and small-scale agricultural activities are located principally in the sunny, well-irrigated coastal lands makai of Kūhiō Highway. Corporate agriculture operations, such as the A&B coffee plantation and the seed corn facility, are located in the area west of Kukui‘ula and the area south and east of Kōloa. Smaller farms and private agricultural parks occupy leased lands throughout the region. Range-fed cattle and other livestock are raised on the pasturelands around Lāwa‘i and Kalāheo, as well as on lands further mauka. | X |
### Table 5-7  (Elements of the) County of Kaua‘i General Plan

<table>
<thead>
<tr>
<th>Issues &amp; Opportunities</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>6.4.3 Issues &amp; Opportunities</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Māhā'ulepū. Grove Farm has proposed low-scale resort development extending east from the Hyatt Regency to Māhā'ulepū, mauka of the shoreline area (which lies in the State Conservation District). Significant archaeological, historic and natural features are located in the shoreline area. The lands proposed for development are designated Open and Agricultural on the General Plan Land Use Map. Grove Farm has outlined the land areas proposed for re-designation but has not proposed any specific development or number of visitor units. Access to the Māhā'ulepū and Kawaiola Bay beaches is currently allowed over unpaved canehaul roads, and use by both residents and visitors is increasing. Grove Farm’s proposal calls for preserving significant cultural and natural resources, setting aside the shoreline area as a natural resource park, and improving public access to the shoreline. Community and environmental groups have expressed concern that development would lead to overuse and degradation and loss of special natural resources. They value the scenic qualities of the area and question the need to extend resort facilities further along the southern shoreline.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B. Wastewater Disposal. There is no County wastewater system serving the Kalāheo-Kōloa-Po'ipū Planning District. Currently, 13 privately-owned treatment plants serve the resort developments in Po'ipū. All but one dispose of effluent using injection wells. As these systems age, they are subject to failure. In addition, County septage pumping logs reveal that Kōloa Town, Lāwa‘i Town and Lāwa‘i Estates have chronic problems with failed individual wastewater systems (septic tank or cesspool). Alexander &amp; Baldwin has developed a 1.1 mgd aerated lagoon plant to serve the Kukui‘ula project and Kōloa Town. It could be converted into a County regional plant, serving the entire Po‘ipū area, but this would be expensive. What should be the long-range plan for wastewater treatment and disposal in this growing resort area?</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>6.4.4.2 Policies</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A. Māhā'ulepū. Involve the community in planning for the future of Māhā'ulepū. Planning should take into consideration various interests and factors, including but not limited to: the long-term need for managing Māhā'ulepū lands to preserve their significant natural and cultural features; the owner’s desire to develop revenue-producing uses in a way that is sensitive to the area's unique qualities; the need to secure permanent public access to the shoreline; and the potential to create a coastal park.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B. Māhā'ulepū. This area needs a community-based planning effort that engages the landowner and local community interests, drawing upon the County government, the State DLNR, and various professional experts, as needed. Options for the area include some development in exchange for a park and/or preservation areas; or purchase of the land for a State park.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Discussion:** Hawai‘i Dairy Farms supports the County's policies related to improving Kaua‘i’s towns and communities and providing for growth, these are not directly applicable to the proposed project. The dairy farm represents a sustainable revenue generating operation on the inland Important Agricultural Land, and is generally supportive of these policies with community engagement throughout its planning process. Long-term operation of the dairy does not preclude the future potential for a coastal park at Māhā'ulepū.

### 7.0 Building Public Facilities and Services

<table>
<thead>
<tr>
<th>Policies</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. In order to preserve rural character and provide for growth in jobs, businesses and households, the County will need to support development within planned urban centers and residential communities. Building basic services involves both the County and State governments. The services include Regional Highways and Roads, Bus Transit, Bikeways, Water Supply, Wastewater Treatment, Drainage and Flood Control, Electrical Power, Solid Waste, Parks and Recreation, Police and Fire Safety, and Schools.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 7.4 Water Supply

<table>
<thead>
<tr>
<th>Policies</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. In general, Kaua‘i’s municipal water systems have adequate source and storage capacity to support the existing maximum water demand and provide storage for fire emergencies. Many systems, however, operate at or near capacity. As a result, DOW places certain operational restrictions on requests for new service. In order to accommodate future growth, most of the water systems would need to be expanded.</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 7.5 Wastewater Treatment

<table>
<thead>
<tr>
<th>Policies</th>
<th>S</th>
<th>N/S</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. Wastewater treatment varies from community to community. The County provides service to a few communities; other communities and larger developments have private treatment systems; and many residents and businesses rely on Individual Wastewater Systems (IWSs) – i.e., cesspools and septic tank systems. In general, wastewater disposal is adequate and does not pose a significant public health or</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
environmental threat. The State Department of Health (DOH) regulates the operations of both County and private wastewater systems. The effluent of most County and private plants is used for irrigation. Service needs include a few areas of Kaua‘i that have failing individual IWSs, but commercial pumping services keep these from becoming a significant problem. The Water Quality Management Plan for the County of Kaua‘i (November 1993) discusses the need to create a regional system serving Kolōa Town, which has subsurface disposal problems, and Po‘ipū, where smaller visitor properties and residences are currently served by a variety of small private plants. Because these plants dispose of effluent by ground injection, there is a long-term risk of polluting adjacent ocean waters. The long-range concept is for the County to develop the regional system by expanding the Kukuiʻula sewage treatment plant and assuming responsibility for plant operation. Effluent disposal is a critical factor hindering development of a regional system.

### 7.6 Drainage and Flood Control

A. Kauaʻi Vision 2020 (Chapter 2) describes a future in which “Kaua‘i streams run freely in their natural courses... Because of careful land management, Kaua‘i is free of concrete-lined drainage channels.” The Vision and the policy statements that follow describe Kaua‘i’s present situation as well as goals for the future. Policies include:

   - Establish zoning and subdivision regulations that (1) strictly limit development on lands that are steeply-sloped and/or have highly erodible soils, in order to prevent flooding, landslides and nonpoint pollution; and (2) strictly limit development on shoreline lands within coastal flood hazard areas or susceptible to shoreline erosion.
   - Focusing on the most heavily impacted urban watersheds, evaluate flooding and erosion risks and develop long-range plans for drainage and flood hazard management. Establish an ongoing program to clear streams and drainageways and maintain their capacity to accommodate stormwater flows.
   - Establish erosion control and drainage regulations that incorporate best management practices for controlling nonpoint source pollution.
   - Regulations and drainage improvements shall be consistent with the following principles:
     1. Use natural drainageways for storm runoff waterways wherever possible.
     2. Avoid channelization or alteration of natural drainageways.
     3. Avoid diversion of storm runoff from one basin to another.
     4. Do not replace natural drainageways with structured, closed systems, except at road crossings.
     5. Require detention basins in new developments, in order to maintain predonation stormwater flow rates. Requirements shall be based on the two-year storm but may be increased.
     6. To conserve land, develop detention basins in conjunction with park or open lands and design for multiple uses.
     7. Protect buildings from the 100-year flood.
     8. Where there are no downstream drainage systems or if the downstream systems lacks sufficient capacity, require retention facilities sufficient to maintain 100-year storm flows at pre-development rates and conditions.

### 7.8 Solid Waste

A. The following general policies apply to solid waste management on Kaua‘i. Specific policies to guide solid waste programs should be provided in the long-range SWMP.

   - Using long-range integrated resource planning, the County shall manage an islandwide system of solid waste collection, reuse, recycling and disposal that (1) is environmentally sound and cost-effective; (2) increases diversion of waste from the island’s landfill(s); and (3) provides for the timely and orderly expansion of solid waste facilities.
   - Through a multi-faceted program of education, management measures, and financial incentives, the County shall support and stimulate Kaua‘i businesses and residents to reduce their solid waste generation and increase the reuse and recycling of materials.
   - The County shall incorporate entrepreneurial principles in managing solid waste, involve private businesses, and support market-oriented innovations and initiatives. Among other options, the County shall consider opportunities for utilizing the waste stream for energy generation.
Discussion: Hawai’i Dairy Farms supports the County’s policies related to improving Kaua‘i’s public facilities and services, development of pasture will help reduce stormwater runoff and soil erosion through best management practices and improved grass and soil conditions.

8.0 Improving Housing, Parks and Schools

8.1 Housing

A. Following are policies to guide housing and community development programs on Kaua‘i.
   (a) Increase the supply of affordable rental housing, as indicated by market conditions.
   (b) Increase opportunities for moderate- and low-income households to become homeowners. Work from the bottom up, serving the 35 percent of residents whose income is 80 percent of the median or less. The intent is to move families out of expensive rental subsidy programs into homeownership, developing housing at a very low cost through self-help programs and reduced-rate mortgage financing.
   (c) Acquire and bank land and infrastructure improvements for future housing development.
   (d) Support the development of housing and support services for elderly and special needs groups, including persons with disabilities, the homeless, and other at-risk populations needing shelter and rehabilitation programs.
   (e) Reserve the program income from the HOME and CDBG disaster grants to fund housing and community development projects. Use the Housing and Community Development Revolving Fund to finance projects and maintain capital.
   (f) Continue to prepare and adopt a five-year Consolidated Plan and one-year Action Plans, with community participation.
   (g) Continue to partner with for-profit and nonprofit organizations in order to provide the highest level of housing and community development assistance possible.
   (h) Develop a flexible planning process for housing programs that monitors current real estate and socio-economic conditions and allows the County to make timely changes in strategy and resource allocation.
   (i) Develop an Affordable Housing Program to standardize the application and administration of affordable housing requirements within the County of Kaua‘i.

8.2 Parks and Recreation

8.2.3 Policy

A. (a) Develop and maintain Kaua‘i’s parks to meet the needs of the island’s various communities and of both residents and visitors.
   (b) Provide convenient access to all of Kaua‘i’s beaches and inland recreation areas.
   (c) Provide for the safe and secure use of public parks and recreation facilities.
   (d) Give high priority to improving maintenance of grounds and comfort stations.
   (e) Give high priority to acquiring and developing additional beach parks and community or neighborhood parks in communities that are under-served or experiencing growth. Consider community concerns in all planning efforts.
   (f) Provide for flexibility in administering the park dedication requirements, so that developer land dedication or fee payments result in a usable park complete with facilities. Create new parks through County-developer partnerships.

8.3 Education

8.3.1 Policy

A. Since public education is a State responsibility, the County’s role is to support excellence in schools through youth programs and other efforts. The availability of adequate school facilities is a concern that the County must address with the DOE in considering the location of new development.
   (a) Strive for a strong education system which provides Kaua‘i’s children, teens, college students, and adults with the knowledge and skills needed to obtain a well-paying job on Kaua‘i.
   (b) Approve new residential developments only after the State DOE certifies that adequate school facilities, either at existing schools or at new school sites, will be available when the development is completed.
   (c) Have developers pay their fair share of all costs needed to ensure provision of adequate school facilities for the children living in their developments.
Table 5-7 (Elements of the) County of Kauaʻi General Plan

<table>
<thead>
<tr>

<td>N/A</td>
</tr>
</tbody>
</table>

**Discussion:** Hawaiʻi Dairy Farms supports the County’s policies related to improving Kauaʻi’s housing, parks, and schools, however, they are not directly applicable to the Proposed Project.

9.0 Implementation

A. Initiating zoning map and development code amendments to conform to the policies of the General Plan X
B. Undertaking planning for infrastructure systems and facilities, parks and housing in order to guide public investment in support of the vision and policies of the General Plan X
C. Recommending approval, approval with modifications or denial of developments seeking zoning or other land use permits, based on their conformance to GP policies and how well they support the vision for Kauaʻi’s development; X
D. Preparing development plans for Kauaʻi’s various communities in collaboration with community coalitions; X
E. Developing indicators and reporting progress on achieving General Plan vision and policies; and X
F. Conducting a comprehensive review of the General Plan every 10 years and recommending revisions as necessary X

**Discussion:** Hawaiʻi Dairy Farms supports the County’s policies related to implementing and reviewing progress on Kauaʻi’s General Plan and related policies, however, these actions are not directly applicable to the Proposed Project.

### 5.11 COUNTY OF KAUAʻI COMPREHENSIVE ZONING ORDINANCE

The purpose of the CZO is to regulate land use in a manner that will encourage development in accordance with the Kauaʻi’s scenic beauty and rural character, and to prevent any inadequate, harmful or disruptive conditions that may be detrimental to the well-being of Kauaʻi residents. The CZO carries out adopted land use policies, including the County of Kauaʻi General Plan and development plans. These standards are applicable to the location, height, bulk and size of structures, yard areas, off-street parking facilities, and open spaces, and the use of structures and land for agriculture, industry, business, residences or other purposes.

The County of Kauaʻi adopted the Comprehensive Zoning Ordinance in September 1, 1972, and is currently updating the CZO in two phases. The first phase will adopt Ordinance No. 935, the newly adopted zoning code for the County of Kauaʻi, and is serving as the official zoning code until the County of Kauaʻi completes the second phase. CZO regulates ag [EXPAND W/OVERVIEW of AG ZONING]; project is in ag; project is in keeping with zoning.
Discussion: The subject property is designated as agriculture by the County of Kaua‘i (Figure 5.12-1). The purpose of the Agricultural district is to both protect and accommodate existing and potential agricultural needs. The zoning designation also serves as a means to limit and control the dispersal of residential and urban use on agriculturally viable lands. Hawai‘i Dairy Farms is consistent with the permitted land uses under the ordinance.

5.12 COUNTY OF KAUA‘I – SPECIAL MANAGEMENT AREA

The Hawai‘i State Coastal Zone Management Program (CZMP) was enacted by Hawai‘i Revised Statutes 205A – Hawai‘i Coastal Zone Management Act (CZMA), as a requirement of the National Coastal Zone Management Program of 1972. The program provides policy guidance for development activities as they relate to coastal land and water resources. The entire land area of the State of Hawai‘i has been determined to be within the Coastal Zone as defined by the CZMA.

The Special Management Area (SMA) permitting system is part of the CZM Program approved by Federal and State agencies. When CZM, first became law in 1975, the legislature established the SMA regulatory function at the county level, and the Kaua‘i Planning Commission is the authoritative agency in the County of Kaua‘i. Based on SMA maps of the region, the site area is located outside the Special Management Area (SMA) (Figure 5.13-1).
Figure 5.12-1  Special Management Area in Vicinity
5.13 COUNTY OF KAUA’I – SOUTH KAUA’I COMMUNITY PLAN

The previous regional planning document, the 1978 Kōloa-Po’ipū-Kalahea Development Plan, was adopted by the County Council in 1983. This has since been replaced by the 2015 South Kaua’i Community Plan (SKCP 2015). The 2015 SKCP serves to update and supersede the maps and land use policies found in the previous development plan.

**Discussion:** The County of Kaua’i South Kaua’i Community Plan serves to guide development in the southern Kōloa-Po’ipū-Kalahea-‘Oma’o-Lawai’ region of Kaua’i, and the policies are reflected in the Community Plan Land Use Map (Figure 5-13.1). Watersheds will be protected through sustainable practices in accordance with county, state, and federal guidelines, cultural resources will be identified and protected per HRS Chapter 6E Historic Preservation requirements. The agricultural use of the dairy project is consistent with the agricultural designation per the South Kaua’i Community Plan Land Use Map, and will continue Kaua’i’s longstanding policy of preserving agricultural lands as a valuable resource base.

![Figure 5.13-1 County of Kaua’i Development Plan Map (2012)](image-url)
6.0

ALTERNATIVES TO THE PROPOSED ACTION
60 ALTERNATIVES TO THE PROPOSED ACTION

6.1 Alternatives Analysis Overview ................................................................. 6-1
6.2 Alternatives Considered & Eliminated .................................................... 6-2
6.3 No Action Alternative .............................................................................. 6-8
6.4 Conventional Feedlot Dairy Alternative .................................................. 6-8
6.5 Alternative Location for Pasture-Based Dairy .......................................... 6-12
6.6 Milk Processing Alternative by HDF ....................................................... 6-15
6.7 Summary Comparison of Alternatives .................................................... 6-16

6.1 ALTERNATIVES ANALYSIS OVERVIEW

This chapter evaluates alternatives that could attain the objectives of the action’s purpose and need, and compares environmental benefits, costs, and risks of each reasonable alternative against those of the proposed action. Additionally, reasonable land use alternatives that emerged from public input during the project scoping phase are documented and briefly discussed. The alternatives that do not meet the project purpose are not advanced for analysis of environmental benefits, costs, and risks. The Environmental Impact Statement Rules, Hawai‘i Administrative Rules Chapter 11-200 (HRS 11-200) requires a discussion of alternatives that could attain the objectives of the action, regardless of cost. There is no requirement for the alternatives analysis to consider every possible land use.

Four alternatives that do not meet the project purpose are discussed. Two of those alternatives would not be viable given existing zoning and private land tenure: rezoning the land for resort or residential development; or a potential conservation condemnation. These two uses are examined and eliminated from analysis. Two additional alternatives were considered as reasonable land uses as they could be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include an Agricultural Park with Processing Center, and development of an Agricultural Subdivision. The alternatives are examined but eliminated from further analysis, as they would not fulfill the project purpose.

The analysis, therefore, focuses on alternatives that meet the project purpose. Rigorous exploration and evaluation of the environmental impacts of the alternatives, including those that might enhance environmental quality or avoid, reduce or minimize some or all of the adverse environmental effects, costs and risks. These alternatives include: (1) the development of a Conventional Feedlot Dairy (a non-pasture-based dairy) at the same location; (2) development of the Pasture-Based Dairy at an Alternative Location on Kaua‘i; and (3) milk products processing by HDF. The alternative of “No Action” is also evaluated.
6.2 ALTERNATIVES CONSIDERED AND ELIMINATED

Among the possible land uses which were considered in the initial alternatives analysis, several options would not meet the project purpose for Hawai‘i Dairy Farms. Two potential options would be rezoning the land for resort or residential development, or condemnation to establish a conservation area. These options would not be reasonably viable given the existing private land tenure and existing zoning, as discussed in Section 6.2.1.

Two additional alternatives were considered in Section 6.2.2 as reasonable land uses that could potentially be permitted within the existing State Land Use Agricultural District and County Agricultural Zoning District. These options include Agricultural Park with Processing Center, and Agricultural Subdivision Development. These alternatives were examined and eliminated from further analysis, however, as they would not fulfill the project purpose.

6.2.1 NON-VIABLE ALTERNATIVES

Two alternative land uses considered but discarded from further analysis in this EIS include those that are not viable given private land tenure and zoning: a) land development for resort or residential, requiring rezoning; and b) conservation condemnation. A brief description of these alternatives eliminated from further analysis in this EIS follows:

a. Non-Viable Alternative: Rezoning Land for Resort or Residential Development

Under Hawai‘i’s land use law (Hawai‘i Revised Statutes Chapter 205), permissible uses are defined within the various use districts. Development for resort or residential zoning on Agricultural lands would require rezoning. Important Agricultural Lands have further restrictions from rezoning for other uses. The County of Kaua‘i directs land use through its General Plan and Communities Plans; the designation for the Māhāʻulepū Valley region is Agriculture, with growth areas identified elsewhere on the island. For these reasons, development for resort or residential is not considered a reasonable alternative for this EIS, and is eliminated from further analysis.

b. Non-Viable Alternative: Conservation Condemnation

Legislative efforts supported by facets of the community have previously suggested that government create a state or national park in the Māhāʻulepū region for conservation and public uses in perpetuity. The process whereby government could take private lands is referred to as condemnation, which can occur when a local, state, or federal government seizes private property and compensates the owner. The power of the government to do this is called eminent domain, which essentially means the government takes private property for public use. With the subject HDF site on Māhāʻulepū farm lands, the public condemnation of the 557 acres of Important Agricultural Land could eliminate the potential future use for crop production or livestock farm use. This action would be contrary to the stated policies of the State of Hawai‘i and County of Kaua‘i which designate this land for long-term food production to sustain the people of Kaua‘i.
6.2.2 AGRICULTURAL PARK AND PROCESSING CENTER ALTERNATIVE

The Agricultural Park Alternative would convert this agricultural property into active crop cultivation for one or several crops, including the development and operation of an agricultural products processing center.

Grove Farm created Mahaulepu Farm, LLC, to enact a long-term vision for Māhāʻulepū Agricultural Valley as a flagship sustainable agricultural area. The intention of the initiative has been to “grow what Kauaʻi eats”. Mahaulepu Farm has planned an agricultural valley that encompasses about 800 acres of food crops. Portions of the Māhāʻulepū lands are currently in use for taro cultivation, fruit trees, small crops, ranching and formerly, seed cultivation. The proposal for a pasture-based dairy (proposed action) would be consistent with the landowner’s and County’s vision for local food production, as would be the alternative for the cultivation of food crops.

Grove Farm has explored the feasibility of growing a variety of produce crops at Māhāʻulepū for local consumption. The long-range plan called for about 300 acres at Māhāʻulepū to be used to grow taro, with the rest of the valley to be dedicated to raising other edible produce. For years, Grove Farm has worked with the University of Hawaiʻi and consultants to pursue an implementation plan. Operations established through the agricultural park offering include Haraguchi Taro Farms, a banana farm and beef cattle grazing.

Apart from the past efforts of the landowner to pursue this approach without success, the Agricultural Park Alternative is examined as a future option. With the Important Agricultural Lands designation, and the existing soils ratings and rainfall conditions, these lands pose some potential suitability to raise a variety of food crops. It would be expected that the Agricultural Park would focus on truck crops with commercial viability. As a farming business, this could be organized under a single business entity or possibly arranged as an agricultural business cooperative. It is recognized that there are many variable and requirements involved with agribusiness development (e.g. land tenure/lease, irrigation water supply, irrigation systems, soil conditions, crop growth, field management, products processing, markets/shipping). The potential details for the agribusiness structure and finance are not evaluated herein. Each of these factors must be satisfied to establish a viable long-term farming venture.

The Agricultural Park and Processing Center Alternative would involve intensive cultivation. Approximately 557 acres could be divided into multiple farming operations, which would share in the development and operation of an Agricultural Processing Center. The Agricultural Park operations could follow examples set by the larger produce farms in the state. Farms operating in ‘Ewa and Central Oʻahu currently raise a range of produce crops, including: green onions, pak choy, choy sum, kai choy, daikon, radish, zucchini, won bok (Chinese cabbage), apple banana, herbs (mint, basil, chives, chinese parsley, lemon grass), sweet onion, eggplant (long), Japanese cucumber, long beans, string beans, paria leaf (bitter melon leaf), camote leaf (potato leaf), head cabbage, cantaloupe, honeydew, sunburst, broccoli, sweet corn, pumpkin, squash and watermelon. It is not known which truck crops could be successfully cultivated at the Māhāʻulepū location. This would require field trials to prove the actual growing conditions to cultivate produce crops at a commercially viable scale.

In support of the Agricultural Park crop production and marketing, an on-site agricultural products processing facility would be developed to serve as the center for the farm operations. The facility would provide sorting, cleaning, washing, packaging, storage, refrigeration and transshipment of
the agricultural products. Development of a 15,000- to 20,000-square foot Packaging Facility would include office space, supply rooms, equipment maintenance shop, backup power generator, restrooms, equipment yard and worker parking.

**Anticipated Environmental Impacts - Agricultural Park and Processing Center Alternative**

Although this alternative scenario would not meet the project purpose, a summary of anticipated environmental impacts is provided.

Intensive cultivation operations of an Agricultural Park would require a conservation plan utilizing Natural Resources Conservation Service technical guidance to document farm-wide objectives and define best management practices. Depending upon the extent of site-specific operational controls, the possibility of bare and tilled soils from intensive cultivation could lead to soil loss and resulting surface water quality impacts consistent. Even with efforts to protect soils with ground cover and runoff control, erosion of farmland soils commonly occurs from large agricultural lands on Kaua‘i. Surface water quality would be degraded through fertilizers and pesticide constituents in stormwater runoff. Depending upon surface water quality effects, there could be measurable downstream effects to ocean water quality in the nearshore area.

The Agricultural Park and Processing Center Alternative would not be anticipated to generate adverse impacts to climate, topography, groundwater, land use, views, flora and fauna species, natural hazards and public services. There would be no adverse effect upon archaeology or cultural resources, with no affect to resources within the farm limits.

With the Agricultural Park and Processing Facility Alternative, there would be some limited effect on roadways and traffic, noise, air quality, hazardous materials, and agricultural infrastructure. Trucks and worker vehicles would access the agricultural park each day, along with shipments of agricultural products and farming supplies. These vehicles would generate noise along local area roadways, and cause dust generation along the farm roadways. Use of hazardous materials would occur, primarily fuels and lubricants for farm equipment and required agricultural chemicals (pesticides, herbicides, fungicides).

The Agricultural Park and Processing Facility Alternative would include farm worker employment for field and processing facility operations. Use of these lands for agricultural cultivation crops would generate lease rent of $300/acre/year for the landowner. Depending upon the types of crops raised, extent of on-site processing and markets for products, the farm could generate over $150,000/year in gross lease rent. The Agricultural Park operations would produce modest positive economic effects through employment, expenditures and State and County tax revenues.

There would be limited substantial cumulative or secondary effects associated with the Agricultural Park and Processing Facility Alternative, potentially long term cumulative surface water effects from suspended soils and farming chemicals in storm water runoff. No irreversible or irretrievable commitments of resources would be anticipated.

**Conclusion of Alternative Evaluation.** This alternative does not meet the purpose and need of the proposed action. The alternative does not fulfill the need for a new agricultural model, and does not provide a critical source of protein for the people of Hawai‘i who are vulnerable to supply disruption. This alternative was not advanced for further evaluation.
6.2.3 AGRICULTURAL SUBDIVISION

The Agricultural Subdivision Alternative would involve the development of land that is currently designated by the land owner and County as IAL. To develop an agricultural subdivision, action would be required to rescind the IAL designation with applicable County real property tax implications. This action would clearly contradict the intention of Grove Farm in its prior initiative to designate the land into long-term productive agricultural function, and the potential to abandon the conversion to urban land classification or subdivision for farm dwellings. For the purpose of this evaluation of alternatives, the creation of an Agricultural Subdivision was assessed.

The County of Kaua‘i Comprehensive Zoning Code (CZO) (Ord 935) specifies allowed uses of Agricultural zoned land, as outlined below for the purpose of calculating the number of agricultural lots and residential densities. Provisions under Sec. 8-8.2 Agricultural District Development Standards state the permitted residential densities shall be calculated as follows:

1. One (1) dwelling unit for each parcel one (1) acre or larger.
2. One (1) additional dwelling unit for each additional three (3) acres in the same parcel, provided that no more than five (5) dwelling units may be developed on any one (1) parcel.

Provisions under Sec. 8-8.3 Limitations on Subdivisions of Parcels in Agricultural Districts states that contiguous lots or parcels of record in common ownership existing prior to or on September 1, 1972, larger than three hundred (300) acres, may be subdivided only in accordance with the following criteria:

A. a maximum of seventy-five (75) acres may be subdivided into not more than ten (10) parcels, none of which shall be smaller than five (5) acres.

B. an additional twenty percent (20 percent) of the total parcel area or three hundred (300) acres, whichever is less, may be subdivided into parcels, none of which shall be smaller than twenty five (25) acres.

Following the County of Kaua‘i CZO allowances, the potential development of the 557-acre site into an Agricultural Subdivision would be calculated as follows:

- 75 acres: Five parcels of 15 acres, yielding 5 homes per parcel, with 25 homes total.
- 111 acres: Four parcels of minimum 25 acres, with 5 homes per parcel, 20 homes total.
- 371 acres: Agricultural land (either integrated with large parcels or separate farm area).

The CZO would allow for the development of a total of 45 homes (farm dwellings) under the Agricultural Subdivision Alternative. Each home would be required have agricultural operations within the property to generate revenue to the occupant of the farm dwelling. It is estimated that roughly 45 acres would be dedicated to the farm dwellings and surrounding accessory uses, another 12 acres dedicated to roadways and drainage, and approximately 371 acres of active agriculture and a central processing facility would be developed. The individual farm lots would also develop agricultural uses on their lands, such as grazing, fruit trees, or intensive cultivation. The farming operations could be conducted on individual lots, or potentially organized under a common farming management entity for uniform crop production across agricultural production zones on each lot, served by a centralized farm processing operation. An overall agricultural plan would be formulated, requiring review and approval by the State of Hawai‘i Department of Agriculture and County Planning Commission.
With the agricultural subdivision alternative there would be substantial needs for supporting infrastructure such as access roadways, potable water supply, fire protection, defined drainage courses, and agricultural support areas/buildings. Individual wastewater systems (septic tank, infiltration disposal field) would be allowed for these homes. Since the development would be approximately 45 homes, this could necessarily trigger the need for a consolidated wastewater treatment system and injection well or irrigation disposal system, along with HRS Chapter 343 compliance for EA/EIS preparation and supporting technical studies. With no consolidated treatment and disposal facility, the 45 homes would necessarily be serviced with on-site individual wastewater systems, pending DOH consent.

**Anticipated Environmental Impacts - Agricultural Subdivision Alternative**

Although this alternative scenario would not meet the project purpose, a summary of anticipated environmental impacts is provided.

With the development of 45 farm dwellings there would be short-term impacts associated with the construction phase of the agricultural subdivision alternative. The short-term impacts would include effects due to soil disturbance, runoff and erosion, dust generation, construction noise, worker vehicles and truck traffic, and vehicle and truck emissions. Development of the internal roadways and support infrastructure (e.g. drainage system, water supply, sewers, electrical and communications) would be substantial to serve the 45 house lots. The individual farm lots would also develop agricultural uses across the majority of their lands, with potential for grazing, fruit trees, and intensive cultivation. There would be construction phase mitigation, such as NPDES construction best management practices, required to limit site development impacts. The construction phase employment associated with the development of the 45 homes would benefit Kaua‘i construction workers. Associated equipment and materials purchases would also generate business sales and State tax revenues.

Over the long term, there would be potential long-term impacts associated with operations of the agricultural subdivision alternative. The occupants of the subdivision would generate the traditional types of impacts associated with a low density 45-home agricultural lot development. Water use for domestic and agricultural purposes would be significant. Potable water use is estimated at 500 gallons per day (gpd) per residential unit, with a total daily demand of 22,500 gpd. Depending upon the type of crops, the 371 acres of farmland would require agricultural irrigation of 2,000 to 3,000 gpd per acre, totaling 742,000 to 1.1 million gpd. Wastewater generation from the subdivision would be substantial, estimated at roughly 500 gpd per unit or 22,500 gpd. Individual wastewater systems (IWS) may not be approved as the site, which would require construction of an onsite sewage collection system and conveyance to a consolidated wastewater treatment facility for treatment and disposal. Disposal from the wastewater treatment plant would be comparable to the over 100 private wastewater injection wells associated with small package plants serving the residential, commercial and resort areas in the Kōloa and Po‘ipū communities. Alternatively, it is possible that agricultural irrigation reuse of treated effluent could be pursued for application on certain agricultural crops, with required 30-day effluent storage ponds and back-up effluent injection disposal during prolonged rainy weather periods. The agricultural subdivision could create measurable downstream effects to surface water and nearshore ocean water quality.

Archaeological resources on the site consist of historic agricultural structures (culverts, bridges, and retaining wall). Archaeological resources identified within 1,000 meters of the site’s northern boundary include two pre-Contact sites that may have been used for ceremonial purposes: an
enclosure; and boulders with petroglyphs. The archaeological resources could be altered or removed with the development of drainage system for the 45-unit agricultural subdivision. The residential use would bring people to the foot of the Hāʻupu slopes and ridges, allowing more access to hikers and hunters and thereby creating a potential for adverse effects to these sensitive sites surrounding the potential development. The nearby coastal area would likely receive more pressure on fishing and resource gathering.

Additional employees for the agricultural subdivision would generate additional worker vehicle trips and truck trips on local roadways. It is estimated that 5 to 10 employees could be involved in the new farming operations at the agricultural subdivision, on individual farm leases or larger scale common area farms. Farm supplies and product shipments from the agricultural subdivision would involve daily deliveries and truck trips. Vehicle noise and air emissions would increase due to the added vehicle and trip trips on local roadways.

Approximately 135 to 180 people would live in the new agricultural subdivision. Residents would travel on local roadways to reach places of employment, shopping, schools and recreational activities. Traffic associated with the 45 agricultural subdivision homes would add a significant number of vehicles on local roadways. It is estimated that up to 68 to 90 peak period vehicle trips could be generated from residents and workers associated with the agricultural subdivision. Most residents of the agricultural subdivision would not be farmers, and they would travel to and from employment locations in Po'ipū, Kōloa and Līhuʻe.

It is estimated that between 45 to 68 school-aged children would live at the agricultural subdivision, placing a new demand on local area public school facilities, libraries and park facilities. The agricultural subdivision would place new demands on County public services such as fire protection, police protection, and emergency medical services. The County of Kauaʻi would need to make provisions to serve this new subdivision development, with offsetting fee contributions from the subdivision developer.

The agricultural subdivision will require substantial electricity use for the 45 homes and agricultural processing operation. This energy demand could be partially offset by on-site solar energy generation by individual homeowners. The agricultural subdivision would require the extension of additional 12 kV power supply, and possibly offsite electrical system upgrades to the Kauaʻi Island Utility Cooperative (KIUC) system serving the Kōloa-Poʻipū area. Roads and home will create impermeable surfaces; utility corridors will require trenching. Improvements will result in irreversible impacts to topography and soils, and add to stormwater runoff in the area.

It is estimated that 5 to 10 new permanent jobs would be created with the operation of the agricultural subdivision farms and processing facilities. State tax revenues would be increased through employment income taxes and sales taxes on products. County real property tax revenues would be increased through higher property value assessment with the 45 homes and lands within the agricultural subdivision. Local businesses in Kōloa and Poʻipū would benefit from the purchasing activity of the residents living in this agricultural subdivision.

**Conclusion of Alternative Evaluation:** This alternative does not meet the purpose and need of the proposed action, as it does not provide support for a unique underrepresented industry like dairy which is overly imported in the state of Hawaiʻi. This alternative did not advance for additional evaluation alternative.
6.3 NO ACTION ALTERNATIVE

The No-Action Alternative would continue future use of agricultural property without the establishment of the sustainable pasture-based dairy operations. With the Important Agricultural Lands designation, this land would be expected to be used for either grazing or cultivation. Use of these lands for cattle or sheep grazing pasture could be reestablished, with cattle and/or sheep grazing on the 500+ acre pasture area. At the stocking rate of two to four animals per acre, common to Kaua‘i grazing lands, the total number of cattle and sheep grazing on the land could potentially range up to 2,000 animals.

Anticipated Environmental Impacts – No-Action Alternative

With a traditional grazing operation in the No-Action Alternative, no special provisions would be required for managing cover crops and runoff. Soil loss and surface water quality impacts would be consistent with other animal grazing operations on Kaua‘i. With no site-specific operational controls, the grazing lease operations would be covered under the existing agricultural conservation plan applicable to the broad suite of agricultural uses on Grove Farm lands at Māhā‘ulepū. Without mitigation and controls, surface water quality could be degraded through storm runoff of animal waste and suspended sediment.

The No-Action Alternative would not be anticipated to generate adverse impacts to climate, topography, groundwater, land use, views, flora and fauna species, natural hazards, roadways and traffic, noise, hazardous materials, agricultural infrastructure, and public services. There would be no adverse effect upon archaeology or cultural resources, unless the grazing operation fails to maintain fences and gates to contain animals.

The No-Action Alternative would include limited employment through the agricultural economic activity. Use of these lands for cattle or sheep grazing pasture would likely be reestablished at the estimated rate of $100/acre/year. The total area within the 557 acres could be leased for cattle or sheep grazing by a Kaua‘i livestock operation. The limited grazing revenues could restrict the amount of operational program manpower and implementation of farm environmental controls. The grazing operations would add limited economic benefits to State and County revenues.

There would be limited substantial cumulative or secondary effects associated with the No-Action Alternative. Potential long-term effects to surface waters from periodic storm water runoff would continue to allow suspended soils and animal waste into the ditch system. No irreversible or irretrievable commitments of resources would be anticipated.

Conclusion of Alternative Evaluation: This alternative does not meet the purpose and need of the proposed action. No support for a unique, underrepresented agricultural industry would occur; no advancement of food sustainability for the state would occur. This alternative was not advanced for further evaluation.

6.4 CONVENTIONAL FEEDLOT DAIRY ALTERNATIVE

The development and operation of a conventional feedlot dairy would potentially achieve the project purpose to increase local milk production. This alternative would utilize the conventional methods for a large-scale commercial dairy in which milking cows are confined in large all-weather barn facilities, without access to forage and without pastures.
The conventional feedlot dairy alternative would utilize large barns to house and feed the dairy cows. A total of either 699 or 2,000 dairy cows would be confined within several large barns. There would be no pasture area utilized in this alternative. The dairy farm complex would occupy a land area of approximately 20 acres, with dairy facilities consisting of several large barns, milking parlor, storage buildings and waste storage lagoons.

With the conventional feedlot alternative, pasture grass would not be utilized as a locally available feed source. Grain and forages would be imported as the primary feed source to sustain dairy cows, at significant additional cost to the dairy operation. Cows would be fed in barns, where they are housed 24 hours each day without natural light and air. Individual animals would be rotated through the milking parlor during twice-daily milking. The requirement to supply imported feed would be significant, estimated at 8 to 10 tons per day for a herd of 699, and 25 to 30 tons per day for a herd of 2,000 mature dairy cows. History showed the decline of Hawai‘i’s dairy industry and eventual demise was largely due to the escalating cost of feed imported from the mainland U.S. Ideally, the portion of feed consisting of forage could be grown locally.

The alternative for a conventional feedlot at the Māhā‘ulepū location would require a program for manure management that collects all manure produced by cows confined within the dairy facilities for 24 hours each day. Potable water would be required to adequately wash down the milking parlor and walkways to maintain animal health. Approximately 30,000 gpd of wash down water would be managed with the manure.

Manure management for a conventional feedlot operation would involve manure collection, transfer and long-term storage in lagoon ponds for evaporation and oxidation breakdown. A scraper system would collect all manure within the cow barns. This material will be the transferred to a lagoon where the parlor wash-down water and cow barn material are mixed. The blended material would be mechanically separated to provide of dry matter that can be dried again and re-used as bedding for the cows. The waste laden water is then captured in a storage pond where it could be managed for irrigation to row crops for silage that could be grown on surrounding lands.

The area and volume of the storage ponds would be sized to allow for the estimated 60,000 gpd for the 2,000 cow dairy. The storage ponds would be three to four times the size of the storage ponds for a pasture-based dairy. Storage ponds would also require sizing to retain rainfall during storm events, which would further expand the volume of waste laden water at the dairy. This alternative would entail significant risk in terms of not being able to comply with waste pond overflow potential.

With the conventional feedlot alternative, manure nutrients would not be returned to pastures through a managed irrigation program intended to balance soils function and pasture grass uptake of the majority of nutrients. Effluent from the waste ponds would be applied daily to nearby crop producing acres. The resultant increased quantities of effluent would require nearly constant disposal in the pasture/fields, as the effluent nutrients would not be managed in a precise manner focused on the optimal growth of pasture grass for forage. This would be a concentrated disposal program that would maximize the application quantities and potentially exceed the nutrient requirements of the surrounding soils.
Anticipated Environmental Impacts – Conventional Feedlot Alternative

</table>

The conventional feedlot operation would generate short-term impacts associated with the construction phase development. There would be soil disturbance, runoff and erosion, dust generation, construction noise, worker vehicles and truck traffic, and vehicle and truck emissions. Construction phase employment would benefit Kaua‘i workers, and equipment and materials purchases would generate local sales and State tax revenues. There would be construction phase mitigation required to limit impacts.

There would be potential long-term impacts associated with operations of the conventional feedlot alternative. Due to the higher density of animals in the barn area and no pasture area, the conventional feedlot alternative collects 100 percent of manure generated. Manure is eventually dried and used as bedding for cows, which generates particulate matter. Manure storage lagoons typically contain waste for roughly 6 months, which fosters off-gassing and contributes to greenhouse gases. Should digesters be used to generate electricity from the gases, the potential exists for unexpected releases of the accumulation of noxious chemicals within the structure.
The concentration of animal waste would pose the potential for increases in populations of vector insects such as flies occurring with the conventional feedlot alternative. Natural fly predators such as dung beetles, cattle egrets, and dragonflies exist in a balanced predator-prey cycle. Populations of arthropods that prey on fly larvae and disrupt the fly life-cycle require soils as habitat. In the barn setting where manure accumulates on impermeable surfaces until it is either washed from the milking parlor or scraped from the barns for transport to lagoons for storage, integrated pest management is not an option.

Conventional feedlots provide silage as feed and forage. Silage is fermented, high-moisture stored fodder made from grasscrops, including maize, sorghum or other cereals. Silage can be made from many field crops using the entire green plant (not just the grain). The fermentation is done on-site, by placing cut green vegetation into a silo or pit, or compressing it with heavy machinery. The pile is then covered with a plastic sheet or baled and wrapped in plastic film until the fermentation process renders the material palatable and digestible by cows. Managing moisture is essential to controlling odor; various odor descriptors can be used to help the dairy operator determine corrective action for the fermentation mix. The odor descriptors include: like ethanol or vinegar; rancid and fishy; or moldy and musty.

Additional odors from the larger manure storage lagoons would be another impact of a conventional feedlot dairy. The lagoons would be sized to hold six months of manure produced; the surface area of the lagoon is significantly greater than that required for the pasture-based dairy which cycles effluent through and re-applies it with irrigation to provide nutrients to the grass.

With the conventional feedlot operation, historical, archaeological and cultural resources would not be affected. Employees for the conventional feedlot alternative operation would generate additional worker vehicle trips and truck trips on local roadways. It is estimated that three to four additional employees would be added to the facility. Feed shipments for the dairy would involve daily truck trips to Līhu‘e, along with fluid milk delivery to processing on Kaua‘i or elsewhere in the state. Vehicle noise and air emissions would increase due to the added vehicle trips on local roadways.

The conventional feedlot operation facilities will require substantial electricity use for ventilation and lighting. Barns are designed for space efficiency with cows in close quarters but allowing room to lie down, as rest is important for a cow to digest its food. Spray misters are often used with fans to provide cooling. Estimates of electrical demand range between 800 and 1200 kWh per cow per year would only be partially offset by the operation of additional on-site solar energy generation. Solar energy collection with photovoltaic panels generating a total capacity of approximately 500 kW would be installed across the roof of the facility, and tied into the overall on-site energy generating system.

There would be an addition of three to four permanent jobs with the operation of the conventional feedlot operation. State tax revenues would be increased through employment and sales taxes. County real property tax revenues would increase with the property value assessment.
6.5 ALTERNATIVE LOCATION FOR THE PASTURE-BASED DAIRY

The Hawai‘i Dairy Farms project emerged from a group of partners and affiliates, including Grove Farm, Finistere Ventures, Kamehameha Schools, Maui Land & Pineapple and Ulupono Initiative. The group conducted grass trials statewide to determine the best site for a rotational-grazing pasture based dairy. Kaua‘i was found to be the optimal location, as it met all the operational requirements for pasture-based dairy:

- Relatively flat, contiguous acres to move cows with minimal stress,
- Soils suitable to efficiently utilize applied nutrients for growth of forage,
- Adequate water for irrigation and operations,
- Suitable climate conditions for animals and grass growth,
- Agricultural-zoned land available for 20 years or more of sufficient acreage to support an economically viable dairy, preferably IAL, and
- Access to required operational support elements (trucking, pasteurization, work force, etc.).

Grove Farm land holdings on Kaua‘i total nearly 33,000 acres, much of which comprise the lands controlled by the former Lihue Plantation Company and Amfac Sugar Kaua‘i operation, which closed in 2000. Nearly half of these lands are designated as State Conservation District, and the remainder is mostly designated as State Agricultural District. Roughly 550 acres are designated as State Urban District in portions of Hanama‘ulu and Līhue town. Over 12,500 acres were classified by the State and County as IAL, placing them into a committed status for long term agricultural purposes. According to the State of Hawai‘i Department of Agriculture, the South Shore of Kaua‘i features some of the state’s most productive farmland due to high sugar yields as a result of steady sunshine and ample fresh water (DOA, 2016).

The high-level evaluation of Grove Farm holdings applying screening criteria to potential lands resulted in a number of findings:

- Conservation District lands and Urban lands owned by Grove Farm could not be considered for the pasture-based dairy due to inappropriate zoning/land use compatibility.
- Long-term farming leases already exist across major portions of the Grove Farm agricultural holdings, along with investments (e.g. crops, livestock, improvements and facilities).
- Inland mauka agricultural lands receive high annual rainfall and lower incident sunlight, with suboptimal pasture grass growing conditions.
- Agricultural lands mauka of Kūhiō Highway and Kaumuali‘i Highway generally have steep slopes, non-contiguous areas and some rocky soils, which are all factors affecting animal stress.
- Irrigation water availability varies due to proximity to existing reservoirs and wells.
- Areas up-gradient of established County and private wells for drinking water supply could not be considered.
- Unavailable or inadequate support infrastructure at mauka locations.

An alternative location for the pasture-based dairy was considered on approximately 972 acres of agricultural land at Kīpū, including a portion of area located in Conservation District Land. The alternative dairy site location is shown in Figure 6.5-1, and analyzed further in this section.

During the scoping for this EIS, the former Meadow Gold dairy site at Moloa‘a has been suggested as an alternate location. The dairy was a conventional confined dairy with 460 dairy cows on 170 acres of land. The site does not meet the criteria for a rotational-grazing pasture based dairy.
The alternative location would potentially satisfy some of the evaluation criteria in terms of slopes, land tenure, soils, micro-climate, water supply and support infrastructure.

Under the four comparative evaluation criteria for site screening identification, the alternative site would provide less suitable properties for pasture-based dairy than the Māhā’ulepū site. Comparative information under key evaluation criteria is summarized below:

- **Slope:** The Kīpū site contains greater slope conditions, with over 10 percent of site containing 5-10 percent slopes, as compared to generally level conditions at the Māhā’ulepū site.
- **Rainfall:** The Kīpū site has higher rainfall, with 65-80 inches per year, as compared to 50-65 inches per year at the Māhā’ulepū site.
- **Sunlight:** Kīpū has lower incident sunlight with an average of 184.77 watts per square meter (w/sm) compared to 196.6 w/sm at the Māhā’ulepū site (U.H. Manoa, 2015).
- **Land Classification:** Roughly 26 percent of the Kīpū site is classified as State Conservation District with the remainder classified State Agricultural District.
- **IAL Designation:** The Kīpū site is not classified as IAL.
- **Sensitive Habitat:** The perennial Hulē’ia Stream running through the site, which eventually drains through the Hulē’ia National Wildlife Refuge.

Of note, Hulē’ia Stream has experienced pollution in the past. The State of Hawaiʻi approved total maximum daily load limits (TMDLs) on the stream in 2008, including limits for enterococci, turbidity, and Total Suspended Solids (DOH, 2014).
Comparative statistics are shown below for the proposed HDF site and alternative site.

1 Grades “A” through “E” and “U” per HRS Chapter 205 – The State Land Use Law

Anticipated Environmental Impacts – Alternative Location

Pasture-based dairy development at the alternative location poses the potential for short-term impacts associated with the construction phase. There would be soil disturbance, runoff and erosion, dust generation, construction noise, worker vehicles and truck traffic, and vehicle and truck emissions. Construction phase employment would benefit Kaua‘i workers, and equipment and materials purchases would generate local sales and State tax revenues. There would be construction phase mitigation required to limit impacts.

Slope conditions at the alternative dairy location would warrant limited site disturbance and soil erosion controls. Specific measures would be required to avoid erosion and sediment runoff entering the perennial flowing waters of Hulē‘ia Stream, which discharges downstream in the Hulē‘ia National Wildlife Refuge and Nawiliwili Bay.

There would be potential long-term impacts associated with operations of the pasture-based dairy. Due to higher rainfall and lower incident sunlight, field trials indicated lower growth rates for the pasture grasses as compared to the Māhāʻulepū site. To provide the same level of forage grass crop for the dairy cows, it would require a larger 300 acre pasture area requirement to support the 2,400 cow dairy for pasture operations, including effluent irrigation.

The design of the waste pond would accommodate the wash water contributed to the waste pond on a daily basis. High annual rainfall at this location would limit the ability to irrigate pasture grass during the wet season, requiring greater waste pond storage retention. Dairy irrigation operation would reuse the diluted effluent accumulated in the waste pond, with no anticipated adverse effects to ground water or surface water quality.
If managed properly, there would be no adverse odors generated by the dairy operations. Archaeological and cultural resources would be protected in a manner similar to the pasture-based dairy. There are cultural resources located along the hillside areas of the alternative dairy property, and historical agricultural features located within the dairy pasture areas.

Employees for the dairy operation would generate worker vehicle trips and truck trips on local roadways. It is estimated that three to four additional employees would be added to the facility to conduct the processing operations. Fluid milk shipments from the dairy would involve daily truck trips to Līhuʻe for shipment to offsite milk processing, located either on Kauaʻi and elsewhere in the state. Vehicle noise and air emissions would increase due to the added vehicle and trip trips on local roadways.

The pasture-based dairy facilities will require substantial electricity use, which would be partially offset by the operation of additional on-site solar energy generation. Solar energy collection with photovoltaic panels would be installed across the roof of the milking parlor facility, and tied into the overall on-site energy generating system. The dairy facility is anticipated to require the extension of additional 12 kV power supply, or offsite electrical system upgrades to the KIUC system serving the Kīpū area.

There would be an addition of 8 to 10 permanent jobs with the operation of the dairy facilities. State tax revenues would be increased through employment and sales taxes on dairy products. County real property tax revenues would be increased through higher property value assessment with the dairy operations.

(Note: Since this alternative location was evaluated in 2015, the land has been contracted for sale to another landowner who is not planning to develop a pasture-based dairy.)

6.6 MILK PRODUCTS PROCESSING BY HDF

As described in Chapter 3, the HDF Proposed Action is the sale of raw milk, wholesale, to a processor/packager. An alternative is for HDF to pasteurize raw milk on the island of Kauaʻi. The pasteurized milk could then be sold to a processor/bottler. Currently Meadow Gold is the only processor/packager with operational facilities on both Oʻahu and Hawaiʻi island. The island's last dairy was owned by Meadow Gold and closed in the year 2000; the facility on Kauaʻi ceased processing at that time, and became a distribution center until it was eventually closed.

Any pasteurization or processing facility would be sited in an appropriately zoned industrial area with access to adequate electricity, municipal potable water and wastewater services, and with existing roadway infrastructure suitable for required truck transport. On the island of Kauaʻi, an opportunity exists to retrofit and utilize the closed processing facility in Puhi, though this alternative requires cooperation of the facility owner, Meadow Gold. Capital expenditure for such a retrofit by HDF could be more than $1 million.

Anticipated Environmental Impacts – Milk Products Processing by HDF Alternative

The processing alternative by HDF would have no significant environmental impacts. The processing facility would be sited on lands with appropriate zoning for milk processing and accessory uses without a need for obtaining additional special permits.

Traffic associated with processing would add worker vehicle trips to the facility, Nawiliwili Harbor, and to and from Honolulu Harbor. Noise from worker vehicles and trucks would increase slightly.
due to the shipping. Vehicle emissions would also occur as a result of these shipments. The interisland transfers would occur as part of other freight components shipped on the existing regularly scheduled barge transits.

In-state milk production would increase agricultural revenues and jobs in Hawai‘i. With HDF processing, employment in the manufacturing industry would increase. Processing would generate substantial positive State and County revenues.

The milk processing operation would require potable water from the County system. The processing operation would also generate wastewater discharged to the County sewer system.

6.7 SUMMARY COMPARISON OF ALTERNATIVES

This chapter provides a comprehensive evaluation of the range of potential alternatives, including the two alternative development scenarios. Although the alternatives are potentially reasonable uses under existing zoning and neighboring uses, each fails to comprehensively fulfill the project requirements defined by the eight Project Objectives and the four established Evaluation Criteria (Chapter 2, Sections 2.3.3 and 2.3.4):

Project Objectives (Section 2.3.3):

1. Provide more than 1,000,000 gallons annually of fresh, nutritious milk for Hawai‘i families at affordable prices and revitalize the dairy industry in Hawai‘i.
2. Apply proven, sustainable rotational-grazing pasture system and state-of-the-art technology to reduce reliance on costly imported fertilizer and feed.
3. Grow local, quality grass as a primary feedstock optimal for dairy cow nutrition and health, utilizing results of forage research conducted at five sites across four Hawaiian Islands.
4. Design facilities to provide animal comfort, including maximum time on pasture and minimal milking time.
5. Effectively integrate dairy operations within the island community setting.
6. Optimize dairy product shipping and marketing.
7. Provide local farming employment and build the agricultural economy.
8. Protect and enhance the area’s natural, cultural, social and economic environment through sound agricultural planning, preservation of open space and protection of sensitive resources, and development of economic benefit.

Evaluation Criteria (Section 2.3.4):

1. Secure sufficient contiguous land area under long-term lease with adequate water supply (including potable water to meet standards under milk rules), suitable soil properties, gentle slope conditions, and road accessibility.
2. Generate new long-term employment in the agricultural sector on Kaua‘i in a wide range of positions including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk products processing and dairy business management.
3. Create a model for dairy operations utilizing IAL, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure to advance food self-sufficiency.
4. Utilize 100 percent of manure on site as nutrients to grow forage for dairy cows. Grow sufficient forage to provide 70 – 85 percent of feedstock required for the herd.

The essential differences as compared to the proposed action are highlighted in the following statements.

- Only one of the alternative actions (conventional feedlot alternative) would create a commercial scale dairy operation in Hawai’i, with the capability to produce 10 percent of the State’s fresh milk demand thus reducing dependence on imported milk (Objective 1). This alternative, however, would not reduce reliance on costly imported fertilizer and feed (Objective 2); grow local, quality grass as a primary feedstock (Objective 3); and would not utilize 100 percent of manure on site as nutrients to grow forage for dairy cows (Criterion 4).

- None of the alternatives would secure a dairy location that meets the requirements for a rotational-grazing pasture dairy: sufficient contiguous land area; available long-term land tenure; adequate potable water supply; suitable soil properties; gentle slope conditions; and accessibility (Criterion 1).

- One alternative (Agricultural Park) could potentially generate new long-term employment in the agricultural sector on Kaua’i in a wide range of positions including pasture agronomy/soils science, environmental resources management (Criterion 2).

- The Agricultural Park alternative could also develop sustainable food production utilizing Important Agricultural Lands, demonstrating the importance of long-term agricultural leases and capital investment for agricultural infrastructure, water systems and support facilities. (Criterion 3). However, after years of trying, it appears there was limited interest in such a venture.

- Finally, addressing the range of potential environmental impacts (natural, cultural, social and economic) (Objective 8) the two alternative development scenarios would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.

In contrast to the other options considered, the planned agricultural operation of Hawai’i Dairy Farms, was determined to be the most viable option and is the preferred alternative. Of all the alternatives considered, this is the only approach that achieves project objectives and meets each of the four Evaluation Criteria.

- Hawai’i Dairy Farms will create a commercial scale pasture-based dairy operation in Hawai’i, with the capability to provide more than 1,000,000 gallons of the fresh milk demand, reducing dependence on imported milk (Objective 1).

- The planned dairy location meets the requirements of minimum land area, soil properties, slope conditions, water supply, land tenure and availability, and accessibility (Criterion 1).

- The planned action will generate new long-term employment in the agricultural sector on Kaua’i, including pasture agronomy/soils science, veterinary and animal husbandry, environmental resources management, milk/milk processing, and dairy business management (Criterion 2).

- Sustainable food production utilizing Important Agricultural Lands (Criterion 3) will occur with the proposed action, demonstrating the importance of long term agricultural leases, and the ability to draw capital investment for agricultural infrastructure including water systems and support facilities (Criterion 3).
- Address the range of potential environmental impacts by utilizing 100 percent of manure as natural fertilizer to grow the majority of food for cows (Criterion 4). The alternatives evaluated would generate fewer beneficial impacts and produce impacts that could potentially exceed those anticipated from the proposed project.
- Creating an economically viable pasture rotational-grazing model maintains agriculture, retains open space, and provides buffer between highly utilized resort and residential development and sensitive natural or cultural resources (Objective 8).

<tr>
<td>TOPOGRAPHY</td>
<td>The dairy facility and associated infrastructure will be constructed in a 10-acre area, less than 1 acre will be utilized for built facilities. Pasture swales previously installed for agriculture and low-lying areas may be smoothed or filled to improve surface drainage and uniformity for grazing. Existing farm road will be slightly elevated, with cow raceways constructed in parallel above grade; swales will be created to direct run-off where needed. Minor effects to topography.</td>
<td>No adverse effect</td>
<td>No significant changes to site topography. Comparatively greater foundation excavation for larger dairy facilities.</td>
<td>Steeper grades would require significant topography changes to establish pasture paddocks and farm roadways. Foundation excavation for facilities.</td>
<td></td>
</tr>
<tr>
<td>SOILS</td>
<td>Short-term soil disturbance for construction of roadways and dairy facilities will be minimized through the adherence to the Conservation Plan, best management practices, and controls per NPDES Construction Stormwater General Permit. Soil loss is expected to be within permitted thresholds and to not be significant. Long-term soil impacts are anticipated to result in improvements to the physical, chemical, and biological condition of the soil. Long term increase in soil organic matter and nutrient properties, expected to improve physical, chemical and biological conditions of the soil.</td>
<td>No adverse effect on soils.</td>
<td>Comparatively less short term soil disturbance for construction of roadways and dairy facilities.</td>
<td>Comparatively greater short term soil disturbance for construction of roadways and dairy facilities. Long term improvement of soil organic matter and nutrient properties.</td>
<td></td>
</tr>
<tr>
<td>LAND USE &amp; AGRICULTURAL SETTING</td>
<td>Hawai‘i Dairy Farms will be in full compliance with its agricultural State Land Use District designation and embodies the IAL designation per the Hawai‘i State Constitution by using the protected lands in the project area for their intended purpose of diversified agriculture and agricultural self-sufficiency. Dairy use will not preclude the future potential for the coastal park at Mā‘alaea.</td>
<td>Cattle/sheep grazing use would retain the agricultural setting. Fallow overgrown lands would be comparably worse by not maintaining active agricultural land use.</td>
<td>Comparable to the proposed action, the feed lot dairy would be a consistent use of Important Agricultural Lands, and would retain the existing agricultural setting.</td>
<td>A pasture-based dairy is a consistent use of County Agricultural Lands, and will retain the existing agricultural setting. There would be potential impacts to downstream wildlife preserve areas.</td>
<td></td>
</tr>
<tr>
<td>VISUAL &amp; AESTHETIC RESOURCES</td>
<td>No public scenic views or lookouts will be affected by dairy development or operations. There will be no adverse effect to public views of the Pu‘u Huluhulu crater, views from the Ala Kinoiki Road corridor, or impediment to views of the Hā‘upu Mountains from the HDF site.</td>
<td>Grazing activity would preserve views, while fallow overgrown lands would be comparably worse for views &amp; aesthetics.</td>
<td>The feed lot dairy would have several large barn structures with comparatively greater visibility than the proposed action, adverse effects to views &amp; aesthetics.</td>
<td>Dairy facilities and pasture paddocks will retain scenic vistas, with no adverse effects to views &amp; aesthetics.</td>
<td></td>
</tr>
<tr>
<td>NATURAL HAZARDS</td>
<td>The dairy facilities will follow Building Code requirements for wind loading. Location is outside tsunami risk area and flood zone. Effluent pond capacity will exceed rain from 25-year/24-hour event. A natural disaster plan has been prepared by the Hawai‘i Dairy Farms’ manager to address hurricane, fire, and potential flooding hazard scenarios. HDF is not in a flood zone or tsunami inundation area.</td>
<td>No structures would be built, posing less risk due to natural hazards.</td>
<td>The feed lot dairy would have more barn structures posing greater comparative risk. Location outside tsunami risk area &amp; flood zone.</td>
<td>The dairy facilities will follow Building Code requirements for wind loading. Location outside tsunami risk area and flood zone. Potential drainage concerns related to surface watercourses in and adjoining the dairy site.</td>
<td></td>
</tr>
<tr>

<td>PROPOSED ACTION (699 COWS)</td>
<td>NO-ACTION ALTERNATIVE</td>
<td>CONVENTIONAL FEED LOT DAIRY</td>
<td>ALTERNATIVE LOCATION</td>
<td></td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------</td>
<td>------------------------</td>
<td>-----------------------------</td>
<td>----------------------</td>
<td></td>
</tr>
<tr>
<td>ARCHAEOLOGICAL &amp; HISTORIC RESOURCES</td>
<td>No archaeological sites were found on the dairy site. Archaeological sites located beyond the mauka dairy boundary will be preserved. Fourteen post-European contact era sites associated with Plantation-era sugarcane cultivation were identified. No further work regarding these sites is recommended. Historic sites will be managed per SHPD for data recovery or adaptive reuse.</td>
<td>There would be no protection or management of archaeological sites and historic sites.</td>
<td>Comparable to the proposed action, per SHPD requirements, sites located beyond the dairy boundary will be preserved, and historic agricultural sites within the dairy site will be managed.</td>
<td>Archaeological sites are not known to exist at the alternative site. Newly identified archaeological sites and historic agricultural sites would be managed per SHPD requirements.</td>
<td></td>
</tr>
<tr>
<td>CULTURAL RESOURCES</td>
<td>The perception of most community members interviewed was that the dairy may have indirect and direct negative impacts on the environment in the area. The findings of research related to preparation of the Cultural Impact Assessment for the dairy site, including interviews of community members, states that it is reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights or any ethnic group related to numerous traditional cultural practices will not be impacted by establishment of the dairy.</td>
<td>No change from existing.</td>
<td>Comparable to the proposed action.</td>
<td>Cultural impact assessment would need to be conducted to determine potential impacts at an alternative location.</td>
<td></td>
</tr>
<tr>
<td>FLORA &amp; FAUNA</td>
<td>No threatened or endangered plants occur on the project property, and no intact native plant habitat exists within or surrounding the site. No critical habitat for endangered flora or fauna species is defined in or immediately surrounding the site; no impacts are anticipated from the dairy. Native plants with potential to stabilize banks will be encouraged and supplemented if needed to enhance the planned buffer strips along drainages. Potential use of paddocks by native, endangered waterbirds may occur. Outside lighting at night will be shielded to prevent attraction to overflying seabirds. No effect to bats is expected from that the dairy farm. HDF will develop an Avian Species Protection Plan and train employees to detect endangered waterbirds and nēnē, to prevent harmful impacts from operations.</td>
<td>Status quo.</td>
<td>The larger facility footprint will reduce open space in the valley. Fields would be unoccupied by cows and irrigation equipment. Large lagoons may provide an attractive nuisance to endangered waterbirds.</td>
<td>Status quo. The larger facility footprint will reduce open space in the valley. Fields would be unoccupied by cows and irrigation equipment. Large lagoons may provide an attractive nuisance to endangered waterbirds.</td>
<td></td>
</tr>
<tr>
<td>INVERTEBRATE SPECIES &amp; PEST INSECTS</td>
<td>Strict dairy operation housekeeping, managed effluent ponds and pasture biological controls (e.g. dung beetle) will avoid fly populations at and beyond the dairy. Integrated pest management will be used disrupt the fly lifecycle and minimize populations of manure-related flies. Use of mechanical insect controls, including traps (outdoors) in paddocks where cows are excluded, and sticky tapes (indoors) will be used as needed for both monitoring and removal of flies.</td>
<td>Status quo.</td>
<td>Concentrations of manure waste would occur at several large feedlot areas, with no dispersion of manure, no soil cycle, and no fly population control measures for larger barns and waste ponds.</td>
<td>Active dairy housekeeping and pasture biological controls (e.g. dung beetle) would avoid fly populations at and beyond the dairy.</td>
<td></td>

<td>------------------------</td>
<td>-----------------------------</td>
<td>----------------------</td>
<td></td>
</tr>
<tr>
<td>NOISE</td>
<td>Construction work at the project site will involve activities that may generate an increase in noise levels. Noise related to construction will be a short-term condition, occurring during daylight hours. Milking equipment will be contained in the milking parlor structure, and field equipment such as tractors will typically be used during daylight hours. Dairy operations will generate noise in keeping with agricultural zoning of the parcel. Noise from the dairy will not exceed the DOH threshold, and will not contribute to excessive noise in the region.</td>
<td>Very limited noise would be generated by grazing and worker vehicle visits. No off-hour noises are anticipated, unless the site remains vacant and is unmanaged.</td>
<td>The dairy would generate low noise levels typical of agricultural activities associated with worker vehicles and transport trucks. No off-hour noises are anticipated.</td>
<td>The dairy would generate low noise levels typical of agricultural activities associated with worker vehicles and transport trucks. No off-hour noises are anticipated.</td>
<td></td>
</tr>
<tr>
<td>HAZARDOUS SUBSTANCES</td>
<td>Illegal dumping at the dairy site will be curtailed by the active control and management of the land. Pesticides, herbicides, fuels and lubricants will be stored according to regulations and utilize secondary containment per best practices and requirements. No significant long-term impacts will occur from hazardous substances related to dairy operations, due to minimization of risk, secondary containment, and compliance with best management practices.</td>
<td>No hazardous materials would be used or stored on-site in the alternative. There would be potential for illegal dumping of hazardous materials if the site is not consistently controlled and managed.</td>
<td>The dairy operation would use a limited number of fuels, lubricants and solvents which will be managed according to State and Federal rules.</td>
<td>The dairy operation would use a limited number of fuels, lubricants and solvents which will be managed according to State and Federal rules.</td>
<td></td>
</tr>
<tr>
<td>PUBLIC SERVICES</td>
<td>Dairy facilities and dairy operations are not anticipat-ed to place a significant demand on fire protection, police, or medical services. The dairy will help to support these services through contributions to County real property tax. New residents to Kaua‘i associated with the dairy will place limited demands on public services, such as schools. A private service will collect solid waste.</td>
<td>Police, fire, and emergency medical service would not be required. Limited County real property tax revenues would be provided to support public services.</td>
<td>Police, fire, and emergency medical service would be required infrequently. The dairy would help support these services through County real property tax expenditures. New residents to Kaua‘i associated with the dairy would place limited demands on public services, such as schools. A private service would collect solid waste.</td>
<td>Police, fire, and emergency medical service would be required infrequently. The dairy would help support these services through County real property tax expenditures. New residents to Kaua‘i associated with the dairy would place limited demands on public services, such as schools. A private service would collect solid waste.</td>
<td></td>
</tr>
<tr>
<td>DEMOGRAPHIC &amp; ECONOMICS</td>
<td>Direct plus indirect employment associated with Dairy development would be expected to average approximately 36 jobs, of which 28 would be on Kaua‘i. With ongoing operations at the committed herd size, 11 direct and indirect full-time equivalent jobs would be created on Kaua‘i, including 5 farm jobs and about 6 indirect jobs. An additional 3 indirect jobs would be created on O‘ahu. Employment for the contemplated herd size would be double. The dairy will generate substantial positive State and County revenues. In-state milk production will expand agricultural revenues and jobs in Hawaii. New residents to Kaua‘i associated with the dairy will place limited demands on public services, with offsetting revenues.</td>
<td>No construction jobs or full time jobs would be created, and no revenues to other agricultural operations on Kaua‘i. Limited County real property tax revenues and State tax revenues would be generated.</td>
<td>The dairy would create construction jobs and over 20 full time jobs, and provide long-term revenues to agricultural partners on Kaua‘i. The dairy would generate substantial positive State and County revenues. In-state milk production would expand agricultural revenues and jobs in Hawaii. New residents to Kaua‘i associated with the dairy would place limited demands on public services, with offsetting revenues.</td>
<td>The dairy would create construction jobs and over 20 full time jobs, and provide long-term revenues to agricultural partners on Kaua‘i. <td></td>
</tr>
</tbody>
</table>
### Groundwater Resources

- **Proposed Action (699 Cows):**
  - There are over 100 wastewater treatment injection wells serving resort development in Poʻipu. The potential inputs to shallow groundwater from the pasture-based dairy will represent less than 5% of the total nutrients disposed each day from the existing wastewater injection wells in Poʻipu. Construction of HDF facilities is not anticipated to deplete the groundwater source or interfere with recharge.
  - Short-term water supply demand during the construction period is anticipated to be nominal. The major water demand during construction will be for fugitive dust control. Water will come from a non-municipal source: either the on-site deep wells; or from the HDF allocation from Waita Reservoir. The dairy will utilize 30,000 gpd of groundwater from on-site wells for potable uses: livestock water; and sanitation in the milking parlor. The demand of approximately 30,000 gpd (0.03 MGD) for potable water is well within the capacity of the existing Māhāʻulepū 14 well which produced 3 MGD during the sugarcane plantation era. Potable water used as wash water will be re-applied to pasture and thus remain a part of the evapotranspiration cycle.
  - The groundwater and surface water assessment determined there is no hydrologic connection between the aquifer in the unweathered volcanic series and the groundwater body in the alluvium. Thus nutrients added by the dairy operation will have no impacts to the County drinking water well and potable water within the deep volcanics, the source of potable water. Further, the assessment concluded that the modest potable water use rate for dairy operations, and the 4,500-foot distance between the onsite potable water well and the nearest County potable water well (Kōloa Well F), mean that no adverse impacts to ongoing use of groundwater in the unweathered volcanics will occur from this use.

- **No-Action Alternative:**
  - The no-action alternative would have limited to no effect on groundwater resources. A small portion of nutrients resulting from cattle/sheep manure breakdown in pasture areas will enter shallow groundwater.

- **Conventional Feed Lot Dairy:**
  - The feedlot dairy will utilize 30,000 gpd of groundwater from on-site wells for potable use at the dairy office and wash down at the milking parlor and barn area. Additional water would be required for the very extensive washdown requirements associated with the conventional dairy. Groundwater source supply and quality at the Kōloa Well F would not be adversely affected by the dairy operations.

- **Alternative Location:**
  - The dairy would utilize approximately 30,000 gpd of groundwater from on-site wells for potable use at the dairy office and wash down at the milking parlor and barn area.
  - The pasture-based dairy would irrigate pastures utilizing non-groundwater from the closest available agricultural reservoir system, blended with water in the effluent storage ponds. Groundwater source supply and quality at the nearest aquifer source would not be adversely affected by the requirements for the dairy operations.
  - Shallow groundwater underlying the pasture paddocks could receive minor contributions of dissolved nutrients in applied effluent irrigation, applied fertilizer and natural manure breakdown.

<th>ENVIRONMENTAL RESOURCE</th>
<th>PROPOSED ACTION (699 COWS)</th>
<th>NO-ACTION ALTERNATIVE</th>
<th>CONVENTIONAL FEED LOT DAIRY</th>
<th>ALTERNATIVE LOCATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>SURFACE WATER RESOURCES</td>
<td>Controls and best management practices to avoid, control, and trap potential erosion associated with construction activities will be implemented. Any stormwater discharge associated with construction in the short-term will be in compliance with relevant regulations. Over the long-term, adherence to the Conservation Plan and best management practices establishes setbacks to minimize impacts to waterways. The setback for effluent application is 50 feet from each side of surface waters. Perimeter fencing to exclude cows from surface waters provides a 35-foot buffer on either side of the drainage ways. Vegetative buffers will be maintained within the 35-foot setback from the drainageways. Episodic, seasonal rainfall events (~10 days/yr) cause groundwater in the alluvium to rise and intersect with the agricultural ditches and groundwater containing nutrients. HDF will release an estimated 10,000 pounds of nitrogen and 900 pounds of phosphorus annually. Contributions of nutrients from episodic rainfall (10 days/yr) will not adversely affect ocean water quality and the marine environment. The nearshore area is a highly mixed environment which actively disperses inputs in several meters from shore. Over 120 wastewater treatment injection wells serving resort development in Po'ipu. Nitrogen input to the marine environment in the Po'ipu region is calculated to be 38,510 pounds annually, or 3.5 times more than the potential HDF nutrient throughput. Phosphorus for both domestic wastewater and landscape fertilization in the region is estimated to be 1,260 pounds annually, or 1.4 times greater than the potential discharge from HDF. State DOH surveys and environmental sampling/testing programs have identified high levels of enterococci bacteria in the agricultural ditches, particularly near the terminus of the ditch near the ocean. State standards apply to recreational waters, and the ditch is not utilized recreationally by bathers. Over the long-term, the surface water quality in the agricultural ditches and Waipoilii Ditch will be improved by active management of the dairy site. The dairy site represents roughly 20 percent of the 2,700-acre Māhā'ulepū Valley sub-watershed, and soil erosion from the HDF site will be reduced by establishment of thick grass ground cover and maintenance of vegetative buffers totaling 70 feet in width – 35 feet on either side of the agricultural drainageways.</td>
<td>The no-action alternative would generate limited surface water quality impacts associated with manure from grazing animals, and soil erosion during peak storm runoff events. If the land is not used for grazing, there would continue to be some level of ongoing soil erosion. Compared to the storm runoff constituents from a pasture-based dairy there would be lower nutrient contributions and greater soil erosion contributions to the ditches and stream. The feedlot dairy operation is expected to generate comparably greater amounts of dissolved nutrients in surface water runoff during large storm events. Natural vegetation buffers would be established along agricultural drainage ditches bordering the effluent disposal fields. Buffers would aid capture suspended sediment and plants/thatch will uptake dissolved nutrients. On average four to five times each year, large rainfall events will generate peak storm water flows from pastures which will enter the agricultural ditches, which merges into Waipoilii Stream. Under peak storm flow conditions, the dairy contributions of suspended sediment and nutrients will represent a minor amount of contaminants of stormwater draining into the agricultural ditches and stream, and eventually reaching the ocean. The nearshore ocean water off Māhāʻelepū is a highly mixed environment which actively disperses natural inputs. Minor contributions of nutrients associated with dairy storm runoff during peak rainfall events will not adversely affect ocean water quality and the marine environment. The feedlot dairy operation is expected to generate minor amounts of dissolved nutrients in surface water runoff during large storm events. Dissolved nutrients in surface runoff will result from applied effluent irrigation, applied fertilizer, and manure breakdown. Natural vegetation buffers established along agricultural drainage ditches bordering the pasture paddocks will effectively capture suspended sediment and uptake dissolved nutrients. On average four to five times each year, large rainfall events will generate peak storm water flows from pastures which will flow into agricultural ditches. Under these conditions, the dairy contributions of suspended sediment and nutrients will represent a minor amount of contaminants entering surface water, and ultimately these drainages discharge into the receiving waters of Hulēʻia Stream. The minor contributions of nutrients from the pasture-based dairy associated with storm water runoff to agricultural ditches during peak rainfall events would not be anticipated to adversely affect stream water quality and the aquatic environment. The alternative site drains into Hulēʻia Stream which leads downstream to Hulēʻia National Wildlife Refuge, and eventually reaching Nawiliwili Bay. The nearshore ocean water off Nawiliwili Bay is a highly mixed environment which actively disperses natural and man-made inputs.</td>
<td>The alternative location for the pasture-based dairy operation is expected to generate minor amounts of dissolved nutrients in surface water runoff during large storm events. Dissolved nutrients in surface runoff will result from applied effluent irrigation, applied fertilizer, and manure breakdown. Natural vegetation buffers established along agricultural drainage ditches bordering the pasture paddocks will effectively capture suspended sediment and uptake dissolved nutrients.</td>

HAWAI’I DAIRY FARMS
Draft Environmental Impact Statement

ENVIRONMENTAL RESOURCE | PROPOSED ACTION (699 COWS) | NO-ACTION ALTERNATIVE | CONVENTIONAL FEED LOT DAIRY | ALTERNATIVE LOCATION
---|---|---|---|---
ROADWAYS & TRAFFIC | Short-term construction traffic will occur during the development of the dairy facilities. For the long-term, worker vehicles and delivery and supply trucks will access the dairy on a weekly basis. The number of vehicles associated with the dairy at the committed herd size will increase by approximately 12 vehicles per day, and will not represent a significant amount of the total traffic on local roadways. Traffic conditions on roadways in Poipū and Kōloa will not deteriorate as a result of the dairy operations. | The no-action alternative would have little traffic, with minimal daily worker vehicle trips associated with a grazing operation. If left fallow, there would be no traffic with this alternative. | Short-term construction traffic would occur during the development of the feedlot dairy facilities. Over the long-term, dairy worker vehicles and trucks would access the site on a daily basis. Without use of the pasture paddocks for grazing, cows would depend 100% upon feed. With a herd of 699 cows, imported feed supply would be a major requirement for this dairy, requiring daily truck deliveries of grain feed for the cows. The number of vehicles associated with the dairy will not represent a significant amount of the total traffic on local roadways. Traffic conditions on roadways in Poipū and Kōloa would not deteriorate as a result of the feedlot dairy operations. | Short-term construction traffic would occur during the development of the dairy facilities. For the long-term, worker vehicles and trucks will access the pasture-based dairy on a daily basis. The number of vehicles associated with the dairy will not represent a significant amount of the total traffic on local roadways. Traffic conditions on roadways in Pāhū will not deteriorate as a result of the dairy operations. |

AIR QUALITY, ODOR & GREEN-HOUSE GASES | Construction effects on air quality including dust and construction vehicle emissions will be temporary and reduced by best management practices and short-term mitigation measures. Odor conditions at the pasture-based dairy will be limited within the dairy project area and immediate vicinity. In the worst-case meteorological conditions, odor may reach approximately 1,670 feet south of the HDF southern boundary. There are no homes or resort facilities in this area. The odors will not reach resort or residential communities. For the area within the modeled odor isopleth, odor may be detectable by 50 percent of the population at a frequency of once every 200 hours, or roughly 44 hours per year. | The no-action alternative would generate no emissions or add to greenhouse gas production. Depending upon the number of grazing cattle or sheep, odors could result from manure waste in the grazing pasture. | For the feedlot dairy option, short-term construction would affect air quality including dust and construction vehicle emissions, reduced by mitigation actions. Odor conditions at the pasture-based dairy will be limited within the dairy project area and immediate vicinity. No adverse odor conditions will result in the 2+ mile distant resort and residential community. The production of greenhouse gases will be reduced by producing milk locally for Hawaii consumers, versus greenhouse gas emissions due to ocean shipping milk from the US mainland. | At the alternative site, there would be short-term construction effects on air quality including dust and construction vehicle emissions, reduced by mitigation actions. Odor conditions at the alternative site for the pasture-based dairy will be limited within the dairy project area and immediate vicinity. No adverse odor conditions will result in the 2+ mile distant resort and residential community. The production of greenhouse gases would be reduced by producing milk locally for Hawaii consumers, versus greenhouse gas emissions due to ocean shipping milk from the U.S. mainland. |

CUMULATIVE IMPACTS | The development and operation of the pasture based dairy will be combined with impacts associated with anticipated future developments in the Poipū and Kōloa region. With mitigation, there will be limited short term impacts such as soil erosion, dust, worker traffic and vehicle emissions. Long-term cumulative effects will include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors will be contained within the dairy and limited adjacent farms. In addition to injected wastewater nutrients entering the nearshore ocean waters generated by the Poipū resort and residential areas, there will be minor amounts of nutrients contributed from the pasture-based dairy. The dairy will provide net economic benefits, adding to the agricultural economy of Kaua’i. | The no-action alternative generally would not contribute to cumulative impacts. Grazing operations without mitigation controls would add to soils erosion, nutrients in storm runoff. Depending upon the herd size, the grazing operation could generate potential odors. | The effects associated with the development and operation of a feedlot confined dairy would combine with impacts associated with anticipated future developments in the Poipū and Kōloa region. With mitigation, there would be limited short term impacts such as soil erosion, dust, worker traffic and vehicle emissions. Less land would be committed with minimal pasture area. Long-term cumulative effects would include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors would likely extend into the resort community. In addition to injected wastewater nutrients entering the nearshore ocean waters generated by the Poipū resorts and residential areas, there will be comparatively greater amounts of nutrients contributed from the pasture-based dairy. The feedlot dairy will provide net economic benefits, adding to the agricultural economy of Kaua’i. | The development and operation of the alternative site for the pasture based dairy would be combined with impacts associated with anticipated future developments in the Poipū and Kōloa region. With mitigation, there will be limited short term impacts such as soil erosion, dust, worker traffic and vehicle emissions. Long-term cumulative effects will include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors will be contained within the dairy and limited adjacent farms. There would be minor nutrients contributions from the pasture-based dairy to Hulii’a Stream. The dairy will provide net economic benefits, adding to the agricultural economy of Kaua’i. |

GREATER COMPARATIVE IMPACTS

The development and operation of the pasture based dairy will be combined with impacts associated with anticipated future developments in the Poipū and Kōloa region. With mitigation, there will be limited short term impacts such as soil erosion, dust, worker traffic and vehicle emissions. Long-term cumulative effects will include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors will be contained within the dairy and limited adjacent farms. In addition to injected wastewater nutrients entering the nearshore ocean waters generated by the Poipū resorts and residential areas, there will be minor amounts of nutrients contributed from the pasture-based dairy. The dairy will provide net economic benefits, adding to the agricultural economy of Kaua’i.

The development and operation of the alternative site for the pasture based dairy would be combined with impacts associated with anticipated future developments in the Poipū and Kōloa region. With mitigation, there will be limited short term impacts such as soil erosion, dust, worker traffic and vehicle emissions. Long-term cumulative effects will include limited soil erosion, storm water runoff, groundwater use, nutrient contributions to agricultural ditches, worker vehicle traffic, and air emissions. Odors will be contained within the dairy and limited adjacent farms. There would be minor nutrients contributions from the pasture-based dairy to Hulii’a Stream. The dairy will provide net economic benefits, adding to the agricultural economy of Kaua’i.

AGENCIES AND PARTIES CONSULTED
7.0 AGENCIES AND PARTIES CONSULTED

7.1 AGENCIES AND PARTIES CONSULTED

This section presents a listing of agencies and parties consulted in the preparation of this EIS.

Table 7-1 lists the agencies, organizations, and individuals who were either: 1) formally consulted, provided a presentation, or notified early in the planning process or are a part of an ongoing consultation effort throughout the environmental review process; 2) officially received a copy of the Environmental Impact Statement Preparation Notice (“EISPN”); or 3) responded to the EISPN with a comment letter. Entities to be sent will have received a copy of the Draft Environmental Impact Statement (“DEIS”) upon publication are also indicated.

Copies of formal comment letters received during the EISPN comment and the applicant’s responses are included in this section. The list of consulted parties will be updated to indicate future comments to be received during the 45-day DEIS review period that commences upon formal notice issued in the Office of Environmental Quality Control’s The Environmental Notice.

8.2 PREPARERS OF THE EIS

Below is a list of individuals that contributed to the preparation and completion of this Environmental Impact Statement (EIS). The list includes the name of the individual and their role, or the name of the company and the subfield of professional expertise utilized to conduct and complete the EIS.

**Hawai‘i Dairy Farms, LCC**

Kyle Datta  
Greg Gaug  
Amy Hennessey  Director of Communications  
Jim Garmatz

**Group 70 International, Inc.**

Jeffrey H. Overton, AICP  Principal Planner  
Paul T. Matsuda, P.E., LEED AP  Principal, Director of Civil Engineering  
Barrie Fox Morgan, AICP  Environmental Planner  
Ryan M. K. Char, P.E., LEED AP  Associate, Project Manager  
Jeffrey Seastrom, AICP  Environmental Planner  
Silas Haglund  Graphics and Document Specialist  
Stephanie Saephan, GISP  GIS Specialist  
Reyna DePonte  Administrative Support

**Technical Consultants**

AECOS Consultants  Flora Survey  
Arcadis  Air Quality/Odor Assessment/Greenhouse Gas  
Group 70 International  Nutrient Balance Analysis  
Marine Research Consultants, Inc.  Surface Water Quality & Marine Assessment  
Plash Econ Pacific Inc.  Demographic and Economic Analysis  
Rana Biological  Faunal Survey  
Red Barn Consulting  Hydrological Assessment  
Russell Yost, Ph. D.  Soils and Agronomy Analysis  
Scientific Consultant Services, Inc.  Archaeological Inventory Survey  
Cultural Impact Assessment  
Steven Lee Montgomery, Ph. D  Entomology (Manure Related Insects)  
Tom Nance Water Resource Engineering  Groundwater and Surface Water Analysis

Introduction and Background

In late 2013, Ulupono Initiative made the investment to fund Hawaii Dairy Farms, the first pasture-based rotational-grazing dairy in the state. Hawaii Dairy Farms LLC (HDF) was formed as a positive step towards the island state's food security, economic diversity and sustainability. Experimental trials were conducted to determine lands capable of growing nutritious forage for dairy cows, and lands meeting the operational requirements for a dairy operation were identified. Kaua‘i was determined to best meet the operational requirements, and Māhā‘ulepū Valley was found to provide ideal grass growing conditions.

At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually at market price. HDF will reduce Hawaii’s reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The application process for a National Pollutant Discharge Elimination System (NPDES), Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time that HDF may decide to pursue an expanded operation.

The project site is located on approximately 557 acres identified as TMK: (4) 2-9-003: 001 por. and 006 por. and (4) 2-9-001: 001 por. Located in Māhā‘ulepū Valley (Figure 1).

This report describes the methods used and the results of the botanical, avian and terrestrial mammalian surveys conducted on the project site as part of the environmental disclosure process associated with the proposed project.

The primary purpose of the surveys was to determine if there are any botanical, avian and terrestrial mammalian species currently listed, or proposed for listing under either federal or State of Hawai‘i endangered species statutes within or adjacent to the study area. We
were also asked to evaluate the potential impacts that the development of the project might pose to any sensitive or protected native botanical, avian or mammalian species, and to propose appropriate minimization measures that could be implemented to reduce or eliminate any such impacts. The federal and State of Hawai‘i listed species status follows species identified in the following referenced documents, (Hawaii Department of Land and Natural Resources (HDLNR) 1998, U. S. Fish & Wildlife Service (USFWS) 2005a, 2005b, 2014a). Fieldwork was conducted on August 20 and 21, 2014.

Hawaiian and scientific names are italicized in the text. A glossary of technical terms and acronyms used in the document, which may be unfamiliar to the reader, are included at the end of the narrative text.

**General Site Description**

The project area was historically used for sugar cane production as part of the Kōloa Plantation until the late 1990s when the Kōloa Mill closed. Since the mill closure, the project area has been leased to various tenants for ranching and diversified agricultural operations. A small plot of land in the lower center of the valley is currently used for mixed agriculture, including taro lo‘i, and will continue to be leased and farmed separate from the dairy and related pastures.

The original sugar cane agricultural infrastructure is largely still in place and continues to be used for on-going agricultural activities. Much of this existing infrastructure will also be used for the dairy, but with significant upgrades and improvements. The existing infrastructure in the project area includes: gravel access roads, field roads, water wells, reservoirs, pipelines, pumps, irrigation ditches, drainage ways and culverts.
Figure 1 – Project Site, Showing TMK Boundaries and Project Boundaries
As previously mentioned the project site is situated in the Māhāʻulepū Valley on the island of Kaua‘i. The valley is on the leeward side of the Hāʻupu mountain ridge, which runs in the east-west direction, and the valley is flanked by ridgelines. Mt. Hāʻupu (Fig. 3) is the highest point on the ridgeline at the back of the valley reaching an elevation of 700 meters above mean sea level (AMSL). From this point, the ground drops away very quickly down to the bottom of the valley to an elevation of approximately 45 meters AMSL. The base of the valley itself gradually slopes from an elevation of approximately 45 meters AMSL down to an elevation of approximately 18 meters AMSL along Māhāʻulepū Road on the makai side of the project site near the taro farm.

Vegetation on the site is best categorized as pasture land (Figures 2 and 3).

Figure 2 - Māhāʻulepū Valley looking south from the northern crossroad showing typical pasture land.
Figure 3 - Māhāʻulepū Valley looking north to Hāʻupu peak from the central road showing typical pasture land and valley walls
**Methods**

*Botanical Survey*

Plant names mostly follow the *Manual of the Flowering Plants of Hawai‘i* (Wagner et al., 1990, 1999) for native and naturalized flowering plants, *A Tropical Garden Flora* (Staples and Herbst, 2005) for crop and ornamental plants, and *Hawai‘i’s Ferns and Fern Allies* for ferns (Palmer, 2003). Some plant species names have been updated following more recently published literature as summarized in Imada (2012).

The botanical survey involved a wandering pedestrian transect method that traversed all parts of the property within the designated survey area (Figure 1). A wandering survey is standard methodology for plant surveys of specific parcels of land as it is superior to fixed, linear transects at discovering rare plant species. A hand-held, global navigation satellite system (GNSS) unit (Trimble, 6000 Series GeoXH) was used to record the progress of the botanist and provide real-time feedback on coverage of the survey area. Plant species were identified as they were encountered and field notations used to develop a qualitative sense of abundance as the survey progressed. For a few species not immediately recognized in the field, photographs were taken and/or material collected for identification in the laboratory.

The survey period represents the dry season in Hawai‘i. Although Kaua‘i was at 87% of normal rainfall for the months of June-August 2014, these values may not reflect conditions along the south coast where the vegetation in the survey area appeared healthy and well-watered during the survey period (rainfall received appeared to be above normal for a dry season).

*Avian Survey Methods*

A total of 28 avian point count stations were sited approximately 300 meters apart along four linear transects running the length of the project site within Māhā‘ulepū Valley. The transects ran roughly in a north-to-south direction. Six-minute point counts were made at each of the count stations. Each station was counted once. Field observations were made with the aid of Leica 8 X 42 binoculurs and by listening for vocalizations. Point counts were concentrated during the early morning hours, the peak of daily bird activity. Time not spent at point count stations was used to search the remainder of the project site for species and habitats that were not detected during count sessions.
Mammalian Survey Methods

With the exception of the endangered Hawaiian hoary bat (Lasiurus cinereus semotus), or ʻōpeʻapeʻa as it is known locally, all terrestrial mammals currently found on the Island of Kauaʻi are alien species, and most are ubiquitous. The survey for terrestrial mammalian species was limited to visual and auditory detection, coupled with visual observation of scat, tracks, and other animal sign. A running tally was kept of all terrestrial vertebrate mammalian species detected within the project area during time spent within the project site.

Results

Botanical Survey

Vegetation

The proposed Kauai Dairy farms project site is presently nearly all pastureland. The pastures vary between recently tilled and various states of weedy regrowth. No active grazing was observed. Consequently, while many of the pastures are a mix of open ground and weedy growth, others are densely overgrown with grasses and other herbaceous plants. Trees are few and scattered, mostly along waterways on the property. Along the edges of the survey area, on the east, north, and west, the sloping land is forested. Since nearly all of this forest is out of the survey area, it was visited at numerous points along the margin but not entered for any significant distance (generally only as far as the old circum-valley ʻauwai). Thus, the vegetation within the project area is herbaceous and typical of regularly disturbed land (i.e., agricultural).

Flora

“Flora” refers to the species diversity of plants growing in the survey area. A plant checklist (Table 1) was compiled from field observations, with entries arranged alphabetically under plant family names (standard practice). Included in the list are scientific name, common name, and status (for example, whether native or non-native, naturalized or ornamental) for each species observed during the survey.

Qualitative estimates of plant abundance were recorded for each species. Abundance values are coded in the table as explained in the Legend to Table 1. For some species, a two-level system of abundance is used; with a letter-number code indicating a species having a somewhat clustered distribution. For example, a species infrequently encountered but numerous where found would have an abundance rating of “R” indicating a plant encountered only one to three times during the entire survey of the site, but an “R2” to indicate several to many individuals present where encountered. An “R3” would be a plant similarly seldom encountered (i.e., rare), but numerous in one or more of the locations where encountered. A species marked “03” would be one seen with some regularity, usually occurring in patches of numerous individuals (as opposed to “C” for a species seen with regularity throughout the survey area). For abundances C or A, attached numbers are
an indication of a patchy distribution: “C3” would be a species generally common (regularly encountered), but especially numerous in patches.

The note “<1>” indicates a species always observed around the margin of the survey area. For most of these species, the recorded occurrences are close to or actually outside the survey area boundary. Consequently, the abundance values are more indicative of the vegetation immediately off the property. For example, all of the ferns recorded are marked with “<1>”. None of these was seen within the survey area; all occurred along dry stream beds immediately off the property, so close to the boundary that the species is clearly representative of the lands surrounding the pasture lands. Eighteen species (15.6%) of the total species fall into this “category” of being mostly representative of the lands outside of the survey area. This percentage is fairly large and reflects the stark contrast between the forested slopes beyond the project area and the project area pastures.

Legend to Table 1

Legend to Table 1

Status = distributional status
End = endemic; native to Hawai‘i and found naturally nowhere else.
Ind = indigenous; native to Hawai‘i, but not unique to the Hawaiian Islands.
Nat = naturalized, exotic, plant introduced to the Hawaiian Islands since the arrival of Cook Expedition in 1778, and well-established outside of cultivation.
Orn = exotic, ornamental or cultivated crop; plant not naturalized (not well-established outside of cultivation, at least at this location).
Pol = Polynesian introduction; brought to the Hawaiian Islands before 1778.

Abundance = occurrence ratings for plants on property in August 2014.
R – Rare - seen in only one to three locations and only one or a few plants present.
U - Uncommon – generally rare, but seen in several locations.
O - Occasional - found regularly, but not abundant anywhere.
C - Common - regularly encountered in many areas; some places may be locally abundant.
A – Abundant; present in large numbers in many places in the survey area.
AA – Abundant; a dominant species.

Notes:
<1> Seen only at margins or just off property; associated with forest border.
<2> Plant lacking fruit or flowers and therefore identification may be uncertain.

In all, 115 species of plants were identified from various parts of the survey area. Only 5 of these (or 4.3%) are native Hawaiian species, all of these are considered indigenous (native to Hawai‘i and other Pacific Islands, as opposed to endemic species that are unique to the Hawaiian Islands). All of the remainder (110 species) are naturalized species, save one regarded as an ornamental. Naturalized species are plants introduced into the Hawaiian Islands that have spread on their own and many now dominate the lowlands of all the Islands.

A somewhat unusual aspect of the flora is the abundance of a number of weedy herbaceous dicots in the fields. Species, such as false ragweed (Parthenium hysterophorus), kikānia (Xanthium strumarium), little bell (Ipomoea triloba), fuzzy rattlepod (Crotalaria incana), sensitive plant (Mimosa pudica), and prickly sida (Sida spinosa), are especially abundant covering large areas of relatively recently disturbed pastureland. Guinea grass (Urochloa maxima) and California grass (Urochloa mutica) are dominate in areas where the pasture has not been disturbed recently by tilling or ungulate browsing, and are abundant mixed with the dicot herbs just mentioned. There are pasture areas where other species of grass predominate.

---

1 Includes a vine and a grass, each seen only once, and not identifiable (not included in Table 1).
**Avian Survey Results**

A total of 1070 individual birds of 31 species, representing 23 separate families, were recorded during station counts (Table 2). Of the 31 species detected during station counts, seven are native species. Four of which, Nēnē (*Branta sandvicensis*), Hawaiian Duck (*Anas wyvilliana*), and the Hawaiian sub-species of the Common Gallinule (*Gallinula galeata sandvicensis*) and Black-necked Stilt (*Himantopus mexicanus knudseni*) are listed as endangered under both federal and State of Hawai‘i endangered species statutes, the remaining three native species detected during point counts, Black-crowned Night-Heron (*Nycticorax nycticorax hoactli*), Pacific Golden-Plover (*Pluvialis fulva*), and Wandering Tattler (*Tringa incana*) are indigenous species. The heron is an indigenous resident breeding species and the plover and tattler are indigenous migratory shorebird species. An additional endangered endemic species, Hawaiian Coot (*Fulica alai*) was recorded as an incidental observation while transiting from one count station to another. The remaining 27 avian species detected are alien to the Hawaiian Islands (Table 2).

</table>
Avian diversity and densities were in keeping with the location of the property and the habitats presently on the site. Four species, Zebra Dove (*Geopelia striata*), Cattle Egret (*Bulbucus ibis*), Common Myna (*Acridotheres tritis*) and Japanese White-eye (*Zosterops japonicus*) accounted for 52% of all birds recorded during station counts. The most commonly recorded species was Zebra Dove, which accounted for 18 percent of the total number of individual birds recorded. An average of 38 individual birds was recorded per station count; a number that is relatively high for a lowland site on Kaua‘i.

**Mammalian Survey Results**

We recorded six terrestrial mammal species while on the site (Table 3). A small herd of cows (*Bos taurus*) were seen within a paddock on the east side of the property. Flocks of recently shorn sheep were present within the Taro farm, which is located within the project site, but is not part of this project. All of the other species detected are detailed in Table 3.

No mammalian species proposed for listing, or listed as endangered or threatened under either federal or state of Hawai‘i endangered species statutes, was recorded during the course of this survey (HDLNR 1998; USFWS 2014a).

**Aquatic Features**

The project area represents bottom-land of upper Māhā‘ulepū Valley; the elevation from the upper pastureland to the lower end representing only about a 20-meter drop, nearly half of which occurs before upper Māhā‘ulepū Road. The valley is fed by several intermittent streams coming off the south slope of the Hā‘upu Ridge between Kāmaulele and Hā‘upu peaks. These normally dry streams feed onto the valley floor, converging at around the 34-meter elevation. Through the upper pastureland, the streams become man-made ditches, incised to a depth of 2-3 meters. At the time we visited, the branch off Kāmaulele had seeps in the bed starting a short distance up from the convergence. Below the convergence, slow moving water is present in a man-made channel running through the project site. The ditch extends southward off the property, passing under lower Māhā‘ulepū Road.
A second ditch parallels to the west the one described above. This second ditch originates in the vicinity of a pond in an area of water wells in the upper west side of the valley. We did not establish the source of the water in this ditch, but the ditch contains water and extends south, passing beside an agricultural operation that includes kalo lo‘i (taro fields), from which it receives additional flow. This ditch then joins a larger ditch known as Mill Ditch (USGS, 1996) carrying water flowing from west to east across the valley within the project area. Mill Ditch turns southward near the center of the valley, passes under Māhā‘ulepū Road, and some 460 meters south, joins the first ditch coming down the valley. The two become Waiopili Ditch, with an outlet at Māhā‘ulepū Beach. Mill Ditch is actually receiving water from a pipe located adjacent to the west side of Māhā‘ulepū Road. Another small intermittent stream enters the project property nearby. This stream originates in a small valley called Kalapa, and is marked by a boulder bed where it crosses under Māhā‘ulepū Road, becoming a dry ditch through the pasture to Mill Ditch.

An old agricultural ‘auwai, called Waitā Reservoir Ditch once brought water from Waitā Reservoir into the upper part of the valley, feeding Māhā‘ulepū Reservoir (off property to the northwest) and wrapping around the upper valley and ending near Pu‘u Keke on the east side close to Waiopili Stream. This ‘auwai is abandoned and no longer functional.

A second ‘auwai extends from Māhā‘ulepū Reservoir to the southwest, paralleling Waitā Reservoir Ditch at a slightly lower elevation (and flowing water in the opposite direction). This ‘auwai is also clearly abandoned and non-functional. An interesting feature associated with this supply ditch is a large, six-sided concrete pipe that fed water into the small reservoir on property (“pond”). Inscribed on a concrete support column for this pipe is “THAIN 10-4-73”.

Spread across the pastures on the valley floor are numerous straight agricultural ditches that serve the purpose of draining runoff from various pasture areas. These were nearly all dry during our survey, and the network was not fully explored, nor was it determined how these presently all interconnect. Presumably these drain eventually into one of the three water-filled features on the property described above.

Many of the aquatic features just described are shown on the USFWS National Wetlands Inventory (NWI) and assigned codes that describe the habitat type presumed by the Inventory (most information in the NWI was derived from aerial photographs and maps, not field investigations; USFWS, 2014b). All of the water ditches on the property (and the ‘auwai around the margin of the valley floor) are coded “R4SBCx”, which represents: intermittent (seasonally flooded) flowing water, in an excavated channel. An exception is the ditch (and channel upslope) directing stream flow off Kāmaulele, which is coded R3RBH: an upper perennial stream with a rock bottom. Characterization as an interrupted
perennial stream is possible given that the stream arises in two branches over 300 meters above sea level, but unlikely.

Three agricultural ponds or reservoir features are coded PUBh, (permanently flooded, man-made pond with sediment bottom). Māhā'ulepū Reservoir is the largest, but located entirely off property. Two reservoirs are indicated within the project area, but one may no longer exist (could not be located in the field) and the other is the small pond in the well area on the upper northwest side. The latter is described by Tom Nance Water Resource Engineering (TNWRE, 2016) as the sump at "Well 14 Battery" and appears to be disconnected from even the local groundwater.

2 The state perennial streams inventory (HCPSU, 1990) lists no streams for Māhā'ulepū, but lists a "Kipu Kai Stream" for Kaua‘i in this general area (ID No. 2-3-01, Lihue Quadrangle). The newer, watershed atlas (Parham et al., 2008) lists Mahaulpeu as a non-perennial stream, assigning the watershed code: 23011. The watershed delineation report (GDSI, 1994) separates Kipu Kai and Mahaulepu watersheds, although mapping them as a single watershed. Physically, the two valleys are quite distinct (and separated by intervening Aweoweonui Gulch).
Figure 4 - Map of aquatic features in the project vicinity in Māhā‘ulepū Valley.
Discussion

Botanical Resources

The nature of the land and its present and historical uses for intensive agriculture very much limit the natural botanical resources anticipated to occur here. The results of our survey substantiate this prediction. The low percentage (4%) of native plant species is an indication that because of constant disturbances, only species adapted to such conditions can survive, and with but a few exceptions, these adapted species are non-natives in the lowlands of the Hawaiian Islands.

A search of Bernice P. Bishop Museum Herbarium records conducted by Anita Manning, yielded 91 entries for “Mahaulepu”. The majority of the natives in the listing were collected along the coast or “Haupu Ridge” or “Puu Pihakapu”. The list of rare native species is impressive. Though the locations are roughly associated with Māhāʻulepū Valley, they represent environments vastly different from those of the upper valley floor (project area). Indeed, all of the plants of interest were collected in either coastal dunes, exposed coastal sites, or steep, rocky cliffs at elevations well above the project. All species in the collection with locations likely to be similar to, if not in, the project pasture lands, are non-native species.

Avian Resources

The findings of the avian survey are consistent with the location of the property, and the habitat present on the site and with at least two relatively recently conducted faunal surveys conducted on lands close to the study site (Guinther and David, 2009; David, 2013; David and Guinther, 2013). During the course of this survey we recorded 31 avian species during point counts, with a further species being recorded as an incidental observation while transiting between count stations. Of the 32 species detected on the site five; Nēnē, Hawaiian Duck, Common Gallinule, Black-necked Stilt and Hawaiian Coot are native endemic species or sub-species all of which are currently listed as endangered species under both federal and State of Hawai‘i endangered species statutes (Table 2). Additionally three other species recorded; Black-crowned Night-Heron, Pacific Golden-Plover, and Wandering Tattler are native indigenous species. The Black-crowned Night-Heron is an indigenous resident water obligate species and the plover and tattler are indigenous migratory shorebird species which nests in the high Arctic during the late spring and summer months, returning to Hawai‘i and the tropical Pacific to spend the fall and winter months each year. They usually leave Hawai‘i and return to the Arctic in late April or the very early part of May. The remaining 24 avian species detected are alien to the Hawaiian Islands (Table 2).

Four of the five endangered birds recorded during the course of this survey were concentrated in or close to the taro cultivation site located on the south-central part of the property, though not part of the proposed dairy operations, were waterbirds: Hawaiian Duck, Common Gallinule, Black-necked Stilt and Hawaiian Coot (Figure 5). Nēnē were also
recorded close to the taro loi, but were also encountered at other locations on the property, and could in future be expected to use resources anywhere on the site with fresh grass. The majority of the Hawaiian Ducks recorded were seen either on the Māhāʻulepū Reservoir located outside of the dairy operations area on the northeast corner of the property (Figure 1), or flying over the greater site or within the taro loi.

Although not detected during this survey, the endangered Hawaiian Petrel (*Pterodroma sandwichensis*), and the threatened endemic sub-species of the Newell’s Shearwater (*Puffinus auricularis newelli*) have been recorded over-flying the general project area between April and the end of November each year (David, 2013; David and Guinther, 2013; Morgan et al., 2003, 2004; David and Planning Solutions 2008). Additionally, the Save Our Shearwaters Program has recovered both species from the general Koloa area on an annual basis over the past three decades (Morgan et al., 2003, 2004; David and Planning Solutions, 2008; Save our Shearwater Program, 2013).

The petrel is listed as endangered, and the shearwater as threatened under both Federal and State of Hawai‘i endangered species statutes. The primary cause of mortality in both Hawaiian Petrels and Newell’s Shearwaters is thought to be predation by alien mammalian species at the nesting colonies (USFWS 1983, Simons and Hodges 1998, Ainley et al., 2001). Collision with man-made structures is considered to be the second most significant cause of mortality of these seabird species in Hawai‘i. Nocturnally flying seabirds, especially fledglings on their way to sea in the summer and fall, can become disoriented by exterior lighting. When disoriented, seabirds can collide with manmade structures, and if they are not killed outright, the dazed or injured birds are easy targets of opportunity for feral mammals (Hadley 1961; Telfer 1979; Sincock 1981; Reed et al., 1985; Telfer et al., 1987; Cooper and Day, 1998; Podolsky et al. 1998; Ainley et al., 2001; Hue et al., 2001; Day et al 2003).

**Mammalian Resources**

The findings of the mammalian survey are consistent with the location of the property and the habitat currently present on the site. We did not record Hawaiian hoary bats overflying the site. Hawaiian hoary bats are widely distributed in the low to mid-elevation areas on the Island of Kaua‘i, and have been documented in and around almost all areas that still have some dense vegetation (Tomich, 1986; USFWS 1998, David, 2014).

Then only rodent species detected during this survey were several European house mice. (*Mus musculus domesticus*). It is probable that one or more of other three established alien muridae found on Kaua‘i, roof rat (*Rattus r. rattus*), brown rat (*Rattus norvegicus*), and possibly Polynesian rats (*Rattus exulans hawaiiensis*) use various resources found within the general project area. All of these introduced rodents are deleterious to native ecosystems and the native faunal species dependent on them.
Figure 5 – Farm Map showing existing Taro Farm and proposed Dairy Farm Infrastructure
Potential Impacts to Protected Species

Botanical

No protected botanical species (for example, threatened or endangered species under state and federal statutes; USFWS, 2014; HDLNR, 1998) occur on the project property. Thus the construction and subsequent operation of the proposed dairy is not expected to result in deleterious impacts to any protected botanical species. Although possibly some areas around the valley margin might have once supported a population of ‘ohia (*Sesbania tomentosa*)—a species of shrub that is listed as endangered—the highly disturbed nature of the valley floor precludes the possibility of any such population surviving after the start of agriculture here. Today, this plant is much more likely to be found very close to the ocean shore or inland where dunes prevail.

Waterbirds

Four endangered waterbird species, Hawaiian Duck, Common Gallinule, Black-necked Stilt and Hawaiian Coot were recorded on the property. The principal potential impacts that the development and operation of the proposed dairy farms on the site poses to these four species fall can be broken down into those potentially associated with construction activities and those associated with dairy farm operations following build-out.

During construction especially during clearing and grubbing phases of the project, clearing vegetation, opening up and clearing of agricultural irrigation features and the construction and/or upgrading of roadways within the farm has the potential to disturb nesting waterbirds, nests, eggs and young. Controls should be put in place to avoid deleterious interactions between endangered waterbirds and construction equipment, vehicles and construction personnel. Waterbirds disturbed when nesting may abandon their nest, eggs and to a lesser degree chicks. Increased vehicular traffic associated with construction activities also increases the risk of birds being run over or hit by vehicles, within the project site.

Nēnē

Nēnē were seen on the site, and in discussions with DOFAW biologists we were told that they are regularly seen on the subject property. It is probable that some nest on or adjacent to the site as this species nests in the general Kōloa area (David, 2013; David and Guinther 2013), and the habitat present on parts of the site are suitable for Nēnē nesting. Potential impacts to this species are similar to those discussed for waterbirds. With the singular difference that Nēnē could potentially nest anywhere on the site which has adequate shrubby or rank grass under which they can build a nest. Unlike the four waterbirds discussed above Nēnē often nest relatively far from water.
Seabirds
The principal potential impact that construction of the proposed dairy farms poses to protected seabirds is the increased threat that birds will be downed after becoming disoriented by lights associated with the project during the nesting season. The two main ways that outdoor lighting could pose a threat to these nocturnally flying seabirds is if, 1) during construction it is deemed expedient, or necessary to conduct nighttime construction activities, and 2) following build-out, the potential operation of streetlights or security lighting.

Hawaiian hoary bats
It is likely that Hawaiian hoary bats overfly the project area on a seasonal basis. The principal potential impact that the development of the proposed dairy farms poses to bats is during the clearing and grubbing phases of construction as vegetation is removed. The removal of vegetation within the project site may temporarily displace individual bats, which may use the vegetation as a roosting location. As bats use multiple roosts within their home territories, the potential disturbance resulting from the removal of the vegetation is likely to be minimal. During the pupping season, females carrying their pups may be less able to rapidly vacate a roost site as the vegetation is cleared. Additionally, adult female bats sometimes leave their pups in the roost tree while they forage. Very small pups may be unable to flee a tree that is being felled. Potential adverse effects from such disturbance can be avoided or minimized by not clearing woody vegetation taller than 4.6 meters (15-feet), between June 1 and September 15, the period in which bats are potentially at risk from vegetation clearing. With that said, there are almost no suitable roost trees within the proposed project site, thus it is not expected that the project will result in deleterious impacts to this listed mammalian species.

Recommendations

Construction
During the construction phase of the project we recommend the following minimization measures and training be implemented to ensure that construction activities do not result in deleterious impacts to the trust faunal species that may be encountered during construction.

- Develop an endangered species awareness training module
- Endangered Species Identification with photographs and description of habitats and areas on the property where species are most likely to occur and/or nest
- Construction workers should undergo endangered species awareness training prior to starting work on the project
- 15 MPH Speed limit signs posted and enforced on all roads within the project
- No pets allowed on property – especially dogs and cats
• Closed trash receptacles for food and beverage containers, and disposal of same, should be provided

• No feeding of birds

• No feeding or watering of feral cats and dogs

• Specified construction personnel parking areas

• Construction materials and construction equipment parking and maintenance areas surveyed and delineated

• These requirements should be included as special Construction BMP contract provisions

• Immediately prior to construction activities Surveys for nesting waterbirds and Nēnē should be conducted by a qualified biologist, if nesting activity is identified within 100 feet of proposed construction activity, construction activity should be halted until nesting activity has ended, or consultation with the state and federal wildlife regulators should be initiated to determine the best course of action.

• If nighttime construction activity or equipment maintenance is proposed during the construction phases of the project, all associated lights should be shielded, and when large flood/work lights are used, they should be placed on poles that are high enough to allow the lights to be pointed directly at the ground.

• If streetlights or exterior facility lighting is installed in conjunction with the project, it is recommended that the lights be shielded to reduce the potential for interactions of nocturnally flying seabirds with external lights and man-made structures (Reed et al., 1985; Telfer et al., 1987).

**Dairy Operations**

Following build-out and the start of Dairy operations we recommend that the following recommendations be implemented:

• Develop an Endangered Species Protection Plan, the plan would include all of the topics outlined above. The material would be presented in more detail and with the rationale for why following those BMP’s is necessary to ensure that Dairy operations do not result in deleterious impacts to protected wildlife. The Plan would also include these additional topics:

• Endangered Species Identification with photographs and description of their habitats, and likely areas on the property where they are most likely to occur and/or to nest
• Employee endangered species training, provided both in writing and as a PowerPoint presentation for use in training new personnel and annual updates of training

• Predator control program

• Downed seabird, and injured waterbird response protocols

**Critical Habitat**

There is no federally delineated Critical Habitat for any species present on or adjacent to the project area. Thus the development and operation of the proposed project will not result in impacts to federally designated Critical Habitat. There is no equivalent statute under State law.
**Glossary**

Alien – Introduced to Hawai‘i by humans
Commensal – Animals that share human food and lodgings, such as rats, mice cats and dogs.
Crepuscular – Twilight hours
Endangered – Listed and protected under the Endangered Species Act of 1973, as amended (ESA) as an endangered species
Endemic – Native to the Hawaiian Islands and unique to Hawai‘i
Indigenous – Native to the Hawaiian Islands, but also found elsewhere naturally
Mauka – Upslope, towards the mountains
Muridae – Rodents, including rats, mice and voles, one of the most diverse families of mammals
Naturalized – A plant or animal that has become established in an area that it is not indigenous to
Nocturnal – Night-time, after dark
‘Ōpe‘ape‘a – Endemic endangered Hawaiian hoary bat (*Lasiurus cinereus semotus*)
Pelagic – An animal that spends its life at sea – in this case seabirds that only return to land to nest and rear their young
Phylogenetic – The evolutionary order that organisms are arranged by
Ruderal – Disturbed, rocky, rubbishy areas, such as old agricultural fields and rock piles
Sign – Biological term referring to tracks, scat, rubbing, odor, marks, nests, and other signs created by animals by which their presence may be detected
Threatened – Listed and protected under the ESA as a threatened species.

**Acronyms**

AMSL – Above mean sea level
CAFO - Concentrated Animal Feeding Operation
HDF - Hawaii Dairy Farms LLC
HDLNR – Hawai‘i State Department of Land & Natural Resources
DOFAW – Division of Forestry and Wildlife
ESA – Endangered Species Act of 1973, as amended
GNSS – Global Navigation Satellite System (formerly as Global Positioning System), an accurate worldwide navigational and surveying facility based on the reception of signals from an array of orbiting satellites.
MSL – Mean sea level
NDI - USFWS National Wetlands Inventory
NPDES - National Pollutant Discharge Elimination System
TMK – Tax Map Key
USFWS – United State Fish & Wildlife Service
USGS – United States Geological Survey
UTM – Universal Transverse Mercator System, a standardized mapping coordinate system that uses grids to identify the specific location of any feature on the surface of the planet

INTRODUCTION
This report summarizes the findings of an insect survey conducted at and near the proposed site of Hawai‘i Dairy Farms (HDF), Māhā‘ulepū, Kaua‘i, (Figure 2, 4) in September 2014.

The primary purpose of the survey was to determine the presence or absence of species associated with the manure of cattle and of the parasites and predators that control them. The survey also was designed to provide information to assist in planning a control program for problem species. The survey also notes species that could be injurious to humans or cattle and was alert to the presence of any Endangered or Threatened species.

Executive Summary
Most insects are obligatorily attached to specific food sources, prey or host plants, being able to use only that source. Those relationships are ancient and intertwined. The amount of food and the levels of predators and parasites determine the abundance or scarcity of species. Those feeding behavior patterns are part of an inter-dependent web in nature, and the basis of integrated pest management (IPM). Knowledge of this web has been used for many decades in Hawai‘i to naturally control alien pest species associated with cattle manure by disrupting reproduction with appropriate means at each part of the life cycle. Birds, spiders, or dragonflies eat adult insects. Ants attack eggs or larva. Birds eat the larva or pupa. Dung beetles minimize food for larvae. Micro-wasps parasitize the larva and pupa.
Survey, Māhāʻulepū, Kauaʻi, Hawaiʻi

Executive Summary continued

The manure of near-by beef cattle was monitored in the field and in the lab to observe that predator / prey web of control. Known manure-related species such as the “stable fly” were present, but so were some of the known control species such as dung beetles. Birds and other vertebrates disturb the dung, eat pest species and make breeding by pests much less successful. Disturbance also exposes the pests to predation by other predator insects. Spiders and dragonflies, apex predators on flying adult pest species also were present. (See pages 11, 14, 18-19)

This web of control is a proven, successful strategy. We experienced it personally when Feb 22-28, 2011, we assisted Hawaiʻi film makers Moana Productions in site location and animal wrangling for a dairy promotion using the pastures and animals of Kohala’s Cloverleaf Dairy. (This was for a continental dairy taking advantage of Hawaii’s mild climate to film in winter for spring showing at home.) We were in the cow paddocks and open fields with the cattle during the day and a crew of 20 ate lunches in an open tent most days in the fields. Flies were not a nuisance or even noted at all on the food or when we were working in the fields. The ongoing, natural web of predator / prey relationships kept pest species under control.

Some of the manure-related insect predatory species long established in the Hawaiian Islands are present elsewhere on Kauaʻi, but not now present near the proposed HDF site. Recommendations are made on their introduction to the site. Other species are not known on Kauaʻi, thus their introduction from other Hawaiian islands is recommended. Together these predatory species hold fly species in check. None of the predator insects have any history of attacking native Hawaiian insects. (See page 24)

The project site does have species that could be injurious to humans or cattle, but none are exclusively associated with cattle. All are common throughout the island chain, have been present on Kauaʻi for many decades, and are seen in virtually every survey we do. Cautions and controls are discussed. (See page 25)

Historically, no native invertebrates of any species are known to be attracted to manure of large herbivores. The field survey around the site confirmed native invertebrates were NOT attracted to manure of nearby beef cattle. This survey showed no evidence of lava tubes (caves) that would support the endangered Kauaʻi cave wolf spider or cave amphipod. Neither the Blackburn’s sphinx moth nor its host plants were observed. The project location does not provide any habitat for Kauaʻi species of native Hawaiian pomace flies listed as endangered (Drosophila musaphilia & D. sharpi) and these have no historical sightings within many miles of the HDF site. (See page 20)
Figure 4. Site of proposed Hawai‘i Dairy Farm, Kaua‘i (Provided by Group 70)
GENERAL SITE DESCRIPTION

The proposed project site at Māhāʻulepū Valley, Kauaʻi, comprises 557 acres, excluding the existing kalo loʻi (taro pond) operation at the makai end (Figure 4). The land is largely in grass with a variety of weedy species\(^1\) (e.g., castor bean, koa haole) along the sides of gravel roads. The grazing area slopes from 150 ft. to 60 ft. along Māhāʻulepū Road at the makai end of the site.

Although most of the ditches running mauka-makai were dry during the September 2014 survey, one small ditch was running with clear water (Figure 5) and a parallel ditch had some slowly moving water and standing water (Figure 6).

\(^1\) Technical terms are defined in the Glossary, page 36.
INVERTEBRATE SURVEY METHODS

Previous Surveys and Literature Search

Prior to the field survey, a search was made for publications relating to invertebrates associated with this particular site or with nearby sites. A search was made for other projects in the general area that generated an Environmental Assessment or Environmental Impact Statement filed at the web site of the State’s Office of Environmental Quality Control (2014). This review did not show any previous invertebrate surveys in the area. The results of recent avian-mammalian and botanical surveys of the project area by David and Guinther (2014) were helpful in preparing for this study. Searches were made in the University of Hawai’i and Bishop Museum library catalogs and in the University of Hawai’i, Hamilton Library’s Hawai’i-Pacific Journal Index (2014). Searches were made for publicly available articles mounted on the web through Google Scholar.

Most helpful were searches in the Bishop Museum’s Natural Sciences databases (2014) and the University of Hawai’i Insect Museum “holdings” database (2014).

As the record of Hawaii’s economic entomology activity for over 100 years, the journal, Proceedings of the Hawaiian Entomological Society, was very useful.

Fieldwork

The field survey was conducted in September 2014, beginning with a general assessment of terrain and habitats. Surveying efforts were conducted at various times of day, a technique that is vital for a thorough survey. See Figure 9 for manure survey location.

Fieldwork schedule
September 15, 2014: 4 hours; Site examination, orientation, general surveying, baiting
September 16, 2014: 7 hours; General surveying, baiting, sample collection

Lab-rearing schedule
September 17-October 13, 2014

Manure collected in the field (Figure 9) was observed in lab to rear any dung associated species. Specimens emerging in the lab are recorded in Table 1 with the field collected specimens.
INVERTEBRATE SURVEY METHODS: continued

Survey Methods
Wandering transects were walked across pastures. Spot surveys were made at both a shallow, flowing ditches and at more slowly moving water that included seepage from the kalo ponds of W.T. Haraguchi Farm, Inc. (Killermann 2014).

Figure 7. Entry point for ditch with flowing water (A) and slow moving water (B) (Group 70 2015)
INVERTEBRATE SURVEY METHODS: continued

The major focus of the survey was on the fresh and dry manure generated by beef cattle (Figure 8) at the adjacent pasture for Mahaulepu Cattle Co. (Figure 9).

The following methods for invertebrate surveying were used as appropriate to the terrain, botanical resources, and target species.

**Visual observation / examination of manure**

At all times, the survey was alert for evidence of any animal presence or interaction with manure. Visual observations provide valuable evidence and provide a cross check that extends the reach of structured sampling techniques. Visual observation also included examination of manure and decaying matter, turning over rocks, dead wood, and other debris.

Daily observations were made of manure samples returned to the lab. Emergence of various species differs based on time from egg to adult. Samples were monitored for more than 21 days, sufficient for most species to emerge.
Figure 9. Location of Mahaulepu Cattle Co. animals (*) where manure was collected for rearing of dung associated species in lab. (map Group 70 2015)
INVERTEBRATE SURVEY METHODS: continued

Baited traps

Baited Multi-Lure traps (Figure 10) were deployed near a resting spot favored by Mahaulepu Cattle Co. animals. On September 15, fresh manure was placed in traps suspended above the ground and directly adjacent to the location where the cattle had deposited manure (Figure 11). No flies came to the traps in 8 hours. On September 16, the traps were moved closer to the ground, but again, no flies came to the traps. The flies stayed on the manure on the ground.

Food scraps were left in the open about 5 yards from the paddock where the Mahaulepu Cattle Co. animals congregated for water and 10 yards from the nearest manure. No flies came to the food scraps, the manure being their preferred ecological niche.

Sweep net

This is the most common method of collecting flying and perching insects. A fine mesh net was swept across plants, manure piles, etc. to collect flying insects. Net contents were transferred into a holding container.
INVERTEBRATE SURVEY METHODS: continued

Survey Limitations / Conditions
The ability to form an advisory opinion is conditioned in the following ways:

Seasons
Weather and availability of food sources play a role in any survey of invertebrates. Arthropod breeding responds to access to food sources for the young and the on-going cattle operation assured a steady source of manure to host the pest / predator population. Nevertheless, monitoring at a different time of the year might produce a longer or slightly different invertebrate list.

Weather
Weather was favorable for surveying during each field day, although relatively warm. Water was present in two ditches, although several were dry.

Limited duration
It is possible that surveying for a longer period of time might enlarge the list of species. To balance that possibility, manure samples were collected and returned to the lab, monitored, and species collected as they emerged. This helped the survey provide a more accurate review of the species present. Nevertheless, it is likely some species present on Kaua’i were not captured, and may later come to manure at HDF. These are noted below in Table 2: Invertebrates known on Kaua’i but not present (page 21).

Selectivity
The survey was focused on finding alien arthropod species present in the area having a relationship to operation of a dairy (Table 1). No attempt was made to document the many non-dairy related alien invertebrate species that might be present in any open field area in Hawai’i (e.g., cabbage butterfly). No attempt was made to document endemic and indigenous Hawaiian invertebrate species, although they were reported when seen. No habitat or host plants of endangered and threatened species were observed.

Diet of Animals
Although the Mahaulpue Cattle Co. animals are fed with pasture grass, as will be the HDF animals, it is anticipated there will be supplemental feeding at the milking site. This diet addition may change the composition of the manure in ways we can not anticipate. This could change the attractiveness of the manure to various invertebrate species already on Kaua’i, but not now found at the site (page 21, Table 2). The management of feed and implementation of integrated pest management techniques should provide controls in anticipation of this option. In addition to the introduction of known predator species already on Kaua’i and in the island chain (See page 29), diet management can be helpful. A prime example is the dog dung fly, which is known to breed in cow manure in small numbers. This can be reduced by omitting corn from feed. Lee and Toyama (1991) showed female flies preferred laying eggs in dairy cow dung containing the residues of digested ground corn.
DISCUSSION

VERTEBRATES NOTED

Because the feces of chickens, cats, and dogs also provide habitat for pest fly species, the survey was alert for the presence of these animals. Although cats and chickens were observed, neither was seen in numbers that added much food for pest flies.

Feral pigs (Sus scrofa) were noted on HDF property. Their rooting is currently one of the factors breaking up manure of the Mahaulepu Cattle Co. animals. It is assumed, however, that the feral animals will be removed as a health hazard to the HDF cattle and as destructive to the pastures and water resources.

Several species of birds are present. Many of them feed on seeds and small insects. Numerous manure piles showed signs of being disturbed by birds scratching at, or beaking the pile to find larvae or undigested seeds. (Figure 12) This assists in the breakdown of the piles making them more easily dissolved by sprinklers and more accessible to other colonizing insects that reduce the pile. A disturbed pile also is much less suitable habitat for fly larvae, reducing breeding success.

![Figure 12](image1.jpg) Undisturbed manure (left) contrasted with manure disrupted by dung beetles and birds searching for seeds or larvae (right).

Cattle egrets (Bubulcus ibis) were sighted among the sheep grazing near the kalo field, including a bird riding the back of one member of the flock. The birds were present among the Mahaulepu Cattle Co. animals and in the open fields on HDF lands. In 1959, the original intent in purposefully introducing these birds was, as their name implies, to co-habit with cattle and eat insects associated with the herd. The commonly seen behavior of egrets following large grass mowers mimics their natural behavior of following large animals like cattle to catch insects disturbed by the animals. Their presence is one part of the integrated pest control web.

Survey Results: Dairy related species  continued

**INVERTEBRATES NOTED**
**ARTHROPODA**
**ARANEAE** (spiders)
Spiders are a part of the natural web of control system against flying insects.

*Argiope appensa* (Walckenaer 1841)
The HDF property has a very large number of orb weaver spiders. The line of Norfolk Island pine trees at the makai end of the property are especially well placed to host the spiders as breezes deliver flying insects to their webs. They are easily spotted by the distinctive white X where they rest ready to rush out and wrap up the next item snagged by their web. These spiders pose no threat to people or livestock.²

*Figure 13. Orb weaver in Norfolk Island pine along lower road. The occupant is easily found on the white X at center of web.*

*Tetragnatha mandibulata* Walckenaer, 1841 long jawed spider
This slender spider was seen on webs spun up over the ditches (Figure 5, 6, 7) to snag flying insects emerging from or going to the water. This spider is not a threat to humans or livestock.

² For anyone skeptical of the safety of these spiders: we used them in filming scenes for the TV series LOST where the actor had to have the spider ON them; we use them with children’s wildlife classes.
Invertebrates Noted: continued

**ARTHROPODA**
**INSECTA**
**DIPTERA (flies)**

Two species of flies were common on the manure piles: *Stomoxys calcitrans* (Linnaeus, 1758) and the smaller and slimmer *Sepsis biflexuosa biflexuosa* Stobl, 1893, 4 mm long. Both are widespread throughout the island chain. *Stomoxys* has the common name “stable fly” due to its association with the manure of horses and cattle, but it also breeds in rotting vegetation, including beach seaweeds. The adult stable fly is 6 millimeters (mm) long, with abdominal spots and prefers to land on animals’ legs, causing much annoyance and loss of productivity. The adults feed on the blood of livestock and nearby humans by piercing the skin. Proven control methods include introduction of parasitic micro-wasps and spreading out of manure. (DuPonte and Larish 2003).

The 5 mm horn fly, *Haematobia irritans*, congregates near the horns of cattle on all isles where their biting causes pain and annoyance, interferes with feeding, but it rarely bites man. It has been widespread since 1898 and Kaua’i herds have benefitted from control by imported micro-wasps and beetles that reduce larvae breeding in dung.

The greenbottle fly (*Lucilia sericata* (Meigen, 1826)) was not seen on site, but was reared in small numbers from manure in the lab. It varies in size 5-10 mm in length. This fly feeds by soaking up fluids with a sponge-like mouth and can not bite or sting.
Invertebrates Noted: continued

**LEPIDOPTERA** (butterflies, moths)

Lycaenidae

*Lampides boeticus* (Linnaeus) or bean butterfly

![Image of a butterfly on manure]

**Figure 16.** The bean butterfly was frequently found on the manure and dirt wet with urine.

At all times of day, these small, attractive bean butterflies were numerous throughout the property. They were observed sitting on manure or wet earth, where it appears they take up minerals in the manure. Their caterpillars are hosted by legumes, on site mostly the alien weed, smooth rattlepod (*Crotalaria pallida* Aiton). In home gardens, however, they are a significant pest of peas and string beans.
Invertebrates Noted: continued

**COLEOPTERA** (beetles)

Dung beetles destroy manure by both physically tunneling into it, using it as food for their larvae, and by burying it. Breaking up the manure also makes it more accessible to other controlling species. For example, opening up the piles makes it easier for birds to find the larvae of flies. Burying of manure aids soil fertility. Some species of these beetles are already active in the adjoining property. Dung beetles are a key part of the integrated pest management web.

**Scarabaeidae**

* Aphodius lividus* (Olivier, 1789)  
Considered a very early, accidental introduction with the first cattle to reach the Hawaiian Islands (Funasaki et al 1988); noted on Kaua‘i in 1985 survey (Markin et al. 1998).

* Onthophagus gazella* (Fabricus, 1787)  
Adults and larvae reduce the cattle manure by eating, dispersing, and excavating it. In Hawai‘i since 1957; re-released in 1959 and 1973 (Funasaki et al 1988); Noted on Kaua‘i in 1985 survey as “most abundant.” (Markin et al. 1998)
Invertebrates Noted: continued

**HYMENOPTERA** (wasps, bees, ants)

Three species of ants were noted in the survey (See Table 1). All are widespread in the island chain. They were observed as present on and under manure where they are predators on eggs and larvae of pest flies. They are part of the integrated pest management web.

- Big-headed ants (*Pheidole megacephala*) are especially fierce predators on other insects, including other ants.
- Carpenter ants (*Camponotus variegatus*), despite the name, do not eat wood, rather the species is attracted to sweet things.
- *Ochetellus glaber* (no common name) is attracted to sweet foods and is recorded as a biter. We have personal experience with *O. glaber* swarming on clean, unused soft paper even in boxes. (e.g., facial tissue) (Figure 18).

None of the three species sting, but all can bite. Still, despite our close interaction with *O. glaber*, we have only rarely been bitten in 15 years, and that when we were removing them from the area.

See *What's Bugging Me?* and *Pests of Paradise* for suggestions on control measures. See also Medically important species section (page 25)

---

3 In 1995, when *What's Bugging Me?* was published, *O. glaber* was only found on Oʻahu and Maui; by 2002 when the same author edited the *Hawaiian Terrestrial Arthropod Checklist*, the species had spread to Kauaʻi and Hawaiʻi islands as well.
Invertebrates Noted: continued

**ODONATA** (dragonflies, damselflies)
Dragon fly adults and young are predators in the integrated pest management web.

Libellulidae: *Orthemis ferruginea*
This handsome dragonfly has both red and pink coloring. It was seen over and near the water in ditches (Figure 5, 6, 7). The adults and young are general predators and so are part of the overall ‘natural control’ system. Pest flies are among adult dragonfly food items. The young, termed naiads, mature from egg masses laid in fresh water. They control the young of pest species that live in water (such as mosquito larvae).

*Figure 19.* Dragonflies patrol seeking prey

*Figure 20.* Pink phase *Orthemis* dragonfly
INVERTEBRATES NOT PRESENT: Native Hawaiian
No federally or state listed endangered or threatened invertebrate species were noted in this survey (DLNR 1997; USFWS 2014). There is no federally designated Critical Habitat for any invertebrate species on or adjacent to the subject property. No anticipated actions related to the proposed project activity in the surveyed locations are expected to threaten entire species or entire invertebrate populations.

MOLLUSCA
Gastropoda (Snails) Pulmonata
Lymnaeidae: Erinna newcombi Adams & Adams, 1855  
Newcomb’s Snail
This threatened Kaua‘i native fresh water snail was not found during the survey. The location does not provide appropriate habitat for this species. None of the designated critical habitat for the snail is on the property. (USFWS 2000, 2006b)

ARTHROPODA
ARANEAE (Spiders)
Adelocosa anops  
Kaua‘i cave wolf spider
This survey showed no evidence of lava tubes (caves) that would support the endangered Kaua‘i cave wolf spider. An archaeological survey of the area (Dega, et al. 2014) also found no evidence of lava tubes. None of the areas designated as critical habitat for the recovery of this species are in the project area (USFWS 2003a).

INSECTA
Diptera: Drosophilidae Drosophila
No native Drosophila were observed on the property. The location does not provide appropriate habitat for the native Drosophila musaphilia listed as endangered on Kaua‘i. (USFWS 2006a). The only critical habitat designated for this species is at Kōke‘e, Kaua‘i. (USFWS 2008).

Lepidoptera: Sphingidae Manduca blackburni
Blackburn’s sphinx moth, an endangered species, was not present (USFWS 2003b, 2005). Neither the moth’s solanaceous native host plant, ‘Aiea (Nothocestrum sp.), nor the best alien host, tree tobacco (Nicotiana glauca), was observed on the property in this survey or recent botanical surveys (David and Guinther 2014).

Odonata:
No native damselfly species were observed during the survey.

CRUSTACEA
Amphipoda: Spelaeorchestia koloana  
Kaua‘i cave amphipod
No suitable habitat for the Kaua‘i Cave Amphipod is located on the property (USFWS 2003a) [see above Kaua‘i cave wolf spider].
INVERTEBRATES NOT PRESENT: Manure-related
Considerable literature exists on manure-related pest species and their parasites and predators. From these sources, it can be theorized what species of invertebrates might be attracted to fresh manure at HDF sites. Table 2 lists invertebrates species recorded as present on Kaua‘i, some for many decades, but not found on site in this survey. The dog dung fly, resident in areas with high pet populations, is notoriously pestiferous due to persistent landings on human legs. Mostly thriving in yards of dog owners not promptly removing dung, farms may be erroneously blamed for high densities of these annoying flies. A few do breed in cow droppings, but this can be reduced with less corn in feed, as Lee and Toyama (1991) showed a positive ovipositional response of *M. sorbens* to residues of digested ground corn in feces of dairy cows.

See Funasaki et al 1988; Markin et al. 1998; Toyama & Ikeda 1976
Invertebrates Not Present: Manure-Related  continued

**Diptera - flies**

These fly species were NOT noted on site in this survey. As these species occur on Kauaʻi, it is possible they could be attracted to cow manure if it were allowed to accumulate in places like the milking areas. The HDF waste management plan minimizes such accumulations of manure. The presence of dung beetles and birds disrupting the manure is an important control mechanism to reduce fly egg laying in the fields. [See also Recommendations page 28]

*Fannia canicularis* (Linnaeus, 1761)  little house fly  

*Fannia pusio* (Wiedemann, 1830)  chicken dung fly  
Although several parasitic species have been introduced to the Hawaiian chain to attack this pest, most have not established on Kauaʻi. As the common name implies, this fly prefers to breed in large accumulations of chicken dung at night roosting locations. It can breed in cow manure, however, it was not noted at the HDF site during the survey.

*Musca domestica* Linnaeus, 1758  house fly  
Breeds in wide variety of materials, including animal manure of many kinds. Several of the micro wasps introduced to control this fly have not been recorded on Kauaʻi.

*Musca sorbens* Wiedemann, 1830  dog dung fly  
As with *F. pusio* and *M. domestica*, species introduced to control this fly have not established on Kauaʻi. Found most commonly in dog droppings that are left in the open, the fly can use cow manure for egg laying.

**Coleoptera – beetles**

Adults and larvae of several beetle species reduce cattle manure by eating and moving it. This disrupts, degrades, and reduces the volume of manure, making less habitat for flies. At no point in their life cycle do dung beetles feed on any living plants, and they are incapable of biting or stinging humans or animals.

In addition to the two species of dung beetles seen during the survey, the manure-feeding species in Table 2 are known to have been present on Kauaʻi for many years. These species would naturally move to the new manure resources created by the HDF operation. The beetles also could be imported to the site to start the population. [See Recommendations page 28]

*Pachylister caffer* (Erichson, 1834)  
In Hawaiʻi since 1957; Noted on Kauaʻi in 1985 as “very common” (Markin et al. 1998).

*Sphaeridium scarabaeoides* (Linnaeus, 1758)  
In Hawaiʻi since 1909 (Funasaki et al 1988); Noted on Kauaʻi in 1985 survey as “common” (Markin et al. 1998)
Invertebrates Not Present: Manure-Related continued

Coleoptera – beetles continued

*Copris incertus prociduus* Say, 1835
In Hawai‘i since 1922 (Funasaki et al 1988); noted as present on Kaua‘i in 1985 survey, but not a robust population (Markin et al. 1998).

*Oniticellus militaris* (Castelnau, 1840)
In Hawai‘i since 1957 (Funasaki et al 1988); noted as present on Kaua‘i in 1985 survey, but not a robust population (Markin et al. 1998).

**Hymenoptera - ants, bees, wasps**

Several extremely tiny parasitic wasps have been introduced to the Hawaiian Islands as a means of reducing pest fly populations for many decades. The adult wasps lay their eggs in the larvae of flies. These wasps do not sting humans or livestock, their ‘stinger’ is actually an ovipositor – a way to put their eggs into the larvae of a fly. The adult male wasp has no ‘stinger’.

*Eucoila impatiens* (Say, 1836)
In Hawai‘i since 1910 (Funasaki et al 1988); known on all major islands

*Brachymeria podagrica* (Fabricus 1787)
This species is established on O‘ahu and Kaua‘i. It was not purposefully introduced, but most likely came into the islands very early aboard a ship carrying livestock or horses and their manure.

*Spalangia cameroni* Perkins, 1910
Introduced to Hawai‘i 1914-1920 (Funasaki et al 1988); Known on all major islands.

---

**Figure 22. Spalangia cameroni attacking** fly pupa to lay her own egg [left (Jones)]. Adult wasp emerging from housefly pupa [right (EntomoBiotics)].

Both images much larger than life size. See Figure 21 for actual size scale.
Potential Impacts of Control Measures on Endangered or Threatened Native Species
Diptera: *Drosophila*

The project location does not provide any habitat for *Drosophila musaphilia*, the only Kaua‘i species of native Hawaiian fly listed as Endangered or Threatened (USFWS 2008). Any control measures taken to curb cattle-associated pest fly species at this site will not affect native *Drosophila* many miles away in high elevation koa forests. In citing the reasons for the decline of the native *Drosophila*, U.S. Fish & Wildlife notes as a threat the yellow-jacket wasp (*Vespula pensylvanica*) a large, aggressive wasp [see following sections Medically important species]. (USFWS 2006a) Yellow-jacket wasps are unrelated to the tiny parasitic wasps used for control of pest flies associated with cattle operations. Venomous yellow-jackets are predators, attacking other insects, and are a danger to humans, pets, and livestock. Parasitic wasps target a few specific species, lay eggs in the larvae of these target flies, and pose no threat to humans, pets, or livestock.

None of the control species (beetles or wasps) for manure-related pests are known to target native Hawaiian species (Funasaki et al. 1988). Additionally, the elevation and habitat at the HDF site are not appropriate for native Hawaiian flies.

No native invertebrates of any species are attracted to manure of large herbivores. As deer, goats, cattle, pigs, and horses were NOT present in pre-human Hawai‘i, native invertebrates did not evolve to use large manure piles as habitat or food.

**Potential Impacts of Control Measures on Beneficial Adventive Species**

All of the parasitic or predator species listed in Table 2 and 3 have been in the Hawaiian Islands for many decades, in some cases for more than half a century. Each species is focused on a particular target species and is not a general predator. For example, as flies and bees are in very different insect lineages, a predator focused on flies would not select bees as a target. Honey bees have not been affected by any fly predators. Recent honey bee declines in the wild on O‘ahu and Hawai‘i islands are due to recent accidental introductions of the Varroa mite that directly targets honey bees, and a souring beetle that ferments nectar in the hive. Neither has been reported on Kaua‘i, and quarantines must be maintained to ensure they do not arrive. Strict compliance with agricultural / equipment inspections and with shipping rules is important.
Medically Important Species

Honey bees (*Apis mellifera*) were seen at the watering trough for the Mahaulepu Cattle Co. stock (Figure 23) and on HDF overhead sprinklers. It is to be expected that honey bees will visit any water source set up for the HDF herd. Bees are an essential part of the overall agricultural ecosystem. A ‘ramp’ should be built into any open water source to allow bees some chance of escape rather than drowning (red circle). A struggling bee, floating in the tank, lapped up by a drinking cow could sting by reflex. It would be appropriate to use a scoop or sieve to remove bees before stock enter the drinking area.

[See Cautions end of this section, page 27]

![Figure 23. Any water source will attract bees, an important part of the agricultural system. An “escape ramp” can reduce drowning.](photo of non-HDF water trough)
Medically important species: continued

**Leaf cutter bees** (megachilids), also on site, may be found in hollow twigs, tubing and similar hollow structures. A member of the public could confuse a leaf cutter bee with a honey bee or large fly, so reports of such should be verified.

![Figure 24. Black female, golden male Carpenter bees; tunnel](image)

**Carpenter bees** (*Xylocopa sonorina*) are on the property. The big, black carpenter bee females and golden males are easily seen. Carpenter bees carve out a short tube shaped tunnel in soft wood (fence post, dry branches) (Figure 24). They do not form colonies, but live solitarily.

Neither leaf cutter nor carpenter bees are a danger to people or livestock if undisturbed.

**Common paper wasps** (*Polistes* sp.) were seen, in several places on the property. There are two species known on Kaua‘i. This wasp may expand their numbers when structures are erected on the property, creating dry, sheltered sites. These wasps are common throughout the island lowlands and especially like to build their ‘paper’ nests under the overhangs of buildings. One was noted in the Norfolk Island pine directly outside the HDF office trailer (Figure 25). They are a danger to humans. They sting repeatedly, unlike honey bees. Nests are best destroyed at night when all wasps are on the paper nest. Destroying the nest during daylight hours will result in rebuilding when the wasps return later in the day.

![Figure 25. Paper wasp nest at office](image)
Medically important species: continued

**Mud dauber wasps** (*Sceliphron caementarium*) were seen on the HDF site. This medium-sized wasp builds a shelter for its young from mud and supplies the nest with food such as small spiders. Occasionally, the wasps will congregate in a sheltered location such as an overhang to rest. They can sting humans, but rarely come in direct contact with people. If encountered, do not interfere with them. The wasps are shy and should not be a risk to the livestock under normal conditions. They are spider predators.

Yellow-jacket wasps (*Vespula pensylvanica* (Saussure, 1857)) (Figure 26 above) were **NOT** seen on HDF property, although the species is present on mauka Kaua‘i. This large, ground nesting, aggressive wasp is a danger to humans, pets, and livestock. HDF staff should be familiar with the appearance of yellow-jacket nest entrances and obtain professional extermination help immediately if one is suspected. Cordon off the area and restrict access until an eradication team with proper protective gear can arrive. Never attempt to deal with this wasp yourself.

The property includes habitat for **centipedes, scorpions, and brown widow spiders**. Although these medically important species were not seen in this quick survey, they are likely to be present in the area. They are general insect predators and will attack a wide variety of species.

**GENERAL CAUTIONS:** Avoid storing boxes or bags directly on the ground or on cement floors, as this provides ‘habitat’ for centipedes and others that can sting when disturbed. Be alert when moving stones or piled brush. Wearing gloves, covered shoes, long sleeves, and long pants will greatly reduce the risk of accidental stings or bites.
Medically important species: Cautions continued

Important to survival of useful insects and vertebrates (e.g., bees, birds) are safe application practices when using any unavoidable herbicide or pesticide. Carefully chosen materials with narrowly targeted applications directed toward the pest species are important. Anyone using herbicides or pesticides should be trained and informed for safety of workers, cattle, and all non-target wildlife. If a honey bee colony location appears to be a danger to workers or cattle, contact a local beekeeper for advice and removal.4

Please see *What Bit Me?* (Nishida and Tenorio 1993) and *Pests of Paradise* (Scott and Thomas 2000) for additional information on human / insect interaction.

**NOTE:** None of the parasitic wasps discussed in this report as potential controls of pest flies are listed as threats to humans in either *Pests of Paradise* or *What Bit Me?*

Employees should be alert for all species named above during work on the property. Some individuals can experience anaphylactic reactions to the venom, not just of honey bees, but to any of the arthropods mentioned in this section. Each of these species may pose a serious risk to some individuals, and supervisors should be aware of any special employee allergy. Any allergic employees should have their antidote nearby at all times and ensure others know where it is and how to assist them.

**RECOMMENDATIONS**

**MONITOR NEAR-BY, NON-DAIRY FLY BREEDING LOCATIONS**

Be vigilant regarding the number of chickens, cats, and dogs in the vicinity of the HDF operation. While these may have their place in a farm operation, each of these species can provide sufficient manure to breed flies, for example, chickens are among the birds disturbing cattle manure and helping to reduce fly habitat. Dogs discourage wild pigs and rats. Cats reduce rats and mice. Proper disposal of dog and cat feces is important. If the chickens increase and congregate, feces may accumulate to an amount sufficient to become a fly breeding location.

Good housekeeping is an important tool in controlling establishment of most flies. Human food waste from on-site workers' meals should be disposed of in a covered, lined container and removed from the site often. Any spilled or waste supplement foods for the cattle should not be allowed to become wet and stay exposed. As it rots, it will provide attractive habitat for fly breeding. Dispose of these materials promptly.

---

4 Find a beekeeper via Hawaii Beekeeper’s Association. www.hawaiibeekeepers.org/list.php
Recommendations: continued

An increase in illegal dumping of household trash may prove to be an unintended consequence of the new Kaua’i County Council’s approval of a variable rate / volume trash disposal fee (Moriki 2014). The anonymity provided by locations such as the country roadsides in the near vicinity of HDF may become a convenient place to drop trash. For example, after large parties, bags of trash containing food remains may be dumped, rather than held at home when a family’s smaller trash cart is filled. Household trash sitting in the open is a recognized fly breeding habitat (Ikeda et al. 1973). HDF personnel should be alert for bags along the roads around the property and remove them if practical. If left, the trash bags could breed flies that would then migrate to the nearest habitat of interest – the cattle manure.

ENCOURAGE ECOSYSTEM TRANSFER:
As Mahaulepu Cattle Co. stock are present in the adjacent property, the species associated with manure breakdown also are present. If the HDF cattle began their journey around the HDF paddocks in the sections near areas where the Mahaulepu Cattle Co. herd was recently grazing, the predators and parasites would more readily migrate to the manure being deposited by HDF cattle.

INCREASE DUNG BEETLE DIVERSITY:
Among the effective methods of controlling flies that breed in cattle manure is to speed the manure toward composting. Dung beetles are specialists in the very important natural process of breaking up and quickly recycling bovine manure pads. Below are outlined short-term and long-term methods of enhancing existing dung beetle numbers to breakdown larger quantities of manure patties.

A. Immediate increase in numbers
In the new pastures, it would be beneficial to quickly boost the breeding population of dung beetles as the cows arrive and begin defecating. This could be accomplished by transplanting adult beetles from older Kaua’i pasture locations. Dung beetles are attracted to light at night, so by visiting locations where beef cattle are established and setting up a typical entomological night collection light with white sheet (Figure 27), it would be possible to collect many adults.

©Figure 27. Typical night collection sheet / light set up.
Recommendations: Increase Dung Beetle Diversity: continued

These could be transported to HDF pastures and placed near fresh manure, which they would quickly colonize and break down as part of their breeding cycle. This would accelerate a dung population increase.

B. Multiple benefits of diverse dung beetle species

Cattle manure contains carbon and valuable soil nutrients, and is a food source for soil microflora, protozoa, and earthworms. For the manure’s value to be realized, it must be incorporated into the soil profile. Dung beetles are nature’s way of recycling these resources back into the soil to be further broken down and encourage plant growth. If manure stays on the soil surface and dries, 80% of the nitrogen is lost into the atmosphere. (Griffith 1997)

Australia provides an example of the efficiency and results provided by dung beetles. Unburied manure from Australia’s imported cattle was a fertile breeding ground for nuisance flies until a comprehensive bio-control project to reduce and recycle bovine manure was initiated by Professor George Bornemissza, Commonwealth Scientific and Industrial Research Organisation (CSIRO). The project replicated the intricately adapted dung processing by beetles known in Africa and Europe. In 1972 the first dung beetles were brought into Australia, and the beetles now break up the pads and bury the rolled away dung balls after laying their eggs in them. This ecologically based work both controlled the fly nuisance and helped to improve soil fertility. Dr. Bornemissza found that 95% fewer horn flies emerged from cow pats attacked by the beetle, *Onthophagus gazella*, than from pats without beetles. (Ürményházi 2010)

In 1998, entomologists George Markin, US Forest Service, and Ernie Yoshioka, Hawai’i Department of Agriculture (HDOA), both now retired, wrote a history and evaluation of a century of manure insect biological control work by HDOA and cooperators. These experts wrote that some of these species could be distributed to new islands to more quickly recycle bovine manure pads and reduce fly larva habitat. Dr. Markin writes:

“In the State of Hawaii, the horn fly control program was one of the longest and most extensive biological control projects for a single insect pest. It resulted in the establishment of a complex of 25 agents, representing 6 families of insects, all using the same ecological resource, cattle dung, in diverse pasture habitats and microclimates. The program appears to have been successful in some parts of the island of Hawai’i, and probably would have also shown similar success on neighboring islands, if vigorous redistribution of the new African beetles had been attempted.” (Markin and Yoshioka 1998)
Recommendations: Increase Dung Beetle: Diversity

In an ideal complex of dung beetles, manure burial would be ongoing 24 hours a day. Though it may take several different dung beetle species to accomplish this goal, the behavioral diversity among species makes it a feasible goal. Some are nighttime flyers, some fly during the day, and some prefer older manure to very fresh. If several species are working together, some may bury the brood ball close to the manure pat, some farther away, some shallow and some deep. (Figure 28) (Thomas 2001)

High populations of dung beetles will bury dung pats in one to three days. This destroys the habitat for other insects and internal parasites to complete their life cycle. Charles Griffith has reported that Texas scholar, Dr. Truman Fincher has studied both the Hawai‘i Parker Ranch dung beetle populations and worked with many Texas cattle herders who changed to holistic management using cell grazing systems and high stock density. Additionally, his work showed less use of veterinary parasiticide chemicals with long lasting residues helped dung beetle populations soar, and kept pastures cleaner. A report by K. Kruger and C. H. Scholtz in a recent publication of the Journal of Agriculture Ecosystems and Environment, on lethal and sublethal effects of ivermectin on dung beetle breeding stated that treated cattle’s manure had suppressed development of the dung beetle *E. intermedius* for 28 weeks after injection. (Griffith 1997)

A long-term, ecological method of combating manure fly breeding would be increasing the diversity of dung beetle species now present on Kaua‘i. The distribution records (Bishop Museum 2014) show only some of the 14 dung beetle species imported between 1898 and 1982 were located on Kaua‘i in a 1985 survey (See Table 3 by Markin and Yoshioka 1998). Bringing some of these additional beneficial species to Kaua‘i might be done in cooperation with the Hawai‘i Department of Agriculture and other cattle owners to the benefit of all cattle operations.
Table 3. Markin and Yoshioka listed enemies of flies not established on Kaua'i (far right) by 1985. A dash indicates their survey did not find that species. (1998, p 47)

- = Not recovered; + = One or two specimens recovered; ++ = Common at a few locations; +++ = Very common at most locations; ++++ = Most abundant species in the complex.

4 Previously recorded as established (Table 1), but not recovered in these surveys.
Figure 2: Graphic illustration of the classic breakdown of dung, shows why establishing species already in the state, but not on Kaua‘i is important. Each dung beetle species uses a different strategy in manure breakdown and cleanup. Multiple species lessen competition by using a different area of the manure and moving it to a different place. (from Bertone et al. n.d.)
ACKNOWLEDGMENTS

Jim Garmatz was helpful throughout the survey in providing location guidance and access. Thanks are extended to David Palama of Mahaulepu Cattle Co. for his kokua in allowing us access to adjacent property. Adam Killermann, AJAR Inc., provided information on water resources and pest responses during the period when the land supported sugar cane fields.

Steven Lee Montgomery conducted all collecting and is responsible for all conclusions. Anita Manning assisted in the field survey and contributed to preparation of this report. Some images used in this report were not taken in the course of this project. These photos, marked by © symbol are not released for other uses. They were made by Anita Manning and/or S. L. Montgomery prior to this contract and were chosen because they best illustrate the subject.

GLOSSARY

Adventive: organisms introduced to an area but not purposefully.

Alien: occurring in the locality it occupies ONLY with human assistance, accidental or purposeful; not native. Both Polynesian introductions (e.g., coconut) and post-1778 introductions (e.g., guava, goats, and sheep) are aliens.

Arthropod: insects and related invertebrates (e.g., spiders) having an external skeleton and jointed legs.

Endemic: naturally occurring, without human transport, ONLY in the locality occupied. Hawaii has a high percentage of endemic plants and animals, some in very small microenvironments.

Indigenous: naturally occurring without human assistance in locality it occupies; may occur elsewhere, including outside the Hawaiian Islands. (e.g., Naupaka kahakai \((Scaevola sericea)\) is the same plant in Hawai‘i and throughout the Pacific).

Insects: arthropods with six legs, and bodies in 3 sections

Invertebrates: animals without backbones (insects, spiders, snails / slugs, shrimp)

Kalo lo‘i: taro farm

Larva / larval / larvae (plural): immature stage of offspring of many types of animals.

Makai: toward the ocean

Mauka: toward the mountains

Native: organism that originated in area where it lives without human assistance. May be indigenous or endemic.

Natural control: the predator – prey balance in nature that keeps numbers in check. For example, if there’s an increase in flies, spiders, dragonflies, and others have more food, are healthier, and can have more young of their own species. The balance is soon restored. This is as opposed to bio-control which involves humans adding predators to the ecosystem.

Naturalized: an alien organism that, with time, yet without further human assistance, has become established in an area to which it is not native.

Pupa: the stage between larva and adult in insects with complete metamorphosis, a non-feeding and inactive stage often inside a case

Purposefully introduced: an organism brought into an area for a specific purpose, for example, as a biological control agent.

Rare: infrequently found, low numbers.

Species: all individuals and populations of a particular type of organism, maintained by isolating mechanisms that result in their breeding mostly with their kind.

University of Hawai‘i at Mānoa

May 24, 2016

Prepared for Group 70 International
Introduction

Hawai‘i Dairy Farms, located in Maha‘ulepu Valley, Kaua‘i (Figure 1), implements a new approach, in Hawai‘i, to sustainable dairy operations. The land application of manure nutrients used for crop production, and the subsequent monitoring and managing of key nutrient cycles, specifically those of nitrogen, phosphorus and potassium, as well as hydrologic and carbon cycles, are used to guide dairy management in order to ensure sustainable production while maintaining or improving soil and ecosystem health. The application of effluents generated from dairy operations via irrigation systems has been shown to be an effective means of both managing the effluent while simultaneously returning nutrients needed by the productive tropical grasses (Fulkerson et al., 2016). The value of returning nutrients from dairy effluent has been demonstrated and documented in Hawai‘i conditions by Valencia-Gica (2012). Effluents also contain large quantities of nutrient salts such as sodium (Richards, 1954; Cameron et al., 2003) and potassium that, under specific conditions, require specific management.

Knowledge of the area’s hydrologic conditions, specifically soil drainage characteristics, is essential to utilizing beneficial nutrients from dairy effluent while reducing or eliminating detrimental accumulations of sodium and salts (Silva et. al., 1999). Because one of the objectives of dairy management is to provide ample quantities of nutritious forage for the dairy animals, an assessment of nutrient status and content is needed to ensure maximum productivity of the tropical grasses selected for the dairy. Lastly, an initial characterization of nutrient status constitutes a baseline for future monitoring of nutrient cycles. Macronutrients, nitrogen and phosphorus are major components of pasture grass productivity, ecosystem health and sustainability. The purpose of this study was to review existing information regarding soil nutrient status and to suggest management that would be needed to improve soil health so as to ensure forage grass productivity and sustainability.

Previous Work

Previous survey, characterization and analysis of the Hawai‘i Dairy Farm site was carried out and produced the following reports:
- Spectrum Soils Data Analysis
- Field Trials and estimates of kikuyu forage grass production
- Groundwater Assessment and Hydrologic Analysis of the Hawai‘i Dairy Farm site
- Waste Management Plan, for 699 Mature Dairy Cows
- Estimates of nutrient balance and management for 699 to up to 2,000 mature dairy cows
**Spectrum Soils Data Analysis**

Samples from all proposed paddocks were taken and analyzed. The results from 22 samples of soils from paddocks 101 to 123 (upper central portion of the dairy) are given in Table 1.

Table 1. Average soil pH, soil organic carbon, and key nutrient levels in soils of the proposed site at Hawai‘i Dairy Farms, Maha‘ulepu Valley, Kaua‘i (Spectrum Analysis of 22 samples – North portion of the dairy).

</tbody>
</table>

These results report that soil pH was highly variable, ranging from a low of 5.6 to a high of 8. This indicates a great deal of variability that should be considered in developing management options. Soil organic carbon levels were moderately high, yet highly variable throughout the sampled area. Plant extractable phosphorus was generally low, but varied greatly – from 4 to 42 mg P kg⁻¹. Exchangeable potassium was generally low (0.45) but also varied widely from 0.13 – 0.97. Average exchangeable calcium was moderately high but also varied the most among soil nutrients from 3.29 to 39.76 cmol kg⁻¹. Average exchangeable magnesium was also relatively high at 7.25 and also varied widely from 3.07 – 11.1 cmol kg⁻¹. Soil salinity and sodicity were not initially measured but were assessed with a subsequent sampling and analysis given in this report.

**Low initial levels of soil nutrients**

A summary of the results indicated that levels of soil nutrients were generally low and inadequate to sustain high forage grass productivity. Such low levels of nutrients were only of moderate concern because the application of manures and effluents are known to supply substantial quantities of nutrients that can enrich and regenerate soil fertility (Valencia-Gica et al., 2012). While initial soil carbon values were moderate, it is likely that management for high forage yield through irrigation and organic fertilization with manure will greatly improve soil carbon levels and improve soil health.
**Field Trials and estimates of kikuyu forage grass**

On site estimates of forage grass productivity were conducted to assess actual forage grass productivity of the Maha‘ulepu.

<td>3.0 – 25.1</td>
</tr>
</tbody>
</table>

\(^1\)Note: It is likely that forage yields would increase considerably with optimal irrigation and application of nutrients. These preliminary results indicate that productivity varies sharply throughout the year requiring some reserve forage.

**Hydrologic analysis of the Hawai‘i Dairy Farm site**

A hydrologic report from TNWRE (2016) reports an analysis of major hydrologic features of the dairy, comprised of surface water and groundwater. This report concludes that potential losses of nitrogen and phosphorus to surface and groundwater, groundwater flow will not be a significant. “…Relative to the surface water, the groundwater flow in the alluvium is very modest. The formation is poorly permeable and even after HDF is in full operation, its contribution to an increase in nutrient load will not be significant in comparison to surface water.”(TNWRE 2016). Thus the potential loss of nitrogen and phosphorus is primarily dependent on the amount of surface water and runoff, which is minimal due to minimal rainfall (98% of the days have less than 0.8 inches). It is estimated there will be 7 to 8 days a year in which rainfall derived runoff will occur (TNWRE 2016). Best management practices outlined in the Waste Management Plan seem more than adequate to reduce and minimize nutrient loss.

**Best management practices identified**

Knowledge of the area’s hydrologic conditions, specifically soil drainage characteristics is essential to utilizing the beneficial nutrients from dairy effluent while reducing or eliminating detrimental accumulations of sodium and salts (Silva et al., 1999). The extensive occurrence of “poorly drained” soils as described further in this report limit leaching of surface water into groundwater as also indicated in the hydrologic report of TNRWE, 2016). Best management practices were identified for controlling surface water in the HDF Waste Management plan (Group70, 2014). The HDF Waste Management Plan (Group70, 2014) calls for a series of BMPs (Best Management Practices) that reduce or eliminate nutrient loading from surface water including set backs, filter strips, buffer plantings and maintaining herbaceous covers. TNRWE, 2016 concludes that the primary challenge will be the operating skills of the HDF personnel, including tracking the actual nutrient balances within the soil, forage, and manure to ensure high forage productivity, avoiding excess fertilizer and anticipating / preparing for weather patterns that might produce runoff. An initial analysis of the nutrient cycling through assessment of the nutrient balances are given below.
**Waste Management Plan, for 699 Mature Dairy Cows**

A comprehensive waste management plan was prepared and presented in the Waste Management Plan (Group 70, 2014). This plan includes assessments and a management plan that includes water resources, flood hazards, soil characterization, dairy management suggestions, irrigation, waste management systems and precautions, as well as monitoring of both soil and water resources.

Implementation of this plan will be essential for ensuring the sustainability of production of forage and the health of the water and soil resources. While quite comprehensive, the report did not include an assessment of the salinity (the addition of nutrient salts) and sodicity (the amount of soil sodium) that might be associated with the high levels of nutrient flux involved as the dairy achieves maximum productivity (Muscolo et al., 2003, El-Swaify, 2000). Other research has shown that effluent in particular contains large amounts of salts (Cameron et al., 2003; Valencia-Gica. 2012). Many of those salts are nutritionally beneficial but some require monitoring such as levels of sodium. The additional sampling, soil characterization, and analysis of the nutrient cycling as represented by the nutrient balance analysis add to nutrient management plan.

**Estimates of nutrient balance and management for 699 to up to 2,000 mature dairy cows: A first approximation of the nutrient balance and estimate of fluxes of nutrients**

An initial estimate of the nutrient balance for the major nutrients nitrogen and phosphorus was reported by Red Barn and Group 70, (2016), Table 3. These calculations provide the basis for estimating nutrient requirements from fertilizers and external sources to ensure grass productivity is sustained at a high level.

Table 3. Estimates of annual nutrient (nitrogen and phosphorus) uptake, manure production, and fertilizer requirements for 470 acres of irrigated dairy pasture (Red Barn and Group 70 report, 2016) revised by including manure contributions from calves.

The nutrients from supplemental fertilizer, shown in Table 3, are not an exact accounting of the total amount of commercial fertilizer to be purchased and applied to the pasture every year. Rather, these values represent the net amount of nutrients required to
maintain high forage productivity and soil health from commercial fertilizer, which is beyond nutrients available from manure sources. Fertilization, especially the additional of nitrogen from a commercial fertilizer can be inefficient with respect to forage production and protein content, and fertilization needs can be as much as 25% to 50% greater than the arithmetical difference resulting from a nitrogen balance calculation. The addition of phosphorus from a commercial fertilizer is also quite inefficient, because of the extensive sorption and binding reactions of phosphorus with the soils at the HDF site, sharply reducing the amount that becomes plant available (Jackman et al. 1997).

Grasses with fibrous root systems are typically among the most efficient plants in using applied (whether through manure or commercial fertilizer) nutrients, especially nitrogen. Previous studies have shown that application of effluents generated from dairy operations via irrigation systems is an effective means of both managing the effluent while simultaneously returning nutrients needed by the productive tropical grasses (Fulkerson et al., 2016), and that the value of returning nutrients from dairy effluent has been demonstrated and documented in Hawai‘i conditions by Valencia-Gica (2012). Therefore, commercial fertilization requirements to maintain high forage productivity and soil health can substantially exceed the arithmetic difference between the nutrients applied by manure and effluent and the forage uptake.

Objectives of the further soil characterization and assessment presented in this report:

Based on the above initial information, several gaps were identified that required further data to characterize and assess soil properties to ensure high productivity and sustainability of the dairy. The assessment of salinity and sodicity potential is important because it can affect forage productivity and soil health. This additional sampling of soils of the Hawai‘i Dairy Farm was carried out with the following purposes:

1. Establish a quantitative baseline of nutrients needed to ensure maximum forage productivity.
2. Establish a quantitative baseline for nutrients that are typically supplied in dairy effluent.
3. Evaluate the extent of the “poorly drained” map units of the proposed dairy
4. Establish a quantitative baseline for the salinity and sodicity status of soils. This baseline will provide a reference point to monitor and ensure sustained productivity and soil health of the dairy land.
Figure 1. Location of Hawaii Dairy Farms site, Kauai'i, Hawaii
Figure 2. Map of the Dairy showing proposed fields, field management units, and proposed facilities. Note the numbered parcels that comprise fenced grazing units, and “Blocks” that represent proposed management units for 699 mature dairy cows (Waste Management Plan, 2014, prepared by Group70, Honolulu, Hawai’i.)

Sampling, Measuring and Analytical Methods

1. Establishing a quantitative baseline of nutrients needed to ensure maximum forage productivity.

Sampling locations were selected on a gridded map, then entered as points into a geographical information system (ArcGIS) and also uploaded to a handheld global positioning system (GPS) for field location (Fig. 3). Once a sampling site was located with the handheld GPS unit, three subsamples approximately one meter apart were taken for each depth, mixed to prepare a composite sample per depth, then prepared and transported for processing. Processing included drying, crushing, and passing the soil
samples through a 2 mm sieve. Processed samples were then delivered to CTAHR’s Agricultural Diagnostic Service Center for the analysis.

Soil Analysis
Soils were analyzed for pH, extractable phosphorus, exchangeable potassium, calcium, magnesium, electrical conductivity (EC), and sodium. Finally soil organic carbon and total soil nitrogen were determined. Total nitrogen and total carbon values were analyzed via dry combustion (LECO, 2002) and expressed in weight percent. Phosphorus was analyzed using Olsen’s extractable P method (Watanabe and Olsen, 1965), and reported in mg kg\(^{-1}\) (equivalent to parts per million or ppm). Cations (potassium, calcium, magnesium and sodium) are reported as centimoles of charge per kilogram (cmol kg\(^{-1}\)) in order to account for the amount of charge of the various cations and to permit the calculation of the relative concentration of sodium. Sodium percent of cations (ESP) was calculated as cmol kg\(^{-1}\) sodium divided by the cmol kg\(^{-1}\) of all cations (potassium, calcium, magnesium and sodium) x 100% in order to compare with literature values in order to evaluate for excessive sodicity. This standard measurement of soil sodicity helps assess the likelihood of soil dispersion, and to compare with recommended values from the NRCS (2012) and other scientific references (McIntyre, 1979; Cameroon et al. 2003). This assessment provides a measure to ensure sustainable productivity and health of the soil resources of the dairy.

Statistical Analysis
The assessment of nutrient adequacy was the statistical comparison and calculations among the soil mapunits. These were carried out using the JMP statistical software (JMP®, 2007). Standard least squares methods were used to test for differences between soil depth and soil mapunit for the nutrient and element contents. Differences were considered significantly different at a probability level of 0.05, although a probability of 0.10 or less was also considered important and worthy of further consideration. Samples from the Ws soil mapunit were not included in the ANOVA since it was only a small portion of the southern portion of the dairy and is basically atypical of the dairy.

Mapping
A geostatistical analysis of the data was also conducted with ArcGIS Geostatistical Analyst Extension using Empirical Bayesian Kriging to map the variability of the fertility characteristics and to interpolate levels of soil measurements to display patterns and trends for the entire dairy. This analysis produces a smooth map of nutrient variation throughout the dairy as illustrated in Figures 3, 4, 5, and 6 illustrating trends and patterns in the soil properties. The analysis also produces a map of prediction error indicating where predictions were less accurate (Figure 7). The map of prediction error helps to identify areas on the dairy which would most benefit from further sampling (Map 10, Sampling Variability). This map of prediction error was almost identical for all response variables, therefore only one (from pH data) is included in this report.
Figure 3. Soil sampling design (43 locations), soil mapunits and initial soil pH map. Note: LuB: Lualualei soil series, well-drained, 2 – 6 % slope; Ws: Waikomo, well-drained, stony clay, PdC: Pakala clay loam, well-drained, 2 – 10% slope; PdA: Pakala clay loam, well-drained, 0 – 2 % slope; Ke: Kalihi clay, poorly-drained; KavB: Ka`ena clay brown variant, poorly-drained, 1 – 6 % slope; KavC: Ka`ena clay brown variant, poorly drained, 6-12% slope; HsD: Hanamaulu silty clay, well-drained, 15-25% slope.
2. Establishing a quantitative baseline for nutrients that are typically supplied in dairy effluent.

The nutrients typically supplied in dairy manure and effluent include nitrogen, potassium and phosphorus, which were measured for input into nutrient balance calculations. A quantitative baseline for these nutrients will enable the monitoring of the balance of nutrient removals by grazing animals and the return and recycling of nutrients through re-use of manures and effluents. Deficits in the recycling of nutrients will be made up by judicious application of nutrients through organic amendments and fertilizers.

The pasture – soil nitrogen status is especially difficult to quantify because nitrogen exists in soil, solution, and gaseous phases. In addition the soil and solution forms are microbiologically mediated between inorganic and organic forms. As a result nutrient nitrogen additions may differ from the simple arithmetic difference between forage and animal outputs and organic and fertilizer inputs. Nonetheless, determining a quantitative baseline of nutrient status is the currently best approach to nutrient monitoring.

The cations (potassium, calcium, magnesium and sodium) are reported as centimoles of charge per kilogram (cmol kg\(^{-1}\)) in order to account for the amount of charge of the various cations and to permit the calculation of nutrient balance and the relative concentration of sodium needed to estimate hazards from sodicity.

3. Determining the extent of “poorly drained” soil mapunits

Two soil samples were taken from each of the 43 locations at the Dairy site, at depths of 0-20cm and 20-40cm, for a total of 86 samples (Figure 2). Thirty-three locations chosen for sampling were from Kalihi Clay (soil mapunit Ke) which is characterized as “poorly drained” and comprises the primary soil mapunit of the south-central area of the dairy. Two samples were taken from the Kaʻena Clay Brown Variant (soil mapunit KavB, KavC), which is also “poorly drained”. Four additional locations were sampled from Lualualei clay (soil mapunit LuB), and two additional locations from Pakala Clay Loam (soil mapunit PdC) and Waikomo Stony Silty Clay (soil mapunit Ws), all of which were classified as “well-drained”, were collected in an effort to gain a broader sense of the site-wide fertility status and to enable a statistical comparison among the various mapunits that comprise the proposed dairy area. In summary the soil mapunits Ke, KavB, and KavC comprised the portion of the dairy that was characterized as “poorly drained.” The management of nutrients and irrigation on this portion of the dairy will differ from that of the “well drained” portion of the dairy (all of the other soil mapunits).

4. Establish a quantitative baseline for the salinity and sodicity status of soils.

Assessing soil salinity and sodicity requires measures of soil cations

The soil salinity is measured as electrical conductivity (EC), which is a quantitative estimate of the amount of salt in the soil. The units are deciSiemens per meter, which is
similar to the historical unit of mmhos/cm (El-Swaify, 2000). A level of soil salinity of 2 to 4 dS m\(^{-1}\) represents an amount of salts in the soil that can cause reduction in growth of some salt-sensitive plants (Hanson et al., 1999). Kikuyu grass, however, seems relatively salinity tolerant (Muscolo et al., 2003).

_Sodicity_, or the relative amount of soil sodium, is expressed as the exchangeable sodium percentage (ESP), which is the concentration of sodium relative to the other cations (calcium, magnesium and potassium). Values of soil sodicity that exceed 15% are recognized as levels that could lead to problems of soil dispersion and altered soil physical properties (Richards 1954; McIntyre 1979; El-Swaify, 2000). This standard measurement of soil sodicity helps to assess the likelihood of soil dispersion, and to compare with recommended values from the NRCS (2012) and other scientific references. These two important measures of soil health provide a quantitative measure useful to monitor and ensure sustainable productivity and health of the soil resources of the dairy.

**Results**

1. **Establishing a quantitative baseline of nutrients needed to ensure maximum forage productivity.**

As indicated in the introduction, the goal and objective of the Hawai‘i Dairy Farm is to improve both the food security of the county of Kaua‘i and state by producing nutritious food while also ensuring and improving soil health. The scientific management of the nutrient cycles is a way to achieve these two goals. The nutrient management of nitrogen, phosphorus, and potassium recommended in this report is designed to achieve both goals. The overall nutrient management strategy proposed in this report is comprised of two steps: 1) Adjust the levels of the critical nutrients in the dairy soils to meet the needs of the fully productive forage grass while avoiding excessive applications that might enter surface and groundwater, and 2) When the pasture and dairy are fully established and achieving full productivity, ensure the sustainability of achieving high productivity while maintaining or improving soil health. A quantitative baseline for these nutrients will enable the monitoring the balance of nutrient removals by grazing animals and the return and recycling of nutrients through re-use of manures and effluents. Deficits in the recycling of nutrients will be made up by judicious application of nutrients through organic amendments and fertilizers.

*Adjustment of nutrient levels on specific soil mapunits*

The first step in ensuring productivity of the forage is to ensure sufficient nutrients are provided to the forage grass. To achieve this, the dairy soils were sampled and analyzed to complement and extend the earlier soil analysis (see Table 1 for preliminary results and Table 4 for the data analysis conducted for this report). These analytical results were obtained by Spectrum Analysis (Table 1) and from the Agricultural Diagnostic and Service Center of the University of Hawai‘i (Table 4).
Table 4. Overall means for soil pH, soil nutrients phosphorus, potassium, calcium, magnesium and sodium. Values for soil salinity, and soil carbon and nitrogen are also given for Hawai‘i Dairy Farms, Maha‘ulepu Valley, Kauai. Analysis by the Agricultural Diagnostic and Service Center, University of Hawai‘i.

The soil mapunits varied widely for the values of soil pH, potassium, calcium, magnesium, salinity (EC), and sodium (Table 4). These baseline results indicate major differences among the soils of the dairy. These results indicate that in order to achieve maximum forage grass production additional nutrients are needed and they need to be gauged according to soil mapunit. In addition, the large differences among the mapunits, especially in calcium, magnesium, and sodium show that the poorly drained soils will likely need to be monitored separately from those that are not poorly drained. This suggests that regular monitoring of the soil status of paddocks on these soil mapunits are needed as part of the overall monitoring program.

†Values followed by the same letter indicate that the values were essentially the same. Otherwise values are ranked by decreasing alphabetical order. Target values are for the following nutrients: phosphorus: 25-35 (mg/kg or ppm), potassium: 0.5-0.76 (200-300 mg/kg or ppm), calcium: 3.75-5.0 (1500-2000 mg/kg or ppm), and magnesium: 2.5-3.5 (300-400 mg/kg or ppm) (Yost and Uchida, 2000).

Soil nutrient levels

Soil phosphorus levels of the dairy were largely inadequate for maximum grass forage productivity (Table 4&5). Portions of the dairy (Figure 4) that are yellow, orange, and red (not green) indicate the regions that were characterized by low levels of the nutrient phosphorus. Soil phosphorus, however, was higher and marginally adequate in the green regions of the dairy. The sharp boundaries of the phosphorus map probably reflect the fact that phosphorus as a nutrient in the soil moves very little and creates localized zones
with high levels next to zones with low levels. The soil potassium map shows much smoother boundaries than does the phosphorus map probably reflecting the much greater mobility of potassium in soils. The soil nutrient potassium was higher on the PdC mapunit of the southwest corner of the dairy site. The higher levels of potassium and phosphorus may have been on fields previously fertilized for other crops. Soil calcium levels were extremely variable representing the sharply contrasting soil mapunits found on the dairy. Levels ranged from marginally adequate in the north portion of the dairy to high and very high in the central southern portion of the dairy. These contrasting levels of calcium may reflect the differences in drainage and nutrient dynamics on the differing mapunits. Calcium levels were adequate but were clearly greater on the Ke mapunit. Soil magnesium levels were similar on all mapunits except the PdC mapunit, which may have included soil of an adjacent field that was previously fertilized and managed differently. The substantially higher levels of soil calcium, magnesium, and sodium on the Kalihi mapunit than on other mapunits probably reflects the results of the lower amounts of water movement through the soil profile and a difference in soil mineralogy – a result of the “poorly drained” water status of the soils. This indication of differing nutrient dynamics may imply monitoring with possible adjustment to the nutrient additions to compensate for nutrient deficits predicted to result from nutrient recycling described below.

Figure 4. Status of soil phosphorus and potassium, Hawai`i Dairy Farms, Maha`ulepu site, Kaua`i.
Initial and maintenance nutrient requirements

As indicated from the initial sampling, soils at the site differ according to the mapunit. A two-step recommendation is proposed. The first step, “restorative nutrient management” is the application of nutrients in the first year to bring the initially low soil nutrient levels to a level to ensure maximum grass establishment and productivity. The second step, “maintenance nutrient management” which is difficult to predict beforehand, is the amount of nutrients to be added for each grazing rotation for each paddock management unit after pasture establishment and grazing frequency and intensity are determined. Applications to paddocks on specific soil mapunits for step 1 were calculated and are given in Table 6. While levels of phosphorus are low on all mapunits, levels of potassium vary and will require adjustment according to mapunit and specific productivity of paddocks on that mapunit. With the initial adjustment of nutrient levels and the close monitoring of nutrients and soil calcium, magnesium, and sodium status on the poorly drained mapunits high productivity and improved soil health is expected.

Table 6. Initial annual levels of nutrient fertilizers that need to be applied to each of the mapunits to achieve potential grass productivity.

The second step in managing nutrient cycles is the careful monitoring of the actual nutrient balances once the dairy is in operation – the “maintenance nutrient management”. The discussion of these recommendations follows in a separate section that describes the monitoring and assessment of the respective nutrient cycles and balances of nitrogen, phosphorus, and potassium. This requirement also depends on the actual animal grazing pressure.

2. Monitoring and balancing nutrients recycled in manure and effluent

In managing nutrient cycles of the dairy the recycling of animal manures constitutes an important input of nutrients to the pasture, particularly in the forms of nitrogen, phosphorus and potassium, all of which are initially present at inadequate levels in the dairy soil. These recycled nutrients substantially reduce the need for fertilizers to maintain forage grass productivity (Fulkerson et al, 2016). The following nutrient balance estimates illustrate the estimated nutrient additions resulting from the recycling.

Nutrient removals in forage and additions in manures
The results presented in Table 7 indicate that the projected removal of nutrients by the highly productive forage grass is not quite balanced by the addition of nutrients in the manures and effluents. This deficit will need to be made up with the addition of nutrients.
from other sources such fertilizers. The amounts that are predicted to be necessary are actually quite small since the dairy will be following a rotational grazing system and animals will be grazing intensively on a paddock for a short period of time. The end of a grazing cycle would be an ideal time for the application of the small amounts of nutrients to restore the nutrient balance.

**Nutrient balance deficit**

Table 7 provides an initial estimate of the nutrient balance deficit. Note that there is a predicted deficit in each of the macronutrients N, P, and K even with the return of manures and effluents. There are two variables that fundamentally determine the nutrient balance estimates of Table 7. The first is the actual forage yield. The estimates in Table 7 for dry matter production are a major determinant of the amount of nutrient removed. The predicted yields for the spring part of the year may well be somewhat less than assumed in Table 7 based on the preliminary yield experiments described in Table 2. The second key variable in determining the actual nutrient balance is the number of animals in the dairy. The number of animals assumed in Table 7 is 699. A nutrient balance calculated with a higher number of animals such as 2000 (data not shown) results in a small excess of phosphorus due to much larger amounts of recycled nutrients.

**Nutrient phosphorus should be monitored carefully**

Soil phosphorus levels were significantly higher in the 0-20cm depth than the 20-40cm depth (Table 8), a not so unusual occurrence where animal manures, as-excreted, are applied. There were no significant differences among soil mapunits. There were some trends in the distribution of phosphorus over the site as illustrated in Figure 4. Nutrient phosphorus is a noteworthy management variable because it typically accumulates or is static because removal rates seldom dramatically exceed application rates. This result also occurs because as indicated earlier, soils especially of the mapunits of the dairy are known to adsorb and retain large amounts of the nutrient phosphorus.

**3. Location and extent of “poorly drained” soil mapunits**

“Poorly drained” soil mapunits tend to reduce leaching of nutrients to groundwater. The previous mapping of the dairy site soils by the Natural Resources Conservation Service (Foote et al., 1972) provides useful information about the status and characterization of the soils of the Hawai‘i Dairy Farms site. The majority of the soils of
the proposed dairy site were classified as “poorly drained” (Figure 3). A further more detailed map of the paddocks that were on the “poorly drained” versus the “well-drained soil is given in Figure 6. A specific listing of the paddocks that are located on “poorly drained” and “well-drained” soil are also given in Appendix 1. It is important to note that the classification of soils as “poorly drained” indicates that on such soils there is less lateral and downward movement of soil water than in soils classified as “well drained”. The designation of “poorly drained” is not an indication of low or poor infiltration, which refers to the ability of water and effluents to enter the soil surface. Said another way, soil “drainage” refers to the movement of water within or through the soil profile.

Additionally, “poorly drained” soils often exhibit anaerobic conditions, which are important in both the presence and movement of nutrients that can affect soil environmental health, most importantly nitrogen and its various soluble forms nitrate, nitrite, and ammonium. Anaerobic conditions typically result in higher rates of nitrogen loss due to denitrification, which is the conversion of potentially environmentally hazardous nitrate and nitrite to gaseous, innocuous forms, reducing or eliminating levels in soils of both the nitrate and very toxic nitrite.

Higher levels of nutrients in “poorly drained” soil mapunits. As a result of the reduced movement of water through the soil profile of “poorly drained” soils, the mobility of other nutrients such as potassium and phosphorus is usually reduced as well. In this way “poorly drained” soils tend to retain more nutrients within the soil profile than do “well-drained” soils. This may well be one of the reasons for the higher soil pH and higher levels of calcium and magnesium noted in the Ke mapunit (Tables 5 and 6). The reduced loss of other nutrients has important impacts on the nutrient balances that need to be calculated and monitored to ensure soil health and quality are sustained. “Well-drained” soils, while allowing movement of water out of the soil profile, still fully support the naturally-occurring, cleansing processes that filter and process water moving through the profile. Other considerations such as depth to the water table and hydrologic conditions are important.
Figure 6. List of HDF paddocks and the soil drainage characteristic of each.

Reduced likelihood of deep leaching of nutrients from surface to groundwater

The hydrology of the proposed dairy site has been thoroughly characterized and documented in the report by Nance (2016). This report indicates that the amounts of soil water that can move from the soil surface into underlying groundwater is minimal when the dairy land is irrigated and manure effluents are applied. While the underlying hydrological conditions tend to separate the surface and underlying aquifers there are important differences reported in the hydrologic study that are discussed above in the section on “poorly drained” soil mapunits. The implications of whether forage is produced on soil mapunits that are “poorly drained” or “well-drained” may affect nutrient and fertilization requirements as well as determination of the nutrient balance of the
various paddocks and nutrient management blocks (Figure 2), thus justifying careful monitoring of the nutrient balance once the dairy is in operation.

4. **Establish a quantitative baseline for the salinity and sodicity status**

The pH of the dairy site soils ranged from the high for the Ke mapunit of to 8 to a low of 4.7 in the KavB and PdC soil mapunits (Table 5, Figure 3). The higher soil pH of mapunit Ke probably was a result of the higher levels of soil sodium recorded in that mapunit. Soil salinity was uniformly low and did not differ much among the soil mapunits (Table 4, Table 9, Figure 7).

†Values followed by the same letter indicate that the values were essentially the same. Otherwise values are ranked by largest (letter a) to smallest. Soil salinity in the range of 2 to 4 dS m⁻¹ are considered high enough to affect salt-sensitive plants. Exchangeable sodium levels are well below the threshold of 15% sometimes considered indicative of potential soil physical problems (Richards, 1954; El-Swaify, 2000, Cameroon et al, 2003).

Soil sodium levels were much, much higher in Ke than in the LuB and PdC soil mapunits, while levels of sodium in the KavB mapunit were intermediate (Table 9, Figure 8). The key measurement of soil sodicity, the ESP value, remained well below the level of 15%, frequently considered as the threshold between low, acceptable levels and high, unacceptable levels. It is interesting to note that while the Ke mapunit contained almost double the amount of sodium than did the KavB mapunit, the calculated ESP was similar on both soils pointing out the importance of considering all cations in evaluating sodicity.
Figure 7. Status of soil pH and salinity (EC), Hawai‘i Dairy Farms, Maha‘ulepu, Hawai‘i.

Figure 8 Status of soil sodium and exchangeable sodium percentage (ESP), Hawai‘i Dairy Farms, Maha‘ulepu, Hawai‘i.
Conclusions and Recommendations

1. **Establishing a quantitative baseline of nutrients needed to ensure maximum forage productivity.**
   The results of the initial soil sampling together with the analysis presented in this report indicate that current nutrient levels are generally inadequate for phosphorus and potassium in the soils of the proposed dairy site.

   The results suggest two steps to restore and ensure adequate levels of nutrients so that the forage grass becomes well-established and achieves and maintains maximum productivity.

   Step 1. “Restorative nutrient management”, which is dependent on the initial, baseline quantitative measurement of soil conditions

   Step 2. “Monitoring and adaptive nutrient management”, which is dependent on number of grazing animals, grass productivity, and amount of recycled nutrients and which may vary with soil mapunit.

2. **Establishing a quantitative baseline for nutrients that are typically supplied in dairy effluent.**
   An initial estimate of the nutrient cycles of nitrogen, phosphorus, and potassium indicate that even if all of the manures and effluents are returned to the pasture there will still be a small nutrient deficit that depends on the numbers of animals managed. At the maximum proposed animal population there might be a slight excess of nutrient phosphorus. Alternative best management practices are available to reduce the amount of phosphorus recycled to the dairy paddocks.

3. **Location and extent of “poorly drained” soil mapunits**
   The occurrence of several “poorly drained” soil mapunits, on one hand, confirms the hydrologic study results that concluded little of the surface water would reach the groundwater. In addition, the “poorly drained” property of many of the soils suggests that nitrogen risk may be reduced due to the expected conversion of unhealthy forms of nitrogen such as nitrate and nitrate, and ammonium to gaseous nitrogen through denitrification.
Nonetheless, the impact of the “poorly drained” property on the soil salinity and sodicity should be monitored because those properties vary according to the soil mapunit and will be sensitive to actual nutrient cycles.

4. **Establish a quantitative baseline for the salinity and sodicity of the dairy soils.**

Initial results of measures of soil salinity and sodicity suggest no threat to soil health at present levels. Due to the differing dynamics of “poorly drained” soils, paddocks of the “poorly drained” mapunits Ke, KavB, and KavC should be monitored carefully.

A general recommendation is that ensuring forage grass productivity and sustainability of the dairy will require at least two steps: 1) Restorative nutrient management to ensure grass establishment and productivity, and 2) Maintenance nutrient management, designed to monitor the actual nutrient balance needs. Factors that are likely to cause major impact on the maintenance nutrient requirements are 1) The actual productivity of forage grass, and 2) The number of animals consuming forage and 3) The efficiency in returning manures and effluents to the growing grass. The amounts of rainfall are also important in determining the actual nutrient cycles.

Monitoring the nutrient cycles is thus a primary management variable for sustainable production and for the improvement and sustaining of health of the dairy site soils.

1.0 Project Overview

In late 2013, Ulupono Initiative made the investment to fund Hawai‘i Dairy Farms, the first pasture-based, rotational-grazing dairy in the state. Hawai‘i Dairy Farms, LLC (HDF) was formed as a positive step toward the island state’s food security, economic diversity, and sustainability. At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually. HDF will reduce Hawai‘i’s reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State of Hawai‘i, Department of Health (DOH) is required. The application process for a National Pollutant Discharge Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The project will be located in the Māhā‘ulepū Valley on the island of Kaua‘i, exclusively within the approximate 556.8 acres of land leased by HDF from Mahaulepu Farm LLC. See Figure 1 - Vicinity Map.
The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that livestock and grazing activities are contained within the project area. The project area has historically been used for agriculture, including commercial sugar cane production for over one hundred years, and is comprised of lands designated pursuant to the Hawai‘i State Constitution as Important Agricultural Lands. Accordingly, the project is consistent not only with past agricultural use of the area, but with ongoing constitutionally recognized interest in maintaining and utilizing the area for agricultural purposes that promote agricultural self-sufficiency.

Unlike traditional conventional feed-lot dairies, in which mature dairy cows are confined and fed only feed such as grain, hay and silages, the project will be the first dairy in the State to utilize rotational, pasture-based grazing. The rotational, pasture-based grazing approach is a system that involves regularly rotating cows through farm paddocks, where they will primarily feed on locally grown grass, supplemented with grain and vitamins as needed. This approach optimizes grass growth, cow health and milk production, facilitates even applications of waste products for fertilization, prevents over-grazing and over-application of fertilizers, and maintains erosion and runoff controls.

The initial herd of up to 699 mature dairy cows will be divided into groups and rotated through a series of paddocks over an 18-day period to access fresh grass and deposit manure throughout the area. Cows will move through a system of raceways to and from the milking parlor, where they will be milked twice a day for a total of two hours. The remaining dry cows, heifers and 90-day and older calves will be managed off-property on existing ranches that are owned and operated by other local ranchers.

HDF has prepared this Nutrient Balance Analysis for its Environmental Impact Statement (EIS), to disclose the planned waste management systems to support the initial herd operation as well as full-production (up to the carrying capacity of the land) operation. The analysis has been based upon the “Guidelines for Livestock Waste Management”, prepared by the University of Hawai‘i-Mānoa Cooperative Extension Service, College of Tropical Agriculture and Human Resources (CTAHR) in consultation with the State of Hawai‘i Department of Health.
Figure 1 – Vicinity Map
Figure 2 – Project Location Map
2.0 Existing Conditions

The project area has historically been used for sugar cane production as part of the Kōloa Plantation until the late 1990s when the Kōloa Mill closed. Since the mill closed, the project area has been leased to various tenants for ranching and diversified agricultural operations. A small plot of land in the lower center of the valley is currently used for taro lo‘i and will continue to be leased and farmed after the dairy and related pastures are in full operation. See Figure 2 – Project Location Map.

The original agricultural infrastructure from the sugar plantation is largely still in place and continues to be used for on-going agricultural activities. Much of this existing infrastructure will also be used for the dairy, but with a significant amount of upgrades and improvements. The existing infrastructure in the project area includes: gravel and dirt access roads, field roads, water wells, reservoirs, pipelines, pumps, irrigation ditches, drainage ways and culverts.

2.1 Topography

The project site is situated in the Māhāʻulepū Valley on the island of Kauaʻi. The valley is on the leeward side of the Hāʻupu mountain ridge, which runs in the east-west direction, and the valley is also flanked by ridge lines on both sides. Mt. Hāʻupu is the highest point on the ridge line at the back of the valley with an elevation of 2,297 feet. From this point, the ground drops very quickly down to the bottom of the valley to about an elevation of 150 feet. The base of the valley itself is somewhat gradually sloped from an elevation of 150 feet to an elevation of 60 feet along Māhāʻulepū Road on the makai side of the project site near the taro farm. See Figure 3 - USGS Map.
2.2 Water Resources

The Māhāʻulepū Valley has been in agricultural use for decades and much of the water resources and infrastructure in the valley are man-made and were constructed to provide irrigation water for commercial sugar cane cultivation throughout the valley. Systems of ditches, reservoirs and irrigation pipes and pumps are still in place and are still used to provide water to the existing taro ponds, and to irrigate fields and pasture. Existing groundwater wells, monitoring wells, and drainage ways and water bodies are shown on Figure 4. See Figure 4 - Water Resources.

2.2.1 Receiving Water Body State Water Quality

The drainage ways and ditches within Māhāʻulepū Valley and within the project site are not classified for protection by the Department of Health. These canals and ditches flow in the makai direction, beyond the project site, across Māhāʻulepū Road, and into the adjacent agricultural lands. The unnamed drainage ways from the valley all converge near Puʻu Keke and are discharged into marine waters along the Māhāʻulepū coastline between Kamala Point and Punahoa Point.

This stretch of open coastal waters is classified as Class A for water quality standards in HAR §11-54, which states: “the objective of Class A [marine] waters is that their use for recreational purposes and aesthetic enjoyment be protected. Any other use shall be permitted as long as it is compatible with the protection and propagation of fish, shellfish, and wildlife, and with the recreation in and on these waters. These waters shall not act as receiving waters for any discharge which has not received the best degree of treatment or control compatible with the criteria established for this class” (DOH, 2014).

2.2.2 Wetlands

Biological resources, including aquatic systems and wetlands, are discussed in the Flora and Fauna, Biological Survey, conducted by Rana Biological Consulting (2016) under separate cover.

2.2.3 Water Wells

The State Department of Land and Natural Resources (DLNR) Commission on Water Resource Management (CWRM) manages and tracks water resources in the State including groundwater
wells. The State database identifies two primary well sites in the Māhā‘ulepū Valley. The Kōloa F Well is a public drinking water source used by the County of Kaua‘i Department of Water Supply. The Māhā‘ulepū Well site includes up to 14 groundwater wells drilled by the sugar cane plantations. The water wells are shown on **Figure 4 - Water Resources**. The Kōloa F well is located over 0.5 miles away from the dairy facility including the milking parlor, and is approximately 580 feet from the westernmost boundary of the farm. Though not required by DOH or the “Guidelines for Livestock Waste Management”, prepared by the CTAHR, a setback of 1,000 feet will be provided around Kōloa F from any pasture activities, application of effluent, or livestock grazing (the guidelines require a minimum 50’ setback for public water drinking sources from land application of effluent).

Existing monitoring wells, recently installed prior to the commencement of the EIS, are located on the project site. **See Figure 4 - Water Resources**. Groundwater resources are discussed in the “Estimates of the Potential Impact on Groundwater and Surface Water by Hawaii Dairy Farms in Mahaulepu, Kauai” report, conducted by Tom Nance Water Resource Engineering (2016).
Figure 4 – Water Resources
2.3 Rainfall Data

The data sources used for sizing of the waste management systems at the dairy facility site and for pasture irrigation scheduling are described in this section.

2.3.1 Normal Precipitation

Normal monthly precipitation depths at the dairy facility were obtained from the University of Hawai‘i Rainfall Atlas of Hawai‘i (2011). The average monthly precipitation depths will be used for sizing of the waste management systems and irrigation scheduling as required by the Guidelines.

2.3.2 NOAA 24-Hour Rainfall

Precipitation depths at the dairy facility, for various durations and recurrence intervals were obtained from NOAA Atlas 14, Volume 4, Version 3. The 25-year 24-hour precipitation data will be used for sizing of waste management systems as required by the Guidelines.

2.3.3 NOAA Rain Gauge Data

Rain gauge data was obtained from NOAA National Climatic Data Center for the Māhāʻulepū 941.1 rain gauge located on the farm off of Māhāʻulepū Road (GHCND:USC00515710 - MĀHĀʻULEPŪ 941.1 HI US). The rain gauge is located at: Elevation = 24.4, Latitude = 21.90194, Longitude = -159.42111. The data record analyzed included daily precipitation records from 1/1/1984 to 12/31/2013 for a total of approximately 10,957 days (30 years). The rainfall events were ranked based on days of consecutive rainfall (DAPR) and the corresponding multiday precipitation total (MDPR). The data suggests that having more than a week of consecutive rain is very unusual for Māhāʻulepū Valley with this only having occurred 5 times in the last 30 years.

### 2.4 Evaporation Data

Pan evaporation data was obtained from State of Hawai‘i DLNR Pan Evaporation Report R74 dated August 1985 for station Māhā‘ulepū 940.00. Evapotranspiration data was obtained from UH Mānoa Department of Geography, 2014 Evapotranspiration Maps (Lat 21.907N, 159.422W). Potential evapotranspiration data (ETo) for a grass reference was used – as the site will have an all grass crop, and then the rate was further adjusted for Kikuyu grass using a crop coefficient of 0.85 to determine an evapotranspiration rate for Kikuyu crop (ETc).

### 2.5 Flood Hazards

The entire project area is located within Federal Emergency Management Agency (FEMA) Zone X based on FEMA Flood Insurance Rate Map (FIRM) panels 1500020316E and 1500020318F. Zone X includes areas determined to be outside the 0.2% annual chance floodplain.

### 2.6 Soils

According to the United States Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS) survey data, the project area consists of a variety of soils. Soil characteristics are summarized in the table below. See Figure 5 - Soil Map.

- Kdf: Kalapa silty clay, 40 - 70 % slopes
- Ke: Kalihi clay
- LuB: Lualualei clay, 2 - 6 % slopes
- PdA: Pakala clay loam, 0 - 2 % slopes
- PdC: Pakala clay loam, 2 - 10 % slopes
- Ws: Waikomo stony silty clay

3.0 Land Use Summary

The total dairy farm area inclusive of pasture and dairy facility, but excluding the existing taro farm, is 556.8 acres. The dairy project site has been divided into two land use areas as described in Table 7 (below): The farm area consists of 547.1 acres for pasture, roads, and setbacks and 9.7 acres for the dairy facility. See Figure 6 - Paddock Map.

The farm is broken up into a total of 119 paddocks, the majority of which are approximately 3 to 5 acres in size. Paddocks smaller in size near the dairy facility would be used for temporary holding for calves less than 90 days old, prior to moving off of the farm, or for temporary holding for other mature dairy cows. See Figure 6 - Paddock Map and Table 8 - Paddock Area Summary. Other land uses within the farm areas include the cow races, walkways, farm roads, drainage ways, animal cemetery, and effluent ponds. The animal cemetery is located on paddock 163 and is included in the total paddock area.

4.0 Farm Description

Dairy-related facilities will occupy approximately 9.7 acres along the western boundary of the project area. Buildings will include a milking parlor/barn with a rotary milking platform and milk storage tanks, two calf sheds, and an implementation shed for tools and equipment. Manure captured during the milking process will be transferred through underground pipes to two nearby effluent ponds, where solids will be settled out and the remaining fluid stored for application to the pasture through the irrigation system. When applied via the irrigation system, non-potable water from the Waita Reservoir will be added to nutrient rich liquid for irrigation use. The effluent ponds will be sealed with a flexible membrane liner, and will be constructed within a secondary containment berm. Paved access roads and a truck turnaround area for milk tanker trucks, feed silos, and a holding yard for cows waiting to enter the milking parlor will also be part of the project.

Agricultural infrastructure from prior sugar cane cultivation within the project area, such as gravel access roads, field roads, reservoirs, pipelines, irrigation ditches, drainage ways and culverts, will be adapted for reuse where possible. Additional field improvements will include a livestock water distribution system, pivot irrigation system, culverts and perimeter and paddock fencing.

The majority of the dairy farm area (i.e. ~83%) is dedicated to pasture. Much of the remaining area is dedicated to access roads, cow races, the dairy facility, and waterway setback / buffers. The dairy facility including the parlor, effluent ponds and secondary containment areas is contained within a 9.7-acre area, which represents about 1.7% of the entire farm. The corresponding building areas are under 0.1% of the total farm area. The dairy farm infrastructure is summarized as follows and shown on Figure 7 - Farm Map:

- Paved Access Road and Truck Turnaround
- Cow Walkways/Races and Farm Roads
- Concrete Holding Yards and Gravel Farm Races
- Milking Parlor
- Implement Shed
- Calf Sheds (2)
Nutrient Balance Analysis
May 24, 2016

- Settling Pond and Storage Pond
- Effluent and Sludge Pumps and Distribution System
- Irrigation Water Storage and Distribution System
- Existing Potable Well and Water Line to Milking Parlor
- Potable Water Tank for Milking Parlor and Livestock Consumption
- Livestock Water Distribution System
- Feed Silos
- Milking Parlor - Individual Wastewater System (IWS)
- Animal Cemetery (Located on Paddock 163)
- Paddock fencing and perimeter fencing
4.1 Physical Setbacks for Water Resources

Physical setbacks are incorporated into the farm’s design, where no active pasture, effluent application, or grazing activities will occur, intended to protect and improve water resource quality. Paddock and perimeter fencing, based upon NRCS Conservation Practice Standard specifications, are set back 35 feet from water resources and are designed to keep livestock from entering and polluting water resources. Though not required by the "Guidelines for Livestock Waste Management", HDF has also agreed to provide a 1,000 foot setback from the Kōloa F County Well through an agreement with the County of Kaua‘i, Department of Water (DOW), where no active pasture, effluent application, or grazing activities will occur within 1,000 feet of the County Kōloa F Well.

Restoration of the banks and edges of waterways with plants suitable for site conditions are also incorporated into the farm’s design. These vegetation buffers are intended for erosion and sedimentation control, and removal of pollutants through bio-filtration of runoff. NRCS Conservation Practice Standard specifications will be followed, and plant species will be identified in conjunction with the NRCS District Conservationist.

The setbacks and restorations are part of an approved NRCS Conservation Plan for Hawai‘i Dairy Farms, which consists of NRCS-approved Best Management Practices (BMPs) for farming activities. The following summary of physical setbacks and related NRCS Conservation Practice Standards will be used adjacent to water resources:

- County Well Kolo‘a F – no active pasture, effluent application, or grazing activity within 1,000 feet radius.
- Paddock Fencing – 35 feet from top of bank of the water resource on both sides.
- Re-vegetation of 35-foot Setback – NRCS Conservation Practice Standard 390
Figure 7 – Farm Map
4.2 Cows Walkways and Races

The dairy farm pasture areas will be divided into 3- to 5-acre paddocks as shown on Figure 6 - Paddock Map. A network of walkways and races will connect the paddocks together and provide access to and from the dairy facility. The walkways and races are generally aligned with existing farm roads where possible, but additional walkways and races will be constructed through the existing fields.

The walkways and races will be compacted crushed rock access ways that are approximately 16 to 20 feet in width. The cow races will allow twice daily movement of the cows from the paddocks to the Milking Parlor. The cow races are not irrigated and will be frequently maintained to maximize efficient and rapid movement to and from the dairy with minimal injury to livestock. The races will be bordered by 3 wire electrical fencing.

At waterways and drainage ways, animal crossings will be added consisting of a bridge or culvert, and will be designed to appropriate NRCS Conservation Practice Standards and Codes.

4.3 Dairy Facility

4.3.1 Calf Sheds

Calf sheds will be constructed to provide safe housing for calves at the HDF site, which are kept until approximately 90 days of age. There will be two open bay calf sheds, which will be steel structures with metal roofs on concrete slabs. Each shed will be approximately 81 ft. long by 26 ft. wide by 15 ft. tall. A minimum of approximately 21 sq. ft. area is allocated for each calf and 20 calves will be kept in one pen (approximately 26 ft. x 16 ft.) at any given time. Each pen is divided in two areas (feeding area and bedding area). Overall, the calf sheds will provide capacity for up to 200 calves. The feeding area will be washed daily and wastewater will be transferred to the effluent ponds via drain inlets and conveyance piping. Calf bedding will consist of sand. Calves will transition to pasture near the calf sheds after 3-4 weeks. See Figure 8 - Facility Site Plan.
4.3.2 Implement Shed

An implement shed will be constructed for storage of equipment, tools, and farm machinery parking. The implement shed will be an open bay steel structure with metal roofs on a concrete slab, similar to the calving sheds. The implement shed will be approximately 65 ft. long by 26 ft. wide by 15 ft. tall for a total area of 1,690 sq. ft. See Figure 8 - Facility Site Plan.

4.3.3 Milking Parlor

The Milking Parlor will be the single largest structure on the dairy farm with dimensions of approximately 256 ft. long by 88.5 ft. wide by 33 ft. tall. The Milking Parlor will contain a highly-automated 60-stall rotary, which completes one rotation of 60 cows in approximately 8-10 minutes. It will operate 365 days a year. See Figure 8 - Facility Site Plan.

The initial herd of 699 mature dairy cows will be managed in mobs of 105 – 115 cows according to their calving, lactation, and health status. At full production, if expanded, up to 2,000 mature dairy cows will be managed in mobs of 300 – 330 cows according to their calving, lactation and health status. The mobs will be brought into the holding yard and Milking Parlor twice a day for milking. Each time, an individual cow’s maximum milking time will be 10 minutes and the maximum time off pasture will be 1 hour. The individual milking time of cows will be the same, regardless of the total number of animals on the farm, with total time in the milking parlor corresponding to the total size of the mob and the amount of animals that must be milked in the parlor. Each mob will still be brought into the holding yard and milking parlor twice a day for milking.

The Milking Parlor building includes the following components:

- Covered Loading Area
- Milking Area
- Holding Pens
- Mechanical Room and Pump Room
- Office Space
- Veterinary Space and Storage
- Staff Restrooms
- Milk Storage
4.3.4 Milking Parlor Feeding System

In-parlor feeding will be offered to the cows to provide additional nutrients, which will improve animal health and milk production. Cows will be eager to enter into the parlor where they will receive feed, so the overall milking process time is typically improved. A small portion of feed (6.6 lbs.) will be offered to cows during the milking time (8-10 min), which will be stored in two 44-ton – 60-degree cone silos.

4.3.5 Holding Yard

The holding yard is designed to hold a single 330-cow mob at any one time, and will be approximately 150 ft. long by 82 ft. wide for a total area of 12,300 sq. ft. The holding yard area will be heavily used by livestock and will need to be cleaned frequently. Manure/nutrient-laden water will be transferred to the effluent pond through underground pipes. No feed will be offered in the holding yard and each mob will spend less than one hour in the yard before entering into the Milking Parlor. See Figure 8 - Facility Site Plan.

4.3.6 Access Road and Tanker Truck Turnaround

A new 20-foot wide paved access road / tanker track will be constructed off of the adjacent farm roads to the dairy facility. The access road will serve as the primary access to the dairy and will be used by milk tanker trucks for transport of milk off-site, as well as for supply trucks making deliveries. A paved truck turnaround will be located at the end of the access road and will lead up to a covered loading area where milk will be pumped directly into the trucks. See Figure 8 - Facility Site Plan.
Figure 8 – Site Plan
5.0 Potable Water Systems

Potable water is required for the washing down of the milk parlor and yards, milk cooling, potable consumption within the dairy facility, washing down the calf facility, and for livestock consumption. At the committed herd size of 699 milking cows, approximately 12,163 gallons will be used per day. At the contemplated herd size of 2,000 milking cows, approximately 34,800 gallons will be used per day. The cows on pasture will also consume approximately 25.0 gallons per day for drinking purposes. Daily consumption of the 699 milking cows will be approximately 17,475 gallons. The 2,000-milking cow herd will drink 50,000 gallons per day. The total potable water demand per day will be approximately 29,638 gallons per day at the committed herd size, and about 84,800 gallons per day for the contemplated 2,000-cow herd size.

5.1 Water Source and Quality

Potable water for the dairy facility and livestock consumption must be of acceptable quality per DOH requirements. Water will be sourced from the Māhā’ulepū Well located within the project site. The well site once contained up to 14 wells, drilled for the sugar plantation between 1897 and 1928. Of the 14 wells, only 3 were located and are able to be utilized by HDF. One well will be used for potable water, one will be used for aquifer / deep groundwater monitoring, and one will be used as a backup. The water source has been tested and is of an acceptable quality. Further information on the wells in the area and baseline water quality information is documented in “Estimates of the Potential Impact on Groundwater and Surface Water By Hawaii Dairy Farms in Mahaulepu, Kauai” by Tom Nance Water Resource Engineering (2016).

5.2 Livestock Water Distribution System

Availability of drinking water has an impact on animal health and milk production. The livestock water distribution system has been designed to supply a large volume of water to meet the seasonal high daily water demand of 25 gpd per cow. The total livestock drinking water demand is estimated to be 17,475 gpd for the initial herd of 699 cows, and 50,000 gpd for up to 2,000 mature dairy cows. Two large covered and lined water storage tanks will be located at the Milking Parlor providing total storage of nearly 80,000 gallons.
Nutrient Balance Analysis  
May 24, 2016

Water from the storage tanks will be distributed into the Milking Parlor and to adjacent buildings for dairy use. Water will also be distributed throughout the paddocks for livestock consumption. Small booster pumps will be used to ensure the required flow will be delivered throughout the farm.

Small diameter water mains, 2 to 3 inches in size, will deliver water to the paddocks. Two concrete troughs, at minimum, will be installed in each paddock to give animals easy access to drinking water at all times. Troughs will be raised and placed on a crushed rock base to provide a firm and stable surface for animal movement around the trough. The trough is high enough for the animal to reach over and in, but will discourage the animal from stepping into the trough. The troughs are also fitted with valves to stop the flow of water into the trough when the trough is full and refill the trough as the water is consumed, ensuring maximum water efficiency.
6.0 Irrigation

The total pasture area of the farm is 469.9 acres. The majority of the pasture area will be irrigated with either irrigation water, liquid effluent, or both through either pivot irrigation systems or through gun irrigators with a hard-hose reel, which can be moved throughout the farm as needed. See Figure 9 - Irrigation Map.

6.1 Pivot Irrigation System

The pivot irrigation system will consist of two center pivots. A center pivot irrigation system is an overhead irrigation system, which includes irrigation pipes supported on trusses mounted on wheeled towers that rotate around a central water supply point. The farm will have two pivots; irrigation pivot #1 will be a full circle (FC) pivot and irrigation pivot #2 will be a partial circle (PC) pivot. See Figure 10 - Irrigated Pasture Areas. The irrigation system including irrigation application rates and emitters is controlled using computer software and GPS receivers to allow very precise application of irrigation on the pasture.

The pivot is capable of spraying at a rate of 1,030 gpm, but the pivots can apply irrigation water at different rates depending on the actual irrigation needs of the farm. A somewhat typical application rotation and rate would include a 48-hour rotation and application of up to 0.39 inches of irrigation onto the paddocks. The various components of the central pivot irrigation control system are shown below:
Pivot crossings at waterways and ditches, provided at the wheel track locations, will allow the pivot to traverse the waterway without impact, and consist of an elevated metal track anchored on both sides of the waterway. Pivot tracks will be replanted with grass as required to minimize erosion and sediment runoff.

### 6.2 Gun Irrigation System

The gun irrigation system will utilize a rotating, hard-hose reel gun system in makai areas of the farm, where the center pivots are unable to reach. The gun irrigators can be moved around the farm to provide maximum reach and even distribution of irrigation water to areas not served by the center pivot irrigation system. See Figure 10 - Irrigated Pasture Areas. Gun irrigators will not apply liquid effluent and will utilize irrigation water sourced to the farm, currently from Waita Reservoir. Irrigation water will be filtered and pumped into the gun irrigation system.

A separate rotating, hard-hose reel gun system will be installed for slurry application and is further discussed in Section 8 – Nutrient Management. This system will be used to apply solids from the settling pond where needed to provide nutrients to the paddocks much like commercial fertilizer would be applied, is not relied upon for regular irrigation to meet the daily water demand of the grass crop. The slurry application system will be completely separate from the gun irrigation system in the makai areas of the farm. Because the slurry is used to provide nutrients to the farm, slurry application is discussed later in this report.

### 6.3 Non-Irrigated Areas (Pasture and Non-Pasture)

Approximately 26.2% of the total pasture area will not be irrigated, primarily in the mauka areas of the farm where the pivots are unable to reach. No gun irrigation system will be used in this area. See Figure 11 – Non-Irrigated Areas.

While non-irrigated areas do not receive regular irrigation to meet crop water demands, some non-irrigated pasture areas will still receive water in the form of precipitation as well as nutrients in the form of fertilizer or slurry required for grass growth. Nutrient application rates in this area, as with other pasture areas, will be properly managed to avoid over-application or application around a significant rain event. Application of slurry is discussed in Section 8.4, Nutrient Application.
Figure 9 – Irrigation Map
Figure 10 – Irrigated Pasture Areas
Figure 11 – Non-Irrigated Areas
6.4 Irrigation Setbacks

Irrigation setback distances have been established to limit irrigation activity or irrigation with liquid effluent within specific areas under the pivot or with the rotating gun system. The pivot irrigation systems are configured with GPS-controlled emitters that will turn off so that liquid effluent is not directly applied to the ditches, cow races and any other agricultural or natural water resources. The following liquid effluent setbacks are incorporated into the design and no irrigation of effluent will occur within the distance specified for each of the following:

- County Well Kolo‘a F – **1,000 feet** on all sides (through County DOW agreement)
- Irrigation ditch, agricultural water, and natural water resource - **50 feet** from top of bank of the water resource on both sides.
- Cow walkways and races - **6 feet** on both sides
- Existing taro farm - **20 feet** on all sides

The setback distances from water resources are based upon requirements contained within the “Guidelines for Livestock Waste Management”, by University of Hawai‘i-Mānoa – CTAHR. While the minimum setback distance for the application of effluent from public drinking water sources is 50 feet per the Guidelines, HDF has agreed to increase this setback to 1,000 feet following consultation with the County of Kaua‘i Department of Water.

Therefore, application of liquid effluent in addition is prohibited within 50 feet of water resources on the farm, while application of as-excreted manure (during normal grazing) is prohibited within 35 feet of water resources on the farm by physical setbacks (fencing) previously described in **Section 4.1 – Physical Setbacks for Water Resources**.

6.5 Irrigation Areas

The irrigated pasture areas are summarized in **Table 9 – Irrigated Pasture Area Summary**, below. The non-irrigated pasture areas are summarized in **Table 10 – Non-Irrigated Pasture Area Summary**, below:
Irrigation water is expected to be provided via Waita Reservoir and it is not anticipated that the potable wells from the Māhā’ulepū 14 well site would provide irrigation water to the pivots or to the gun irrigation system.

While non-irrigated areas do not receive regular irrigation to meet crop water demands, some will still receive water in the form of precipitation as well as nutrients in the form of fertilizer or slurry application that is required for grass growth, which will be properly managed to avoid over application or application around a significant rain event. Because the slurry is used to provide nutrients to the farm, slurry application is discussed later in this report.

### 6.6 Irrigation Demand

The irrigation demand will not change depending on the amount of animals on the farm. With a herd size of 699 milking cows or 2,000 milking cows, the same amount of irrigated pasture will be utilized for each rotating mob of dairy cows.

Under typical conditions, the irrigation systems will be designed and sized for an upper-end application rate of 0.24 inches per acre per day on 285.1 acres of pivot area and 61.4 acres of gun
irrigation area, which equates to approximately 2.26 million gallons per day (MGD) of irrigation per day, on average. This demand is used conservatively for infrastructure planning purposes.

The actual amount of applied irrigation and schedule of irrigation days will depend on the number of rain days and amount of precipitation. Therefore, irrigation demand is further examined on a monthly basis for operational purposes, based upon historical rainfall data, the pasture grass crop evapotranspiration (ET) rates, and average monthly precipitation. Effective precipitation is assumed to be up to 0.80 inches of the daily rainfall amount at the Māhāʻulepū Rain Gauge Station 941.1, with the assumption that remaining rainfall greater than 0.80 inches is either lost to deep percolation into the soil or runoff, thereby reducing precipitation available to the crop (Refer to the Estimates of the Potential Impact on Groundwater and Surface Water by Hawaii Dairy Farms in Mahaulepu, Kauai by Tom Nance Water Resource Engineering, 2016).

The calculated monthly irrigation demand is summarized in Table 12 – Monthly Irrigation Demand. The demand indicates a clear deficit in precipitation (and need for irrigation) during the spring, summer and fall seasons with only a modest demand for irrigation during the winter season. Actual irrigation volumes to meet the actual crop demand will likely be approximately 10 - 20% higher than the estimated demand shown below, depending on irrigation equipment efficiency (lost to evaporation) and current conditions. The table below are conservative estimates of irrigation demand without taking into account these factors.
During the wet winter months of November, December and January, the demand for irrigation, and therefore, the frequency of use of the pivot and gun irrigators, is significantly lower than other times of the year. Yet, as there are a number of dry days in those months, irrigation is still required, with an average monthly irrigation demand of between 26.0 MG and 30.3 MG, compared with up to 52.5 MG in the dry summer months.

A weather station is installed on-site, capable of measuring temperature, humidity, rain, wind direction and speed, irradiance and evaporation. Soil moisture meters will also be added to determine the ideal moisture bandwidth for grass growth, and will support irrigation decisions and management.

**Pe**  
Effective precipitation assumed to consist of up to 0.80 inches of rain, shown at the Māhā‘ulepū Station 941.1. Daily amounts greater than 0.80 inches are assumed to become runoff.
Nutrient Balance Analysis
May 24, 2016

The proposed irrigation systems for the farm are high-tech in nature and require significant coordination and calibration prior to and during farm operation. Irrigation for the entire farm will be managed precisely based upon the various factors previously discussed, including but not limited to the amount of precipitation, number of rain days, soil moisture and nutrient content, irrigation supply sources, and effluent pond levels and volumes.

Based upon the demand estimates and methodology above, an Irrigation Water Management Plan, which will detail specific farm operating procedures, will be developed to provide the farm operator a plan for proper management and application of irrigation water to allow efficient use of water, minimize energy consumption, and maximize crop yield. Refer to NRCS Practice Code Standards 430 Irrigation Pipeline, 442 Irrigation System, Sprinkler, & 449 Irrigation Water Management.
The dairy farm is a pasture-based, rotational-grazing operation, and the mature dairy cows spend a limited time in the holding yard and milking parlor. Livestock waste and wastewater generated from the milking parlor, holding yards, and calf sheds, including any stormwater and wash down runoff from these areas, will be collected, stored, and reused on the farm as natural fertilizer. Fundamentally, the wastewater system at the dairy facility recycles 100% of all livestock and wash water from the milking process with no direct discharge into State waters from the dairy facility. The objectives of the design are:

i. To capture all of the animal effluent that is produced at the milking parlor holding areas, and calving sheds.
ii. To spread the effluent on the grazing land to meet the nutrient demand of the crop/pasture
iii. To control the effluent application rate and spread effluent only on the desired areas within the project boundaries
iv. To keep effluent completely separate from potable water to prevent contamination of the potable water sources or storage
v. To comply with all regulatory requirements under the state and federal laws

Figure 12 – Dairy Facility Site Plan
The dairy facility including the wastewater ponds and other infrastructure will be sized and constructed for the capacity of 2,000 mature dairy cows, though the initial herd will start at 699 mature dairy cows. Calculations provided herein will show effluent and nutrient operational values of the dairy farm at a proposed herd size of 699 mature dairy cows as well as the contemplated expansion of up to 2,000 mature dairy cows. Refer to NRCS Practice Code Standard 633 Waste Utilization.

### 7.1 Effluent/Manure Volume

Several criteria serve as the basis of calculating the total amount of manure and effluent that will be collected within the milking parlor, holding yards, and adjacent sheds, and then conveyed to the ponds. The following describes the methodology behind calculating the total manure and effluent volumes, which will need to be accounted for in sizing the waste management ponds in this section, and then managed during reapplication to the pasture areas, as described in Section 8 - Nutrient Management.

HDF is a pasture-based, rotational-grazing dairy farm that is being designed for kiwi-cross animals. A mature kiwi-cross cow’s weight is about 1,200 lbs. and it produces an average of 90.8 lbs. of manure per day or 10.9 gallons of manure per day, or 0.68 gallons average per waking hour. These values were calculated using the Cornell Net Carbohydrate Protein System (CNCPS) model, further discussed in Section 8.3 - Nutrient Balance.

The 699 cows in the initial herd will be maintained in mobs of 105-115 animals and each mob will rotate through a group of 18 paddocks. Under full operation as part of a contemplated herd expansion, up to 2,000 mature dairy cows will be maintained in mobs of 300-330 animals. The cows graze for one day per paddock, so once every 18 days the entire mob will produce the majority of its effluent on that one paddock as it grazes.

Grass-fed dairy cattle produce significantly more liquid manure than cattle fed on concentrate and Kikuyu is also a relatively wet grass (87% water). The total amount of manure produced in the milking platform and holding yards each day is calculated below:
**Table 13: Manure Produced in the Milking Parlor and Yard for Mature Dairy Cows**

<table>
<thead>
<tr>
<th>Initial Herd Size of 699</th>
<th>951 gpd</th>
<th>$699 \times (1 \text{ hr} \times 2 \text{ milkings per day}) \times \text{manure of 0.68 gallon per hour}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contemplated Expansion to 2,000</td>
<td>2,720 gpd</td>
<td>$2,000 \times (1 \text{ hr} \times 2 \text{ milkings per day}) \times \text{manure of 0.68 gallon per hour}$</td>
</tr>
</tbody>
</table>

From a waste volume perspective, a dairy operation should also account for the calves that will be on site. For the committed herd size of 699 milking cows, there will be approximately 150 calves on the HDF site at any one time, 50 of which will be housed within the calf sheds. Should HDF decide, in the future, to expand operations to the contemplated herd of up to 2,000 mature dairy cows, there will be approximately 500 calves at any one time, 167 of which will be housed within the calf sheds. The remainder will be on the pasture grazing, depending on their age, size and health. Once the calves reach 165 lbs or are 90 days old, they will be transferred to an off-site calf raising facility. A calf produces approximately 2.244 gallons of manure per day. Because manure in the calf sheds is conveyed to the effluent pond system, the total amount of manure produced in the calf sheds (for the 699 herd size and 2,000 herd size) is calculated below:

**Table 14: Manure Produced in the Calf Sheds for Calves**

<table>
<thead>
<tr>
<th>Initial Herd Size of 699</th>
<th>112.2 gpd</th>
<th>$50 \text{ calves in pen} \times \text{manure of 2.244 gallon per calf per day}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contemplated Expansion to 2,000</td>
<td>374.7 gpd</td>
<td>$167 \text{ calves in pen} \times \text{manure of 2.244 gallon per calf per day}$</td>
</tr>
</tbody>
</table>

The holding yard and milking parlor are washed twice a day after each milking, and the calf sheds are also periodically washed (collecting manure generated by the calves on-site that are housed in the pens – further discussion of calf manure is discussed in **Section 8 – Nutrient Balance**). All of the manure produced in the milking parlor, yards, and calf sheds is washed out and the nutrient-laden water is transferred to the settling pond. The milk storage tanks located within the milking parlor are also washed out after milk is pumped to tanker trucks for delivery. Wash water from the milk tanks is also transferred to the settling pond. Total wash water from all processes at the parlor, yards, calf sheds (including calf manure), and remaining facility is estimated to be at 17.4 gpd per mature dairy cow.
Table 15: Wash Water Produced in the Milking Parlor, Yards, and Calf Sheds

</tbody>
</table>

See Figure 13A & B - Water Flow Schematic for a schematic diagram of the water and wastewater flow through the pasture-based, rotational-grazing system. Two diagrams are provided: one for the initial herd size of 699 and one for the contemplated expansion to 2,000.

Figure 13A - Water Flow Schematic for 699 Mature Dairy Cows
Figure 13B - Water Flow Schematic for 2,000 Mature Dairy Cows

All of the manure and wash down water that is collected from the milking facility, yards, and calf sheds is transferred to the effluent ponds, consisting of a two-stage system including a settling pond and a storage pond, prior to application on the pastures through the irrigation system. The sizing and the operation of the effluent ponds is described below:

7.2 Effluent Ponds

The effluent ponds will be constructed for effluent collection, management and proper utilization of nutrients available from livestock waste. The pond design is based on a two-step system, which includes a settling pond and storage pond. The settling pond allows for the settlement and accumulation of wastewater sludge with the overflow of liquid effluent entering the storage pond. The settling pond and storage pond separate solids from liquids and hold the
Nutrient Balance Analysis
May 24, 2016

effluent, respectively, for management purposes. The ponds will be located a minimum distance of 1,000 feet from public drinking water resources and 50 feet from surface water resources as required by the “Guidelines for Livestock Waste Management”, by University of Hawai’i-Mānoa – CTAHR. See Figure 8 - Facility Site Plan.

Sizing of the effluent ponds is highly dependent on the amount of effluent and subsequently the nutrients collected, the normal precipitation collected, and the volume of a 25-year, 24-hour storm event. In turn, sizing of the ponds is dependent on how often and at what rate, the collected effluent and precipitation will be reapplied to the field. As previously discussed, in effect, 100% of all manure and effluent captured at the dairy facility will be reapplied to the pasture for its nutrient value.

Nutrient application means and methods are further discussed in Section 8 - Nutrient Management. However, the following criteria will be used in sizing both the settling and storage ponds for both the committed 699 herd size scenario, as well as at the contemplated herd size of 2,000 mature dairy cows:

7.2.1 Pond Operation and Sizing Criteria
Wastewater from the dairy facility, yards, and calf sheds is discharged into the settling pond first. Solids settle and accumulate at the bottom of this pond as liquid effluent collects over several days. A stirrer pump is operated two hours per day to break up the solids in the settling pond. Once the settling pond is full with both solids and liquid, any additional liquid effluent (minus settled solids) that enters the settling pond daily, overflows to the adjacent storage pond through screened overflow pipes (13,225.8 gpd for 699 mature dairy cows and 37,894.7 gpd for 2,000 mature dairy cows). The settling pond remains full in normal steady state until the solids are utilized on the pasture.

Accumulated solids in the settling pond will be pumped out as weather and paddock conditions permit (slurry application – discussed in Section 8.4 Nutrient Application), but at a minimum of once every 45 days (will be emptied with no more than 45 days’ worth of accumulated solids). An appropriate mixing volume of liquid is required for stirring the solids into a slurry suspension, for pumping to the pasture.
The storage pond will be emptied according to a 4-day application schedule (i.e. planned every 4 days). The effluent will be applied only when there has been no significant rain in the last two days and no significant heavy rain is forecasted for the next two days.

While the settling pond typically remains full, the level of the storage pond will rise slightly during each milking wash down, when the daily amount of manure and effluent from the dairy facility will enter the storage pond, and will lower on irrigation days when the pond is emptied.

On irrigation days, liquid effluent from the storage pond is applied onto the pastures after being diluted and injected into the irrigation water stream through the center pivots. The daily amount of effluent added to the storage pond (13,225.8 gpd for 699 mature dairy cows and 37,894.7 gpd for 2,000 mature dairy cows) is only a small fraction of the upward estimate of a potential daily irrigation application of 2.26 MGD. This daily amount is still only a small fraction of irrigation even during the winter months, where the daily irrigation demand is at its lowest at 839,474 gpd (in the month of December). As such, effluent pumped to the center pivots is diluted and applied to the pasture at an application rate significantly less than the nutrient requirement of the grass (See Section 8.4 Nutrient Application).

The minimum required effluent volume in both ponds shall also include the additional storage required during periods of heavy, sustained rainfall when irrigation application of effluent or slurry application of solids is not possible. The design effluent period includes allowances for the following volumes:

- Effluent volume for 4-day period between scheduled irrigation of effluent
- Effluent volume for maximum 17 consecutive rain days based on NOAA rain gauge data, See Table 3 - NOAA Rain Gauge Data
- Effluent volume for 2 day period prior to forecasted heavy rain
- Effluent volume for 2 day period for minimum of pasture dry time after heavy rain

Based on the above volumes, the minimum effluent volume provided should include 25 days of effluent volume. The design volume required will be set to 30 days of effluent, which will provide an additional capacity buffer.
The ponds have the capacity for the following volumes:

- Volume of manure, wastewater, and other wastes accumulated during the period between effluent irrigation application
- Volume of accumulated solids during the period between the maximum time allowed for slurry application
- Depth of the 25-year, 24-hour storm precipitation
- Depth of highest monthly average precipitation for the 30-day design volume period

The pond volume calculations are based on the following assumptions:

**Table 17 – Effluent Pond Sizing Criteria**

</tbody>
</table>

The effluent ponds and concrete holding areas are not covered. All rainfall in these areas is collected and conveyed to the ponds. Approximately 1.76 acres of area at the dairy facility drain to the ponds and are accommodated in the pond sizing and minimum volume requirements including runoff from the calf sheds and concrete gutter, the uncovered holding pens and yards, the uncovered loading areas, and the settling and storage pond areas. Rainfall collected from the roofs of the milking parlor and implement shed is discharged directly to grassed/landscaped areas adjacent to the buildings, and does not enter the effluent system.
Evaporation from the water surface of the ponds is likely to occur, as the ponds are not covered. However, for the purposes of sizing the effluent ponds, evaporation is not taken into account. The volume of evaporation during the 30-day design period adds to the ponds’ available holding capacity.

7.2.2 Settling Pond Size
As previously mentioned, the settling pond is sized to include the volume of accumulated solids for a maximum of 45 days, based on the maximum period between solids application.

In addition to the solids volume, a mixing volume will be provided within the settling pond, to allow for the stirring and suspension of solids when slurry application to the pastures is initiated. The minimum mixing volume is dependent on type of equipment, operational needs and operator preferences. For the settling pond, the mixing volume in the pond will be 362,020 gallons for the 699 mature dairy cow herd size, or 350,919 gallons for the contemplated 2,000 herd size. Additional mixing water can be injected, as needed, when applying the slurry.

The top of the settling pond is 87’ x 133’ with a total depth of 12’ from invert to overflow spillway. The settling pond total available volumes are shown in the figure below.

![Settling Pond - 699 Cow Facility](image)

**Figure 14A - Settling Pond Typical Section & Volumes for 699-cow Herd Scenario**
Figure 14B - Settling Pond Typical Section & Volumes for 2,000-cow Herd Scenario

See Section 8.4 – Effluent Application for additional information about the slurry application.

7.2.3 Storage Pond Size

When the settling pond fills completely with effluent over a period of several days following slurry application and lowering of the settling pond, liquid effluent then overflows through three 6-inch screened overflow pipes into the storage pond. The clear screens are fitted into the overflow pipes and do not allow solids to enter into the storage pond.

As previously mentioned, the volume of effluent storage within the storage pond is sized to allow for a minimum of 30 days of design volume storage for the contemplated herd size of up to 2,000 milking cows based upon a conservative evaluation of the irrigation schedule and rainfall data.

The top of the storage pond is 215’ x 133’ with a total depth of 16’. The storage pond total available volumes are shown in the figure below.

Figure 15B - Storage Pond Typical Section & Volumes for 2,000-cow Herd Scenario
The storage pond design incorporates an emergency spillway to direct overflow in case of a cataclysmic event. In normal operation, the storage pond provides additional spare volume at the top of the pond. In the 699-cow scenario, the spare volume is an additional 45% of the total volume required. In the 2,000-cow scenario, the spare volume represents an additional buffer of up to 12%. These spare volumes provide even greater buffer above the design capacity which includes storage for the required 25-year, 24 hour storm event, as well as volumes for 30 days of storage and normal precipitation on the adjacent areas which will drain to the ponds.

### 7.2.4 Effluent Pond Design

Ponds will have a bottom elevation that is a minimum of 2-feet above the seasonal high water table. Excavated side slopes will not be steeper than 2 horizontal to 1 vertical. An inlet pipe with a minimum diameter of 8 inches will be used for milking parlor waste for discharge into the settling pond. The pipe terminates a sufficient distance from the shoreline of the pond to ensure good distribution. A cleanout is also provided for removing obstructions. Three (3) 6-inch diameter pipes will be used for daily overflow from the settling pond into the storage pond.

The minimum elevation of the top of the settled embankment shall be 1 foot above the pond’s required volume. The combined side slopes of the settled embankment shall not be less than 5 horizontal to 1 vertical, and neither slope shall be steeper than 2 horizontal to 1 vertical unless provisions are made to provide stability. Embankments and disturbed areas surrounding the pond are treated to control erosion. This includes the inside slopes of the pond as needed to protect the integrity of the liner.

Pond lining will be installed to prevent seepage of wastewater from the waste impoundment structure for water conservation and environmental protection. All inlets, outlets, ramps, and other appurtenances will be installed in a manner that does not damage or impair the proper operation of the liner.

The pond perimeter will be fenced and warning signs posted to prevent people from using the area for activities other than its intended purpose. A marker or water level measuring device will be installed in the pond to indicate the stored volume and/or storage capacity remaining.
7.2.5 Emergency Spillway and Secondary Berm

The storage pond will have an emergency overflow spillway that will allow discharge from the pond in the event of a cataclysmic emergency such as a rainfall event greater than the 25-year,
Nutrient Balance Analysis
May 24, 2016

24-hour storm or other natural disaster. A secondary berm will also be constructed downhill of the effluent ponds before the existing drainage way and access / farm road, to contain an emergency discharge from the pond from the overflow spillway. Although not required by the guidelines, this secondary containment area will provide additional containment that will be roughly equivalent to 30 days of total liquid effluent volume collected over the 30-day storage period, or 1,136,841 gallons of additional emergency storage.
Nutrient Balance Analysis
May 24, 2016

8.0 Nutrient Management

HDF has committed to establishing the dairy with up to 699 mature dairy cows and associated calves. This size of operation does not require a Concentrated Animal Feeding Operation (CAFO) permit to be issued prior to operation.

Following establishment of the initial herd of 699 mature dairy cows, HDF is contemplating expansion of the herd to up to 2,000 mature dairy cows and associated calves. This size of operation will require a Concentrated Animal Feeding Operation (CAFO) permit to be issued prior to exceeding 699 mature dairy cows. Previous Environmental Protection Agency (EPA) regulations based the definition of CAFO’s on the number of “animal units” confined. EPA no longer uses the term “animal unit,” but instead refers to the actual number of mature dairy animals at the operation to define a CAFO. Additionally, though the cows are grazing in the paddocks and pasture and are not “confined”, the EPA still permits a CAFO based on the number of “animal units”.

From a nutrient management perspective, a dairy operation must also account for the calves that will be born on site. For the initial herd, there will be approximately 150 calves on the HDF site at any one time. At full operation as part of a contemplated herd expansion of up to 2,000 mature dairy cows, there will be approximately 500 calves at any one time. Some calves will be housed in the calving sheds, while others will be on the pasture grazing, depending on their age, size and health. Once the calf reaches 165 lbs or is 90 days old, they will be transferred to an off-site heifer raising facility. Nutrient management data and calculations hereon are presented for both the initial herd size and contemplated herd expansion.

8.1 Historical Background

The historical use of the land has been for sugar cane production terminated in the late 1990s, and after that time, for a beef cattle operation. The historical uses of the farm have left the soils depleted of the essential nutrients required for crop growth. A well-managed, pasture-based, rotational-grazing dairy focused on the application of nutrients will be a benefit to the existing soil structure and composition.
8.2 HDF Pasture-Based Dairy Background

The proposed HDF is a pasture-based system where cows are divided and managed in a series of fenced paddocks for rotational grazing. Through internal herd growth and the purchase of additional young stock when needed, the dairy herd is planned to consist of 699 head of mature dairy cows and approximately 150 calves at the initial operation, and may be expanded to up to 2,000 head of mature dairy cows and approximately 500 dairy calves at full operation. Although, at full production, a 2,000 mature dairy cow stocking density is contemplated, the number of cows will ultimately be decided by the land that is supporting the pasture-based system. The 469.9 acre pasture has been and will continue to be planted with Kikuyu grass that will serve as the base diet for the grazing animals.

The mature dairy cows will be managed in small groups (initially 105 – 115 cow mobs, but up to 300-330 cow mobs at the contemplated herd size) and are milked twice a day (1 hour per milking). Only one mob can be held in the milking facility at any one time. Manure deposited within the dairy facility will be collected and stored into a two stage manure storage system located to the south of the milking parlor. The manure storage is connected to two GPS enabled center pivot irrigation circles as well as a hard hose reel irrigation application system for the areas outside of the center pivots.

The farm is managed under a Conservation Plan developed with Natural Resource Conservation District (NRCS) guidance, and approved by the West Kaua‘i Soil and Water Conservation District. The Conservation Plan specifies a variety of agricultural best management practices (BMPs) to be installed and implemented, as appropriate, prior to farm population and operation of the dairy. Each BMP follows the current specifications for the Pacific Islands conservation practice standards. Each of these BMPs is designed to minimize agricultural impacts to waters of the State of Hawai‘i.

8.3 Nutrient Balance

Managing the amount, source, placement, and timing of plant nutrients and soil amendments is critical for the nutrient balance of the farm, and is the purpose of the Nutrient Management
Nutrient Balance Analysis  
May 24, 2016

Plan (NMP), which is prepared under technical guidance from the NRCS for nutrient management on the farm. A NMP, submitted for 699 mature dairy cows in July 2014 and titled “Waste Management Plan for Hawaii Dairy Farms”, has been reviewed by DOH, while an updated NMP for up to 2,000 mature dairy cows, will be prepared for review by DOH for the larger herd size, should the herd size increase past 699 mature dairy cows.

This type of planning minimizes the agricultural impacts to surface water and groundwater by properly utilizing manure and commercial fertilizers in balance with plant nutrient requirements. By following the Natural Resource Conservation Service Nutrient Management Standard (590), HDF will optimize nutrient applications through proper timing, placement, utilization, and monitoring of nutrients. NMPs typically include the following components:

- An inventory of nutrient sources on the farm, including manure and crop residues.
- Nutrient analyses of each nutrient source.
- A budget to supply and conserve nutrients for plant production.
- Soil tests to determine the nutrient needs of the crops to be grown.
- Procedures for when and how to apply the manure to maximize crop benefit and minimize the environmental impacts of the nutrients.
- Best Management Practices that minimize the potential for nutrient loss from the fields.
- Best Management Practices that minimize agricultural impacts to surface and groundwater resources.
- Procedures to monitor and maintain or improve the physical, chemical, and biological condition of the soil.

One of the most important considerations in nutrient management planning for farms is the understanding that the NMP is an adaptive management tool. Some even describe it as a living, breathing document that is constantly monitored and updated as the conditions of the farm evolve. The results from annual soil testing, manure testing, and forage testing will be used to update and inform the nutrient management process for HDF as the farm becomes established and operations mature.
8.3.1 NMP Basis of Design
The first year of the Nutrient Management Plan will be based off of a combination of available field data and theoretical modelling in order to come up with the proper nutrient application rates and timing. In year one of the plan, a nutrient mass balance will be performed to balance application rates. The variation of nutrient application will be based upon localized weather events and other management factors. Once manure has been excreted, captured and stored, a site specific manure analysis will be taken and analyzed.

8.3.2 Data Acquisition
Through the utilization of on-site grass data gathered by HDF, and the Cornell Net Carbohydrate Protein System (CNCPS) model, an estimate of the grass productivity, farm carrying capacity, milk production and manure excretion has been calculated, respectively.

8.3.3 Manure Excrete Models
The CNCPS model was used to determine and model the metabolizable energy (ME) and metabolizable protein (MP) requirements generated from varying levels of neutral detergent fiber intake (NDFi) and complementary grain given at milking time. After accounting for daily maintenance requirements, grass and grain analytics, and dry matter intake (DMI), the expected milk production and manure excretion can be calculated. This analysis was performed by Robert C. Fry, DVM, a dairy nutritionist with Atlantic Dairy Consulting.

Estimates of manure volume and nutrient quantity, calculated by CNCPS, were compared against the USDA/NRCS Agricultural Waste Management Field Handbook (March 2008), along with the USDA/NRCS Ag Waste Management Software Program. The field handbook utilizes established American Society of Agricultural Engineers (ASAE) values. The calculated and estimated values from the CNCPS Model will be replaced with actual site specific data once HDF is in operation and site specific manure analysis can be conducted.

8.3.4 Manure Model Analysis and Outputs
The CNCPS model was also utilized to calculate manure production per cow per day. CNCPS was also utilized to forecast the nutrient concentration of the as excreted manure collected at the dairy facility, slurry, and stored lagoon effluent that will be applied through irrigation systems. Total collected manure includes parlor wash down water, rain water deposited on the holding
area and within the manure storage system, and manure produced during the two hours of milking per day as well as the manure produced in the calf sheds. The CNCPS Model Manure Production = 90.8 lbs per cow per day. ASAE D384.2 MAR2005 publication from the American Society of Agricultural Engineers was utilized to estimate the calf manure production and associated nutrient content. ASAE Calf Manure Production = 19 lbs per calf per day.

Based upon the CNCPS Model, the following nutrient characteristics for the as-excreted manure of both mature dairy cows and calves are shown below:

Based upon these parameters, the amounts of monthly effluent generation collected within the effluent ponds serving the dairy facility are calculated below for the 699 mature dairy cow scenario and the 2,000 mature dairy cow scenario. These numbers are critical in validating the size of the effluent ponds, as well as tracking the overall movement, collection, and distribution of nutrients through the farms systems, from grass uptake to as-excreted manure in the facility, to collection in the effluent ponds, and ultimate redistribution and nutrient for grass growth.

8.3.5 Grass Yields

The pasture-based system enables the mature dairy cows to spend 22 hours (16 waking hours) in the paddocks, where a corresponding proportion of their excreted manure will be discharged directly onto the paddocks. The dominant grass is Kikuyu; (*Pennisetum clandestinum*) a high yielding species, that (when properly fertilized) can yield more than 20 tons (U.S.) per acre. This grass is more adapted to warm or hot seasonal conditions under moist or dry environments and is known to produce more than 35 tons of dry matter per acre per year.

The Kikuyu is extremely effective in the tropics and adds significant protection to soils in terms of creating a tight organic thatch. As the cattle excrete on the Kikuyu thatch, it is incorporated into what is effectively an organic net. Due to the high moisture and moderate temperatures, the microbial activity in the thatch is very high and the effluent will be largely broken down by microbial activity within 24 hours.

The Kikuyu thatch will also reduce runoff during heavy rain events by holding water in its dense but also porous structure. Preventing and reducing runoff will keep nutrients within the paddocks and soils on the farm for uptake by the grass, where effluent can be broken down quickly as noted above. Additionally, grass yields are directly related to soil compaction, whether through hoof compaction of soils or disturbance in the soil structure caused by machine cultivation. Once the Kikuyu thatch is established, the soil itself is not disturbed by cultivation; the thatch will be exposed to grazing pressure.

The grass will need significant additional nutrient application with conventional fertilizers for the initial herd size of 699 mature dairy cows. The grass will also need some, but less, additional nutrient application with commercial fertilizer at the contemplated herd size of up to 2,000 cows. Nutrient mass balance scenarios for both herd sizes are discussed in Section 8.3.9.
Nutrient Balance Analysis
May 24, 2016

The project has an estimated yield goal of 20 tons (U.S.) of dry matter production of Kikuyu per acre. Kikuyu yield ranges between 4 tons unfertilized and 20-plus tons of dry matter (DM)/acre/year depending on levels of N fertilization. Kikuyu’s response to fertilization is very good and linear, and combined with irrigation, anticipated growth rates in Māhā'ulepū are estimated to be some of the best in the world. The average local temperature is in the ideal 60°F and 104°F range for Kikuyu pastures.

Although the goal is for a 20-ton Kikuyu yield for mature pasture grass, actual yield data, based on 15 months of growth trials on 70 acres of pasture on the farm is available, and is the basis for all nutrient application rates. The Kikuyu grass trials have averaged 16.3 tons of Dry Matter (DM) / acre / year. Calculations provided hereon will utilize a grass production of 16.3 tons of DM / acre / year, although after several years of pasture maturation and establishment, yields closer to or exceeding 20 tons of DM / acre / year are realistic. The more grass that is grown allows more cows to be sustained on the farm as grass provides the majority of their feed and also uptakes nearly all of their manure / effluent.

Based upon the grass growth trials on 70 acres of pasture on the farm, the nutrient uptake rates for Kikuyu in lbs of uptake per ton of Dry Matter (DM) are as follows:

**Lbs of Nitrogen (N) uptake per ton DM = 64 lbs. N**

**Lbs of Phosphorus (P) uptake per ton DM = 11.4 lbs. P**

**Lbs of Potassium (K) uptake per ton DM = 90 lbs. K**

HDF coordinated the collection of Kikuyu grass samples beginning September 2, 2014 and repeated sampling every fourth harvest after an 18-day rest period. The intent was to simulate the harvest of grass by cows grazing a paddock every 18 days. The trials were conducted in different locations on the farm for over a year.

Kikuyu grass samples were collected at 18 days of rest. The procedure for collection included random grab samples to replicate a cow grazing. Samples were collected every 5 steps while walking diagonally across the field. About 30 grabs were collected from each field and mixed to create a composite sample for the field. These samples were collected and dried at the same time as the production data samples and sent to Cumberland Valley Analytical services for wet chemistry and in vitro assay of forage quality.
8.3.6 Grass Nutrient Content

Cumberland Valley Analytic Services, certified by the National Forage Testing Association, performed wet chemistry analysis for Dry Matter, Crude Protein, Soluble Protein, Acid Detergent Fiber, Neutral Detergent Fiber, Ash, Calcium, Phosphorus, and in vitro NDF analysis as a method of assessing the nutritive value of the grass trial samples. NDF digestibility was reported at 30, 120, and 240 hour time points for the generation of rates and pools used in the CNCPS model.

8.3.7 Soils Analysis

The NRCS soils classifications and descriptions provide a good base layer of information to use for nutrient budgeting. However, additional soil testing is required to determine soil nutrient levels to be used in the nutrient budget analysis. Soil samples have been taken throughout the farm and have been analyzed for pH, phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients and other constituents.

The farm has approximately 469.9 acres in pasture, which is divided up into 119 total paddocks of about 3 to 5 acres in size. In 2014, soil sample grabs were taken at various locations on the farm and within the different paddocks, and then combined into one representative sample per paddock. The samples were tested by Spectrum Analytical, and soil fertility recommendations were then provided based off of baseline of soil chemical composition and content. This baseline data has been used to inform the nutrient balance of the farm by indicating the fertility requirement of the crop. Subsequent sampling will occur during operation to monitor nutrient levels in the soils so the nutrient budgets can be adjusted during operation.

In 2015, Dr. Russell Yost and Nicolas Krueger, of the University of Hawai’i-Mānoa – CTAHR, conducted additional soil sampling to provide additional baseline data of soil quality, nutrient, status, and health of the sections of the dairy with comparisons to different soil types. Soil cores were collected at sampling locations using a standard probe with locations identified by GPS. Samples were collected and analyzed, with resulting data plotted, mapped and interpreted. Composite samples were taken at approximately 50 locations with two depths for each sample (0-20cm and 20-40cm). The composites were comprised of three samples per composite sample. Saturated paste electrical conductivity was determined as well as exchangeable sodium percentage, calcium, magnesium, and potassium. Levels of nitrogen and phosphorus were also
assessed to establish the nutrient baseline. Refer to the “Hawai‘i Dairy Farms Baseline Nutrient Status: Implications for Long-Term Sustainability, Productivity, and Soil Health” report by Russell Yost & Nicholas Krueger, University of Hawai‘i-Mānoa – CTAHR.

8.3.8 Soils Risk Assessment Classification

Because the basis of design for the farm is pasture-based, rotational-grazing, and no significant amount of annual tillage planned, soil loss tolerance (T) is manageable in accordance with the NRCS Conservation Plan prepared by Hawai‘i Dairy Farms, and approved by the West Kaua‘i Soil and Water Conservation District in December 2013. Additional risk assessments for nitrogen and phosphorus leaching are indicated below:

**Nitrogen Leaching Index per Hawai‘i NRCS 590 Standard**

The risk for leaching nitrogen is low to moderate in all locations of the farm, and nitrogen applications on areas with a moderate risk will be managed and timed to the crop growing season (Kikuyu growing season is year-round in Hawai‘i). Therefore, application of nitrogen could occur year-round in amounts appropriate to the soil type and crop growth.

**Low** - phosphorus can be applied at rates greater than crop requirement not to exceed the nitrogen requirement for the succeeding crop if manure or other organic materials are used to supply nutrients.

**Mod** - phosphorus can be applied not to exceed the crop requirement rate.

**High** - phosphorus can be applied not to exceed the crop removal rate if the following requirements are met: A soil phosphorus drawdown strategy has been implemented, and an assessment for nutrients and soil loss has been conducted to determine if mitigation practices are required to protect water quality. Any deviation from these high risk requirements must have the approval of the Chief of the NRCS.

The phosphorus leaching index was run on each soil type. Below are the results by soil type:

Nutrient Balance Analysis
May 24, 2016

The risk for leaching phosphorus is low in all locations of the farm and phosphorus could be applied at rates greater than the crop requirement not to exceed the nitrogen requirement for the succeeding crop, to maximize crop productivity and improve soil health. However, since the grass crop is not newly planted for each rotation and the growing season is constant and year-round, the phosphorus application is planned to be managed and adjusted to not exceed the crop requirement rate once the pasture has been established.

8.3.9 Nutrient Mass Balance
The annual net nutrient (nitrogen and phosphorus) demand for Kikuyu is summarized in the following tables. The crop nutrient needs will be satisfied by the application of effluent, manure, and supplemental commercial fertilizer. The commercial fertilizer need is expressed as a nutrient deficit of nitrogen and phosphorus based upon the 16.3 tons DM Kikuyu yields.

The following table may be updated as crop yields change, as the nutrient balance of the farm is a dynamic environmental analysis. As the yield of Kikuyu increases as expected, due to pasture maturation and establishment as well as nutrient management (to reach the yield goal of 20 tons DM per acre per year), the annual net nutrient demand of nitrogen and phosphorus will also increase, meaning either more manure (and more cows, up to 2,000) or more commercial fertilizer may be used to maintain a healthy pasture and soil nutrient balance. The pasture-based, rotational-grazing system must manage these different environmental variables.

It is important to note that even as nutrient demand increases as the crop yield improves and the pasture matures, nutrients (nitrogen and phosphorus) will not be applied at rates that exceed the recommendations of the leaching indexes interpretations shown in the NRCS 590 Standard above once the pasture has been established.

The nutrient mass balance approach for HDF assumes that 100% of the manure nutrients are 100% available at the time of application. This is a very conservative way of calculating nutrients that are available for crop uptake, and ultimately the stocking density and number of animals that can be supported on the pasture. Because of nitrogen dynamics, most nutrient management plans only account for 50% of the nitrogen to be plant available while the other 50% is lost to the environment through volatilization. This nutrient balance analysis does not take any volatilization into account. Plant nutrient uptake is also inefficient with respect to
phosphorus because of the extensive sorption and binding reactions of phosphorus with the soils at the HDF site, sharply reducing the amount that is plant available. This mass balance uses the full amount of manure nutrients applied to the fields, whether it is irrigated, applied as slurry, or is excreted by the cow directly onto the pasture, as available to the crop, in the management of the farm's nutrient cycle and to determine the overall stocking density. If volatilization or soil sorption were taken into account, more manure nutrients (and therefore more cows) could be used to maintain a healthy pasture and soil/crop nutrient balance.

While the nutrient deficits shown in the tables below represent the supplemental fertilizer required for the Kikuyu crop, they are not an exact accounting of the total amount of commercial nutrients that must be applied to maintain high forage productivity and soil health. Rather, these values only represent the net amount of nutrients that need to be provided to and utilized by the crop through commercial fertilization, beyond the nutrient that is available to the crop from manure sources. Fertilization, especially the application of commercial nitrogen, can be inefficient with actual requirements with respect to forage production, and fertilization needs can be as much as 25% to 50% greater than the arithmetical difference resulting from a mass balance calculation - due to volatilization or soil sorption as mentioned above. Refer to the previously mentioned soils report by Russell Yost & Nicholas Krueger, UH-Mānoa – CTAHR. It should be noted and planned that the commercial fertilization requirements to maintain high forage productivity and soil health can exceed the simple arithmetic difference between the nutrients applied by manure and the forage uptake.

While these two factors in nutrient availability may seem contrary to each other in nutrient management analyses, where it would appear that manure nutrients are 100% available to the crop but more commercial nutrients would be needed due to inefficiencies in fertilization, the manure nutrient application and availability are first and foremost, the primary factors in measuring the stocking density of the farm, as the manure is the primary source of nutrients for the kikuyu crop. The commercial nutrient application is only meant to provide the needed deficit of nutrients to the crop, beyond what is provided by the manure, to maintain high forage productivity and soil health. The inefficiencies of nutrient application from a mass balance perspective and from a commercial fertilization perspective do not have the same impacts on the pasture-based rotation grazing dairy system. By assuming 100% of manure nutrients are
available to the crop (though it is anticipated that nutrients are lost to volatilization of nitrogen and soil sorption of phosphorus), HDF is proposing a very conservative mass balance approach that reduces the stocking density of the farm. By understanding that commercial fertilizers are inefficient due to these same dynamics, HDF is realistic in its commercial fertilizer expectations and what is needed to provide the remaining nutrients to the crop that it does not get from manure sources.

HDF will utilize a proven, pasture-based, rotation grazing dairy system with high productive forage grasses. These grasses, with fibrous root systems, are typically among the most efficient plants in using applied nutrients (whether through manure or commercial fertilizer) and studies have shown that application of effluents generated from dairy operations via irrigation systems is an effective means of both managing the effluent while simultaneously providing nutrients needed by these productive tropical grasses. Still, HDF must be diligent and balance its planned applications of manure, effluent, slurry, and commercial fertilizer to ensure environmental sustainability and protection.

*** See next page.
Phosphorus is applied to the pasture as nutrient in the form of manure and fertilizer. At 699 mature dairy cows, the amount of phosphorus applied in the form of manure only (P Total Deposited on Farm in lbs/month) does not meet the crop demand (P Total Uptake From Farm in lbs/month) at a crop yield of 16.3 tons of DM per acre per year, as shown in the tables above. Additional phosphorus must be applied using commercial fertilizer to maintain high productivity and soil health. At 2,000 mature dairy cows, the amount of phosphorus applied in the form of manure only slightly exceeds the crop demand at a crop yield of 16.3 tons of DM per acre per year, as shown in the tables above. An excess of over 300 lbs of phosphorus per month could be expected.

As previously mentioned, nutrient management and mass balance analyses are dynamic and are influenced by the many different environmental variables that enter into nutrient cycle planning from grass yields, stocking density, manure nutrient content, soil nutrient content, and crop nutrient content.

Soils analyses currently indicate that the farm soils are extremely deficient in phosphorus. In the initial phases of the farm, HDF anticipates that larger amounts of phosphorus beyond the crop need will improve soil conditions, as the binding of phosphorus to the soil ensures that it stays in the soil profile and is available for continued use by the grass during the paddock’s 18-day rest period. Ultimately, when the farm is established after a few years, HDF intends to provide only the nutrient the grass crop needs, once the soil conditions improve and the farm nutrient balance and management becomes a "maintenance" operation. Until then, additional phosphorus, beyond the crop demand, is allowable in soils with low phosphorus leaching properties, per the NRCS Risk Analyses.

Based upon the soils health report by Dr. Russell Yost and Nicholas Krueger, University of Hawai‘i at Mānoa, College of Tropical Agriculture and Human Resources (CTAHR), an application of over 230,000 lbs of phosphorus per year over 469.9 acres of pasture will be beneficial to the current soil nutrient content to maximize productivity for the grass crop. The planned application for phosphorus for the 2,000 mature dairy cow herd is approximately 91,000 lbs of phosphorus annually. While 91,000 lbs of phosphorus per year, exceeds the crop uptake demand at a grass yield rate of 16.3 tons of DM per acre per year, representing a 3,700 lbs overage per year, the planned amount of applied phosphorus in this scenario is only a
fraction of what could be applied to improve soil conditions as recommended by Dr. Russell Yost when soil nutrient content was measured. At 699 mature dairy cows and 150 calves, there is simply a deficit of nutrient to meet crop demand, regardless of the soil nutrient conditions.

Other management options exist to keep phosphorus in balance. Higher grass yields would demand additional phosphorus. With an increase from the current 16.3 tons of dry matter (DM) per acre per year to a yield of 17.3 tons DM per acre per year, phosphorus demand by the pasture crop will eliminate any phosphorus overage at 2,000 mature dairy cows and 500 calves. Based on grass field trials by consultants to HDF, yields of 20 tons DM per acre per year are anticipated following establishment of the committed herd of 699 milking cows and several years of pasture maturation.

Should yields not increase as planned, the carrying capacity of the farm would be reduced to approximately 1,875 mature dairy cows (from 2,000 mature dairy cows). With reduced quantities of manure, phosphorus application levels would be in balance with phosphorus demands of the pasture, and meet the nutrient need of the grass without fertilizer.

It is critical to manage nitrogen applications as well, especially since nitrogen is soluble and typically moves through the environment quickly through rainfall, runoff, and groundwater. As shown by HDF's nutrient mass balance, however, in either the 699 mature dairy cow or up to 2,000 mature dairy cow scenario, nitrogen will not be applied in quantities exceeding the crop demand. In fact, nitrogen for commercial fertilizer will be required to maintain high pasture productivity and soil health.

### 8.4 Nutrient Application

As previously mentioned, managing the amount, source, placement, and timing of plant nutrients and soil amendments is critical for the nutrient balance of the farm. Application of these nutrients, whether via the liquid effluent collected in the storage pond, slurry suspended in the settling pond, as-excreted manure on the pasture, or commercial fertilizers used as supplement, must be managed to ensure that nutrient is not over-applied or under-applied to different areas of the farm. Multiple criteria must be taken into account when discussing application of nutrients and are discussed in further detail below. The following tables
represent a summary of the nutrient mass balance (from Section 8.3.9 - Nutrient Mass Balance) on the farm anticipated for 699 mature dairy cows and for up to 2,000 mature dairy cows. Refer also to Figure 18A & B – Nutrient Management Map.

Figure 18A – Nutrient Management Map (699-cow Herd Size Scenario)
Figure 18B – Nutrient Management Map (Up To 2,000-cow Herd Size Scenario)
8.4.1 Typical Liquid Effluent Application

Liquid effluent, containing vital nutrients for the Kikuyu crop that will support and feed the mature dairy cows on pasture, will be applied through either of the two center pivots, providing nutrient over a total application area of 285.1 acres (this area excludes the access roads, cow raceways, gun irrigation areas, and 50-ft. setback from drains/watercourses).

Although it is possible to apply effluent through both center pivot machines at the same time, it is much simpler from a management and control perspective to only apply effluent through one pivot machine at a time – the other pivot will either be applying only irrigation water or not operating. The best time to apply the effluent water is a few days after the cows have finished grazing, allowing for the as-excreted manure on the paddocks from the grazing cows to decompose and provide nutrients to the grass immediately after the paddock is used for grazing. This still allows approximately 15 days for the grass to utilize the nutrients from the pivot irrigation of liquid effluent before the cows next enter that paddock.

As mentioned in Section 6.1 – Pivot Irrigation System, the design allows both pivots to do a typical rotation every 48 hours, with a planned application of 0.39 inches of irrigation and effluent. The maximum flow rate from the pump injecting the effluent from the storage pond is 320 gallons per minute (gpm), which is 30% of the total flow capacity of the nozzle package fitted to either center pivot (capable of spraying at 1,030 gpm). During the 48-hour cycle, this means that a maximum of 0.12 inches of liquid effluent could be applied via injection into the irrigation water stream to the center pivot, as part of the full 0.39 inches of irrigation per cycle. However, at any given time, either pivots will not be applying 0.12 inches of liquid effluent per run, as the total volume of liquid effluent in each application would greatly exceed the stored amount of volume of effluent in the storage pond. More irrigation water in lieu of liquid effluent will be applied on a typical basis.

A typical liquid effluent application, which is planned for every 4 days during the spring, summer, and fall months, and whenever able based on rainfall, is shown below:

As the pivots apply effluent, the storage pond effluent level is managed and a safe buffer of spare volume is maintained.

Soil moisture and the amount of precipitation will ultimately determine the actual amount of both irrigation water and effluent to be applied in an application, with the deficit below field capacity determining the amount that can be applied. The number of rain days will dictate the schedule of both irrigation water and effluent application.

8.4.2 Liquid Effluent Application during the Winter Season

Effluent application during the wet winter months will be closely monitored such that the irrigation of effluent does not exceed the capacity of the soil, but also is not building up within the ponds, when irrigation demand of the crop is lowered due to higher amounts of rainfall. The center pivot irrigators can be adjusted to apply as little as 0.04 inches of irrigation per cycle, to minimize over-irrigation of the crop. The pivots can also be adjusted to apply liquid effluent and irrigation water at a 1:1 dilution, in lieu of the smaller percentages of effluent anticipated in a typical liquid effluent application, so that less irrigation water is needed per cycle.

In the winter, because more rain events are anticipated, longer periods between applications will be needed (still less than the 30-day storage period). As the number of available irrigation cycles per month decreases due to the rainy season, it is important to maximize effluent distribution while ensuring that the irrigation demands of the crop are not exceeded. A 1:1
dilution allows for more effluent application in some instances when irrigation can be applied, while the adjustment of the center pivot irrigators to provide less overall flow is important for control of the irrigation amounts to not exceed grass crop demands when there is more rain.

</tbody>
</table>

Minimizing the amount of liquid effluent irrigation days means that the amount of liquid effluent application must be maximized to ensure proper management of the pond levels, but must be carefully balanced with the grass crop irrigation demand. The table indicates that running the pivots, at minimum, only twice a month during the wet winter months will ensure that the effluent levels in the ponds do not exceed the 30-day storage period, and that an application twice a month will not exceed the irrigation demand of the crop.

As the historical rain data indicates, having a period of more than 5 days of continuous rain (in which irrigation would be prohibited) is very unusual, with only 5 occurrences in the last 30 years. In most cases during the winter months, the application of liquid effluent may occur more than two times that month – utilizing less effluent each time and greater dilution.
Nutrient Balance Analysis  
May 24, 2016  

Operationally, both ponds also have the capacity to store suspended solids, liquid effluent, slurry mixing volume, normal precipitation for up to 30 days, and rainfall from the 25-year, 24-hour event. Therefore, the total required volume of both ponds, when completely full from 30 days’ worth of storage and no irrigation of effluent or application of slurry within that 30 day storage period is 2.28 MG or 2,276,645 gallons.

As previously mentioned, both pivots could apply 0.93 MG or 928,938 gallons of liquid effluent at maximum over two days. It would only take 3 application runs to completely empty both effluent ponds for a total application of 2.79 MG or 2,786,814 gallons of effluent, during a winter month. If running at 1:1 dilution, the minimum amount of total liquid effluent and irrigation water, combined, that would be applied over those three runs would be 5.58 MG or 5,573,628 gallons. Such application of liquid effluent and minimal irrigation water is still well below the total irrigation demand of the crop during the winter months, which varies between 26.7 MG and 31.0 MG, meaning that additional irrigation water will still be required to meet the irrigation needs of the grass. These monthly irrigation demands far exceed the required monthly volume capacity of the ponds for the 30-day storage period, showing that the ET of the crop ensures that irrigation of liquid effluent is required even during the winter months.

Further, the daily irrigation demands during the winter months range from 0.84 MG to 0.98 MG per day. While it may appear that the irrigation demand would be exceeded by a single run of both pivots with liquid effluent water and minimal irrigation water, there is room to cut back the amount applied. The center pivot irrigators can be adjusted to apply as little as 0.04 inches of liquid effluent per cycle or 0.31 MG of liquid effluent per run. The total irrigation application at 1:1 dilution is 0.62 MG, which is less than the daily irrigation demand low of 0.84 MG.

Finally, the liquid effluent applied by one run of either pivot, even at minimum application, is well above the daily effluent generation of 13,225.8 gallons per day (699 scenario) or 37,894.7 gallons per day (2,000 scenario), ensuring that the storage pond effluent level is cumulatively lowering after each application cycle, and that pond levels can be effectively managed.

As noted above, the center pivot technology used on the farm has been carefully selected to adequately adapt and apply the effluent in different volumes and capacities to manage irrigation and effluent application for the varying conditions between the seasons.
8.4.3 Slurry Application

The first of the effluent ponds is for the settling of solids (i.e. the settling pond). It will typically be filling with or full of liquid effluent, with the solids content having settled to the bottom and the liquid component then flowing from the top of this pond into the second pond for storage (i.e. the storage pond).

Solids (mostly soft organic matter, but also some sand and mud, etc.) will be mixed with liquid effluent or irrigation water into a slurry suspension, and will be applied on designated areas, at a minimum, of every 5 weeks (within 45 days). The slurry will be applied through a slurry gun irrigation system. The slurry gun system is separate from the hard-hose reel gun system used only for irrigation at the makai side of the farm.

The slurry application areas will vary based upon the number of mature dairy cows on the farm, as the total amount of slurry varies as well. In the initial herd size of 699 mature dairy cows, less manure is generated and less land area could be used to apply the slurry without exceeding the nutrient demand of the Kikuyu crop. Therefore, slurry can be applied, typically, in approximately 42 acres of non-irrigated areas on the eastern portion of the farm, which are outside of the liquid effluent application area from the center pivot as well as the gun irrigation system using only irrigation water. The extent of this type of application has been reviewed by DOH within the Waste Management Plan submitted for 699 mature dairy cows in July 2014. See Figure 19A – Slurry Management Map (Up To 699-cow Herd Size Scenario).

If and when the herd expands up to 2,000 mature dairy cows, more manure will be generated and management of the farm's nutrients will need the option to apply slurry to other nutrient deficient areas, which will likely include all non-irrigated areas on the farm, but also expand to include areas under the gun irrigation system. When it is determined that the slurry application has met the nutrient demand of the crop in a specific area, other areas will be utilized as needed to ensure that nutrients are not over-applied. This change in slurry application at the larger 2,000 mature dairy cow herd size, as compared to the reviewed 699 mature dairy cow Waste Management Plan, will be reviewed as part of a NPDES CAFO Permit application process. See Figure 19B – Slurry Management Map (Up To 2,000-cow Herd Size Scenario).
Figure 19A – Slurry Management Map (Up To 699-cow Herd Size Scenario)
Figure 19B – Slurry Management Map (Up To 2,000-cow Herd Size Scenario)
It is not anticipated that the area within the liquid effluent application area from the center pivots will receive slurry, although based upon the nutrient requirement of these areas, slurry could be applied in lieu of using more commercial fertilizer. Typically, however, HDF will not utilize the areas under the pivots for slurry application, so that nutrients are spread out upon areas not already receiving nutrients from liquid effluent. However, as the slurry is meant to offset the need for commercial fertilizer, slurry may be applied in any location on the farm where it is determined such application would not exceed the nutrient demand of the Kikuyu crop, regardless of where or how the nutrient is supplied (as-excreted manure, liquid effluent from the ponds, slurry, or commercial fertilizer). Proper utilization of the slurry nutrients may reduce the need for commercial fertilizer, reduce operating costs, and improve soil health as a natural source of soil nutrient. As previously mentioned, the application of slurry within the larger 2,000 mature dairy cow scenario will be reviewed as part of the NPDES CAFO Permit application process.

While the total volume of the settling pond will be emptied at least every 45 days, operationally, HDF expects to apply slurry more often than just once every 45 days, helping to manage levels within the settling pond and thereby reducing the overall volume utilized within the storage pond, as more liquid effluent in the settling pond would be used as mixing volume for slurry application in lieu of being injected into the center pivots from the storage pond. Each application of slurry will be managed by area and volume, to ensure nutrients or irrigation water is not excessively applied in any particular area, exceeding Kikuyu crop nutrient demand. Applications will be timed to prevent and eliminate opportunities for nutrients to potentially run off the site.

The slurry application consists of bringing the solids into suspension through adding liquid mixing volume, to the settling pond’s capacity, and then stirring the pond. This liquid, along with the suspended solids, is then pumped through a 4-inch underground pipe to a number of hydrants which have a 'gun sprinkler' with a 5/8-inch nozzle attached via a length of flexible hose. The guns (and their 65-foot radius of spray area) will be moved around the paddocks after a period of running so that the solids become evenly spread.
Under normal circumstances there will be two guns running and the pump will be pumping 158 gpm. At this rate it will take approximately a total of 40 hours to nearly empty the settling pond, when full, depending on the amount of mixing volume.

### 8.4.4 Nutrient Mass Balance by Application

As indicated, nutrients are applied to pasture via four different mechanisms and sources: 1) manure as-excreted on pasture by the mature dairy cows, 2) liquid effluent collected at the dairy facility applied by the center pivot system, 3) suspended solids collected at the dairy facility applied as slurry by a gun sprinkler system, and 4) commercial fertilizer applications.

Each method of applying nutrients must be managed by area and volume, to ensure nutrients are not excessively applied in any particular area, exceeding Kikuyu crop nutrient demand. Applications will be timed to prevent and eliminate opportunities for nutrients to potentially run off the site.

The following tables show the nutrient mass balance of each application type, with the deficit of nutrient equal to the required amount of nutrient to be applied from commercial fertilizer.

** 167 Calves in Pens Accounted For. 333 Calves in Pasture.
*** See next page and Section 8.3.9 - Nutrient Mass Balance
Nutrient Balance Analysis  
May 24, 2016

As discussed in **Section 8.3.9 - Nutrient Mass Balance**, phosphorus is applied to the pasture as nutrient in the form of manure and fertilizer. As shown in the tables above, at 699 mature dairy cows, the amount of phosphorus applied in the form of manure only (P Total Deposited on Farm in lbs/month) does not meet the crop demand (P Total Uptake From Farm in lbs/month) at a crop yield of 16.3 tons of DM per acre per year, regardless of the how the nutrient is applied (as-excreted, liquid effluent, or slurry). Additional phosphorus must be applied using commercial fertilizer to maintain high productivity and soil health. At 2,000 mature dairy cows, the amount of phosphorus applied in the form of manure only slightly exceeds the crop demand at a crop yield of 16.3 tons of DM per acre per year, in both the liquid application and slurry application areas. An excess of over 300 lbs of phosphorus per month from these two application types, could be expected.

As previously mentioned, nutrient management and mass balance analyses are dynamic and are influenced by the many different environmental variables that enter into nutrient cycle planning from grass yields, stocking density, manure nutrient content, soil nutrient content, and crop nutrient content. Refer to the discussion in **Section 8.3.9 - Nutrient Mass Balance**, for options to manage phosphorus on the farm, which may include and are not limited to planned additions of phosphorus to improve soil health, reduction in the carrying capacity of the farm to approximately 1,875 mature dairy cows from up to 2,000 mature dairy cows, or the expected increase in the grass yields from 16.3 tons of DM per acre per year to 20 tons of DM per acre per year (though an increase to 17.3 tons of DM per acre per year would be sufficient to bring phosphorus applications back into balance with crop demand).

### 8.4.5 Contingency Applications

It should be noted that the ponds are sized to accommodate 30 days of storage of effluent, normal precipitation, and the 25-year, 24-hour storm event. It will be highly unlikely that the storage pond will be full at any time, which would require a set of highly unlikely events occurring at the same time (large storm events in tandem, extended heavy rain periods, no irrigation days, no application of the settling pond slurry, and spare volume / buffers filled). At 699 mature dairy cows, the spare volume in the storage pond (as the ponds were designed for 2,000 cows) provides an even greater factor of safety. Throughout the 30-day storage period,
Nutrient Balance Analysis  
May 24, 2016  

Effluent is planned for application every 4 days and the slurry application is expected at least once every 45 days, ensuring that the pond levels are kept at manageable levels.

Nonetheless, if the storage pond were full and if a cataclysmic storm was forecast, the time to empty the pond is around 100 hours. If warranted due to potential impact from an approaching storm event, the settling pond could also be pumped empty within an additional 40 hours. If the forecasted storm is forecast six days prior, then virtually no effluent would remain in the ponds when the storm arrives.

8.4.6 Nutrient Application Schedule  
Manure effluent is typically applied in liquid form with irrigation equipment, and application conditions are documented in the Nutrient Management Plan. All materials will be handled in a manner to minimize the generation of particulate matter, odors and greenhouse gases.

Solid manure effluent will be brought into a liquid suspension and also applied in liquid form with irrigation equipment. Similarly, application conditions are documented in the Nutrient Management Plan. All materials will be handled in a manner to minimize the generation of particulate matter, odors and greenhouse gases.

Manure effluent will be applied at a rate significantly less than the crop (Kikuyu) nutrient requirements and best management practices will be used for maintenance of soil structure. Manure effluent will be applied on recently grazed paddocks and before pasture re-growth starts.

8.4.7 Potential Special Management Areas  
The Māhāʻulepū soils, particularly in the south-central portion of the farm are perceived as heavy, flood frequently and are difficult to grow crops upon. Much of the water from the northern part of the farm runs through this area. The dominant soils on the lower farm are Kaʻena Clay, Kalapa Silty Clay and Kalihi Clay, which are prone to compaction and the USDA characterizes as “poorly drained”. The poorly drained soils retain nutrients as the soils tend to hold water. While this makes grazing difficult, it also protects other surface water resources as runoff, and therefore nutrients, are contained. However, less than two days after heavy rain and with management of surface water after a significant rain event (diversion to a retention
area, etc.), the soils are observed to be dry enough to graze, even without a Kikuyu thatch. Drains may also be installed and used to remove non-nutrient laden water from the surface of these areas to reduce soil dry time and to restore grazing.

Once the farm is in operation, different operational conditions may be used to manage different areas of the farm based on soil types and drainage characteristics. Kikuyu itself doesn’t grow as effectively in inundated or overly-wet conditions, so the farm must be managed to make sure the drainage system is effective. Winter weather may dictate if certain areas or paddocks are used, and if nutrients are applied at all in specific areas.

The nursery used for the grass growth trials was intentionally located within an area characterized as "poorly drained" to test grass growth, nutrient application, and drainage. To date, operational and management decisions have allowed the nursery to perform well.

8.5 Soil Sampling Procedures

8.5.1 Soil Testing Frequency

Soils samples and testing will be performed at least annually, and more frequently as needed, during the farm operation, to assist with managing nutrient content of the soils. Soil samples will be collected from each field receiving manure as described in the University of Hawai‘i CTAHR Cooperative Extension Service publication (SCM-9).

Soil samples will be submitted for analysis to the University of Hawai‘i ADSC laboratory or another laboratory accepted in state-certified programs, the North American Proficiency Testing Program (Soil Science Society of America), or laboratories whose tests are accepted by the University of Hawai‘i CTAHR Cooperative Extension Service. All soil analyses will be conducted using methods approved by the University of Hawai‘i CTAHR.

Soil samples will be analyzed for pH and phosphorus, nitrogen, potassium, calcium, magnesium, organic matter, salinity, micronutrients, and other constituents pertinent to monitoring or amending the annual nutrient budget.
8.6 Manure Sampling

8.6.1 Manure Sampling Frequency

Manure samples will be collected at least quarterly, and more frequently as needed, from both (liquid and solid) effluent ponds, as well as the as-excreted manure, and the result of manure analyses will be used in determining land application rates of manure.

8.6.2 Liquid (Effluent and Slurry) Manure Sampling

Effluent and slurry samples will be taken at the same depth from five sites around the pond. Sub-samples will be mixed in a large, clean plastic container and analyzed while the contents are still swirling.

One pint of material will be collected in an unbreakable container that is no more than three quarters full and sent to the laboratory for analysis.

Samples will be transported in a cooler with ice packs, if necessary. Any stored samples will be refrigerated or frozen before being sent for analysis.

8.6.3 Solid Manure Sampling

Samples from five locations from around the settling pond will be taken at the same depth from which the slurry will be removed for application. Sub-samples will be combined in a clean plastic container and mixed thoroughly.

At least one pint of material will be collected in an unbreakable container, which is no more than three quarters full (a quart-sized freezer bag will be used).

Samples will be transported in a cooler with ice packs. Any stored samples will be refrigerated or frozen before being sent for analysis.
8.7 Forage Sampling

Kikuyu crop samples and testing will be performed at least quarterly, and more frequently as needed, to determine the nutrient content and nutritional value of the crop, both to manage the land application rates of manure and to manage the nutrition of the mature dairy cow.

8.8 Feed Management

A feed management plan will be developed and implemented utilizing the USDA NRCS Feed Management 592 Standard. This standard specifies certain criteria that must be followed and will become an essential component of the NMP. Feed management uses an assortment of tools, including regular analysis of feeds, milk, and manure, to more frequently review nutritional diet formulas and reduce the uncertainties of feed delivery. This process enables maintenance efficiency, improvement in milk production, and/or the improved health of livestock. Stabilizing nitrogen and phosphorus nutrient levels in the manure are also key objectives of HDF, to allow for more precise nutrient management within the farm.

The feed management plan will contain the following information and be developed by a certified animal nutritionist:

- Diets and feed management strategies based upon a benchmark manure sample
- A laboratory analysis completed for the various sources of animal feed (forage or commercial) used to formulate the diet to determine nutrient content for the ration
- Feed analysis conducted by an accepted accredited laboratory
- Adjustments to nutritional levels to improve or sustain livestock productivity
- Diet adjustments to reduce (or not exceed) nitrogen and phosphorus levels in as excreted manure
- Feed management records will be kept on site and reviewed annually along with manure analysis results
8.9 Water Quality Monitoring

HDF will implement a plan for water quality monitoring to assess baseline water quality and monitor water quality during operation, as well as assess the effectiveness of and to adjust HDF’s irrigation, nutrient management and conservation practices.

Monitoring Goals:

- Determine baseline water quality
- Monitor water quality during operation of the dairy
- Evaluate and adjust the frequency and timing of nutrient application and irrigation schedule
- Evaluate and adjust conservation practices
- Detect any potential problems early to allow adjustment of practices before the impacts are significant

8.9.1 Sampling Parameters

Parameters for measurement may include the following:

- Temperature
- Flow
- pH
- Dissolved oxygen
- Turbidity
- Total suspended solids
- Bacteria
- Pesticides
- Nitrogen (N), Phosphorus (P), Potassium (K)

A variety of actions could be taken to manage water quality and to prevent water quality issues from arising at the site. It is likely that one or more of the following actions would be considered and taken to address typical water quality concerns for this type of agricultural operation:

- Addition/modification to erosion and sediment controls
- Addition/modification to conservation measures
- Adjustment to irrigation application schedules
- Adjustment to effluent and sludge application schedules
Nutrient Balance Analysis
May 24, 2016

- Adjustment to nutrient application
- Adjustment to pasture rotation
- Changes to sampling routines, procedure or scheduling

8.10 Conclusion

This nutrient balance analysis is a very conservative analysis of all nutrients that will be produced on the farm. These conservative assumptions will be replaced with actual field collected data once the farm goes into operation. The Nutrient Management Plan(s) (reviewed by DOH for 699 mature dairy animals and to be prepared and reviewed for operations for 700 to up to 2,000 mature dairy animals) will be updated on an annual basis to reflect actual conditions of the farm, once the farm is in operation. The update will include an accounting of the acres in pasture, number of animals present, grass yields, and the overall dairy operation.

Fundamentally, HDF will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based, rotational-grazing system utilizing 21st century technology. The farm will be very different from conventional feedlot dairy operations. Manure nutrients produced on the farm will be utilized for forage crop growth, but balanced with crop nutrient need and commercial fertilizer applications to produce maximum forage yield.

One of the most important considerations in nutrient management planning for farms is the understanding that a NMP is an adaptive management tool. Some even describe it as a living, breathing document that is constantly monitored and updated as the conditions of the farm evolve. All nutrient application records, soil sampling records, forage sampling, water resource quality testing, and manure analysis records will be kept on site with the Nutrient Management Plan, for use by the farm operator to make informed nutrient management decisions. The results from annual soil testing, manure testing, forage testing, and water resource quality testing will then be used to update and inform the nutrient management process for HDF as the farm becomes established and operations mature.

As the current nutrient balance analysis indicates, with the 2,000 milking cow herd size, mass balance projections for HDF show the pound-per-month quantity of phosphorus will exceed the amount of phosphorus that the pasture crop requires for adequate growth.
Nutrient Balance Analysis
May 24, 2016

Nutrient management and mass balance analyses are dynamic and are influenced by the many different environmental variables that enter into nutrient cycle planning from grass yields, stocking density, manure nutrient content, soil nutrient content, and crop nutrient content. Several management options exist to keep phosphorus and other nutrients in balance, which may include and are not limited to planned additions of phosphorus to improve soil health, reduction in the carrying capacity of the farm to approximately 1,875 mature dairy cows from up to 2,000 mature dairy cows, or the expected increase in the grass yields from 16.3 tons of DM per acre per year to 20 tons of DM per acre per year (though an increase to 17.3 tons of DM per acre per year would be sufficient to bring phosphorus applications back into balance with crop demand and eliminate any phosphorus overage). Higher grass yields would demand additional phosphorus. Based on field trials, yields of 20 tons DM per acre per year are achievable after several years of pasture maturation. Should yields not increase as planned, the carrying capacity of the farm would be reduced. With reduced manure, phosphorus application levels would decrease and balance with the nutrient need of the grass. Nitrogen from commercial fertilizer would be required at both 1,875 and 2,000 milking cows.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. In keeping with the NRCS Nutrient Management practice code and best practices, herd growth would be gradual, and the herd size will be dynamic and based upon the monitoring of nutrients in the manure, uptake by grass, nutrient content of soil, and total acres in pasture.

In accordance with the “Guidelines for Livestock Waste Management”, prepared by the University of Hawai‘i-Mānoa – CTAHR, and through consultations with the State of Hawai‘i Department of Health, NRCS District Conservationist, and the West Kaua‘i Soil and Water Conservation District, HDF has prepared this Nutrient Balance Analysis for its Environmental Impact Statement (EIS), stating the intended management methods and techniques which will be used to properly manage its wastewater systems and the nutrient balance of the farm, at a herd size from 699 to up to 2,000 mature dairy animals.
APPENDIX E

ESTIMATES OF THE POTENTIAL IMPACT ON GROUNDWATER AND SURFACE WATER BY HAWAII DAIRY FARMS IN Mahaulepu, Kauai

INTRODUCTION

This report presents estimates of the potential impact of the proposed Hawaii Dairy Farms (HDF) on groundwater and surface water in Mahaulepu on Kauai. The 557 acre project site will be developed on former sugarcane lands in Mahaulepu Valley. Initially, HDF will have a herd of up to 699 cows. Depending on the success of the initial herd size, expansion of the herd up to the carrying capacity of the site may occur. That carrying capacity is presently thought to be 2000 cows. In the evaluation of impacts in this report, both herd sizes – 699 and 2000 cows – are evaluated.

This report begins with descriptions of groundwater and surface water occurrence within and around the HDF site, including results from the four monitor wells that have been drilled on the site and the results of surface and ground water quality sampling. After these descriptions, estimates of the project’s potential impact on water resources are presented. These estimates draw heavily from two reports: (1) “Nutrient Balance Analysis for Hawaii Dairy Farms” by Group 70 and Red Barn Consulting dated March 2016; and (2) “Hawaii Dairy Farms Drainage Memorandum” by Group 70 dated August 2015.

GROUNDWATER OCCURRENCE IN MAHAULEPU

Overview of the Two Groundwater Bodies in Mahaulepu Valley

Groundwater in Mahaulepu Valley occurs in two different geologic formations. The aquifer of highest value and use resides in the unweathered Waimea volcanics which are exposed in the valley walls and buried beneath the thick alluvium which covers the valley floor. All 14 wells of the Grove Farm sugarcane plantation’s Well 14 Battery were drilled through the alluvium into the volcanics at depth. The Kauai Department of Water’s (DOW’s) Koloa Well F (State No. 5425-15) taps into the volcanics of the west valley wall. Two other DOW wells, Koloa C and D (Nos. 5426-04 and -05), tap into the volcanics just outside of the valley (refer to Figure 1). At present, static water levels in all of the wells that tap groundwater in the volcanics stand between 22 and 26 feet above sea level and all of the wells produce water that is of potable quality.

The other groundwater body in Mahaulepu exists in the dark brown to black silty clay and clayey silt that comprise the thick alluvial blanket that covers the valley floor. The permeability of the alluvial mud is highly variable and orders of magnitude less than the permeability of the unweathered Waimea volcanics. Four monitor wells on the HDF site have been drilled into the alluvium (their locations are shown on Figure 1). Water levels in these wells vary from about 80 feet above sea level toward the inland end of the HDF site (wells HDF-1 and HDF-2) to about 50 feet at the makai end of the HDF site (HDF-3). These levels are 30 to more than 50 feet higher than the groundwater levels in the unweathered volcanics.

Scale: 1" = 1500'
Water Levels and Quality of Groundwater in the Alluvium

Water Levels. Elevations and depths of the four HDF monitor wells are listed in Table 1. Water levels of the four HDF monitor wells were recorded over the May 13 to 20, 2015 period to establish the water levels of groundwater in the alluvium and to depict its mauka-to-makai gradient. Results are shown on Figures 2 through 5. Toward the inland end of the HDF site at the HDF-1 and -2 wells, groundwater levels in the alluvium are about 80 feet above mean sea level (MSL). The level drops rapidly going makai, to 68 feet (MSL) at HDF-4 and to 49 feet at HDF-3. In general, the movement of groundwater in the alluvium is from mauka to makai with ultimate discharge into the marine environment. The gradient is on the order of 35 feet per mile. This is far greater than is typical in Hawaii for groundwater in permeable, unweathered volcanics.

The low permeability and low effective storage of the mud that comprises the alluvial blanket across the valley floor is illustrated by the water level recordings of the HDF-2 and HDF-3 monitor wells over the November 19 to December 28, 2015 period. On November 21st, 5.95 inches of rainfall as measured by the HDF onsite rain gage produced a 2.63-foot rise in HDF-2 (Figure 6) and a 3.91-foot rise in HDF-3 (Figure 7). Over this same period, there was essentially no change in the water level in the Well 14 Battery wells which tap the aquifer in the volcanics at depth below the alluvium.

Water Quality. Table 2 presents the water quality results of two sample sets from the monitor wells taken in May and July 2015, with sampling at two depths in each well. In general, groundwater in the alluvium is fresh (salinities on the order of 0.18 to 0.47 PPT). However, the nitrogen and silica levels are much lower than typical for groundwater in Hawaiian basalt. Typical nitrogen levels in Hawaiian basalt aquifers are 70 to 80 µM. Typical silica levels are 700 µM. For the groundwater in the alluvium sampled from the monitor wells, nitrogen and silica are about half the levels typical in basalt aquifer wells.

Wells Drawing from the Aquifer in the Waimea Volcanics

Available Information on the Well 14 Battery. The Well 14 Battery in Mahaulepu consists of 14 wells which were drilled through the alluvial mud to tap the aquifer in the volcanics at depth (refer to Table 3). The first 10 wells (State Nos. 5425-01 to -10) were drilled in the 1897 to 1901 time period. All of the well depths were between 300 to 303 feet below the existing ground at a reported elevation of 85 feet. All were outfitted with 12-inch solid steel casing to below ground depths between 210 to 242 feet. Lengths of open hole below the solid casing were from 61 to 92 feet, equivalent to between 157 and 218 feet below sea level.

Note: Information from the State Commission on Water Resource Management's Groundwater Index
The original 10 wells were linked together by a manifold system about 50 feet below ground. Steam-driven pumps in a pit delivered water from the manifolded wells to the furrow-irrigated sugarcane fields. Difficulty with the stability of the walls of the pump sump led to a major modification of the facility in 1927 to 1928. Four new wells were drilled (Nos. 5425-11 to -14) and the original 10 wells, connecting subsurface manifold, and pump sump were abandoned in place. No plans or drawings could be located that depict the portions of the system that were abandoned. There is a perennial water feature in the near vicinity which is likely to be the location of the abandoned pump sump.

The four new wells that were added to the Well 14 Battery in 1927 to 1928 were drilled deeper than the original 10 wells (to below ground depths of 505 to 532 feet) and also had 12-inch solid casing installed to greater depths (245 to 319 feet). Only three of these four wells can be found today. All three of these wells at one time were outfitted with oil lubricated line shaft turbine pumps, but only one of the three also had a motor when work on this assessment was initiated in 2014. The pumps were still in the other two wells but their motors had been removed. According to recollections of plantation personnel, only the well with the motor was in use for the last 20 or so years of the plantation’s existence (it is the westernmost of the three wells and adjacent to what is believed to be the abandoned pump sump for the first 10 wells). Its pump and motor reportedly delivered about 3.0 MGD. The depths of three wells were measured to try to correlate these with historic records. However, the measured depths do not correlate with the historic records (from west to east, the measured depths were 506.1, 494.3, and 500.8 feet).

Information on the Kauai Department of Water (DOW) Wells. DOW has three wells in the near vicinity of the HDF site (refer to Figure 1 and the bottom of Table 2). The closest is Koloa Well F (No. 5425-15). It is located in the west valley wall and is about 580 feet from the HDF’s western boundary. The other two wells, known as Koloa Wells C and D, are located at the foot of the valley’s west ridge and are 1170 and 2140 feet, respectively, from the nearest point of the HDF site. All three wells are outfitted with 1200 GPM pumps. Depths of these wells are notable, ranging from 247 feet below sea level for Koloa Well F to 198 feet below sea level for Koloa Well D. All three were drilled through weathered volcanics (saprolite) to reach the unweathered, water bearing volcanics.

Possible Hydrologic Connection Between the Groundwater Bodies in the Alluvium and at Depth in the Unweathered Waimea Volcanics

Since groundwater levels in the alluvium are 30 to more than 50 feet higher than the piezometric head of groundwater confined in the underlying and unweathered volcanics at depth below the alluvium, it is reasonable to question whether groundwater in the alluvium discharges into the lower, confined groundwater body in the unweathered volcanics. Several types of information are available to assess this possibility: (1) logs of the last four wells drilled of the Well 14 Battery which fully penetrated the alluvium to the unweathered volcanics at depth; (2) contrasting salinity and temperatures of groundwater in the two groundwater bodies; (3) results of a pump test of one of the Well 14 Battery wells drawing water from the
unweathered volcanics at depth with monitoring of the possible response in groundwater in the alluvium; and (4) measured responses of groundwater in the alluvium to operation of the Koloa Well F pump. Each of these is described in the sections following. All indicate that there is complete hydrologic separation of the two groundwater bodies.

Driller’s logs of the Well 14 Battery Wells. Driller’s logs for the last four wells of the Well 14 Battery are in the 1960 Bulletin 13 of the Hawaii Division of Hydrography (pages 154 to 156) and are reproduced here as Table 4. Sticky red, brown, and purple clay layers are logged from depths of 75 to 300 feet. These layers are essentially impermeable and function as an aquiclude to separate the shallow groundwater in the alluvium from the confined groundwater in the underlying volcanics.

Comparative Salinity and Temperature Profiles. Figure 8 is a conductivity and temperature profile through one of the Well 14 Battery of wells, very likely No. 5425-14 based on the depth of its solid casing. Groundwater in the confined aquifer at depth below the solid casing has an essentially uniform conductivity of 335 µS/cm and temperature of 72.0°F. Conductivity and temperature profiles in the monitor wells are shown on Figures 9 to 12. In contrast to the water in the unweathered volcanics, water in the alluvium is two to six degrees warmer and its conductivity is significantly different, being both fresher (in HDF-2) and significantly more saline (in HDF-1, HDF-3, and HDF-4) than in the groundwater in the volcanics at depth. The source of recharge to groundwater in the alluvium is percolation of rainfall directly on to the alluvium and surface runoff from the upland areas, both of which provide exceptionally fresh water. The source of the much higher salinity water at depth in the HDF-3 and HDF-4 wells is not known. In any event, there are significant salinity and temperature differences of the water in both aquifers which suggest that discharge of water from the alluvium into the volcanics at depth is not occurring.

Pump Test of the Middle Well of the Well 14 Battery. On March 17, 2015, the middle of the three remaining wells of the Well 14 Battery was pumped tested for 10 hours to see if this would produce a response in groundwater in the alluvium. Water level recorders were installed in the pumped well, in the two other Well 14 Battery wells, and in the HDF-1 and HDF-2 monitor wells. All water levels were recorded at 30-second intervals.

Pumping rates and water level response in the pumped well are depicted on Figure 13. Its drawdown at the end of the test was quite substantial (17.1 feet at a pumping rate of 825 GPM) and the drawdown and recovery had a time-dependent component typical of a confined aquifer (Figure 14). Drawdowns in the two adjacent wells of the Well 14 Battery were essentially instantaneous (in the same 30-second recording interval) and were also quite substantial (5.3 and 3.7 feet in the wells to the east and west as shown on Figure 15). These wells are 96 and 67 feet from the pumped well, respectively. They also exhibited similar time-dependent drawdowns and recoveries (Figures 16 and 17).

Water levels recorded in the two monitor wells are shown on Figures 18 and 19. The HDF-1 well is 190 feet to the east of the deep well used for the pump test of the Well 14 Battery. It had an actual build up (rather than drawdown) of 0.05 feet during the pump test, the result of disposal of the pumped water on the ground surface (the clay and silt of the alluvium is compressible, hence the build up). There was otherwise no response to the pumping. The HDF-2 well is 1300 feet to the east of the pumped well of the Well 14 Battery. No response to pumping occurred.

Response of Groundwater in the Alluvium to Pumping of DOW’s Koloa Well F. Recorders were installed in all four of the HDF monitor wells and in DOW’s Koloa Well F for the 7-day period from May 13 to 20, 2015. The objective was to see if operation of the 1200 GPM pump in Koloa Well F creates an identifiable response in the groundwater in the alluvium. If a response were to occur, it would be most easily identified in the monitor well nearest to Koloa Well F, the HDF-4 well which is 630 feet from Koloa Well F. Figure 20 compares the water level in Koloa Well F with that in HDF-4 at the same vertical scale. Figure 21 shows this comparison with an expanded vertical scale for HDF-4 and over a shorter, 2-day period. If a response were to occur, it would most likely be as a pressure pulse arriving at HDF-4 several minutes following a pump start and/or stop of Koloa Well F. No such response occurred.

SURFACE WATER OCCURRENCE AT MAHAULEPU

Surface Water Courses and Drainage Channels

The main surface water course which crosses the HDF site is not named on the USGS quadrangle map. At its mauka end above the HDF site, it is a relatively steep, naturally occurring water course with several small tributaries. Across the HDF site and for some distance further makai, the stream channel is manmade to facilitate former sugarcane cultivation. Toward the inland end of the HDF site in the vicinity of the HDF-1 and HDF-2 monitor wells, the groundwater level in the alluvium fluctuates with seasonal rainfall-recharge. In wetter periods, the groundwater level rises above the invert elevation of the manmade channels and a modest amount of discharge of groundwater from the alluvium into the drainage channel occurs. Toward the makai end of the HDF site in the vicinity of HDF-3, the groundwater level in the alluvium is substantially below the manmade channel invert, meaning that groundwater discharge from the alluvium into the channels does not occur at the makai end of the HDF site.

There are a number of other drainage channels which cross the HDF site, all of which were constructed to facilitate sugarcane cultivation. These convey surface runoff originating offsite and crossing the HDF site to ultimate discharge at the shoreline. It should also be noted that the Waïta Reservoir Ditch circumnavigated the Mahaulepu Valley floor, bringing water into the Mahaulepu Reservoir and also providing direct delivery for furrow irrigation. This ditch apparently fell out of use when the method of irrigation was converted from furrow to drip. From that time forward, water from the Well 14 Battery was apparently the sole source of irrigation for sugarcane in the valley. In the post-plantation
Figure 18. Water Level in the HDF-1 Monitor Well During and Following the Pump Test of the Well 14 Battery on March 17, 2015
Figure 19. Water Level in the HDF-2 Monitor Well During and Following the Pump Test of the Well 14 Battery on March 17, 2015
Figure 20. Recorded Water Levels in DOW's Koloa Well F and the HDF-4 Monitor Well
Figure 21. Comparison of the Water Levels in Koloa Well F and HDF-4
period (from about 1999), water from Wa`ia has been delivered to Mahaulepu via a 12-inch pipeline. In addition to irrigation of about 70 acres of Kikuyu grass at the mauka end of the HDF site, the pipeline supplies a taro farm, banana cultivation (near DOW’s Koloa Well F), a quarry (on the east side of the valley), and agriculture makai of the HDF site.

Table 5 is a compilation of five surface water sample sets taken at the 12 sample sites above, within, and makai of the HDF site as shown on Figure 22. Sites 1 and 2 are above the HDF project area, sites 3 through 10 are within the HDF site, and sites 11 and 12 are downstream of the HDF site. Depending on location, the samples reflect various components of surface runoff from offsite, Wa`ia Reservoir water brought in for irrigation use, and seepage of shallow groundwater from the alluvium into the drainage courses. Other than all of the samples being of very low salinity, there is significant variability at most sites and from site to site.

Other Perennial Surface Water Features Within or Near to the HDF Site

There are two perennial surface water features in Mahaulepu in addition to the water courses which cross the HDF site. One is the Mahaulepu Reservoir which is just mauka of the HDF site and the other is the presumed pump sump for the original 10 wells of the Well 14 Battery. Each is described below.

**Mahaulepu Reservoir.** The reservoir was developed to facilitate furrow irrigation of sugarcane at Mahaulepu. It fell out of consistent use after the conversion from furrow to drip. Today, a low water level is maintained in the Reservoir as a watering hole for beef cattle. The water in the reservoir consists of surface water runoff from the upgradient tributary area supplemented, when necessary, by water from Wa`ia Reservoir. The reservoir has an overflow spillway at its east end which discharges directly into the adjacent branch of the unnamed stream.

**Perennial Sump at the Well 14 Battery.** It appears likely that this perennial water feature is the remnant of the pump sump developed for the battery’s first 10 wells and abandoned when the last four wells were drilled and put into operation in 1928. At present, the water depth in the sump is about three (3) feet and the mud bottom is soft. Before the HDF monitor wells were developed, it was assumed that the water level in the sump was a reflection of the groundwater level in the alluvium. Information subsequently developed has shown that this is not the case:

- The water level in the sump is about 70 to 72 feet (MSL). The water level of groundwater in the alluvium in the nearby HDF-1 monitor well is eight to 10 feet higher.
- In December 2014, the sump was pumped for 95 minutes at about 800 GPM (until the pump broke suction). The water level in the sump drew down and did not recover as it would have if it

</table>
were groundwater in the alluvium (Figure 23). In fact, the level in the sump had not recovered as of July 2015, six months after pumping.

• During the pump test of the Well 14 Battery, there was no drawdown in the sump and no response to disposal of the pumped water such as was recorded at HDF-1 (compare Figure 24 of the sump's response to the HDF-1 response on Figure 16).

Based on this information, the perennial sump is hydrologically disconnected from the groundwater in the alluvium and also from the groundwater at depth in the unweathered volcanics. The isolation of the sump from groundwater in the alluvium surrounding it could be due to the remnants of the sump's walls and/or infilling of silt and clay.

ESTIMATES OF POTENTIAL IMPACTS TO GROUNDWATER AND SURFACE WATER

Identification of the Major Potential Impacts to Consider

There are two major impacts to consider for the operation HDF: (1) its use of surface and groundwater; and (2) its potential increase of nutrients (specifically nitrogen and phosphorus) leaving the HDF site and ultimately discharging into the marine environment. Each of these is discussed and quantified in the sections following.

Expected Use of Groundwater and Surface Water by HDF

Use of Groundwater. HDF will require potable quality water to wash down the milking parlor area (about 30,000 GPD) and for consumption by the cows (at 25 GPD per cow, about 17,500 GPD for the initial 699 cows and up to about 50,000 GPD for expansion up to 2000 cows). This supply will be provided by a pump installed in one of the three remaining wells of the Well 14 Battery. Another pump may be installed in a second well to provide redundant capacity. The total draft of about 47,500 GPD for the initial 699 cows and up to 80,000 GPD for expansion to 2000 cows is a small fraction of the three (3) million gallons per day (MGD) that the Well 14 Battery produced when it was formerly used for sugarcane irrigation. The modest use rate by HDF and the 4500-foot distance to the nearest other operating well (DOW’s Koloa Well F) mean that no adverse impact to ongoing use of groundwater in the volcanics will occur as a result of this use.

Use of Water from Waita Reservoir to Irrigate the Grass. About 347 acres of HDF’s 470 acres of pasture will be irrigated. Two center pivot systems will irrigate 285 acres and 62 acres will be gun irrigated. On Table 6, the estimated monthly and year-round average irrigation rates are compiled (refer to the notes at the bottom of the table for the basis of the calculations). The average irrigation rates are estimated to vary from 0.84 MGD in the wettest month (December) to 1.71 MGD in the driest (June), with a

Notes:
2. Actual evapotranspiration is 0.85 times potential evapotranspiration, 0.85 being the crop factor for Kikuyu grass.
3. Average rainfall is from the 30-year daily record of Mahaulepu Station 941.1 from January 1984 through December 2013.
4. Effective rainfall is approximated as the daily rainfall amounts up to 0.80 inches at Station 941.1. Daily amounts greater than 0.80 inches are assumed to become runoff.
5. Applied irrigation is actual evapotranspiration less effective rainfall applied to 347 acres of irrigated pasture.
year-round average of 1.31 MGD. This additional use of the Waita Reservoir system is well within its capacity.

Potential Increases of Nitrogen and Phosphorus Leaving the HDF Site

**Methodology.** The approach to estimate potential increases of nitrogen and phosphorus in surface and groundwater resulting from the development of HDF is to calculate the flow volumes and nutrient loading under “present” (pre-HDF) conditions and to compare those amounts to forecast conditions with the initial farm size of 699 cows and the possible subsequent expansion of up to 2000 cows. The estimates herein rely heavily on information in the “Nutrient Balance Analysis for Hawaii Dairy Farms” (by Group 70 and Red Barn Consulting dated March 2016) and “Hawaii Dairy Farms Drainage Memorandum” (by Group 70 and dated August 2015).

With regard to groundwater, the estimates of potential impacts focus exclusively on the groundwater in the alluvium on which the HDF site sits. As described earlier in this report, the groundwater in the underlying volcanics is hydrologically separate from groundwater in the alluvium and will not be impacted by HDF activities. The surface water estimates include the runoff from the areas outside of the HDF site which flow through the HDF site via the system of natural and manmade waterways which ultimately discharge in one or the other of the two ditches leaving the makai end of the HDF site.

**Existing Groundwater Flow and Nitrogen and Phosphorus Loading.** Two order of magnitude estimates of the groundwater flow in the alluvium beneath the HDF site have been made to provide an approximation of the flowrate. The area of the alluvium in Mahaulepu Valley is approximately 720 acres. HDF comprises 557 acres of this area and will irrigate 347 acres of its 557-acre site. Rainfall across the alluvium varies from 45 inches per year at the makai end (site of Mahaulepu Station 941.1) to about 55 inches at its mauka end. One order of magnitude estimate assumes 10 percent of the rainfall on the 373 acres of unirrigated area and 10 percent of the applied irrigation on the remaining 347 acres becomes recharge to groundwater in the alluvium. These assumptions amount to a year-round average flowrate of groundwater in the alluvium of about 0.27 MGD.

The other order of magnitude approximation uses the apparent groundwater gradient between the upstream HDF-1 and HDF-2 monitor wells and the downgradient HDF-3 monitor well (a water level drop of 30 feet over a 4800-foot distance), an approximation of the flow’s cross sectional area (4500-foot width and 250-foot depth), and an estimate of the formation’s average permeability coefficient (almost certainly less than five feet per day; it is highly variable in both horizontal and vertical directions). For these values, the approximated average flowrate is 0.265 MGD, essentially the same as the approximation based on recharge by rainfall and return irrigation. For the computations to follow, it is assumed that the flowrate is 0.27 MGD.
The nitrogen and phosphorus content in this groundwater leaving the makai end of the HDF site is taken as the average concentrations of the four samples taken from the HDF-3 monitor well (refer to Table 2). For the 0.27 MGD average daily flowrate, these concentrations are equivalent to 0.91 and 0.074 pounds of nitrogen and phosphorus per day, respectively, in groundwater in the alluvium leaving the makai end of the HDF site.

**Existing Surface Water Flow and Nitrogen and Phosphorus Loading.** Approximately 1770 acres of area drain into the two major mauka-to-makai drainageways which leave the makai end of the HDF site. About 720 acres (including all of the 557-acre HDF site) is relatively flat land and the remaining 1050 acres is the steeply sloping surrounding ridges. Average annual rainfall across the flat land is 45 to 55 inches. Average annual rainfall on the steeper ridges is about 60 inches. As a first order approximation, it is assumed that the surface water runoff consists of 15 percent of the rainfall on the flat land and 30 percent of the rainfall on the steeper surrounding ridges. These assumptions translate to average annual runoff rates of 0.40 MGD from the flat land and 1.41 MGD from the steeper ridges. Notably, this estimate of the surface runoff is about seven times greater than the estimated groundwater flowrate in the alluvium.

Nitrogen and phosphorus concentrations in runoff from the flat land are assumed to be the same as the samples from Sample Site 10 at the makai end of the HDF site (Table 5). Concentrations in runoff from the steep surrounding lands are assumed to be the same as Sample Sites 1 and 2 which are inland of the HDF site. For this set of assumptions, the average daily amounts of nitrogen and phosphorus in surface runoff leaving the HDF site are 3.20 and 0.22 pounds, respectively. These amounts are about three times greater than the estimated amount carried in groundwater moving through the alluvium.

Based on the calculations and assumptions described above, the estimated total annual load of nitrogen and phosphorus from groundwater in the alluvium leaving the makai end of the HDF Site under existing conditions is 332 and 27 pounds per year, respectively. The totals for nitrogen and phosphorus in surface water leaving the site are 1170 and 80 pounds per year, respectively.

**Potential Nutrient Additions by Hawaii Dairy Farms.** From the perspective of potential nutrient additions to surface and groundwater, the operation of HDF can be characterized as a semi-enclosed loop system: nutrients are taken up by the Kikuyu grass; the cows eat the grass as their primary food supply (they will also eat commercial feed while in the milking parlor); nutrients in the grass and commercial feed consumed by the cows are returned to the ground, either as manure excreted on the pastures or as manure collected in the milking parlor and applied to the pastures; and the shortfall of nutrients in the manure to grow the grass is made up by the application of commercial fertilizer.

**Quantification of Circulating Nutrient Amounts in the Dairy Operation.** Table 7 is a quantification of monthly amounts of nitrogen and phosphorus produced and consumed at HDF, initially with 699 cows and ultimately if the HDF expands up to 2000 cows. The compilations are based on the following:
## Nutrient Balance Calculations for Herd Sizes of 699 and 2000 Cows

</table>
• Grass will be grown on 470 acres of the HDF site during the initial herd size of 699 cows and if HDF expands up to 2000 cows;
• Nutrient uptake (specifically nitrogen and phosphorus) by the Kikuyu grass is based on trials at the HDF site conducted to date;
• Manure production rates by the cows are based on available data from cows elsewhere. In the future, the nutrient balance calculations will be updated based on actual manure production at HDF;
• The cows will be awake for 16 hours a day. In two daily 1-hour sessions, the cows will be in the milking parlor or the adjacent holding yard. All manure produced in the milking parlor and holding yard will be collected and redistributed to the pastures, either as diluted liquid effluent in the irrigation water or as slurries applied by pumps to selected pastures;
• In the 14 hours of the day when cows are awake and in the pastures, all manure produced by the cows will be deposited in the pastures.

Based on the forgoing and as detailed on Table 7, the nutrient amounts in the manure produced by the cows will not be sufficient to grow the grass. The shortfall of the manure-supplied nutrients, detailed in the last two columns of Table 7, define the amounts of nitrogen and phosphorus that will need to be provided by applications of commercial fertilizer. These amounts are summarized on an annual basis on Table 8. It should be noted that, with the present data and assumptions listed in the bullet points above, the calculations show that the phosphorus in the manure produced by 2000 cows exceeds the uptake by the Kikuyu grass (last column on the right at the bottom of Table 7). HDF believes that the current tested grass yield of 16.3 tons of dry matter per acre will increase to about 20 tons of dry matter per acre. With such an increase, an excess of phosphorus in the manure of 2000 cows would not actually occur. If the increase in grass yield does not occur, the ultimate herd size would be less than 2000 cows and the number of cows would be limited by the actual grass yield. Increasing the herd size beyond the initial 699 cows would be gradual and monitoring of nutrients in the manure, actual uptake of nutrients by grass, and the nutrient content in soil would be ongoing.

Potential Losses of Nitrogen and Phosphorus to Surface and Groundwater. In rounded numbers and on an annual basis for both herd sizes, HDF will be circulating 490,000 pounds of nitrogen and 87,000 pounds of phosphorus. These amounts are about 325 and 815 times greater than the estimates of nitrogen and phosphorus currently carried in surface and groundwater moving through the HDF site and ultimately discharging into the marine environment. At issue is how much of the nitrogen and phosphorus deposited on the farm as manure and in applied commercial fertilizer will leave the site and increase the present nutrient load that ultimately discharges into the marine environment. There are several aspects to consider in arriving at an estimate:

• Relative to the amount of surface water moving through the HDF site, the groundwater flow in the alluvium is relatively modest. The formation is poorly permeable and even after HDF is in

full operation, the contribution in the groundwater flow to an increase in nutrient load will be significantly less than in surface water.

- The Hawaii Dairy Farms Drainage Memorandum (Group 70, August 2015) identifies a number of design and best management practices intended to limit the amount of runoff and to filter the sediment in that runoff. Most significant among these are set backs, filter strips, and buffer plantings on both sides of drainageways. The herbaceous cover area will be 35 feet wide on both sides of the drainageways.
- Perhaps the biggest factor will be the operating skill of the HDF personnel, including tracking the nutrient balance to avoid excessive use of fertilizer and in anticipating weather patterns to avoid irrigating in advance of heavy, runoff-producing rainfall.

Based on the 30-year daily rainfall record of the Mahaulepu 941.1 gage (January 1984 through December 2013), which was located at the makai end of the HDF site, rainfall on the proposed pasture lands is actually quite modest. Fifty eight (58) percent of the days had no rainfall and 97 percent of the days had less than 0.8 inches (Figure 25). Using the NRCS curve number method to compute runoff for the site’s B and D class soils and irrigated pasture in good condition, it is anticipated that actual runoff into drainageways from HDF’s pastures will only occur on days when the rainfall exceeds 0.8 inches. Using the 30-year record of the Mahaulepu 941.1 gage, such rainfall will occur on about three percent of days or about ten days a year on average. These runoff-producing rainfall events will be the primary mode of conveyance of nitrogen and phosphorus into drainageways and ultimately into the marine environment. The amounts are estimated as follows:

- As a first order approximation, it is assumed that two (2) percent of the nitrogen and one (1) percent of the phosphorus of HDF’s annual manure and commercial fertilizer amounts are carried into the drainageways and/or percolate to the shallow groundwater in the alluvium. In round numbers, this would amount to about 10,000 pounds per year of nitrogen and 900 pounds per year of phosphorus. Notably, these amounts would be the same for both the 699- and 2000-cow herd sizes.
- Compared to the present contribution from and through the HDF site, these additions would represent 6.6- and 8.4- fold increases of nitrogen and phosphorus moving to ultimate discharge into the marine environment, respectively
- These increases would primarily occur during and immediately following runoff producing rainfall events rather than occur continuously throughout the year.

Relative to the nutrient loading under existing conditions, the potential increases due to the operation of HDF are obviously substantial. To provide some perspective, a comparison to ongoing nutrient additions to the marine environment by other projects and/or users along the Poipu coastline is instructive. These additions include the production of domestic wastewater and the application of fertilizers
Figure 25. Frequency of Occurrence of Daily Rainfall Amounts at Mahaulepu Station 941.1 (January 1984 thru December 2013 Data)

- 97 Percent of Days with Essentially No Runoff from the HDF Site
- 58 Percent of Days with No Rainfall
on the area’s two golf courses and other landscaping. Their potential contributions of nitrogen and phosphorus to the marine environment are conservatively estimated as follows:

- The total production and disposal of domestic wastewater in the Koloa-Poipu area is on the order of 1.5 MGD. About 1.36 MGD is in DOH-UIC authorized disposal wells (Table 9) and the balance is an approximation of the contribution from household cesspools and septic tank-leach field systems.
- Nitrogen and phosphorus concentrations in the domestic wastewater are 40 and 10 MG/L, respectively.
- Ultimately, 15 percent of the nitrogen and two (2) percent of the phosphorus enter the marine environment.
- Fertilizer is applied on 400 acres in the Koloa-Poipu area (two golf courses, numerous parks, and other landscaped areas).
- Fertilizer applications of nitrogen and phosphorus average eight (8) and one (1) pound per 1000 square feet per year, respectively.
- Eight (8) and two (2) percent of the applied nitrogen and phosphorus escape to the groundwater below and are ultimately discharged into the marine environment.

For this set of assumptions, the ongoing input to the marine environment along the Poipu shoreline is as tallied below. For nitrogen, the ongoing amount is about 3.8 times the estimated potential contribution from HDF. For phosphorus, the ongoing discharge is about 1.4 times as great as the potential discharge from HDF. These discharges are essentially constant throughout the year in comparison to the expected episodic discharges from HDF.

I. INTRODUCTION AND PURPOSE

In late 2013, Ulupono Initiative made the investment to fund Hawai‘i Dairy Farms, the first pasture-based rotational-grazing dairy in the state. Hawai‘i Dairy Farms, LLC (HDF) was formed as a positive step toward the island state’s food security, economic diversity, and sustainability. Experimental trials were conducted to determine lands capable of growing nutritious forage for dairy cows, and lands meeting the operational requirements for a dairy operation were identified. Kaua‘i was determined to best meet operational requirements, and Māhā‘ulepū Valley was found to provide ideal growing conditions.

At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually at market price. HDF will reduce Hawai‘i’s reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The application process for a National Pollutant Discharge Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

Dairy-related facilities will occupy approximately 10 acres along the western boundary of the project area. Buildings will include a milking barn with a rotary milking platform and milk storage tanks, two calf sheds, and an implementation shed for tools and equipment. Manure captured during the milking process will be transferred through underground pipes to two nearby effluent ponds, where solids will be settled out and the remaining fluid applied to the pasture through the irrigation system. When applied via the irrigation system, non-potable water from the Waita Reservoir will be added to nutrient rich liquid for irrigation use. The effluent ponds will be sealed with a flexible membrane liner, and will be constructed within a secondary
containment berm. Paved access roads and a truck turnaround area for milk tanker trucks, grain silos, and a holding yard for cows waiting to enter the milking parlor will also be part of the project.

Agricultural infrastructure from prior sugar cane cultivation within the project area, such as gravel access roads, field roads, reservoirs, pipelines, irrigation ditches, drainage ways and culverts will be adapted for reuse where possible. Additional field improvements will include a livestock water distribution system, pivot irrigation system, culverts and fencing.

Surface waters draining the project site meet Waiopili Ditch, and will eventually reach the ocean. While all construction and operational activities of HDF will utilize best management practices to protect groundwater and surface water resources and the marine environment downslope from the dairy site, it is nevertheless important to identify any potential impacts that may be associated with the planned dairy. Proposed land uses do not include any direct alteration of coastal areas or nearshore waters. However, the dairy operation will result in some changes to the composition and volume of surface water and groundwater that flows beneath the property. Therefore, evaluating the potential for alterations to water quality and marine life from material input from the dairy constitutes an important factor in the planning process.

In the interest of addressing these concerns and assuring maintenance of environmental quality, a program to assess groundwater, surface water, and nearshore marine water quality and potential impact analysis of the nearshore areas off the HDF was conducted in 2014-1015. Baseline data on groundwater, surface water, and nearshore marine water quality was recorded. The rationale of the water quality assessment was to determine the contribution of groundwater to the marine environments down gradient of the HDF site, and to evaluate the effects this input has on water quality at the present time, prior to the commencement of any dairy activities. Combining this information with estimates of changes in groundwater and surface water flow rates and chemical composition that could result from the proposed project provides a basis to evaluate the potential future effects to the marine environment.

Predicted changes in surface water and groundwater composition and flow rates have been supplied by Tom Nance Water Resource Engineering (TNWRE 2016).

Results of the combined evaluation provided an estimate of the degree of change to the marine environment that could occur as a result of Hawaii Dairy Farms project.
II. METHODS

A. Water Quality/Chemistry

Twelve survey sites were established in the surface waters that traverse the HDF property (see Figure 1). Stations 1 and 2 were located outside the mauka boundary of the site, Stations 3-6 were located within the HDF site, while Stations 7-10 were positioned at the makai end of the HDF site. Stations 11 and 12 were located off the HDF property between the boundary and the ocean. Site 12 was located near the juncture of the ditch and the ocean. Samples were collected by monitoring personnel filling pre-rinsed linear polyethylene bottles with undisturbed surface water. Sampling was conducted on six separate occasions (October 14, 2014, October 29, 2014, November 11, 2014, March 4, 2015, May 8, 2015 and July 9, 2015).

In addition, on October 6, 2014 four transects extending from the shoreline to approximately 200 meters (m) offshore were established for marine sampling (Figure 1). Water quality was evaluated on transects that were oriented perpendicular to the shoreline and depth contours. Water samples were collected at five locations on each transect from just seaward of the shoreline to approximately 200 meters (m) offshore (1, 5, 10, 25, 100 and 200 m). Such a sampling scheme was designed to span the greatest range of salinity with respect to potential freshwater efflux at the shoreline. Sampling was more concentrated in the nearshore zone because this area receives the majority of groundwater and surface water discharge, and hence is most important with respect to identifying the current status and potential future impacts.

All water samples were collected by swimmers working from a jet-ski. Owing to the shallow depth of the nearshore shelf, at stations with water depth less than 1 m a single sample was collected within 20 cm of the sea surface by swimmers working from shore. At stations with water depths greater than 1 meter, samples were collected at two depths; a surface sample was collected within approximately 20 cm of the sea surface, and a bottom sample was collected within 1 m of the sea floor.

In order to determine the existing chemical constituents of groundwater, samples were collected from several wells on and around the project site in 2015 (see report by Tom Nance Water Resources Engineering for locations of wells and results of well water analyses).

Water quality parameters evaluated included the ten specific criteria designated for open coastal waters in Chapter 11-54, Section 06 (b) of the State of Hawaii Department of Health (DOH) Water Quality Standards. These criteria include: total nitrogen (TN), nitrate + nitrite nitrogen (NO\textsubscript{3}^- + NO\textsubscript{2}^-), ammonium nitrogen (NH\textsubscript{4}^+), total phosphorus (TP), orthophosphate phosphorus (PO\textsubscript{4}^{3-}), Chlorophyll a (Chl a), turbidity, temperature, pH and salinity. In addition, silica
(Si) was also reported because these parameters are sensitive indicators of biological activity and help determine the degree of groundwater input in the coastal ocean.

Sampling protocols followed the relevant State of Hawaii Department of Health Clean Water Branch Quality Assurance Project Plan. Surface water samples were collected by filling pre-rinsed, 1-liter polyethylene bottles. Deep water samples were collected using a Niskin-type oceanographic sampling bottle. The bottle is lowered to the desired sampling depth with spring-loaded endcaps held open so water can pass freely through the bottle. At the desired sampling depth, a weighted messenger released from the surface triggers closure of the endcaps, isolating a volume of water.

Subsamples for nutrient analyses were immediately placed in 125-milliliter (ml) acid-washed, triple rinsed, polyethylene bottles and stored on ice. Analyses for Si, NH₄⁺, PO₄³⁻, and NO₃⁻ were performed on filtered subsamples with a Technicon Autoanalyzer using standard methods for seawater analysis (Strickland and Parsons 1968, Grasshoff 1983). TN and TP were analyzed in a similar fashion following digestion. Total organic nitrogen (TON) and total organic phosphorus (TOP) were calculated as the difference between TDN and dissolved inorganic N, and TDP and dissolved inorganic P, respectively.

Water for other analyses was subsampled from 1-liter polyethylene bottles and kept chilled until analysis. Chl a was measured by filtering 300 ml of water through glass-fiber filters; pigments on filters were extracted in 90% acetone in the dark at -20°C for 12-24 hours. Fluorescence before and after acidification of the extract was measured with a Turner Designs fluorometer. Salinity was determined using an AGE Model 2100 laboratory salinometer with a readability of 0.0001‰ (ppt). Turbidity was determined using a 90-degree nephelometer, and reported in nephelometric turbidity units (NTU) (precision of 0.01 NTU). Vertical profiles of salinity, temperature and depth were acquired using a RBR-620 CTD calibrated to factory standards.

Surface water samples were also analyzed for the indicator bacteria Enterococcus and Clostridium perfringens. Separate water samples were collected in autoclaved polyethylene bottles and returned to the analytical lab within 6 hours of collection. Enterococcus were analyzed according to EPA Method 1600 (Enterococci in Water by Membrane Filtration Using membrane-Enterococcus Indoxyl-β-D-Glucoside Agar [mEI]), while Clostridium were analyzed using membrane filter enumeration following the protocols in Bisson and Cabelli (1979). All indicator bacterial analyses were conducted by Analytical Services, LLC in Honolulu, HI.

All fieldwork for all surveys was conducted by Dr. Steven Dollar. All water chemistry laboratory analyses were conducted by Marine Analytical Specialists located in Honolulu, HI (Labcode: HI 00009). This analytical laboratory possesses acceptable ratings from EPA-compliant proficiency and quality control testing.
III. RESULTS

A. Surface Water Chemistry

1. Distribution of Chemical Constituents

While the main surface water course which crosses the HDF site is called “Waiopili Ditch” this feature is not named on the USGS quadrangle map. At its mauka end above the HDF property, it is a relatively steep, naturally occurring water course with several small tributaries. Across the HDF property and for some distance further makai, the channel is manmade to facilitate former sugarcane cultivation. Along part of the course across the HDF property, the channel functions as a drain for groundwater discharged from the alluvium on a seasonal basis. Most of the channel is overgrown by dense vegetation, making access to flowing water difficult. At no point can the ditch be considered a recreational resource, including the channel near its terminus at the ocean.

Tables 1 and 2 show results of water chemistry analyses for samples collected in surface waters and the adjacent ocean during six increments of sampling in 2014 and 2015. Table 1 shows concentrations of dissolved nutrients in micromolar (μM) units; Table 2 shows concentrations in micrograms per liter (μg/L). Concentrations of twelve water chemistry constituents from the six sampling events are shown in Figures 2-5.

Several patterns of distribution are evident in Tables 1-2 and Figures 2-5. With the exception of Si, concentrations of all dissolved nutrients (NO₃⁻, PO₄³⁻, NH₄⁺, TN, TP) are relatively low at mauka sampling stations 1-3 located near the upper boundary of the property (Figures 2 and 3). Concentrations of these constituents increase to higher values at Stations 4-10, located within the boundaries of the HDF site. Values then decrease to relatively constant values at Stations 11-12 makai of the HDF site. Concentrations of all nutrients in the nearshore ocean samples are of similarly low values as concentrations from stations located at the mauka boundary of the HDF property.

As noted above, dissolved Si is the only nutrient that deviates from this pattern. Concentrations of Si are highest at the mauka end of the sampling scheme and lowest at the ocean (Figure 2). As Si is generally higher in groundwater relative to surface water, the observed pattern suggests that the surface water at upper elevations contains a higher proportion of groundwater. The contribution of low Si surface water makes up a progressively larger component of surface water downgradient of the HDF property. As natural marine waters contain substantially less Si than either surface water or groundwater, mixing of these waters at the shoreline results in the observed lowest concentrations of Si.

The pattern of Si distribution provides an indication of the processes driving the observed patterns of other dissolved nutrients described above (low levels at mauka
boundary, higher levels on HDF site, low levels below makai boundary). Composition of surface water at the mauka regions appears to consist primarily of groundwater, as it is relatively low in dissolved plant nutrients (N and P). As water flows through the HDF site, it appears that nutrient concentrations are augmented by input from drainage of surface water that contains some leachate from surrounding lands. Such leachate may contain some subsidies from either prior or ongoing land usages. However, between the time that surface water leaves the HDF site and reaches the ocean, nutrient concentrations return to levels similar to those above the site. As these subsidies are not evident in surface water samples collected below the HDF site, it is likely that the nutrient subsidies are small and rapidly diluted with flow through the ditch to the ocean. By the time surface water reaches the ocean, nutrient concentrations are similar to those above the HDF site, suggesting that the values at the surface water-ocean boundary are the same as what they would be without the nutrient subsidy from leachate observed on the HDF site.

Plots of salinity at each of the surface water sampling stations shows essentially no change until surface water mixes with ocean water (Figure 4). Plots of turbidity and Chl a show similar patterns as the dissolved nutrients. Values are lowest at the mauka end of the sampling regime about the HDF site, show elevated levels at several of the sampling stations within the dairy, and return to baseline low levels below the dairy site and in the nearshore ocean.

2. Indicator Bacteria

Tables 1 and 2 also show counts of Enterococci and Clostridium indicator bacteria measured in surface water during four of the sampling events. For both indicators, there is a general pattern of increasing counts moving closer to the shoreline. During all but one sampling date, the highest single count of enterococcus occurred at either Station 11 or 12 (during the May 8, 2015 survey, the peak value was at Station 5A). Of the two sampling sets that included Clostridium, the May 8, 2015 set showed a clear progression of increasing values, while the July 9, 2015 set revealed no consistent pattern. While the bacteria are generally intended to serve as indicators of human fecal contamination, it is clear from the elevated counts in surface waters that there are other sources contributing to the colony counts. These sources may include feral animals (e.g., pigs) or domesticated animals (sheep) that are being raised near the HDF site. As no dairy cattle were present on the site during any of the sampling events, it is clear that the observed counts of indicator bacteria are not a result of dairy operations.

However, an overall consistent pattern for both indicator bacteria is that counts in nearshore ocean water were consistently lower than in surface waters. During the March 4, 2015, enterococcus counts were 780 at Station 12, and below detection for both samples collected near the juncture of the ditch and ocean. While not reaching levels of non-detection during the other two events where ocean samples were analyzed, counts were substantially lower in the ocean than in the ditches. As these samples are collected within several tens of meters of each other, it is apparent
that both physical mixing processes and the lethal effects of high saline water on bacteria result in substantial reduction in the nearshore ocean.

B. Marine Water Chemistry

1. Distribution of Chemical Constituents

Tables 3 and 4 show results of ocean water chemistry analyses for samples collected on October 6, 2014. Table 1 shows concentrations of dissolved nutrients in micromolar (μM) units; Table 2 shows concentrations in micrograms per liter (μg/L).

Concentrations of eight dissolved nutrient constituents in surface and deep samples are plotted as functions of distance from the shoreline in Figure 6. Values of salinity, turbidity, Chl \( a \) and pH as functions of distance from shore are shown in Figure 7.

Several patterns of distribution are evident in Tables 3-4 and Figures 6-7. It can be seen that on Transects 1, 2 and 4 that dissolved nutrients do not display any distinctly elevated concentrations throughout the length of the sampling transects. Low concentrations at the shoreline with progressively lower values with distance from shore indicates that there is little groundwater or surface water emanating at the shoreline near Transects 1, 2 and 4. Examination of the trends of salinity in Tables 3 and 4 and Figure 7 indicate that only at Transect 4 is there an indication of slightly lower salinity at the shoreline (31.6‰). While there is a corresponding increase in Si, there is no such corresponding increase in NO\(_3\)-, suggesting that the lower salinity is a result of dilution from surface water rather than inputs from groundwater.

Examination of the patterns of nutrient concentrations and salinity as functions of distance from the shoreline at Transect 3 provides an entirely different picture than for the other transects. Samples collected within 5 m of the shoreline exhibit substantially higher values of all dissolved nutrients. These elevated values are the result of input of surface water from Waiopili Ditch. While the values close to the shoreline are elevated, beyond 10 m of the shoreline they return to values similar to the other transects. Hence, while there is a distinct signature from input of surface water, such input is rapidly mixed to background levels within 10 meters of the shoreline.

Salinity, turbidity and Chl \( a \) on Transect 3 exhibit the same patterns as dissolved nutrients. Within 10 m of the shoreline all of these constituents display elevated values that rapidly return to background levels.

It is important to note that the southeast coastline of Kauai, where the sample sites are located are subjected to direct effects of tradewinds, as well as south, north and east swells. As a result, vigorous physical mixing processes are the typical condition in the nearshore ocean. As safety considerations dictate, ocean sampling can only be conducted during relatively calm seas, as were the conditions during the October 6,
2014 sampling event. In addition, sampling was conducted at low tide, when mixing between groundwater/surface water and ocean water is minimized. Hence, the results of the present study represent a case with minimal mixing of water masses in the nearshore ocean. Under these conditions, the effects of input of groundwater/surface water will be most apparent. It is likely that during typical tradewind conditions, and with larger surf, the zone of mixing would be far smaller than is evident in the data presented in this report.

2. Conservative Mixing Analysis

A hydrographic mixing model is used to interpret the extent of material input from land. In the simplest form, the model plots the concentration of a dissolved nutrient constituent as functions of salinity. The concept of using such mixing models that scale nutrient concentrations to salinity is utilized by the State of Hawaii Department of Health for establishing a unique set of water quality standards for the West Coast of the Island of Hawaii [Hawaii Administrative Rules, §11-54-06 (d)]. While the HDOH has not yet extended this method of analysis to monitoring in other areas of the State, it is useful to employ the techniques as a way of better understanding the sources of material input to marine waters.

Figure 8 plots the concentrations of Si, NO$_3^-$, PO$_4^{3-}$, and NH$_4^+$ as functions of salinity for the samples collected at each ocean transect site. Each graph also shows two conservative mixing lines constructed by connecting the endmember concentrations of open ocean water and groundwater from two monitoring wells that penetrate the alluvium underlying the HDF site, and the mean values of nutrient concentration from Station 12 in Waiopili Ditch (see Figure 1).

Comparison of the curves produced by the distribution of data with conservative mixing lines provides an indication of the origin and fate of the material in question. If the constituent in question displays purely conservative behavior (i.e., no input or removal from any process other than physical mixing), data points should fall on, or near, the conservative mixing line. If however, external material is added to the system through processes such as leaching of fertilizer nutrients to groundwater, data points will fall above the mixing line. If material is being removed from the system by processes such as biological uptake, data points will fall below the mixing line.

Dissolved Si represents a check on the method as this material is usually present in high concentrations in groundwater, low concentration in open coastal waters, and is not a major component of fertilizer or sewage effluent. In addition, Si is not utilized rapidly within the nearshore environment by biological processes. It can be seen in Figure 8 that all data points for all four transect sites fall in a linear array on the conservative mixing line created with end-point concentrations from the water from Waiopili Ditch; none of the data points line near the groundwater mixing line. However, as the concentrations from the samples collected off Transect 3 are so much higher than off the other transects, it is likely that small amounts of groundwater
discharge would be masked by surface water input. This plot indicates that at the
time of sampling, most of the freshwater entering the ocean emanated from Waiopili
Ditch.

The plots of NO₃⁻ versus salinity show a different distribution than Si. Data points from
Transects 1 and 2 fall near the groundwater mixing line. Such a result is not
unexpected as these transects are the farthest from the point of discharge of Waiopili
Ditch. The two low salinity points from Transect 3 lie between the mixing lines,
suggesting that there is a contribution of both surface water from Waiopili Ditch and
groundwater. While this result appears somewhat contradictory to the interpretation
of the Si data, it may be explained in that the mean concentration of NO₃⁻ at Station
12 was less than the concentration on the day of ocean sampling. Data points from
Transect 4 lie below the Waiopili Ditch mixing line, suggesting that there is input to the
ocean of surface water slightly lower in NO₃⁻ than found in Waiopili Ditch.

While PO₄³⁻ is also generally found in groundwater in higher concentrations than
open coastal water, it occurs in far lower concentrations compared to NO₃⁻, owing in
part to a high absorptive affinity of phosphorus in soils or rock. It can be seen in
Figure 8 that the concentrations of PO₄³⁻ are higher in surface water than in Well
water. When plotted as functions of salinity, concentrations of PO₄³⁻ do not prescribe
linear patterns similar to Si and NO₃⁻. Values of PO₄³⁻ in samples collected near the
shoreline of Transect 3 lie far below both mixing lines. As all values of PO₄³⁻ are below
0.2 µM, there is essentially no influence from inputs from land.

Plots of concentrations of NH₄⁺ versus salinity show similar relationship as PO₄⁻³. Plots of
concentrations of NH₄⁺ versus salinity indicate that the range of values is small, even
with the substantial input of surface water at the shoreline.

3. Compliance with DOH Criteria

DOH Water Quality Standards include specific criteria for three situations; criteria that
are not to be exceeded during either 10% or 2% of the time, and criteria that are not
to be exceeded by the geometric mean of samples. Comparing sample
concentrations to these criteria provide an indication of whether water quality is near
the stated specific criteria.

Noted in Tables 1 and 2 are samples that exceed DOH 10% water quality standards
for open coastal waters under "dry" conditions. The criteria for dry conditions are
applied to the Mahaulepu area under the probable assumption that this region
receives less than 3 million gallons of groundwater input per mile per day.

Comparison of water chemistry results with DOH criteria reveals that during the
October 2014 sampling, the only constituent on transects 1-3 that exhibited consistent
exceedance of the “not to exceed more than 10% of the time” criteria was turbidity
and Chl a. Samples collected with 10 m of the shoreline on transects 2 and 3 had
turbidity values that exceeded DOH standards. As these samples were collected in the surf zone at the shoreline, such elevated turbidity is expected as a result of resuspension of naturally occurring marine sands. Similarly, Chl a at stations near the shoreline was elevated, likely as a result of resuspension of plant material.

At transect 4, however, all nutrient values in the samples collected within 5 m of the shoreline exceeded the DOH standard. As discussed above, these elevated values are the result of mixing of surface water with ocean water in the nearshore zone. Within 10 meters of the shoreline, water quality is within DOH standards.

IV. DISCUSSION and CONCLUSIONS

The purpose of this assessment is to assemble the information to make valid evaluations of the potential for impact to the marine environments from the proposed Hawaii Dairy Farms operation. The information collected in this study provides the basis to understand the processes that are operating in the nearshore ocean, so as to be able to address any concerns that might be raised in the planning process for HDF.

It is important to note that planning for HDF project will utilize best management practices for nutrient generation and runoff stabilization in order to minimize or even reduce sediment discharge to the channel and groundwater that will eventually reach the ocean.

The proposed HDF does not include plans for any direct alteration of the shoreline or offshore areas. Therefore, potential impacts to the marine environment can only be considered from activities on land that may result in delivery of materials (primarily fresh water and nutrients) to the ocean through either infiltration to groundwater with subsequent discharge to the ocean, and surface runoff. To evaluate the possible magnitude of these processes, a report has been prepared by Tom Nance Water Resource Engineering entitled “Estimates of the Potential Impact on Groundwater and Surface Water by Hawaii Dairy Farms in Mahaulepu, Kauai” (TNWRE 2016). The findings of the report are summarized below.

The TNWRE report considers all sources of groundwater and surface water that flow through the project site to the ocean. Based on existing data, the estimated total load of nitrogen from groundwater and surface water leaving the makai end of the HDF site under existing conditions is 1502 pounds per year. Of the total nitrogen, 332 pounds is from groundwater moving through the alluvium and 1170 pounds is from surface water flow. The total load of phosphorus leaving the site is 107 pounds per year, with 27 pounds in groundwater from the alluvium and 80 pounds in surface water. Surface runoff estimates from the HDF site are approximately three times greater than the estimated amounts carried in groundwater moving through the
alluvium. Relative to nutrient loading in most areas in Hawaii, these amounts are very low.

From the perspective of potential nutrient additions to surface and groundwater, the operation of HDF can be characterized as a semi-enclosed loop system: nutrients are taken up by pasture kikuya grass; the cows eat the grass as their primary food supply (they will be fed supplemental grain in the milking parlor); nutrients in the grass consumed by the cows are returned to the ground, either as manure excreted on the pastures or as manure collected in the milking parlor and applied to the pastures. Estimated amounts of nutrient in the manure produced by the cows will not be sufficient to promote growth of pasture grass to maintain the system in steady state. The shortfall of nutrients in the manure to grow the grass will be made up by the application of commercial fertilizer.

In rounded numbers and on an annual basis, HDF will be circulating 490,000 pounds of nitrogen and 87,000 pounds of phosphorus. These amounts are 325 and 815 times greater than the estimates of nitrogen and phosphorus currently carried in surface and groundwater moving through the HDF site that ultimately discharge into the marine environment. At issue is how much of the nitrogen and phosphorus anticipated from manure and from applied commercial fertilizer may leave the site and increase the present nutrient load that ultimately discharges into the nearshore marine environment. There are several aspects to consider in arriving at such an estimate:

• Relative to surface water moving through the site, the groundwater flow in the alluvium is very modest. The formation is poorly permeable and even after HDF is in full operation, its contribution to any increase in groundwater nutrient loads will be significantly less than in surface water.

• A number of design and best management practices are proposed to limit the amount of runoff and to filter the sediment in that runoff. Most significant among these are setbacks, filter strips, and buffer plantings on both sides of drainageways. The herbaceous cover area will be 35 feet wide on both sides of the drainageways.

• Perhaps the biggest factor in controlling nutrient discharge from the site will be the operating practices of HDF personnel to track the nutrient balances in order to avoid excessive use of fertilizer and in anticipating weather patterns to avoid irrigating in advance of heavy, runoff-producing rainfall. It is anticipated that actual runoff into drainageways from HDF’s pastures will occur on less than three (3) percent of days, which is the equivalent of an average of about ten (10) days per year. These runoff-producing rainfall events will be the primary mode of conveyance of nitrogen and phosphorus into drainageways and ultimately into the marine environment.

• As a first order approximation, it is assumed that two (2) percent of the nitrogen and one (1) percent of the phosphorus of the annual production by HDF are carried into the drainageways and/or percolate to the shallow groundwater in the alluvium.
These percentages would amount to 9,800 pounds per year (lb. /yr.) of nitrogen and 870 lb. /yr. of phosphorus. Notably, these amounts would be the same for dairy herd sizes of both 699 and 2,000 cows.

- Compared to the present contribution of nutrients presently passing through the HDF site, these amounts are 330 and 840 times greater than current nitrogen and phosphorus, respectively. These increases would primarily occur during and immediately following runoff producing rainfall events, and would not be a continuous input throughout the year.

Relative to the annual nutrient loading under existing conditions, the potential increases resulting from the operation of HDF are substantial. To provide some perspective, it is instructive to compare the ongoing nutrient additions to the marine environment along the Poipu coastline. These additions include the production of domestic wastewater and the application of fertilizers on the two golf courses and other landscaping in the Poipu area. The potential contributions of nitrogen and phosphorus to the marine environment from these sources can be conservatively estimated as follows:

The total production and disposal of domestic wastewater in the Koloa-Poipu area is on the order of 1.5 MGD. About 1.36 MGD is in DOH-UIC authorized disposal wells. The balance is an approximation of the contribution from household cesspools and septic tank leach field systems. Nitrogen and phosphorus concentrations in the domestic wastewater are estimated at 40 and 10 MG/L, respectively. Ultimately, 15 percent of the nitrogen and two (2) percent of the phosphorus enter the marine environment.

Fertilizer is applied on 400 acres in the Koloa-Poipu area (two golf courses, numerous parks, and other landscaped areas). Fertilizer applications average eight (8) and one (1) pound per 1000 square feet per year. Eight (8) and two (2) percent of the applied nitrogen and phosphorus escape to the groundwater below and are ultimately discharged into the marine environment. These percentages are estimated based on field validation measured from other golf courses in the State of Hawaii in similar coastal settings as the Poipu Courses (Dollar and Atkinson, 1992).

For this set of assumptions, the ongoing input to the marine environment along the Poipu shoreline is about 38,510 lb./yr. for nitrogen and 1,260 lb./yr. for phosphorus. This amount of nitrogen is about 3.8 times (380%) higher than the potential contribution from HDF (10,000 lbs./yr.). For phosphorus, the ongoing discharge from the Poipu area is about 1.4 (140%) times as great as the potential discharge from HDF (900 lb./yr.). In addition, these discharges from Poipu are essentially constant throughout the year in comparison to the episodic discharges from HDF that will only occur as a result of rainfall associated with storm conditions.

For evaluation of the potential effects of the HDF operation, it is important to consider the composition of the receiving waters. The part of Waiopili Ditch that bisects the
HDF site is narrow, highly overgrown by vegetation, and is a man-made feature created for sugar cane irrigation. It does not represent a recreational resource and does not likely provide value as a unique biotic habitat, functioning mainly as a drainageway. The area of the ditch near the junction with the ocean consists of a deep muddy basin that connects to the ocean through a shallow channel that flows through beach sand. The nearshore marine environment consists of a shallow intertidal reef flat that terminates in a reef crest that slopes sharply on the seaward side to sand and rubble flats. The intertidal reef flat where surface water mixes with ocean water is consistently subjected to substantial wave action and current flow to the west. Owing to shallow depth and almost continuous rough water conditions, the reef flat where mixing occurs can be considered dangerous for humans to use, and does not represent an area of safe or unique recreational use. Measurements made of water chemistry in the marine environment on a rare day of low wind and wave action indicated that mixing of surface water in the ocean occurs rapidly within a short distance of the shoreline. During periods of more typical tradewind weather with larger waves breaking on the reef crest, the zone of mixing would be even more restricted within the nearshore area. While these measurements were made during a period of dry weather, it is likely that the zone of mixing in the ocean would not be significantly different during higher surface water flow, as wind and surf conditions would likely also increase during storm condition.

Combining these results with the estimates of changes to surface drainage (there are no changes to groundwater discharge) during HDF operations, it can be concluded that the project will not cause substantial effects to marine water quality beyond the immediate area of merging of surface and ocean water near the shoreline. Analyses of surface water quality indicates that while there are presently increases to nutrient concentrations at sampling sites within the HDF property, these increases drop back to levels that occur mauka of the property at stations near the shoreline. Nutrient subsidies to surface drainage should only occur during occasional episodic rainfall events estimated to occur no more than ten days per year. Any increases to surface water nutrient and sediment concentrations resulting from HDF operations should be limited to occur only during these episodes of heavy rainfall. Extreme physical factors in the marine receiving environment should result in mixing of surface water to background marine conditions within a small area near the point of discharge from the ditch.

Measurements of indicator bacteria in the surface water flow reveal elevated numbers under the present conditions that include no dairy cattle. As a result, it can be concluded that these bacterial counts are the result of existing “natural conditions.” Like other constituents of water chemistry, indicator bacteria counts decrease rapidly in the marine environment within a small area close to the point of discharge. The rapid decrease in bacterial counts following discharge of surface water to the ocean is likely the result of both physical mixing (i.e., dilution), and toxicity from saline waters. There is no reason to expect that these factors will not continue to keep bacterial counts low in the marine environment.
It is also important to consider that, on an annual basis, ongoing processes in the Poipu area of golf course fertilization and domestic sewage disposal continually discharge up to 3.8 times nitrogen and 1.4 times phosphorus to the marine environment relative to the episodic discharges projected from the HDF operation. This discharge occurs along the entire length of the Poipu coastline, rather than as the limited point source discharge at the mouth of Waiopili Ditch draining Mahaulepu Valley. As noted above, the point of discharge of Waiopili Ditch is not a safe area for marine activities, and does not represent a recreational site. Hence, the potential for impacts to the marine environment from the HDF operation in the confined area of the ditch discharge is small or non-existent in comparison to the potential for impacts associated with ongoing functioning of the Poipu community.

V. SUMMARY

1. Evaluation of water chemistry and indicator bacteria were carried out during six surveys from October 2014 to July 2015 in the section of Waiopili Ditch extending from the mauka boundary of the proposed Hawaii Dairy Farms (HDF) in Mahaulepu, Kauai, across agricultural lands Makai, and to the ocean. In addition, marine water chemistry was evaluated during a field survey which consisted of sampling along four ocean transects downgradient of the HDF site that extended from the shoreline to a distance offshore deemed to be beyond the influence of land. All surveys included analysis of water chemistry constituents listed in State of Hawaii Department of Health water quality standards.

2. With the exception of Silica (Si), surface water samples revealed relatively consistent patterns for all nutrient constituents (NO₃⁻, PO₄³⁻, NH₄⁺, TN, and TP). Concentrations of these nutrients were lowest at the stations outside the upper mauka HDF site, increased at stations located within the HDF site, and returned to low levels between the makai end of the site and the ocean. The concentrations of Si displayed a different pattern, with the highest values at mauka sampling stations that steadily decreased closer to the ocean. As Si is typically higher in groundwater than in surface water, the observed pattern for Si indicates that the groundwater contribution to surface water is highest at the mauka end of the property, and decreases through the HDF site and downgradient towards the ocean.

3. As no dairy cows were on site before or during the sampling, the elevated nutrients sampled in the central region are the result of input from existing sources on the property that likely include feral animals, farm animals or crop fertilization in Mahaulepu Valley. The elevated concentrations may also be a result of lower flow in the central sector of the channel resulting in longer residence time. However, the observation that elevated nutrients return to near background levels at stations makai of the HDF site suggest that the inputs are small and localized.
4. Analysis of water chemistry constituents sampled in the marine environment indicates two major patterns. Small elevations of inorganic nutrients (Si, NO$_3^-$, PO$_4^{3-}$, TN, and TP) along with corresponding decreases in salinity along the Mahaulepu shoreline indicate only a small input of groundwater to the ocean. While detectable in the nearshore area, groundwater nutrient input is mixed to background oceanic values within meters of the shoreline.

5. At the marine sampling station at the juncture of Waiopili Ditch and the ocean, steep gradients of nutrients, salinity, Chl a and turbidity were observed. These gradients were the result of a narrow zone of mixing of surface water and ocean water in the intertidal region of the reef flat. Typical oceanographic conditions with tradewind-generated seas and long-period swells breaking on the reef platform result in rapid mixing and dilution of surface water constituents within a narrow zone that only extends several meters from the shoreline. As a result, input from surface water is highly restricted in terms of spatial distribution and effects to the marine environment.

6. Counts of indicator bacteria (Enterococcus, Clostridium) in surface water samples and nearshore marine samples indicate no repetitive pattern: counts were high and variable within surface water sites and between times of sampling. As no dairy cow activities existed during the sampling, the high levels of indicator bacteria are the result of naturally occurring sources (feral animals), as well as other existing land uses including crop fertilization.

7. Counts of indicator bacteria decreased substantially in samples collected in the nearshore ocean in the zone where surface water from Waiopili Ditch mixed with marine waters. The rapid decrease is likely a result of both physical mixing of water masses and toxicity to bacteria from saline water. In any event, the elevated levels of indicator bacteria found in surface water samples do not extend beyond the shoreline.

8. Evaluations of changes to groundwater and surface water flux and composition resulting from the project performed by Tom Nance Water Resource Engineering. In rounded numbers and on an annual basis, HDF will be cycling 490,000 pounds of nitrogen and 87,000 pounds of phosphorus annually through the system in terms of nutrient uptake in grass, excretion by dairy cows, and application on pastures as nutrient sources for pasture grass. These amounts are 330 and 840 times greater than the estimates of nitrogen and phosphorus currently carried in surface and groundwater moving through the HDF site that ultimately discharges into the marine environment. Hence, during dairy operations, cycling of nutrients through the essentially closed system will be far greater than occurs at present.

9. However, as a first order approximation, it is calculated that only two (2) percent of the nitrogen and one (1) percent of the phosphorus of the annual production by HDF
will be lost from the internal cycle, and actually be conveyed beyond the dairy boundaries into the drainageways. The mechanisms for the significant reduction in nutrient transport to the ocean include implementation of design and best management practices that will limit the amount of runoff, and tracking nutrient balances in order to avoid excessive use of fertilizer. It is anticipated that actual runoff into drainageways from HDF’s pastures will on an average of about ten days per year. These episodic runoff-producing rainfall events will be the primary mode of conveyance of nitrogen and phosphorus into drainageways and ultimately into the marine environment. Compared to the present contribution of nutrients presently passing through the HDF site, these additions would represent about seven and nine-fold increases of nitrogen and phosphorus, respectively.

10. A comparison to ongoing nutrient additions to the marine environment along the Poipu coastline from the production of domestic wastewater and the application of fertilizers on the two golf courses and other landscaping in the Poipu area indicates that these sources contribute about 3.8 times (380%) more nitrogen and 1.4 (140%) times more phosphorus than the potential discharge from HDF. The Poipu discharges are essentially constant throughout the year, and occur across the entire coastline, including areas of high recreational use. On the other hand, the HDF discharges are episodic, occurring only several times per year, and are restricted to a single small area of discharge at a site not suitable for recreational use.

11. As a result of these findings, it can be concluded that as long as BMP’s and other operational practices perform as anticipated in minimizing excess nutrients from leaving the HDF site, all indications are that there is little evidence that operation of the Hawaii Dairy Farm will result in any substantial changes to the marine environment.

12. The water chemistry and indicator bacterial studies conducted for this report can serve as an initial baseline for any monitoring programs that may be required for the Hawaii Dairy Farms.

TABLE 2. Results of surface water chemistry sampling in the vicinity of the site of the Hawaii Dairy Farm (HDF)
collected on six occasions in 2014-15. Surface water samples were collected at 12 locations from mauka of
the HDF site and along Waiopili Ditch to the coastal area (Sampling sites 1-12). "BEACH" indicates ditch flow
across the beach prior to reaching the ocean. "OCEAN" indicates samples collected makai of the coastal
shoreline. Nutrient concentrations are shown in units of micrograms per liter (µg/L). "bdl" indicates below
detection level. For locations of sampling sites, see Figure 1.

TABLE 3. Results of water chemistry sampling of nearshore marine waters off the Mahaulepu watershed on October 6, 2014. Samples were collected along four transects downgradient of Mahaulepu Valley, and extended from the highest wash of waves on the beach to the open coastal ocean approximately 200 meters from shore. Two samples were collected at each of 16 locations on each ocean transect. The sample collected at the shoreline of Transect 3 was from the point that Waiopili Ditch stream meets the ocean. Nutrient concentrations are shown in micromolar units (µM). Also shown are State of Hawaii Dept. of Health Water Quality Standards for Open Coastal waters under dry conditions. Shaded values are greater than "not to exceed more than 10% of the time" criteria. Abbreviations are as follows: DFS=distance from shore; BDL = below detection limit. "S" indicates surface sample; "D" indicates deep bottom sample. For locations of survey transects and sample sites, see Figure 1.

### TABLE 4. Results of water chemistry sampling of nearshore marine waters off the Mahaulepu watershed on October 6, 2014.

Samples were collected along four transects downgradient of Mahaulepu Valley, and extended from the highest wash of waves on the beach to the open coastal ocean approximately 200 meters from shore. Two samples were collected at each of six locations on each ocean transect. One sample was collected just below the ocean surface, and one just above the ocean floor (on each transect site 1 on was located at the beach-water interface and only a single sample was collected). The sample collected at the shoreline of Transect 3 was from the point that Waipio Ditch stream meets the ocean. Nutrient concentrations are shown in milligrams per liter (mg/L). Also shown are State of Hawaii Dept. of Health Water Quality Standards for Open Coastal waters under dry conditions. Shaded values are greater than "not to exceed more than 10% of the time" criteria. Abbreviations are as follows:

- DFS = distance from shore
- BDL = below detection limit
- "S" indicates surface sample; "D" indicates deep bottom sample. For locations of survey transects and sample depths see Figure 1.

Kōloa, Kaua‘i, Hawai‘i 96765
ABSTRACT

Scientific Consultant Services, Inc. (SCS), conducted an Archaeological Inventory Survey (AIS) on behalf of Hawaii Dairy Farms, LLC (HDF) in connection with a proposed dairy farm (project) that HDF seeks to develop on 557-acres within Māhā'ulepū Valley, Māhā'ulepū Ahupua’a, Kōloa District, Island of Kaua‘i [TMK: (4) 2-9-001:001 por., (4) 2-9-003-001 por., and 2-9-003:006 por.]. The property comprising the project area is owned by Mahaulepu Farm LLC and leased to HDF for the purpose of developing the proposed dairy farm.

A 100% pedestrian survey was conducted over the entire project area. In addition, through consultation with the State Historic Preservation Division (SHPD), a 100-meter wide zone bordering the northern flanks of the project area was also surveyed. This extended survey area is also owned by Mahaulepu Farm LLC but are not included within the premises leased to HDF. Because the extended survey area is outside HDF's leased premises, HDF was required to obtain permission from Mahaulepu Farm LLC to enter and survey this area. No project impacts are anticipated in this area; thus, the extended survey area is not part of the defined project area although historic properties identified within the extended survey are described in this report.

During the course of the pedestrian survey of both the project area and extended survey area, a total of sixteen historic properties were identified—six of these sites were located within the project area and the remaining ten sites were all located in the extended survey area. All six sites found in the project area are associated with sugar cane cultivation. Of the ten sites located outside the project area, two are associated with pre-Contact and/or early historic times, one of which was previously identified (Site 50-30-10-3094); the remainder of the sites are affiliated with sugar cane cultivation. Because the project will not have impacts outside the project area, and because the sites within the extended survey area are located on lands that HDF has no control over, no further work is recommended for any of these sites at this time. Accordingly, these sites will remain in their existing condition, under the control of landowner Mahaulepu Farm LLC.

In addition to pedestrian survey, a total of seventeen long trenches were mechanically excavated in various portions of the project area, particularly in a portion of the project area which contained a complex of Land Commission Awards. No cultural materials or burials were identified in any of the trenches. Finally, multiple test units were manually conducted in the pre-Contact enclosure (Site 50-30-10-2250) located in the extended survey area, which aided in functional interpretations.

Sites 50-30-10-2250 through -2264 have been assessed as significant under Criterion D (information important in prehistory or history). No further work is recommended for any of the sites in the project area, although adaptive re-use is possible with several sites. Sites -3094 and -2250, both occurring outside the proposed project area, have been assessed as significant under Criterion D and E. No mitigation or further work is recommended herein for any sites occurring outside of the project area, including Sites -3094 and -2250, as they will not be adversely affected by the current project and fall under the purview of Mahaulepu Farm LLC, not HDF.

INTRODUCTION

Hawai‘i Dairy Farms LLC (HDF) has leased certain agricultural lands from Mahaulepu Farm LLC (landowner and lessor), located in Māhā‘ulepū Valley, Māhā‘ulepū Ahupua‘a, Kōloa District, Island of Kaua‘i (TMK: (4) 2-9-001:001 por., (4) 2-9-003:001 por., and (4) 2-9-003:006 por.), to establish and operate a dairy farm on the leased property (project) (Figures 1 and 2). It is proposed that the 557-acre leased property will undergo some changes in connection with the development of the project, including: modifying existing dirt roads, grading ground surfaces for the construction of buildings, the excavation of effluent ponds, and the excavation of pipelines for the watering of cattle (Figure 3). Previously the entire project area was utilized for sugar cane cultivation.

At the request of HDF, Scientific Consultant Services, Inc. (SCS) performed an Archaeological Inventory Survey (AIS) of the project area, comprised of the leased premises, along with an extended survey area of approximately 100 meters upslope (Figure 1 and Figure 2). The land within the extended survey area is owned by Mahaulepu Farm LLC, and is not under the control of HDF; accordingly, HDF and SCS had to obtain the permission of the Mahaulepu Farm, LLC to enter those areas. The 557-acre project area, together with the extended survey area, compromise the total surveyed area in this report.

Pursuant to Hawai‘i Revised Statutes (HRS) Chapter 6E and Hawai‘i Administrative Rules (HAR) Chapters 13-284 and 13-276, the AIS was performed to:

- Identify historic properties that may be present in the project area, and given the level of prior disruption of this area, to also identify historic properties in the extended survey area that may provide context and assist in the interpretation of any historic properties in the project area;
- Gather information to evaluate the significance of any newly discovered historic properties;
- Determine what effects, if any, the proposed project would have on any identified significant historic properties; and
- Propose mitigation commitments to address possible adverse effects the project would have on the identified significant historic properties.

SCS conducted a 100% pedestrian survey of the project area and extended survey area. The survey revealed one previously identified historic property, a carved petroglyph boulder (State Site 50-30-10-3094) and 15 newly identified historic properties were documented during the survey. Six sites occur in the project area, and the remaining ten sites were documented in the extended survey area outside of the project area.
Fourteen of the sixteen sites are affiliated with sugar cane cultivation *i.e.*, bridges, ditches, retaining wall remnants, and culverts dating from the late 19th-20th century. All six of the sites within the project area, and eight of the sites that are in the extended survey area, fall within this site classification. The remaining two sites in the extended survey area- an enclosure and three petroglyph features- are associated with pre-Contact and/or early historic times.

In addition to pedestrian survey, a total of seventeen long trenches were mechanically excavated in various portions of the project area, particularly in a portion of the project area which contained a complex of Land Commission Awards. No cultural materials or burials were identified in any of the trenches. Finally, multiple test units were manually placed in the pre-Contact enclosure (Site 50-30-10-2250) in the extended survey area, which aided in refining functional interpretations of that site.

**HAWAII DAIRY FARMS PROJECT DESCRIPTION**

Hawai'i Dairy Farms, LLC (HDF) was formed as a positive step toward the island state's food security, economic diversity, and sustainability. Experimental trials were conducted to determine lands capable of growing nutritious forage for dairy cows, and lands meeting the operational requirements for a dairy operation were identified. Kaua'i was determined to best meet the operational requirements, and Māhā'ulepū Valley was found to provide ideal growing conditions.

At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually at market price. HDF will reduce Hawai'i's reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai'i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The application process for a National Pollutant Discharge

---

1 Text for this section provided by Group 70 International.
Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

Figure 3. Proposed dairy facilities within the project area.
PROJECT AREA AND EXTENDED SURVEY AREA

The area of potential effect (APE) of the proposed dairy farm, and thus, the project area, for purposes of the AIS, is comprised of the 557 acres HDF has leased from Mahaulepu Farm, LLC, a subsidiary of Grove Farm Company, Inc. (Grove Farm). When the dairy is operational, the leased property will be fully enclosed by a fencing system that will ensure that all impacts of the project are maintained within the leased area.

At the request of the SHPD, HDF and SCS agreed to include in the AIS an additional area outside the project area, comprised of approximately 100 meters (m) along the northern portion of the valley floor and slightly above, referred to herein as the extended survey area (see Figures 1 and 2). The project is not anticipated to have any impacts in this extended survey area. As the project area was previously used for intensive sugar cane cultivation and is heavily disturbed, it was thought that looking outside the project area could provide additional information that is not readily apparent from its current condition, as well as provide context and information helpful to interpreting sites found within the project area. The project area, together with the extended survey area, is referred to herein as the surveyed area.

Overview of Surveyed Area Location and Environment

The surveyed area is situated entirely within Māhā'ulepū Valley, on the southeastern side of the island of Kaua'i. The surveyed area does not extend up any of the adjacent slopes or ridgelines on the east, or west, and does not extend south beyond Māhā'ulepū Road. The 100 m extended survey area covers additional land along the northern portion of the valley floor, and also reaches slightly up the northern flank of the valley. Informal survey by the SCS crew extended to the top of the eastern and northeastern ridgelines in attempts to locate any trails (see below). Māhā'ulepū Valley is separated by a ridge from Aweoweonui Valley, within Kipu Kai Ahupua'a, to the east. The ridge is of interest because the northern end is composed of basalt, the middle is limestone, and the southern end is composed of the Haula Sand Dunes, near the coastline. The ahupua'a boundary with Kipu Kai crosses this ridge, and the beach front boundary of Māhā'ulepū Ahupua'a extends from Kawelikoa Point in the north to Makahuena Point in the south. Kalapa ridge separates Māhā'ulepū Valley from Paa Valley, an ahupua'a on the west (Figure 4). The north end of Māhā'ulepū Valley is formed by Ha'upu Ridge and dominated by Mount Ha'upu (Figure 5 and Figure 6). There are named peaks on all three ridges. South of the surveyed area lies Kapunakea Pond, a relictual water feature. Māhā'ulepū is literally translated as “and falling together” (Pukui et al. 1974:138), a likely allusion to the ridges bordering the expansive valley.
The surveyed area occurs at an elevation of c. 80 feet amsl to 200 feet amsl and is partially bounded by Māhā’ulepū Road. The road enters the valley along the base of a slope on the western side, extends north, then runs to the east, several hundred meters from the north end of the valley. Traversing the valley, the road then turns south along the eastern ridge slope base, continues the length of the ridge, then turns west, eventually rejoining the entrance. The eastern and western sections of the road form part of the survey area boundaries.

Two parallel dirt roads extend north to south along the center of the valley floor. Both roads have an irrigation ditch parallel to their lengths. Māhā’ulepū Ditch is present on the eastern flank and consists of a modified stream course, the source of which are a series of braided streams at the north end of the valley. These streams enter the valley on the eastern and western sides of the ditch and are referred to as “east stream” and “west stream” in documentation and field notes. The western ditch was constructed in the 20th century and its origins are the Māhā'ulepū Reservoir, at the northwest end of the valley. The reservoir is filled by a series of wells in the immediate vicinity. The ditch does not appear to have originally been a natural stream course that was modified during the Plantation era. This course is referred to here as the Main Ditch. The primary road up the valley is alongside the Main Ditch. This ditch currently feeds the active taro farm at the southern end of the valley. The taro farm borders the southern edge of the project area, but is not within the surveyed area. Smaller ditches run both parallel and perpendicular to the two larger ditches. The Main Ditch and Māhā’ulepū Ditch join south of the project area to form what is then referred to as Waiopili Stream. Waiopili Stream eventually joins a natural spring and the remnants of Kapunakea Pond, then runs by Waiopili Heiau, one of the most significant cultural sites on Kaua'i, and on to the ocean. Land Commission Awards (LCA) along Māhā'ulepū Ditch in the center of the valley are noted as being in Kawailoa Ili, but it is unclear if this stream also went by the same name (see below).

The climate of the surveyed area is not extreme, with rainfall accumulating at an average rate of 53 inches per annum, with average temperatures ranging from 72-86 degrees in the summer and 64-80 degrees in the winter (NPS 2008:7).

LANDFORM, SOILS, AND VEGETATION

The mountain range that flanks the surveyed area to the north and northeast are composed of the most ancient volcanic series in the high islands, the Waimea Canyon Basalts (NPS 2008:11). These formed during the shield-building stage of the Kaua'i volcano, as eruptions gradually built up its sides and widened its base. Most of the range is part of the ancient Napali member of the Waimea series, dating from 4.35 to 5.1 million years ago. The caldera of Mount
Ha'upu is a separate geological feature from the rest of the range and remains undated (Blay and Siemens 2004).

Māhā'ulepū lands below Ha'upu ridge are part of the Kōloa series that cloaks most of the eastern half of Kaua'i. The series formed as the Kaua'i volcano ceased major eruption and began to erode, with occasional small eruptions at lava domes, cinder cones, and spatter cones. These produced a layer of lava that, though not large in mass, nevertheless covered a large area. Kōloa volcanics within the study area at Māhā'ulepū include both underlying lava and visible vents, ranging from 0.5 to 2.0 million years in age (Blay and Siemens 2004).

Portions of the valley's slopes have been identified as Rockland (rRK; Foote et al. 1972: Sheet 32). This is composed of areas where exposed rock covers 25 to 90 percent of the surface. Rock outcrops and very shallow soils are the main characteristics. The rock outcrops are mainly basalt and andesite. This land type topography is characterized as nearly level to very steep. Elevations range from near sea level to more than 6,000 feet, with annual rainfall amounts between 15 to 60 inches. The vegetation at lower elevations consists mainly of *kiawe*, *klu*, *piligress*, Japanese tea and *koa haole*.

Soils on the slopes of the valley are also associated with the KEHF series or Kalapa very rocky silty clay (Foote et al. 1972: Sheet 32). This is a well-drained soil that occurs at the base of slopes and is associated with moderately sloping to very steep topography. Elevations range from 200 to 1,200 feet above sea level, with annual rainfall amounts between 60 to 100 inches. Associated vegetation consists of guava, *lantana*, sensitive plant, *piligiliula*, *ohia*, Japanese tea, and ferns.

Soils within the valley have been classified as LPE or Lualualei Series, composed of extremely stoney clay (Foote et al. 1972: Sheet 32). This series consists of well-drained soils on the coastal plains, alluvial fans, and on talus slopes. They are nearly level and gently sloping. Elevations range from 10 to 125 feet above sea level, with annual rainfall amounts to 50 inches per year. There is a prolonged dry spell during the summer. These soils are associated with sugarcane, truck crops, pasture, wildlife habitat, urban development, and military installations on Kaua'i. Associated vegetation consists of *kiawe*, *koa haole*, bristly foxtail, *uhaloa*, and fingergrass. This soil type, extremely stoney clay, was identified in several trenches during the AIS, with most stratigraphic trenches excavated on the valley floor being composed of a shallow O-horizon overlaying brown/yellow clays. In other words, there are exceptions to the general soil survey.
Figure 4. Project area overview. View to the southwest towards Kalapa ridge.
Figure 5. Project area overview. View to northwest. Note Mount Ha'upu at right.
Figure 6. Project area overview. View to north from center of Māhā'ulepū Valley.
Twelve different soils within Māhāʻulepū Valley are identified on a USGS/USDA Soil Map kindly provided to the field crew by HDF (NRCS 2006; Figure 7). The soils map depicts the various soil regimes across the valley floor; these soil differences are most likely a product of water, whether through transport, ground water, or run-off deposition. During pedestrian survey of areas with sparse or no ground vegetation, the transition of soils was visibly recognizable.

The project area has been utilized for commercial sugar cane cultivation and/or livestock pasturage since the middle of the 19th century and is fairly clear of vegetation. Most of the project area lies fallow with the soils exposed. Some of the areas are covered with grasses up to 0.3 m tall, and smaller areas at the northeast and northwest ends of the valley are 100% covered by grasses up to 2.0 m tall. Within the surveyed area are few scattered koa haole and java plum trees. These occur outside the main valley footprint/project area, which has been extensively cleared for well over a hundred years. The slopes of the valley outside the project area are forested.
Figure 7. Soils of Māhā'ulepū Valley (USDA; Soils NRCS 2006).
TRADITIONAL AND HISTORIC SETTING

Early settlement and agricultural development is thought to have first occurred on the windward sides of the Hawaiian Islands, including Kaua‘i, sometime in the A.D. 900-1000 range during what is known as the Colonization Period (Kirch 2011:22). Most likely arriving from east Polynesia, these early inhabitants brought with them a variety of tools, fishing gear, and household goods. Dogs, pigs and chickens were brought by these Polynesian voyagers for food. The Polynesian rat also arrived with the voyagers, but whether these were intentionally transported as a food source is unclear. Considering that every food crop cultivated by the Polynesians arrived with them, it is evident that these people had considerable knowledge not only regarding how to plant and harvest these crops, but also how to transport the crops' seeds, cuttings, and roots.

Prior to European Contact in 1778, Hawaiians cultivated taro in both irrigated and dry fields. Other dryland agriculture crops included 'uala (sweet potato), uhi (yams), maia (bananas), ipu (gourds), and ko (sugar cane). Grasses were utilized for thatching the roofs of structures and covering floors, which were then covered by hala (pandan) mats. Hala was also used in the making of matting and sails. Important arboreal crops included niu (coconut) and ulu (breadfruit). Other trees were utilized for the construction of canoes, house frames, tools, and weapons. Kapa cloth from wauke (paper mulberry) was also tended. There were a variety of medicinal plants utilized and plants, such as olona, grown to provide fibers for making cordage (Handy and Handy 1972).

Hawaiian aquaculture was extensive, and included the construction and maintenance of coastal and riverine fish ponds. Fishing ranged from shoreline to pelagic, with different strategies for each. In order to maintain and benefit from all of these resource zones, Hawaiian polities were organized into ahupua‘a, which gave residents access to a wide array of resources extending from mountain top forests to deep sea fishing zones. An ahupua‘a was an ancient land division that ran from the ocean to the mountains and allowed those living there to proffer from all the different environmental zones of the land. Ahupua‘a boundaries could expand, contract, appear, and disappear, depending upon political events. Given the size of Māhā'ulepū Valley, Māhā'ulepū Ahupua‘a was highly valued.

PRE-CONTACT ERA

Initial Polynesian settlement of Kaua‘i occurred in the resource-rich regions surrounding Wailua River on the east coast; the equally verdant Waimea River region on the southern coast; and the Hanalei region on the north coast (Joesting 1984). As with all the Hawaiian Islands, each district and region was eventually settled. These settlements developed into polities which allied,
warred, and co-existed with one another until Kaua'i came under unified rule of a single king. This process occurred in different stages on different islands. Because of the relative distance of Kaua'i from O'ahu, Moloka'i, Maui, Lana'i, and Hawai'i Island, the polities of Kaua'i and her neighbor Ni'ihau became their own entity, while the other islands struggled first for internal control and later, for the conquest and rule of several, and ultimately all, the islands.

The primary residence of the high king was in the Wailua River region of Kaua'i, with miles of cultivated lands, mountain resources, religious sites, and shoreline to pelagic fishing. Broad stretches of beach allowed for canoe landings but there was no deep water anchorage, despite the presence of the Wailua River.

Initial settlement is presumed near the coastline in the A.D. 1000-1200 range, with expansion inland during the A.D. 1400-1600s, as was typical across the islands (see Kirch 1985). Agricultural field systems were created at these inland areas, closer to fresh water resources and soil more amenable to kalo and sweet potato production. Permanent habitation locales were present from the coast to this more inland area, with ceremonial sites, walls, and other associated structures being built. Within the mountainous areas, such as at the back of Māhā'ulepū Valley, temporary habitation loci such as rock shelters/caves or small enclosures (C-shapes) were utilized by those gathering upland resources. The middle zone, between the coastlines and mountains, such as Māhā'ulepū, was ideal for agriculture and homesteads, as witnessed by the numerous LCA's occurring in a small section of the valley later. However, historic land use obliterated much of the archaeological signatures for these settlements.

In early 1778 Captain James Cook and the two ships under his command, H.M.S. Resolution and H.M.S. Discovery arrived off of Kaua'i. Finding that they could not make land fall at Wailua, Cook continued westward until reaching Waimea. This would be the beginning of contact between Europeans and Hawaiians (Salmond 2003).

EUROPEAN CONTACT AND THE KAMEHAMEHA DYNASTY

The third voyage commanded by Captain Cook was undertaken primarily to discover the fabled Northwest Passage, which supposedly linked the Pacific, Arctic, and Atlantic Oceans. As he had during previous journeys, Cook visited Tahiti and it was from there that he set out for the northern Pacific coast of North America.

The voyage put him within sight of the island of O'ahu, but adverse winds prevented his arrival. Continuing on to Kaua'i, he sighted Wailua, but could not make landfall. The ships continued southwest and then westward, past Mount Ha'upu and Māhā'ulepū Valley. Both were
sketched and drawn by expedition artist John Webber, the first European artwork to depict a Hawaiian Island.

Cook found a manageable anchorage at the mouth of Waimea River. Several trips ashore by him and a select group of his officers, marines, and crew led to generally good relations with the Hawaiians. It is unclear what Cook and the others learned about the politics of Kaua‘i and her eastern neighbor. It is probable that at this time (1778) Kaeokulani was ruler of Kaua‘i. He was of high rank, a chief born on Maui, and the half-brother of the paramount king of Maui, Kahekili.

After a short time on Kaua‘i in the early months of 1778, Cook departed to continue the search for the Northwest Passage. A year passed after which Cook returned to the Hawaiian Islands. This time, Maui was sited and briefly visited, but the island of Hawai‘i became the focus of the remainder of the voyage of Cook and ultimately of his demise, at Kealakekua Bay (Salmond 2003).

After the death of Cook, the journey continued, now under the command of Captain Clerke. The ship passed O‘ahu, and returned to Waimea, Kaua‘i. After their departure a short time later, it would not be until 1786 that Europeans returned to the Hawaiian Islands, with Waimea (Kaua‘i) receiving her share of British and American vessels focusing on the lucrative fur trade in the Pacific Northwest. These visits coincided with, and perhaps accelerated, the growing conflict for control of the eastern islands.

Beginning in approximately 1790, battles on and around Maui, Moloka‘i, and Hawai‘i Island between several rulers occurred with increasing ferocity. Safely in control of Kaua‘i, Kaeokulani became a participant, bringing fleets of warriors to assist his half-brother on Maui. Many European and American ship captains had contact with all the rivals, and a fairly coherent chronology of events is known. What certainly is known is that Kaeokulani was killed during a battle in Honolulu in 1794 while fighting his nephew Kalanikupule, who had taken rule of Maui and O‘ahu upon the death of his father Kahekili in Waikiki, several years earlier in 1791 (Ridley 2010).

The son of Kaeokulani was Kaumuali‘i. Born around 1780, the young king went through a period where a Regent (an older relative) made the decisions, but Kaumuali‘i eventually came to rule on his own. The remainder of his days was spent trying to keep Kamehameha, who had consolidated the rule of the other islands, from bringing Kaua‘i in as well.

Kamehameha had difficulty solidifying his rule. Rebellions, plague, and appeasing subordinates all kept him from mounting more than two serious efforts at physical conquest of Kaua‘i. The first effort to fail occurred in 1796 when Kamehameha sailed with an invasion fleet for Kaua‘i. Hit by a heavy storm, the fleet turned back to O‘ahu (Kamakau 1961). The second
effort failed in 1804 when Kamehameha mustered his forces on O'ahu, but the army fell victim to *oku'u*, a smallpox epidemic. Kamehameha himself almost died, and far too many of his troops, counselors, and their families did succumb (Kamakau 1961). In 1810 Kamehameha used diplomacy, suggesting that he rule the eastern islands in name and deed, while Kaumuali'i acknowledge his suzerainty but continue to rule Kaua'i and Ni'ihau. It was agreed that the arrangement would end with the death of Kaumuali'i and that rule would then pass to the heirs of Kamehameha. It was an arrangement that Kamehameha and Kaumuali'i would honor, but that the heirs of Kamehameha would not (Joesting 1984).

This arrangement lasted between 1810 and 1822. It endured the death of Kamehameha the Great in 1819. During these 12 years, Kaumuali'i solidified rule of his kingdom and engaged in efforts to gain foreign weapons and support from the Russian Fur Company (Mills 2002). Also during this time, the trade in sandalwood flourished. Harvested in the Hawaiian Islands, traded for goods to European and American captains, and sold in the Chinese trade ports of Macao and Canton, sandalwood became the first Hawaiian cash crop (Ridley 2010). The Hawaiians called it *laau ala* (sweet wood) or *iliahi* (fiery surface) for its reddish blooms. They used this wood for scenting bark cloth, making dyes, and for medicinal purposes (Ridley 2010).

At first, the sandalwood revenue went solely to the paramount chiefs, Kamehameha and Kaumuali'i. However, with the death of Kamehameha, nearly all of his chiefs called upon the young heir, Liholiho, and the Regents, among whom was Ka'ahumanu, the favorite wife of Kamehameha but not mother of his heirs, to allow the chiefs to harvest sandalwood for their own profit. This practice would affect and disrupt the rule of Hawai'i and the welfare of the common people for decades.

The upland forests were scoured, crops were neglected, commoners suffered malnutrition and disease, chiefs went into debt to foreigners, and Liholiho was hard pressed to find new resources for his chiefs to exploit. Kaua'i appeared to be the answer. While continuing to honor the arrangement made by his father, Liholiho arrived on Kaua'i in 1822, visited with Kaumuali'i, and then kidnapped him, returning to O'ahu with his captive. In order to secure the rule of Kaua'i, Kaumuali'i was forced to marry not an heir of Kamehameha, but his wife, Ka'ahumanu. To ensure her hold, she also wed her new husband's son, Keali'iiahonui. This second marriage was later dissolved. However, ties between dynasties stayed strong as Keali'iiahonui married a granddaughter of Kamehameha, named Kekauōnohi (Mills 2002).

Ka'ahumanu had been instrumental in the overthrow of the *kapu* system of Hawaiian governance and social behavior, as well as one of the earliest and most prominent proponents of conversion to Christianity. That she utilized polyandry to achieve control of Kaua'i is just one
example of her abilities to utilize both traditional and introduced ways of life to achieve her goals (Joesting 1984).

While still titular ruler, Kaumualii'i did not exercise any power. Governors were appointed by the Regents, the first of these being the brother of Ka'ahumanu, named Kahekili Ke'eaumoku. Beginning with this Governor, land acquisitions beneficial not just to the Kamehameha line but to their powerful subordinates started.

The practice of allowing individual chiefs to harvest sandalwood was carried over to Kauai. How many Kauai chiefs retained their lands during this time is not certain. What was certain is that the mountains of Kauai, including Ha'upu, yielded the valuable resource. And practically the only place that it could be shipped was from the only secure anchorage at Waimea River. Waimea also served as a provisioning port of call to the growing number of whaling ships that began to appear in the Pacific.

The independent rule of Kauai came to an end in 1824 with the death of Kaumualii'i. This same year, the heir of Kamehameha, Liholiho Kamehameha II also died. The kingdom of Hawaii would now be ruled by a queen.

THE REGENCY OF KA'AHUMANU

Ka'ahumanu was one of Kamehameha's primary wives, his favorite in fact, but not of sufficient rank to be mother of his heirs. It appears she never bore the king, or anyone else, any children. From her actions following his death in 1819, it is apparent that Ka'ahumanu considered herself Kamehameha's heir. The mother of the heirs, Keopuolani, died in 1823. Her first son was Liholiho, born in 1796, made king in 1819, and died visiting London in 1824. Her second son was Kauikaouli Kamehameha III, born in 1813. Her daughter, Nahienaena was born in 1815 (Day 1984). With the death of Liholiho and his mother, Ka'ahumanu became Regent of the kingdom until Kauikaouli would come of age. Her rule of Hawaii in general, and Kauai specifically, was adroit, intelligent, and shrewd.

George Kaumuali'i and a number of Kauai chiefs forcefully resisted the rule of the Kamehameha line, and their revolt was crushed. As with many Byzantine events in Hawaiian history, some Kauai chiefs stood with the old, while others stood with the new. In this case, as with any other, people chose who they thought would benefit them most. Those who rebelled had their lands and lives taken, while those who did not, benefitted.

The first long term governor during the regency was Kaikioewa, a high chief born at Waimea, Kauai. He was a first cousin and brother-in-law of Kamehameha, a guardian of Kamehameha III, and a principal leader in crushing the 1824 rebellion (Mills 2002). He reigned
as governor from 1825 until his death in 1839. During his tenure, we know of at least one konohiki, or land manager, for Māhā'ulepū. Documents show that in 1826, Hukiku was konohiki. He was in attendance that year during a visit by the governor. Kaikioewa was accompanied by missionary Samuel Whitney of Waimea, who left an account of this event. It is unknown if Hukiku was Kaua'i born, or one of the conquerors invested with this stewardship. He may be the chief Kukiku, who Kaikioewa named commander of Paulaula o Hipo, also known as “The Russian Fort” (Mills 2002).

During his term as governor, Kaikioewa claimed Ha'upu Ridge, to the east/northeast of Māhā'ulepū, as his personal sandalwood reserve. One of the duties Hukiko performed may have been overseeing the efforts to harvest sandalwood from the ridge and transport it to foreign ships at Waimea or Kōloa. Eventually, as did so many other aliʻi, the governor would go into debt to foreign captains and merchants. When the sandalwood ran out, it is not clear how Kaikioewa paid his bills (Joesting 1984).

Kaʻahumanu ruled as Regent until her death in 1831. A daughter of Kamehameha, Kīnaʻu, took over as Regent until 1834, at which time Kauikeaouli Kamehameha III took the throne. He had lived on Kauaʻi as a boy under the protection of Kaikioewa but had spent the majority of his youth on Oʻahu. Ruling until his own early death in 1854, his reign was admirable for its civil rights, efficiency, and the creation of the Great Māhele, by which land awards to commoners and granting ownership to the disenfranchised was achieved. In Māhāʻulepū, there were many Land Commission Awards (LCA), discussed below, but the majority of the acreage was retained by the government. During his reign, there was an increase in the number of immigrants from Europe, the United States, and China. Missionaries, merchants, laborers, and farmers of multiple nationalities added to the diversity and complexity of the Kingdom.

LAND COMMISSION AWARDS

The Great Māhele was yet another drastic change in the lives of Hawaiians. Commoners, also known as makaʻainana, had for centuries been allowed use, but denied ownership of the lands they worked. This changed in the late 1840s when private ownership of lands was made into law. Certainly aliʻi, or nobles, had the better of the deal, but commoners were allowed to claim, through right of labor and longevity of occupancy, Land Commission Awards (LCA). King Kauikeaouli Kamehameha III was a sovereign brought up in the old ways who saw that some things must change, and orchestrated this new policy. A legal process was established, in which land claimants testified, and had others support their testimony, before a Commission appointed by the king. Traditional land use was communal and land use was often dendritic, following the course of streams and occupation zones from the coast to the mountains. Claimants
were often related and the lands they claimed were as varied in their usage as they were in their location. For a traditional ahupua'a to work, those mauka (towards the mountains) had to work with those makai (towards the ocean). The private ownership offered through the Māhele, however, created new risks for landowners. A commoner who did not own the land could not go into debt; but, one who did could achieve profit or debt. Land claim testimonials are complex documents. Boundaries are defined in a variety of ways. Land divisions descend in size from ahupua'a to kuleana to 'ili, thence apana, and finally mala, which are individual garden plots, fields, and/or lo'i (Pukui 1957). Other boundaries are defined by names of neighboring occupants or by use of the land. Testimonies were given regarding which chief had granted the occupant use of the land. This is compelling, because occupants claimed title based on grants from Kaumuali'i, last independent king of Kaua'i, to Kaikioewa, governor from 1824 to 1839 for the Kamehameha Dynasty, to his konohiki for Māhā'ulepū, Hukiki. They invoked the names of Ka'ahumanu, the Regent for nearly a decade, to Kīnaʻu, Regent and half-sister to King Kauïkeaulani Kamehameha III until he took the throne. Some claims were contested, others were not, and some were won on appeal. When one studies the LCAs of Māhā'ulepū, it can be seen that claims of land, in a variety of places, for a variety of uses, were made by individuals throughout the ahupua'a. With modern ownership, a traditional lifestyle could be maintained, but once individual plots began to be sold, and relationships were sundered, life for the commoners and nobles alike began to change drastically.

On Kaua'i, and in Māhā'ulepū Valley specifically, a number of land claims were made by residents who had been allowed use of the land during the reign of the previous king. In the valley, LCA 5080 to Kiko, LCA 4767 to Napaliala, and LCA 4769 to Nahuma, for example, were all claimants who had tenure from Kaumuali'i. It is presumed that their neighbors had similar histories (Ching 1974). That these residents all received their awards is notable because their claims were based on the right of use granted by the former ruler, and not by permission of the Kamehameha Dynasty. An 1896 map of the valley, depicts a “house” and “cattle pen” in the northern part of the valley and the LCA's just below, in what today is the mid-section of the valley (Figure 8). The 1896 map also shows the word “Path”, far above the LCA area. This “path” was fully investigated during the current survey and shown not to exist (see below). An 1897 survey map by Monsarrat (Figure 9) shows a better view of the LCAs.

Many of LCAs for Māhā'ulepū are tightly clustered within the 'ili of Kawailoa (Figure 10). There is a cluster east of Māhā'ulepū Ditch near the center of the valley. The remainder of the valley was deemed government land. Thus, no LCAs occur elsewhere in the project area or the extended survey area. It is interesting to note the estimated population of this portion of Māhā'ulepū Valley at this time. In 1848, 46 male names appear in genealogical records (M.
Ching, LDS Records). If one were to reasonably add one wife and at least one child per household, the population would have been 138 persons. In 1855, a total of 36 male names occur in the Māhāʻulepū records. Using the same figures, the total would have been 108 persons. This represents a fairly sizeable population for this upper valley at that time, all likely associated with the LCAs.

The following provides a representative sample of names and LCAs that are both present on the LCA map within the project area and are described in previous literature (Ching 1974). Claimants used owners of adjacent lands as boundary references and/or supporters of their claims. Many claimants were related in some way. The claimants of LCAs within the project area often also had additional claims downstream of Māhāʻulepū Ditch on the coast or elsewhere. Thus, only some of the claims discussed (kula lands, etc.) may actually be in the project area. A good example is LCA 5080, where a salt pan is discussed. Such claims related to salt pans would have occurred far outside the current project area near the coastline. In addition, some of the claims also include information about other LCAs claimed by the same person. While somewhat confusing, the summary of records are presented in full here in order to get a clearer picture of the LCAs in and around the surveyed area.
Figure 8. Registered Survey Map #1898 (1896) showing location of “House”, “Cattle Pen”, and LCAs in mid-valley. Note: “Path” in map center.
Figure 9. Registered Survey Map #1900 (1897) of LCAs in Māhā'ulepū Valley.
Figure 10. Modern TMK map of Māhā'ulepū Valley depicting LCAs.
LCA 4767 Napaliala received his lands in the days of Kaumuali‘i, who died in 1824. This was waste land when Napaliala took it over, occupied it, and developed it. He died in the late 1840s and his wife then possessed the land.

LCA 4769 Nahuma was another native who occupied lands prior to 1824. One piece was waste land when he took it over, built on it, and fenced it with stone. In addition he received on the death of relatives other lands occupied previous to 1824: two (2) lo‘i in the 'Ili of Kauki‘i, which had belonged to his wife through her parents; 7 dry taro patches in Kioea received through his father-in-law, kula land at Waipa which his brother had taken possession of, planted orange trees and cultivated; and two salt ponds. Nahuma appears to have been an affluent native.

LCA 4910 Kahee claimed property in the 'Ili of Kapakalehu; this property in the late 1840s had one orange tree. The konohiki contested the title of this property, claiming that Governess Kekaonohi had given it, and two more, to him and that he had cared for them, harvesting the fruit. Kahee never collected the oranges but contended that the governess had no right to give the trees to the konohiki as they had belonged to Kahee's parents, who had planted them and he was the rightful heir. That was the foundation of his claim.

LCA 5080 Kiko took over waste land, built his own fences and dug his own salt pond in the 'Ili of Kawailoa (Note: the salt pond would be outside the project area, near the coastline). The date of occupancy is not given but it probably was later than Kaumuali‘i, for Kiko's lo‘i came from Kīna'u's time. Kīna'u was a daughter of Kamehameha, mother of the kings Kamehameha IV and V, and was Regent between the death of Ka'ahumanu and the ascendancy of Kamehameha III, her half-brother.

Ching (1974) argues the recovery of waste land mentioned in LCA records was the clearing of previously untouched lands for cultivation. However, Putzi (2014) argues that these were previously cultivated areas left unattended due to a declining native population, but were brought back into production because of the incentive of individual ownership. It may be that ownership, as well as the threat of feral cattle and pigs, led to the construction of fences of either stone or wooden posts to delineate property boundaries. Other claimants shown on the LCA map were identified in the Mahele Database:

LCA 4770 Naahuao. The land came to Naahuao through his father, who was granted the land by Hukiku, the konohiki of Māhā'ulepū during the reign of Governor Kaikioewa. He gives his testimony as follows:

Greetings to the Land Commissioners: Be it known to you, the ones who quiet land titles, that I, Naahuao, a man living at Māhā'ulepū, island of Kauai‘i have a claim for land, and the kula. The genuine land is 56 fathoms long by 26 fathoms wide. The mala of noni is 26 fathoms long by 13 fathoms wide. The salt land is 6 fathoms long by 4 fathoms wide.
Another salt land is 10 fathoms long by 7 fathoms wide. A house lot is 28 fathoms on the long sides and 25 fathoms on the wide side. My message is ended. A respectful farewell to you, Naahuao.

**LCA 6667** Mika received lands from Ahukai (owner of LCA 4543) on the LCA map, but no further information has been gained. Mika received lands from Kaikioewa in the days of Kinau. His testimony reads:

The Land Commissioners, greetings: I, Mika, a Hawaiian subject living in Māhā'ulepū, hereby state my claim for 4 lo'i, 5 sweet potato enclosures, 4 mala of noni, and 3 orange trees. However, these claims are not situated together, but are in various cultivated places of Māhā'ulepū, also 1 mala of uhi/yam/ a kula planting of wauke and one other lo'i. 1 loko/ either fish pond or taro pond/ and 13 lo'i are bounded 80 fathoms on the east, 80 fathoms on the south, 20 fathoms on the west and 10 fathoms on the north. That is my claim which was received from Ahukai. There is also a kula named Hoopouliloa. Respectfully, Mika

The testimony of Mika says much about how Hawaiians utilized the Māhā'ulepū landscape and environs. Parcels were utilized for the cultivation of several food crops, for raising fish, and the growth of wauke for the production of kapa cloth. Except for the orange trees, this is a classic example of traditional Hawaiian life. The mention of sweet potato enclosures is interesting because 'uala were traditionally raised in long rows of intermittent mounds. It may be that these fields were fenced in to protect them from pigs or cattle, or that land ownership required definitive boundaries.

It is worthy to note that all the LCAs in the Māhā'ulepū project area are confined to a central area, on the east side of Māhā'ulepū Stream, with the remainder of the valley claimed as government lands. These LCAs form a tight cluster. Of additional interest is that during the height of the sandalwood trade the adjacent Ha'upu Ridge was claimed by Kaikioewa. It would appear that after his death in 1839 these mountain claims would revert to government control.

The Governor of Kaua'i in 1842 was Kekauonohi, the granddaughter of Kamehameha who had wed Keli’iahonui after having been a wife to her uncle Liholiho Kamehameha II. During her governorship, Kekauonohi partook in land exchanges, consolidating her grants in Māhā'ulepū and Kōloa. These consolidated lands would become the basis for the next cash crop – sugar, which, unlike sandalwood, could be rejuvenated and continued. From the 1830s until the 1980s, sugar would be the economic focus of Māhā'ulepū. Remnants of industrial-level sugar cane cultivation in the area represent the greatest number of historic properties documented during the current AIS.
The sugar cane history of Māhā’ulepū is intricately tied with the history of Kōloa. Sugar cane began to be grown and milled commercially in Māhā’ulepū Valley and around Kōloa in the 1820s, one of the first places in Hawai‘i where sugar was commercially grown (Donohugh 2001). Some of the earliest efforts were undertaken by Chinese immigrants (post 1820s-30s) who had a small mill in Māhā’ulepū, as well as in Kōloa and other parts of the island. The mills were small, producing raw sugar and molasses for local consumption. By 1835, however, many of these farmers were out of business and were later employed by new plantation owners.

In 1835, a sugar cane plantation owned by Ladd and Company was located to the west of the surveyed area. This was the first attempt at producing sugar cane at an industrial scale. The land was leased for a fifty year period from Kaua‘i Governor Kaikioewa and King Kamehameha III. Importantly, the lease was the first of its kind in Hawai‘i and represented the first formal recognition that someone other than a chief could control land use. Koloa Plantation, formally established in 1841, is universally known to be the first commercial sugar plantation in the islands. Ladd and Company was the first owner of the plantation but financial difficulties caused them to sell in 1845. Robert Wood and his brother-in-law bought the plantation and kept the plantation going until 1899 when the Koloa Agricultural Company, the McBryde family, bought the plantation. The Koloa Plantation merged with Grove Farm in 1948 and continued operations through 1996.

The sugar industry grew sporadically between 1845 and 1875. At this latter date, the Hawaiian government scored a coup of its own when a reciprocity treaty with the United States was negotiated. This allowed all unrefined Hawaiian sugar to be admitted into the United States duty free. The cultivation of sugar was going to become profitable (Alexander 1985:74).

Koloa Plantation commenced growing sugar cane in Māhā’ulepū Valley in 1878, having focused more on lands to the west near Kōloa. A total of 875 acres of the flat valley floor was made available. The land was level, sheltered, and had a good underground water supply. However, there was an initial problem with the ground water as some of the valley was saturated and other areas were dry. Accordingly, Koloa Plantation undertook efforts to build infrastructure that would drain waters from the saturated areas, and divert that water to irrigate drier fields (Alexander 1985). Sugar cane requires much water so in 1897, the Koloa Plantation also excavated several wells to irrigate the cane in Māhā’ulepū Valley (see Donohugh 2001).

By 1897, the main source of irrigation water for the valley came from the ground water. At the northwest end of the valley, six wells were drilled and the water was pumped approximately a quarter mile to the north into the recently constructed Māhā’ulepū Reservoir.
The area of the wells was known as “Māhā'ulepū 14”, probably because that was the number of wells eventually drilled and/or in service. The primary source of irrigation water for Māhā'ulepū appears to have been the six wells drilled in 1897. Four more were drilled later and all were located near the western side of the valley. These wells pumped water to Māhā'ulepū Reservoir, where it was stored and released, when needed, to various parts of the valley via the irrigation ditch.

Irrigation ditches at both the north and south ends of the Māhā'ulepū Reservoir served to transport water to the crops and to receive water from existing streams descending from Ha'upu Ridge (Alexander 1985:97-98). A pumping station was built and manned with full-time resident staff who lived with their families in a camp here. The larger north to south, excavated irrigation ditch that extends the length of the valley was excavated but does not appear on the 1935 Koloa Plantation map (Figure 12). Intensification of irrigation efforts, which added to the waters provided by Māhā'ulepū Ditch, began after this date.

The thick clay soils of the Valley were difficult to till using plows pulled by teams of oxen. However, with the introduction of steam powered tractors, more land began to be put into production. Development thus began to escalate at the start of the 20th Century. The number of laborers increased from 430 in December, 1900 to 769 in July, 1901. In February, 1904 it was reported that 600 out of 730 men were “working on permanent improvements.” (Ibid.) Infrastructure modifications in Māhā'ulepū Valley also intensified at the start of the 20th Century, with the excavation of canals, reservoirs, and wells. A narrow gauge railway was also constructed in the valley. The railway extended from Koloa Mill to “Māhā'ulepū 14”, the series of wells on the valley floor at the northwestern end of the valley itself. The railway tracks were movable, but SCS found no evidence of them in the valley during the current AIS. Other portable narrow gauge rail systems were utilized to facilitate the harvest.
Figure 11. Koloa Plantation infrastructure (1912 USGS Territory of Hawai’i Quadrangle portion).
In 1904, $16,420.81 was spent on additions to the plantation railroad system, including “a three-mile addition to the Puuhi railroad and a short cut road to Maha'ulepu” (Ibid.). Considering a laborer in the fields made about $17 per month, this was quite an expenditure at the time (Alexander 1985:122).

While the Plantation owned all the land, they contracted with groups of approximately a dozen men to manage parcels of fifty to one hundred acres. Koloa Plantation “…furnish[ed] land, seed-cane, water, fertilizer, and tools, and perform[ed] such portions of the work as require[d] expensive machinery, such as plowing, furrowing and hauling the cane to the mill” (Ibid. 97-98). The contractors, however, otherwise took care of their parcels from planting to harvest, selling the cane to the Plantation at a set price. This method kept the land under one owner, but provided the contractors incentive to raise a bountiful crop (Ibid. 123).

Early 20th century maps document the extent of the fields throughout the Kōloa and the Māhā'ulepū Valley areas. The fact that Māhā'ulepū Valley was used for extensive sugar cane cultivation is also evidenced by the infrastructure developed within the valley over time. Thus, the available information demonstrates that HDF’s project area consists of lands that were previously used for sugar cultivation.

Grove Farm continued to produce sugar cane in the greater Kōloa area, including Māhā'ulepū, until 1974, when it leased its Kōloa lands and mill to McBryde Sugar Company (Donohugh 2001). Sugar production continued under McBryde until September, 1996 when the mill officially closed.

The Wilcox Family sold Grove Farm to S. Case in 2000. From the early cultivation times until then, the lands extending from Māhā'ulepū Valley to the sea were extensively modified for the cultivation of sugar. Fields were plowed, streambeds cleared, irrigation ditches excavated, reservoirs created, roads built, and wells drilled.

During the remainder of the Kingdom, then the Republic, through the Territorial Period, and into Statehood, sugar cultivation and Māhā'ulepū would be synonymous. More recently, since sugar cane cultivation operations ceased, Māhā'ulepū Valley has been the location of cattle ranching (2002) and taro cultivation (2007), the latter being done through lease to W.T. Hara.
Figure 12. Distribution of Koloa Plantation lands (1935).
PREVIOUS ARCHAEOLOGY

There have been numerous archaeological studies along the coast of Māhā'ulepū, but archaeological studies within Māhā'ulepū Valley and nearby inland environs have been limited. Figure 13 shows the location of relevant studies both within the current project area and close to the project area. The reader is also referred to a National Park Service (NPS; 2008) regional study for a praxis of the projects conducted along the coastline. A sampling of other studies that are further removed from the Māhā'ulepū project area are also briefly described below to provide additional context on a regional scale. Studies performed in areas closer to the ocean include those conducted by Farley (1898), Thrum (1907), Bennett (1931), Kikuchi (1963, 1980, 1981, 1988-d), Ching et al. (1974), Neller (1981, Rosendahl (1988, 1989), Hammatt (1979, 1989a, b, 1990 a, b) Pietrusewsky (1990), Walker and Rosendahl (1991) and Firor and Rosendahl (1994). Four projects were conducted directly with the current project area: Thrum (1907), Kikuchi (1963), Ching et al. (1979), and NPS (2008). The studies described below are listed in chronological order, not by geographic location, and provide both a regional and local context to previous archaeological work in the Māhā'ulepū area.

The earliest study was by F.K. Farley in 1898. During this study, petroglyphs were discovered beneath sand dunes at Keoneloa Beach, to the southeast of the current project area near the Hyatt hotel. According to Farley, local residents knew of the petroglyphs and reported that they had been exposed previously.

The antiquarian T.G. Thrum documented two heiau on Kaua'i named Weliweli and Waiopili (Thrum 1907). The former was not accurately plotted on any map, while the latter was located along the stream of the same name that descends from Māhā'ulepū Valley. Waiopili Heiau was formerly just south of the current project area, near the present-day quarry.

Within the valley itself, but outside of the project area, Thrum identified the possible location of a large heiau named Hanakalauea. This heiau was reported to have been dismantled in the 1860s by a gentleman named Fredenberg and the stones then used to build cattle pens (Thrum 1907). Thrum also reports a fourth heiau, named Keolewa, on the crest of Mount Ha'upu (Thrum 1907; see also Bennett 1931, Site 90). It is not certain if Thrum or Bennett actually visited the site, but both noted that it was a small heiau dedicated to a goddess named Laka (Thrum 1907; Bennett 1931). A cursory field inspection of the summit by SCS archaeologists in December 2015 did not note any definitive structural remnants of this heiau.

During an archaeological survey conducted in 1928-1929, Bennett (1931) located or re-located the heiau at Weliweli and Waiopili. The Keoneloa Beach petroglyphs were not exposed
during this visit but he collected information about them from local residents. Bennett also recorded human burials within the sand dunes at Makahuene Point.

According to Bennett (1931:46), at Waiopili Heiau, “a tower of stone stands in one corner. It is solid enough to climb upon and an excellent view is afforded from the top. It is a unique feature for Kaua'i heiau, and if modern, defies conjecture as to the reason of its construction.” According to Ching (1974), “Waiopili Heiau is a rectangular walled enclosure, which lies on a smooth pahoehoe lava bed. The limestone cliff which forms a natural boundary between Māhā'ulepū and Pa'a lies almost directly to the south of this temple.” Chang (1974) further states that Kapuneka Pond is nearby and that the walls were large, 2.5 m wide and 2.0 m high, constructed of pahoehoe slabs. The heiau was still mostly visible in 1974. By 2006, only a very small portion of the southern wall of the heiau was visible, near a spring pump house. The heiau has been mostly destroyed by quarrying activities, as well as by the quarry road which runs along the southern boundary of the former structure.

Kikuchi (1963) conducted an archaeological investigation of coastal Kōloa. In addition to identifying new sites near the coast, he re-located several sites described by Farley, Thrum, and Bennett: Site 96 (Kane'aukai Heiau); Site 97 (dune burials); Site 98 (Keoneloa Beach Petroglyph Field); Site 99 (Weliweli Heiau); Site 100 (Keoneloa Beach Walls); Site 101 (Makaweki Point petroglyphs); and Site 102 (a structure).

Kikuchi also documented the only previously identified site within the surveyed area, Site -3094. This site is composed of a large boulder sitting in a pasture at the northern end of the valley. Kikuchi (1963) notes this boulder as occurring some 2 miles inland. Some twenty anthropomorphic figures, two pecked cups (4 inches deep), and a long groove are etched on the surface (Ching et al. 1974; McMahon 2007; see also Cox and Stasack 1970). The groove may represent a stream, but interpretation is uncertain. As discussed below, this site was fully recorded and mapped during the current project. In addition to the one boulder previously identified by Kikuchi (1963), two additional petroglyph rocks associated with this site were also documented during the current AIS (see Results section below). Thus, Site -3094 now consists of three features.
Figure 13. Previous archaeological studies in the Māhāʻulepū area.
During surface survey of 1,100 acres along the coastal lands of Weliweli, Paa, and Māhā'ulepū Ahupua'a, Ching et al. (1974) wrote of Weliweli Heiau: “no actual alignments or other features were noted at the reported location of this temple. This site has either been completely destroyed or is located elsewhere” (Ching et al. 1974:81). During the Ching study, the archaeologists found and sketched the petroglyphs at Keoneloa (Site 84), found sand dune burials (Sites 3096, 3097 and 3024) and re-located Waiopili Heiau (Site 87). They also located Waiopili Pond and Kapunakea Spring, but these were not given site designations (Firor and Rosendahl 1994).

Kikuchi (1984) continued archaeological investigations along the coastline of Keoneloa Beach. Kikuchi documented numerous sites and at least one, but possibly two, cultural layers that extended along the length of Keoneloa Bay (Kikuchi 1998a). This was the beginning of an era of extensive archaeological excavations and monitored construction excavations in this area. Work by Neller (1981), Rosendahl (1988, 1989), Hammatt (1979, 1989a, b, 1990 a, b) Pietrusewsky (1990), Walker and Rosendahl (1991) and Firor and Rosendahl (1994) followed.

McMahon (1996) conducted an archaeological field inspection of an area approximately 25,000 square feet in size on the southeast flank of Ha'upu ridge for the proposed installation of a radio tower. The project area for that study was located at 1,500 ft. asl. No sites were identified, nor were any trails observed along the ridgeline; the area was, as McMahon notes (1996), only accessible by helicopter.

Following this study by McMahon (1996), a letter was submitted by the Office of Hawaiian Affairs (OHA) in March 1998 to the Federal Communications Commission opposing the construction of a radio tower on Mount Ha'upu. The letter stated that the mountain is of special significance to Native Hawaiians as a wahi kapu (sacred place): “Ha'upu is our kin, descendent of Papa [Earth mother] and Wakea [Sky father], and older sibling of the Hawaiian people. This is the main reason why we, as Hawaiians, hold Ha'upu sacred in our hearts”. According to the OHA (1998) document, Ha'upu was named after a demi-god/warrior who took a large boulder from Kaua'i and threw it across the Ka'ie'ie Waho Channel, where it killed an enemy chief on O'ahu. The small heiau atop Mount Ha'upu is dedicated to the goddess of hula (Laka). Both the heiau and the wooded areas at Ha'upu Summit are known as keolewa, a word common in Hawaiian oral traditions. In addition, Ku and Hina, the first Hawaiian god and goddess, live on Ha'upu Ridge. Mount Ha'upu was also an important navigational landmark for traditional Native Hawaiian fishermen, and Hawaiians today still view the mountain with reverence (OHA 1998).
Beginning in the 1990s, Burney and Kikuchi began excavating the Makauwahi Cave and Sinkhole. They stated that within the cave “in a single stratigraphic sequence and encapsulated view of the full span of human occupation, including the millennia preceding human arrival, earliest human evidence, subsequent population increased and cultural change, European contact, and modern transformation” (Burney and Kikuchi 2006). Amongst the many discoveries from this study are bones of a Polynesian rat, which dated to 1039-1241 A.D. Because the rats were in the canoes with Polynesian voyagers, this is some of the earliest evidence for human occupation of this area. Excavations also exposed intact cultural layers, as well as culturally sterile deposits. Artifacts such as files, picks, scrapers, adzes, fish hooks, octopus lures, game stones, sling stones, and hammer stones were recovered. The preservative qualities of the deposits in the sinkhole were excellent. Fiber cordage, wooden fragments from canoes, paddles, and tool handles were also recovered. These materials came from three excavations. There is much potential for more information to be gained from this site (Burney and Kikuchi 2006).

Archaeological surveys and field work were conducted farther to the southwest along Waikomo Stream by Cultural Surveys, Hawai'i, Inc. (Hammatt, et. al. 2004). The terrain this stream flows through is different from the terrain that the stream which flow out of Māhā’ulepū Valley travels through. Features originating during the pre-Contact era include agricultural terraces, habitation terraces and platforms, and irrigation auwai along both crests and bases of long, low ridges were observed (Hammatt, et. al. 2004). This complex of sites is designated the Kōloa Field System.

The most recent comprehensive effort at documenting the biology, botany, geology, ecology, and archaeology of the region is that compiled by the National Park Service (NPS; 2008). “The Māhā’ulepū, Island of Kaua‘i Reconnaissance Survey” published in 2008 consists of an effort by the NPS to re-identify multiple natural and cultural features in the Māhā’ulepū Valley and environs. The goal was to argue for the importance of conducting a more thorough natural and cultural study of the area along the southeast coast of Kaua‘i from Kōloa to Poipū, and northward along Māhā’ulepū, Kipu Kai, Niumalu, and Nawilili Harbor. Included in the study is Mount Ha‘upu and the ridgelines extending from it (NPS 2008). The study presents a summary of the natural and cultural features for the area and effectively argues for additional research.

SETTLEMENT PATTERN AND SITE EXPECTATIONS

Prior to European contact, the rulers of the Hawaiian islands divided the landscape into political entities known as ahupua‘a. These landholdings varied in size but shared a few common traits. Their boundaries extended from the mountains to the sea shore, with fishing rights extending to pelagic waters. Where possible, the boundaries incorporated natural features such as
ridgelines and streams. Each ahupua'a was ruled by single ali'i, or noble, and the holdings were managed by konohiki, persons of slightly lesser status. The pre-Contact population was composed of farmers, fishermen, craftsmen, priests, rulers, and soldiers. Given the size and natural diversity of Māhā'ulepū Ahupua'a, there was probably a large population scattered throughout.

A PREDICTIVE MODEL OF TRADITIONAL SITE DISTRIBUTION.

Dega and Powell (2003) developed a landscape model of variation in physiographic and environmental zones in eastern Kaua'i as a way of predicting the general location of traditional sites and features, including buried sites. This model is being applied across Kaua'i. [Note, Hammatt et al. have used a slightly different variation of this zone model idea in numerous reports (e.g., Masterson et al. 1994)]. This section describes the zone model, as defined by Dega and Powell, and modifies it slightly to more explicitly include the potential impact of historic activities on traditional sites (e.g. road cuts, utility excavations, irrigation ditches and pipelines, sugar cane cultivation), but also the preservation and protection of surface and/or buried traditional sites. These historic impacts are discussed in relatively broad terms here. Specific archaeological and historic data directly relevant to the project area are presented in the following section.

Particularly for traditional Hawaiians in pre-Contact times, resources and opportunities to exploit them were distributed unevenly across the landscape, and the archaeological record should reflect this. The model divides landforms into five general zones, and Dega and Powell (2003) integrate broad patterns in the known distribution of archaeological finds within these zones. This allows for more specific – and scientifically testable – predictions than simply the probability of finding sites in a given location. The model predicts, for example, not only that the coast and near-coast were more intensely inhabited than the foothills and plateaus, but also that the types of sites created in these zones would be different. The zone model is therefore based on empirical data documenting variation in the physical as well as the cultural landscape of Kaua'i. As stated, historic impacts on traditional sites should be considered, and some fairly general observations can be used to predict at least some of these. Here, only general references and broad trends in the archaeological record of Kaua'i are relevant.

SITE TYPE PREDICTIONS AND FREQUENCY BY ZONE

The model divides the landscape into five broad zones: Coast (I), Back Beach (II), Marsh (III), Hills/Plateau (IV), and Mountains and Steep Slopes (V). According to the model, the first three zones (coast to marsh) have been more or less continually utilized, in some way, from very
early times into the present. Especially in traditional times, Zone II has been most important for habitation for two main reasons: (1) it straddles two highly productive and accessible eco-zones (i.e., marine-coastal and pond-estuary), meaning that its inhabitants could easily exploit both areas; and (2) in geomorphological terms, Zone II is a relatively stable landform not prone to flooding from either the sea (as with Zone I) or the uplands (as with Zone III). Note that the model does not take into account population pressure or chiefly edicts that might cause people to settle in marginal areas or cause people to pursue less than optimal adaptive strategies.

Māhā'ulepū Ahupua'a contains all five zones, with the survey area primarily occurring in Zone IV to the base of Zone V.

**Zone I (Coast)**

Zone I consists of beach sands and adjacent coastal dunes, which include frontal accretion deposits, backslopes, the crest, and the slip face. Zone I includes the area from the high-tide water mark of the ocean to the lower portion of the slip face near the interdune area, or, where the backside of the dune becomes flat and expansive. Zone I sediments are primarily composed of beach sands. These sands are subject to variable sorting when energy depositional events such as storm surges or tsunamis lead to the deposition of coarser sand grains while low energy events can lead to well-sorted, often fine-grained, sedimentary deposition. This is a dynamic zone in terms of landscaped morphology as it constantly evolves through wind and tides, particularly if vegetation or modern impediments do not curtail dune migration.

Archaeological work in Zone I commonly yields habitation sites and features, but there are rarely the remains of permanent settlements. The potential difficulties of living permanently in Zone I include dangerous flooding, high winds, and shifting sand. Landscape features can be quickly buried and/or exposed in Zone I, where more temporary sites, such as fishing camps were located. Archaeological evidence of activity area, such as tool and gear workshops and maintenance sites, are also common in Zone I, but these tend to be relatively ephemeral because they are usually the result of short duration visits. Traditional Native Hawaiian burials are another important site type in Zone I sediments. Burials in this zone would be located at or above the typical high tide mark, i.e. near the transition to Zone II, rather than towards the seashore itself. Note: With the recent increase in beach erosion, burials have been found in more frequency in these tidal zones.

Historic impacts in Zone I include the construction of sea walls, jetties, and retaining walls. Sea walls and retaining walls, in particular, have the effect of stabilizing and sometimes burying Zone I sediments, potentially locking in subsurface deposits. Much of the Māhā'ulepū coast has been modified in this manner, especially at Poipu and Kōloa.
Zone II (Back Beach)

Zone II occurs inland from Zone I, and represents a more stable land surface. This zone comprises the coastal plain or back beach environment. Like Zone I, Zone II primarily consists of calcareous sand beaches derived from the decomposition of coral and seashells. These deposits and associated coralline basements occur far inland in some areas, reflecting the Holocene high sea stand occurring between c. 5,500 years ago and lasting until about 2,000 years ago (Fletcher and Jones 1996). Zone II represents an area that almost never floods, except in the rarest of conditions (e.g., a 100 year event). Along the Māhā'ulepū coast there are windblown modern dunes, and a fossil-rich lithified dune system in Zone II (NPS 2008).

Archaeological work in Zone II commonly yields permanent habitation sites and burials from traditional Native Hawaiian occupation. In fact, all manner of sites, and features associated with settled, near-coastal communities were located in Zone II, and large population centers were common.

Because Zone II landforms are stable, accessible, near-coastal settings, usually over relatively level terrain, historic impacts have been severe. These impacts include road building, residential and commercial construction, excavation for utility trenches, and mining of the sand for construction purposes.

Zone III (Marsh)

Zone III consists of wet marshland, or slightly depressed pond areas, inland of Zones I and II. Zone III is amenable to soil catchment (i.e. sedimentary deposition), and is located at or very near seal level, yet retains more terrigenous characteristics. This marshland does contain some sandy sediment, but alluvial silty clays and clays from the uplands dominate soil matrices. Zone III would have a unique eco-zone for hunting marsh birds for food and feathers, and the collecting of their eggs.

In traditional times, Zone III provided a near-coastal alternative for agricultural production normally only afforded at locations farther inland. Archaeological work in Zone III commonly yields evidence of traditional walls, ditches and terraces of the lo'i (irrigated) field systems. Fishponds were sometimes located in this zone. Residents on either side of Zone III could utilize this area for agriculture, aquaculture, and wildlife harvest.

South of the project area, Māhā'ulepū Ditch, formerly a natural stream, joins with a natural spring and the remnants of Kapunakea Pond, and regains a more natural appearance. It continues to the coast, re-named Waiopili Stream (NPS 2008). It flows near Waiopili Heiau, and a unique site in Hawaiian archaeology, Makauwahi Cave. Makauwahi Cave is a limestone sinkhole with interior caves containing a complex stratigraphy with the different layers.
containing evidence of traditional Hawaiian occupation and the natural deposits accumulated prior to the arrival of the first voyagers.

**Zone IV (Hills and Plateau)**

Zone IV is characterized by hills, valleys, and grassy plateaus that lead into more mountainous terrain. Subsurface deposits are dominated by silty clays and clays derived from the decomposition of underlying basalt, as well as the deposition of alluvial and colluvial clays, particularly in valley areas. In many places, the soils are also rich in iron and other nutrients amenable to the cultivation of traditional food crops and, historically for the industrial production of Kaua‘i’s most lucrative commercial crop, sugar cane. Archaeological evidence has documented a number of site types in Zone IV:

1. Trails connecting lowland and upland sites and resource areas, varying in construction and size;
2. Agricultural plots, with terraces and retaining walls, for garden and/or medicinal plants, and terraces for dry land agriculture such as ‘uala (sweet potato) could be present within this zone;
3. Arboriculture would have flourished in this zone. Thus, evidence of the cultivation and maintenance of ulu (breadfruit) and other tree resources could be found here.
4. Permanent and temporary habitation sites; and
5. Heiau.

The project area for this AIS is located in Māhā‘ulepū Valley, on relatively level ground previously utilized for sugar cane cultivation. The intensive transformation of the landscape through clearing, plowing, and harvesting has resulted in the removal and/or destruction of archaeological sites and related features. However, at the base of slope in the extended survey area (outside the project area) there is what appears to be an agricultural heiau. This site is within Zone IV but near the transition to Zone V.

**Zone V (Mountains and Steep Slopes)**

Zone V consists of the steep slopes of mountains and those of major drainages such as gullies and ravines. Lands classified as Zone V are typically rugged, remote areas of the terrain where human occupation and utilization are temporary and/or episodic. Soils and sediments in Zone V drive from the decomposition of the underlying bedrock. Because of the prevalence of steeps slopes in this zone, soils and sediments are relatively thin and subject to downslope movement. Cultural features such as retaining walls, terraces and trails are usually found in association with rock outcrops and caves. Erosion is the greatest threat to whatever cultural deposits might be found on these slopes. During informal survey of this zone by the SCS crew, several sets of agricultural terraces were located on the eastern slopes of the valley, far outside
the project area and extended survey area, the terrace sets were in poor condition due to natural erosion and located adjacent to several small drainages.

Traditionally, Hawaiians did construct *heiau* at elevations, but in some instances a natural place could be considered sacred without an actual structure (*i.e.*, Ha'upu Ridge). Stone was quarried traditionally for tools of high grade basalt and the forests were harvested for building materials. Increasingly through the first four decades of the 19th Century, sandalwood was collected until near extinction, which increased the risk of erosion in the mountains. Later in the 19th Century and into the 20th Century, irrigation infrastructure for the sugar cane industry was carved into the mountains and slopes as well.

**SITE DISTRIBUTION AND CHRONOLOGY**

Site distribution across these five zones is often determined by historic land use, when landowners and others utilized the same lands as were previously cultivated and occupied during pre-Contact times. Sometimes these earlier signatures are erased, depending upon the intensity of historic land alterations; sometimes, however, they are not, as evidenced by the many inland, pre-Contact sites occurring across southern Kaua‘i. Pre-Contact sites are identified in coastal or near coastal areas, locations removed from intensive sugar cane production, but also in large valleys and uplands that were not disturbed through time. *Heiau*, as seen via this report, and fishponds, among other pre-Contact site classes, are also preserved inland. This pattern occurs beyond the south shore as well, where pre-Contact sites are preserved inland, such as in Waimea Canyon and Makaweli, for example. Typically, however, the earliest dates for initial settlement of an area, for this part of Kaua‘i, occur at the coastline.

Dates from the coastline fall in the A.D. 1000-1200 range for this part of Kaua‘i, with expansion inland proposed to have been during the A.D. 1400-1600s, as was a pattern across the islands (see Kirch 1985). Agricultural field systems were created within inland areas, closer to fresh water resources and soil more amenable to *kalo* and sweet potato production. Permanent habitation locales were present from the coast to more inland areas, with ceremonial sites, walls, and other associated structures being built near the coast and far upland. Within the mountainous areas, such as at the back of Māhā‘ulepū Valley, temporary habitation loci would have been utilized by those gathering upland resources. The middle zone, such as Māhā‘ulepū Valley, was ideal for agriculture and homesteads, as witnessed by the numerous LCA’s occurring in a small section of the valley. However, it appears that historic land use would have erased many of the archaeological signatures for such settlements/land use. This is evidenced by the presence of a ceremonial site (Site -3094; see below) in the extended survey area. What is more apparent now
in the archaeological record of Māhā'ulepū is infrastructure associated with that intensive sugar cane production from the plantation period.

**METHODOLOGY**

Several phases of fieldwork were undertaken as part of this AIS. Prior to fieldwork, a review of the archival record and previous archaeological work in the surveyed area and environs was completed. This archival work was integral in determining the types and nature of sites that could be encountered, as well as to aid in determining trenching locations. A search of Kaua'i Historical Society photograph collections by M. Ching did not yield any photos significant for the surveyed area or this study.

**FIELD METHODS**

Fieldwork was conducted between July 7 through 25, 2014 and August 20 through 26, 2014 by Jeff Putzi, B.A., James Powell, B.A., Milton Ching, B.A., and Michael Dega, Ph.D (Principal Investigator). Fieldwork consisted of a systematic 100% pedestrian survey of the entire project area and extended survey area, representative mechanical trenching on the valley floor, and manual excavation units placed at one site, the enclosure (Site -2250). For purposes of the pedestrian survey, the crew was spaced a variable 5 m-10 m, depending upon ground visibility. Visibility was very good across the valley floor and good around the perimeter of the floor. When sites were identified, they were mapped to scale using tape and compass (except for the longer ditches), digitally photographed, and GPS recorded. The longer ditches were recorded using GPS (both terminal ends) and appear on most maps/aerial photographs for the area. Sites were recorded in detail to reflect their overall integrity, size, and location in the surveyed area.

As noted above, given the historic land use in the project area and associated likelihood of the destruction of historic properties through that land use, the SHPD-Kaua'i requested that the scope of the AIS be extended beyond the project area to include the extended surveyed area at the back of the valley to the north, east, and west flanks. Because the extended survey area is outside of the footprint of historic sugar cultivation, surveying this area could provide information and context no longer available in the project area. The land in the extended survey area is owned by Mahaulepu Farm LLC but not within the property leased to HDF for the project. Thus, HDF and SCS needed to obtain permission from the landowner to enter and survey the extended survey area, which ultimately increased the surveyed area by some 1,300 square meters beyond the original survey area.

In addition, a total of seventeen stratigraphic trenches were mechanically excavated by backhoe across portions of the valley floor. Trenches were mostly focused on the cluster of
LCAs in the central/eastern portion of the project area and, through the area of the proposed effluent ponds, where excavation for the project is proposed. All trenches were examined, profiled, and photographed. Manual testing of nine units was completed at Site -2250, the enclosure in the extended survey area. This additional testing was also approved by the SHPD-Kaua‘i to further understand the function of the site. The number of units was increased to a total of nine units as no cultural materials were identified in the first several test units. All sediment from the units was screened through 1/4” and 1/8” wire mesh screens, to recover any smaller cultural material fractions. All units were plotted on a site planview map, profiled, and back-filled. No units were left open at the end of each day.

In addition, an SCS crew field visit was completed on June 19, 2015 to the location where the word “Path” was marked on Registered Survey Map #1898. The additional survey was recommended to assess the presence/absence of a “path” or trail in the area. As discussed further below, this field visit re-confirmed that there is no evidence of a path/trail present in the noted map location or in the vicinity. The “path” survey point marked the location of a ditch on the eastern flank of the valley.

LABORATORY METHODS

As only one artifact was recovered during surface survey, trenching, and testing, laboratory methods were primarily limited to drafting field site plan view maps, stratigraphic trench profiles, profiles of the test units, cataloguing all photographs and maps acquired during the AIS, and reporting. The single artifact, from a test unit outside Site -2250, the enclosure in the extended survey area, was analyzed and catalogued. This artifact was returned to the site during a February 3, 2015 field visit with the SHPD and others. All field notes, maps, and photographs pertaining to the AIS are currently being curated at the SCS main laboratory in Honolulu.

CONSULTATION

Preliminary consultation, as described further below, was undertaken in connection with the current AIS by the archaeological field crew. A more formal consultation, via a Cultural Impact Assessment, has also been undertaken to provide much more in-depth information and through personal interviews related to the project area. For the AIS, the following individuals and groups were consulted:

State Historic Preservation Division-Kaua‘i Lead Archaeologist

The Lead Archaeologist for Kaua‘i was consulted prior to the commencement of fieldwork, during fieldwork, and post-fieldwork. Following one of two field visits to the project area, the
Lead Kaua‘i archaeologist recommended that survey be conducted not only of the immediate project area in the valley, but also up to the ridgeline. The presence of Keolewa Heiau, on Ha'upu Ridge, and a former heiau, Hanakalaua Heiau, within the valley, suggest the possibility that pre-Contact/historic era trails may have at one time connected the project area to the upper ridgeline. However, as discussed below, SCS did not observe any evidence of trails.

The presence of the enclosure, interpreted to be an agricultural heiau in the extended survey area (Site -2250, see below) and small terracing, the latter occurring well beyond the extended survey area, also suggested that additional pre-Contact sites could possibly be present further upslope from the project area proper. However, the fact that additional sites may be located upslope does not mean the proposed project will have any impacts on such properties. As discussed above, given the scope of the project and the manner in which it will be managed and contained, impacts outside of the leased property are not anticipated; thus, the project area for purposes of this AIS is the area leased by HDF. Nonetheless, in an abundance of caution, and to maximize the possibility of finding information relevant to the project area, HDF agreed to include the extended 100 m survey area within this study.

Kaua‘i Historical Society

Research was undertaken here prior to fieldwork, during fieldwork, and following the completion of fieldwork. M. Ching and J. Powell, part of the field crew, researched old photographs and maps of the Māhā‘ulepū area (none were found), as well as text references (i.e., Bennett 1931) to further understand the sites they had documented during prior fieldwork.

Individuals

SCS (M. Ching) conducted interviews with several local residents who lived and worked for decades in the Kōloa-Māhā‘ulepū area. M. Ching talked primarily with 84-year-old Nelson Abreu and his nephew Russell Abreu. Discussions centered on land use through time and their knowledge of any historic or cultural properties in the Māhā‘ulepū area. Their insights regarding Plantation Era land use in the area, as well as the families who lived there, were invaluable.

SCS also interviewed James Case, now 95 years of age, who was born on Grove Farm and grew up in the Kōloa area. His thoughts on trails in the area and in general, life from the 1920s onwards, are presented below in short form. Mr. Case offered a tremendous historical recollection of these times, from Kōloa through Māhā‘ulepū and beyond to Nawiliwili and Līhu‘e, among other locations.

SCS is currently conducting a Cultural Impact Assessment (CIA) for the project, with many of the individuals noted herein getting additional time to discuss their knowledge of the area with SCS. This CIA will be completed in the near future.
February 3, 2015 Field Visit

On February 3, 2015, SCS, a representative from the SHPD-Kaua'i archaeology branch, land representatives, and community members met at the project area to conduct a field trip of the sites documented during this study and to obtain any insight these individuals may have on said sites. The secondary purpose was to get more overall feedback on the AIS, should they have any questions or comments. The following individuals from the community were present on the fieldtrip: Terrie Hayes and Billy Kaohelaulii, Mary Jane Naone (SHPD), Teddy Blake, , Kalani Kumai, Bridget Hammerquist, Rupert Rowe, and Jim Garmatz (manager for HDF). SCS was represented by J. Powell and M. Dega. During the visit, the group first stopped at the petroglyph rocks and second, at the heiau (Site -2250) in the extended survey area. In both locations, Kalani Kumai (aka Branch Harmony) conducted ceremonies to consecrate the sites. He also spiritually “closed” the heiau. The one artifact recovered during the AIS project, a lithic chopping tool (see below), was placed back in its original location, as witnessed by the group. Overall, the group visit was well received and the ceremonies accomplished goals set by many for being there. Both the petroglyph rocks and heiau were discussed in terms of the AIS, with these interpretations noted below.

Office of Hawaiian Affairs (OHA)

A copy of the original Archaeological Inventory Survey report was submitted to OHA on May 16, 2015 for comments. As of this writing, SCS has not received any formal comments from OHA. We will submit this revised report to OHA concurrent with submittal to the SHPD.
A total of sixteen (16) sites were identified during the AIS (Figure 14 and Figure 15). These sites were all identified through pedestrian survey of the project area and extended survey area. Fifteen (15) of the sites were newly identified during the current survey and one (1) site, State Site 50-30-10-3094, was previously identified and re-located. Of the sixteen identified sites, six (6) sites occur in the project area and ten (10) sites occur in the extended survey area (Table 1). Only one of these newly identified sites is believed to be associated with pre-Contact and/or early historic times, the Site -2250 enclosure. The remaining sites consist of historic-era bridges, ditches, culverts, retaining walls, and a flume system dating from the 20th century and affiliated with sugar cane cultivation. That a majority of the documented sites are related to the historic-era is not surprising, given the extensive landscape modifications that occurred during intensive sugar cane cultivation on the valley floor. Even historic era cultural materials associated with the many LCAs in the project area were non-existent, as explored through survey and subsurface exploration.

In addition to survey, a total of seventeen (17) trenches were mechanically excavated in various portions of the project area, with no cultural findings. Trenching was concentrated in areas where excavation will be required for the proposed project and second, in the area where many LCAs are clustered in the valley. In addition to this trenching, multiple manual test units were placed in Site -2250, the pre-Contact enclosure, which aided in refining functional interpretations.

Note that Sites -2251, -2252, -2253, and -2259 all appear to conform to the same ditch (Figure 15), with the Site -2258 reservoir also being present near the ditch line. The ditch, as constructed following the creation of the reservoir, may have followed the course of historic or pre-Contact auwai, but no evidence of such water ways along or perpendicular to the ditch were found during the survey. Sluice gates emptying into the valley were found, but there were no associated ditches, suggesting the gates may have been placed there to deal with overflow or flooding, and not necessarily for the irrigation of a specific field. The flume with trestle bridge over the irrigation ditch appears to have been constructed after the ditch/reservoir system was built. The flume and trestle appears to have been constructed to continue the flow of water from streambeds off the ridgeline, into the natural water courses in the valley itself.

The following presents the sites in numerical order, as site numbers were presented to and provided by the SHPD. Please note Table 1 above which depicts the sites occurring inside the project area (N=6) and those occurring outside the project area (N=10).

STATE SITE NO. 50-30-10-2250 (TS-1)

Site -2250 consists of a rock enclosure occurring at the back of the valley within the extended survey area (Figure 16). The site lies c. 30 m off the valley floor. The enclosure is rectangular and measures 20 meters north-south by 9 meters east-west (180 m sq.; Figure 17 through Figure 20). The corners of the enclosure all occur at cardinal directions. The northeast wall is constructed of an alignment of small basalt boulders, at least 0.5 m in diameter, all of them fairly uniform in size. Two taller, but not wider, boulders are upright in this alignment. There is an opening at the west side of the northern end, which appears to form a formal entrance/exit for the enclosure.

The southeast wall of the site is constructed of basalt cobbles and boulders stacked and piled two to three courses wide and two courses high (0.30 m above surface, average). The cobbles and boulders range in size from 0.2 m in diameter to 1.0 m in diameter. Some portions of this wall appear to have collapsed but on the whole, the enclosure wall is in good condition. At the south end of the site are two upright boulders approximately 0.60 m in diameter and up to 1.4 m high. These are adjacent to a very large boulder that forms the south corner of the enclosure.

One large boulder at the southern corner is pyramidal in shape. It measures 4.0 m by 3.0 m by 1.4 m tall. Test Unit 4 was placed against this boulder (see below) as it would have acted as a “catchment” for any eroding cultural materials from the slightly uphill, northern end of the site. Extending westward are several other large boulders. Overall, a few small boulders are piled but the majority of the enclosure wall along the southern flank is formed by these roughly aligned boulders.

The long western wall is constructed in much the same manner as the long east wall. However, the former extends northwest before turning northeast to the presumed entry/exit to the enclosure. An upright boulder is present south of the corner, with two more upright boulders occurring to the north of the corner.

The area within the enclosure is mostly level but with a slight southward descent. The ground to the north is slightly higher in elevation. The site area is lightly forested with java plum, eucalyptus, and haole koa, but there is a dense grove of hau 25.0 meters to the southeast of the enclosure. There are no interior features within the site.
Figure 16. Location of Site -2250 (outside project area).

Figure 18. Site -2250. View to south.
Figure 19. Site -2250. View to west.
Figure 20. Site -2250. Note uprights in construction. View to west.
No cultural materials of any era were identified within the enclosure, its walls, or outside the enclosure. Given the size and shape of the site, its proximity to Māhā'ulepū Stream, its placement at the head of the valley, and the southern commanding view over the valley itself, the site was initially interpreted as either a large hale or an agricultural heiau. The site did not appear to be a traditional residence as these were most often multi-structural affairs spread over the landscape. None were found nearby. The site was also defined with each wall built in a different, distinct manner, with many upright boulders being incorporated into wall construction. Testing was needed to confirm or modify initial interpretations of the site.

**Testing**

A total of eight test units (TU) were excavated within the Site -2250 enclosure, with a ninth unit excavated 20 m to the northwest. Testing was completed in two phases, with 4 units being completed at the start of the survey and 5 units toward the end of the study. SCS consulted with the SHPD on all the excavation work, discussing the lack of cultural data recovered from the first few units, and agreeing to add several more units to Site -2250 in an effort to obtain more information about the feature, as its function was still in question.

Shovel Test Units 1 and 2 were excavated during the initial field work in July, 2014 with the remainder excavated during the additional efforts in August, 2014. The large number of test units was necessary given initial site interpretations (significant site) and second, the lack of findings in the first few test units. Testing aided in refining the site function determination.

TU-1 measured 0.5 m by 0.5 m and was excavated to a depth of 0.38 m below ground surface (Figure 21). The unit was placed along the interior of the west wall, south of the corner where the wall turns from the northwest to the northeast. This corner is defined by two upright boulders north of the corner and one upright boulder south of the corner. The unit was placed along the base of the upright boulder south of the corner. Two strata were present in TU-1: Layer I (0-0.30 mbs) was composed of dark brown (10YR3/4) silty clay. Layer II (0.30-0.38 mbs) consisted of a layer of gravel and cobbles, with silty clay between them. Excavation ceased after exposing the surface of a deposit of small sub-angular basalt cobbles and gravels. The goal was to keep it intact to assess the presence/absence of other possible pavements at the same depth in the enclosure. Layer II represented a paving and/or a foundation for the upright and the west wall. No cultural materials were observed in the unit.

TU-2 measured 0.5 m by 0.5 m and was excavated to a depth of 0.3 m below the ground surface (Figure 22). This unit was placed midway along the length of the interior, north wall. The north wall is an alignment of small boulders with one cobble extending south into the interior of the enclosure. The TU was placed with the boulders of the wall to the north and the cobble to the
east. Excavation extended to a depth below the boulders to determine the presence of any cultural materials, particularly charcoal to date site construction. One stratum was present in TU-2: Layer I (0-0.3 mbs) was composed of dark brown (10YR3/4) silty clay. Roots and rootlets were common from surface to the base of excavation. No cultural materials were observed. The unit was sterile.

TU-3 measured 0.7 m by 0.7 m and was excavated to a depth of 0.2 m below the ground surface. This unit was placed at the approximate center of the enclosure. One stratum was present in TU-3: Layer I (0-0.2 mbs) was composed of dark brown (10YR 3/4) silty clay. No evidence of paving or cultural materials were identified in the unit.

TU-4 measured 1.0 m by 1.0 m and was excavated to a depth of 0.34 m below the ground surface. This unit was placed along the interior base of the large, pyramidal-shaped rock that forms the south corner of the enclosure (Figure 23). It was theorized that placement of the unit here would act as a “backstop” and could have been a location where midden/artifacts could have been culturally or naturally deposited. Large in situ boulders rendered the unit smaller so that by the base of excavation there was little soil to excavate. One stratum was present in TU-4: Layer I (0-0.32 mbs) was composed of dark brown (10YR 3/4) silty clay. Roots and rootlets were common from surface to the base of excavation. Clastics were not common but increased in frequency with depth. They represent natural deposits and were not representative of a paving or cultural formation. No cultural materials were observed in the unit.

TU-5 measured 0.7 m by 0.7 m and was excavated to a depth of 0.59 m below the ground surface (Figure 24 and Figure 25). This unit was placed along the interior of the north wall, approximately 0.7 m to the west of TU-2. Three strata were present in the unit. Layer I (0-0.07 m) consisted of dark reddish brown (2.5YR 3/3) silty clay. Layer II (0.07-0.29 m) was composed of reddish grey (5YR 5/2) silty clay with many cobbles and gravels. This layer was interpreted as a possible paving and/or a foundation for the north wall. Continuing below the cobbles and gravels was natural sediment, Layer III (0.29-0.59 m) composed of reddish brown (5YR 5/4) silty clay. Unlike the nearby TU-2, no roots were present. No cultural materials were observed in the unit.
Figure 21. Site 2250, TU-1 profile. West face.
Figure 22. Site -2250, TU-2 profile. North face. TU-6 measured 0.7 m by 0.7 m and was excavated to a depth of 0.2 m below the ground surface. This unit was placed adjacent to TU-3 at the center of the enclosure. The surface of the boulder found in TU-3 was entirely exposed. The rock's diameter measured 0.7 m and was interpreted as an isolated, natural stone. One stratum was present in TU-6: Layer I (0-0.2 mbs) was composed of dark brown (10YR 3/4) silty clay. No evidence of paving cobbles and no cultural materials were observed in the unit.

TU-7 measured 0.5 m by 0.6 m and was excavated to a depth of 0.2 m below the ground surface. This unit was placed within the interior of the enclosure approximately 5.0 m south of the passageway at the northern corner. TU-7 was placed 6.0 m north of TU-3 and 3.0 m south of TU-5. One stratum was present in TU-7: Layer I (0-0.2 mbs) was composed of dark brown (10YR 3/4) silty clay. Roots and rootlets were common from surface to the base of excavation. No evidence of paving cobbles and no cultural materials were observed. The unit was sterile.

TU-8 measured 0.4 m by 0.4 m and was excavated to a depth of 0.3 m below the ground surface. This unit was placed to the north of TU-7. Excavation exposed the surface of a deposit of small, sub-angular basalt cobbles and gravels. These were originally thought to represent a paving such as was exposed in TU-2 and TU-5. However, TU-8 is not adjacent to any wall and the stones appear to represent a natural deposition. One stratum was present in TU-8: Layer I (0-0.3 mbs) was a dark brown (10YR 3/4) silty clay. No roots were present here, as compared to the nearby TU-7. No cultural materials were observed in the unit.

TU-9 measured 0.70 m by 0.70 m and was excavated to a depth of 0.20 m below the ground surface and ceased on bedrock. This unit was placed 20 m to the northwest of the enclosure and contained only one layer, dark brown (10YR 3/4) silty clay (see TU-7 for a representative profile, they are identical to TU-9). The unit was excavated amidst a scattering of large and small boulders to assess if they were natural or an extension of the -2250 enclosure. At 0.17 m below ground surface, a small cobble-sized basalt chopper was recovered (Figure 26). The basalt tool has a fractured end, which may have been a deliberately formed edge. There are no signs of pecking or flaking, and no signs of wear, but it may have been a tool formed specifically for one task and then discarded. No other cultural materials were observed in the unit. The scattered boulder area was determined not to be an extension of the enclosure itself, even though one artifact was present. The rocks were misaligned and did not connect to the enclosure. These rocks were also not a separate site; only the presence of the isolated artifact shows cultural use of the area.

Figure 25. TU-5 at base of excavation. View to west.
Figure 26. Chopper tool from TU-9. Note: this artifact was taken back to the site in February, 2015 and placed in the same location where it was discovered.
Results of Testing

A total of eight test units were excavated within the Site -2250 enclosure, with a ninth unit excavated 20 m to the northwest. No cultural materials were observed in any test units within the enclosure; the only discovery was a single chopping tool found in TU-9, outside the site. TU-1, placed against the interior of the west wall, at the base of an upright basalt boulder, and TU-5, placed against the interior of the north wall, both exposed a deposit of sub-angular basalt cobbles and gravels that is interpreted as a paving, a foundation for their respective walls, or a combination of both. TU-8, placed approximately 5.0 m south of the entrance at the north corner of the enclosure, also exposed a similar deposit. TU-2 was placed along the interior of the north wall, but did not expose this cobble and gravel deposit. TU-4, TU-7, and TU-9 did not expose the cobble and gravel deposit. TU-3 and TU-6 together exposed the flat surface of a boulder, but it was determined to be a natural occurrence. Excavation of TU-4 was halted due to tightly packed naturally-deposited boulders.

The deposit of sub-angular basalt cobbles and gravels exposed along the walls in TU-1 and TU-5 appear to be a paving and/or a foundation for the walls. A similar deposit exposed in TU-8 appears to be a paving. TU-8 was placed 5.0 m south of the entry/exit, at the northern corner and 3.0 m south of TU-5 along the interior of the north wall.

TU-9, excavated 20 m from the enclosure proper along what initially appears to be a connected alignment, yielded the only associated artifact, a small, smooth, oblong basalt cobble that could have been utilized as a chopper. The artifact was composed of fine-grained basalt and measured 16 cm long by 15 cm wide. It was fractured on one end and rounded on the other end, with smooth flanks. The artifact was found in TU-9, directly below a large boulder. The extended alignment was later interpreted to be a natural feature; the alignment was not proven to link with the enclosure in any way after the area was cleared. The artifact is considered to be an isolated find and was repatriated to its place of origin during a community fieldtrip in February, 2015. There is no exacting relationship between the single stone tool and the Site -2250 main structure. Again, it appears to be an isolated find, given that nothing was found in the enclosure after 8 test units were completed.

The site is interpreted to be an agricultural heiau. The enclosure is large (180 m sq.), with single-course, well-constructed walls that are in excellent condition. In planview, the enclosure is rectilinear and the four corners are at the cardinal directions. There is a formal passageway at the north corner of the structure. One very large boulder forms the corner of the east and south walls, and several large boulders form the south wall, which faces into Māhāʻulepū Valley. There are no surface features within the enclosure but there are several large boulders. The ground within the enclosure is flat with a slightly descending slope to the south. Trees are scattered throughout the
site area, including a grove of hau trees to the southwest. The interior of heiau were often paved, but the extent of the paving varied. The absence of cultural materials in all of the test units suggests that this structure was not associated with the everyday tasks attributed to a kau hale or habitation complex. The uprights appear to distinguish this site even more.

**STATE SITE NO. 50-30-10-2251 (TS-2)**

Site -2251 is composed of two plantation-era features, both in fair condition. This site occurs in the extended survey area. Feature 1 is a sugar cane irrigation ditch approximately 2.0 m wide and ranging from 0.5 m to 1.5 m deep (Figure 27). The feature is approximately 800 meters long and extends along, and just above, the base of the northern survey area slope. The feature alternates between being covered by high grasses and also passing through and along the edge of the tree line. The ditch passes south and west of -2250 (enclosure) and terminates at the streambed which forms the eastern side of -2252 (ditch, sluice gates). On plantation maps, the feature extends northward from P-154 to P-163.

Feature 2 consists of a plantation-era sluice gate directly affiliated with Feature 1 (Figure 28). This feature occurs in the extended survey area and is located 25 m southeast of the -2250 enclosure and is built on the southern side of the main ditch. The gate is composed of an upright, concrete slab 1.5 m long by 0.06 m thick. The exterior face is 0.75 m high but the interior is 0.20 m high, the latter portion obscured by the main ditch filling with eroded and water-born soils and detritus. The concrete slab has an interior slot on its top that contains an iron door for the gate. Basalt cobbles are aligned along the interior of the ditch on either side of the concrete. Approximately 1.0 m east of the gate, on both sides of the ditch, are two retaining components built of metal posts and sheet metal. These components worked in conjunction with the main gate. Neither the ditch nor the sluice gate have been maintained for some time.
Figure 27. Site -2251, Feature 1 ditch and Feature 2 sluice gate. View to southeast.
Figure 28. Plan view of Site -2251, Feature 2 sluice gate.
STATE SITE NO. 50-30-10-2252 (TS-3)

Site -2252 is composed of three historic irrigation features, all directly related to sugar cane production. The site occurs in the extended survey area. Feature 1 consists of an irrigation ditch measuring approximately 2.0 m wide and is a variable 1.0 m to 1.5 m deep (Figure 30). This ditch connects to, and is perpendicular with, two southward descending streambeds, which are approximately 100 m apart. Within the valley, these two streams join and form the Main East Ditch. Feature 1 is the same ditch as -2251, Feature 1 to the east and Site -2253, to the west. These features received different site numbers as they are non-contiguous in places. The ditch is identifiable but partially collapsed and filled with soil and detritus.

Feature 2 consists of a Plantation era sluice gate, similar to that described above at Site -2251, and having been identified in the southern face of Feature 1 and 30 m east of the western stream (Figure 29). This feature occurs outside the project area. The feature is 70 m west of Feature 3. This feature is in good condition.

Feature 3 consists of another sluice gate, occurring outside the project area, and present in the south face of Feature 1 and 10 m west of the east stream (Figure 31). The feature is 70 m east of Feature 2. This feature is in poor condition: the metal door is missing and the concrete is weathered.
Figure 29. Site -2252, Feature 2 sluice gate. View to northwest.
Figure 30. Site -2252, Feature 1 ditch and Feature 2 sluice gate. View to south.
Figure 31. Site -2252, Feature 3 sluice gate. View to southwest.
STATE SITE NO. 50-30-10-2253 (TS-4)

This site consists of a single feature: a sugar cane Plantation era irrigating ditch that extends west and southwest from the western stream at Site -2252. This site is outside the project area, in the extended survey area. The ditch terminates at Site -2258, Māhā'ulepū Reservoir. The ditch is entirely earthen and measures 2.0 m wide by up to 1.5 m deep. Site -2253 measures approximately 2,007 feet long and is in poor condition, having been neglected and filled with eroding soils and rocks.

STATE SITE NO. 50-30-10-2254 (TS-5)

The site is a single-feature site consisting of a retaining wall that was constructed of dry stacked, sub-angular basalt cobbles and boulders (Figure 32). The site is present in the project area. Site -2254 was built into the east bank of the east stream descending from above Site -2252. Given that the features comprising Site -2255 (Plantation era culvert bridges) occur to both the north and south of -2254, this retaining wall appears to be associated with them (historic era). The retaining wall measures 7.3 m long by 1.8 m high and the visible ground surface width is up to 1.0 meter. The wall is 6 to 8 courses high, two courses wide, and was built of cobbles on an earthen bench, the latter being a remnant of the original stream bank and bed. This bench or terrace extends 4.0 m north and 4.0 m south from the ends of the wall (Figure 33). The bench extends 1.0 m out from the base of the wall. Both upstream and downstream from Site -2254, the sides of the stream have been excavated so as to make them nearly vertical. Such modifications did not occur at the Site -2254 locale as the wall has kept the slope vertical through time. No artifacts of any era were present within the wall. Also, there was no concrete or coral-based mortar used on this wall. The short wall segment is in fair condition.
Figure 32. Site -2254 retaining wall. View to east.
Figure 33. Plan view of Site --2254 retaining wall.
STATE SITE NO. 50-30-10-2255 (TS-6)

Site -2255 is composed of four (4) culvert bridges crossing over the east stream that descends from above Site -2252. These culverts were designated as Features 1, 2, 3, and 4, with Feature 1 being the most northern of the group. Features 1 and 2 are present to the north of Site -2254 (retaining wall) and Features 3 and 4 are south of the wall. Site -2255 occurs in the project area.

Each culvert was constructed in the same way. A corrugated metal pipe, measuring 1.3 m in diameter, is placed directly at the base of the ditch. Packed earth extends from each bank to the pipe, to a height of 0.50 m, with the remainder composed of small boulder-sized, quarried basalt.

Feature 1 measures 6.5 m north-south by 6.0 m and is 2.0 m high from the road surface to the base of the ditch. The bridges long axis is 340 degrees. From the southwest corner of Feature 1 to the southeast corner of Feature 2, the distance is 52 m.

Feature 2 measures 5.8 m east-west by 4.5 m north-south and is 2.4 m high from road surface to the base of the ditch (Figure 34 and Figure 35). The bridge long axis is 90 degrees.

Feature 3 measures 6.1 m east-west by 5.8 m north-south and it is 2.4 m high from road surface to the base of the ditch (Figure 36 and Figure 37). The bridge long axis is 90 degrees. Feature 3 is present 44 m from Feature 4.

Feature 4 measures 6.0 m east-west by 5.6 m north-south and it is 2.9 m high from road surface to the base of the ditch. The bridge long axis is 90 degrees. Feature 4 is approximately 25 m north of the junction of the two streams that pass to either side of Site -2252 (ditch, sluice gates).
Figure 34. Sites -2254 and -2255, Feature 2. View to north.
Figure 35. Plan view of Site -2255, Feature 2.
Figure 36. Site -2255, Feature 3. View to south.
Figure 37. Plan view of Site -2255, Feature 3.
STATE SITE NO. 50-30-10-2256 (TS-7)

Site -2256 is composed of a concrete bridge crossing over the west stream that descends from above Site -2252. The bridge is present in the project area. The bridge itself was manufactured of poured and formed concrete, with a 0.2 m raised curb along each edge. The bridge measures 5.3 m north-south by 5.0 m east-west. The height from the top of the curb to the base of the stream is 3.6 m. The long axis of the bridge is 20 degrees (Figure 38).

Both stream banks have retaining walls supporting the bridge (Figure 39). These are constructed of boulder-sized, quarried basalt and are mortared or cemented together. The wall faces are 3.6 m apart. The base of the west end, of the northern wall is weathered. A surprisingly large tree root is protruding out of the south wall's face. There are no trees remaining on the surface in this area, but there are several dead or cut trees rooted in the stream bed and banks in the immediate vicinity.

The stream bed of the western stream, north and south from the bridge, is deeper and not as modified as the eastern stream. Also, the western stream bed is nearly covered by both water worn basalt and sub-angular basalt. The eastern branch had perhaps 10% of these materials. The eastern branch may have had these materials removed during plantation maintenance. The mix of materials in the west branch suggests that not only was this a flowing stream, but that the other materials may have been pushed into the stream when fields were being cleared. It is possible that those materials were from traditional features such as walls, mounds, or terraces and platforms. The junction of the two streams is 110 m and 150 degrees from Site -2256.

STATE SITE NO. 50-30-10-2257 (TS-8)

Site -2257, occurring within the project area, is a retaining wall similar to Site -2254 but is not as well preserved (Figure 40). The feature is constructed of dry stacked, sub-angular basalt cobbles and boulders and is 7.5 meters northwest to southeast, built into the south bank of the Main East ditch's western stream. The width of the surface is approximately 1.0 m. However, the terminus of the southeastern end has partially collapsed and stacked cobbles and boulders are visible in the collapsed bank, suggesting that the internal width is greater than that of the surface. The retaining wall is 4.0 m tall and composed of up to 6 courses of cobbles and small boulders, extending from ground surface to stream bottom. As with Site -2254, there is a bench or terrace present upon which the wall was built. This short segment also appears to shore up the ditch in this area as it continued to function well through time, at least until present times. It is interpreted to be associated Historic times and is in very poor condition.
Figure 38. Plan view of Site 2256 bridge concrete deck and floor.
Figure 39. Plan view of Site -2256 bridge retaining walls.
Figure 40. Site -2257 retaining wall remnant. View to southwest.
STATE SITE NO. 50-30-10-2258 (TS-9)

Site -2258 consists of the Māhāʻulepū Reservoir (Figure 41), occurring outside the project area. Built early in the 20th century, it is unknown if there was a spring at this location. The reservoir is large, measuring c. 200 m in diameter. During the time of the field survey in July, 2014 the water level appeared low. The south and east sides of the reservoir are bordered by high, long, and wide dikes or levees. The ground level ascends to the north and west and so additions were not required on these sides. A metal catwalk extends from the southern dike into the reservoir. This is part of the irrigation pipe and pump system that releases water into the Main western ditch that feeds the taro fields at the south end of the valley. The base and flanks of the reservoir are all earthen, compacted soil with no physical architecture supporting the flanks. The reservoir is a man-made construction and likely took some time, given its breadth and depth (c. 4+ meters). It is not known if the reservoir is at its original size or was expanded through time. The reservoir functioned in concert with the many ditches and irrigation works occurring throughout the valley and documented herein.

STATE SITE NO. 50-30-10-2259 (TS-10)

Site -2259 consists of a Plantation-era irrigation ditch that extends southward from Site -2258 along the base of a slope at the western side of Māhāʻulepū Valley. Site -2259 occurs outside the project area. The earthen ditch is c. 2 m wide and extends near the northern borders of the survey area (Figure 42). The feature is similar in design, measurement, and function to Site -2251. The ditch measures 2.0 m wide and the depth varies up to 2.5 m deep. The length of the ditch is approximately 1,020 m (3,323 ft.) and extends south from the reservoir.

STATE SITE NO. 50-30-10-2260 (TS-11)

Site -2260, occurring outside the project area, is an historic bridge that crosses over a natural stream that enters Māhāʻulepū Valley from the western ridge (Figure 43). The stream originates between named peaks, Kalaeakohani to the south and Kolopa to the north. Like the streams entering the valley from the north, this watercourse has been modified upon its entrance into the valley. The bridge surface is comprised of two concrete slabs measuring 7.5 m north-south by 3.0 m east-west and are 0.2 m thick. The long axis is oriented at 210 degrees and the slabs have a 0.1 m gap between them. The west side of the bridge is not modified. The east side of the bridge has a concrete curb that extends 6.8 m and 0.31 m wide. The interior height of the bridge is 0.56 m, while the exterior height is 0.89 m. An iron railing is affixed to the top of the curb. This railing appears to be from the narrow gauge railroad that once extended along the southwestern flank of Māhāʻulepū Valley. Within the stream bed, there are remnants of dry
stacked basalt cobble retaining walls on the north and south banks of the west side of the bridge. The walls are composed of cobbles and small boulders extending up to 12 courses high. Inscribed on the exterior face of the curb is the number or date “1951”, with a flourish on the upper bar of the “5” (Figure 44 through Figure 44).

Figure 44. Site -2260 bridge date. View to southwest.
Figure 45. Plan view of Site -2260 bridge attributes.
Figure 46. Plan view of Site -2260 bridge.
STATE SITE NO. 50-30-10-2261 (TS-12)

Site -2261, occurring outside the project area, consists of a bridge crossing over the Main East ditch at the southern end of the survey area. Māhā'ulepū Road crosses the bridge (Figure 47). This bridge is unique to the project area in that it shows two distinct phases of construction. The bridge measures 10 meters east-west by 8.5 m north-south, with each style of construction composing approximately half of the bridge.

The northern half of the bridge is constructed of boulder-sized, quarried basalt which are mortared into place to form retaining walls on the east and west stream banks, as well as the north and south flanks. The northern side is clearly visible from the fields and road to the north but the southern side must be viewed from within the stream bed. Both of these sides show an artisan's flair in that there is an arch to the bridge that is not seen on any other feature within the valley. On the north edge of the bridge surface there is a concrete curb with a basalt cobble alignment upon it. Inscribed in the surface of the concrete is “July 30, 1908”. There is 0.35 m of gravel and dirt forming the road above the concrete. From road surface to the base of the stream bed measures 2.4 meters.

The southern half of the bridge is constructed entirely of concrete. Concrete retaining walls line both banks of the watercourse. These descend 1.9 m to an extended 0.5 m foundation on the stream bed. On the southern side of the concrete bridge is a concrete curb which is 0.9 m high and extends to the surface of the concrete retaining walls. An iron rail is affixed to its surface, which is similar to that at Site -2260. Clearly, the narrow gauge railroad along the southern portion, of the western half of the valley, was dismantled. Salvaged materials were utilized for other plantation projects. On the southern face of the concrete curb there is the inscription “1951”, again with a flair on the upper bar of the 5 (Figure 48). “1951” appears to be the year in which many modifications occurred on the plantation. No other bridge found during the AIS shows such obvious evidence of additional phases of construction.
Figure 47. Site -2261 bridge, showing 1908 section and 1951 section. View to northeast.
Figure 48. Site -2261 bridge date. View to south.
STATE SITE NO. 50-30-10-2263 (TS-14)

Site -2263 consists of a bridge crossing over the Main East Ditch, inside the project area, on the east-west extent of Māhā'ulepū Road. The bridge is adjacent to, and northwest of, the many LCA awards at the center of the valley. The site is a culvert bridge which appears to have been built in stages (Figure 49). The base within the streambed consists of 3 to 4 courses of boulder-sized, quarried basalt which are mortared on either side of a concrete culvert, the latter which measures 1.0 m in diameter. The culvert appears to be younger in origin than the walls to either side. The mortared blocks extend halfway up the side of the concrete culvert. On them are dry stacked, sub-angular, vesicular basalt boulders which extend from 0.5 m to 1.5 m above the stream bed. On top of this are boulders of a similar type which are mortared together and extend from 1.5 m to 2.0 m above the stream bed (Figure 50). Additionally, along the western side of the large culvert are two smaller concrete culverts, one above the other. This culvert bridge appears to have been constructed and provided with additions over time.

STATE SITE NO. 50-30-10-2264 (TS-15)

Site -2264, occurring inside the project area, is the remnant of an irrigation pipe that appears to have crossed over the Main East Ditch, immediately south of the location where the east and west streams that pass Site -2255 join together. There is a partially collapsed concrete foundation on the east side of the ditch, with a corrugated metal pipe 0.6 m in diameter extending 0.9 m from it (Figure 51). The intact remnant of the concrete foundation measures 2.2 m north-south by 1.0 m east-west and is 0.6 m high. On the far bank, concrete rubble is present. Upstream from this point, the stream beds are dry, but downstream there is an increasing water flow. It is unclear at present if the source of the flow is from the pipe or from a spring within the stream bed.
Figure 49. Site -2263 bridge. View to south.
Figure 50. Plan view of Site -2263, retaining walls and culverts.
Figure 51. Site -2264 culvert and pipe. View to northeast.
STATE SITE NO. 50-30-10-2262 (TS-16)

Site -2262, occurring outside the project area, is composed of three features and was identified in the northwestern portion of Māhāulepū Valley (Figure 52). This site was identified during August, 2014 sweeps of the extended survey area. Feature 1 consists of an irrigation flume constructed of concrete foundations, a trestle of wooden beams, a concrete bridge, a concrete wall that extends east and west from the southern end of the bridge, and an open-topped metal culvert (Figure 53 through Figure 59). The overall length of the entire structure is 14.0 m and the overall width is 2.3 meters. The culvert measures 14.0 m long by 1.0 m wide and is 0.5 m deep. The supporting concrete bridge is 14.0 m long by 1.5 m wide and is 0.2 m thick. The southern concrete foundation measures 2.0 m long by 0.45 m wide and is 0.85 m tall. The long axis is oriented east-west. The southern foundation contains a trestle of wooden beams on top that support the base of the concrete bridge. The northern concrete foundation measures 2.3 m long by 0.45 m wide and is 2.5 m tall. The north foundation directly supports the base of the concrete bridge. The base of the concrete bridge is 3.2 m above the base of the irrigation ditch (Site -2253) that the flume crosses over. The ends of the flume are within a stream course which descends from the north into the valley. This stream course eventually braids with the two courses to the east and forms Māhāulepū Ditch. Each branch of the concrete wall extending east and west from the south end of the concrete bridge measures 2.0 m long by 0.45 m high and is 0.15 m thick. Feature 2 extends from the eastern flank of the east wall.

Feature 2 consists of a concrete sluice gate. The overall length is 3.0 m, with the central opening measuring 1.0 m wide. The concrete side walls measure 1.0 m long by 0.45 m tall and are 0.15 m thick. Where the walls face each other, the concrete is grooved vertically, but there is no remnant of a metal or wooden gate. The opening faces east. On top of the south wall “J Torre” is inscribed into the concrete. On top of the north wall is the inscription “1924”.

Feature 3 consists of a pair of sluice gates located to the south of, but not contiguous with Feature 2. They are placed at the end of a short ditch extending away from the stream course. The walls of this ditch are paved with concrete. At the gates, there is a central concrete pillar separating the openings, as well as concrete walls extending away from the opening. Basalt cobbles support the exterior of the concrete walls. A narrow gauge railroad rail is incorporated into the top of, but not on top of, both walls and the column. Each gate opening measures 0.6 m wide by 0.9 m tall, from the base of the ditch to the top of column. The column measures 0.2 m on each side and is 0.9 m tall. Each concrete wall measures 0.7 m long by 0.2 m wide by 0.9 m tall. The ends of the concrete walls facing the column and the corresponding faces of the column
are grooved vertically but there is no remnant of a metal or wooden gate. Inscribed into the concrete surface of the north wing wall is “Koloa Plantation, April 12/24 By D.S.K.”.

Site -2262 crosses over Site -2253, to the northeast of Site -2258, Māhā’ulepū Reservoir. Site -2253 is an irrigation ditch which terminates at the reservoir on its south end and connects to Site -2252 on its north end. The north and south ends of Site -2262 are within a streambed that descends from the north. Site -2262 was built after the excavation of Site -2253. Site -2262 has multiple functions: to carry stream water over the irrigation ditch and continue its flow into the valley as a source for Māhā’ulepū Ditch. With three mountain born water sources braided together at the north end of the valley floor, the original Māhā’ulepū Stream, later modified to become Māhā’ulepū Ditch, would have been a substantial water course even prior to the sugar cane industry.

The sluice gates of Features 2 and 3 face eastward. Flow from the stream would have emptied into Site -2253, the irrigation ditch and presumably carried it to Site -2258, Māhā’ulepū Reservoir. The date of the inscriptions at both gates gives the year “1924”. This shows that excavation of the ditch that incorporates Sites -2251, -2252, -2253, and -2259 predates the construction of -2262. The concrete bridge of Feature 1 is collapsed upon the northern concrete foundation. The wooden trestle is standing but the beams are rotting.

Figure 58. Site -2262 flume system. View to northeast.
Figure 59. Site -2262 double gate with cement and rock wall to prevent erosion. View to north.
Site 3094 consists of a previously identified petroglyph rock (designated as Feature 1), along with two other petroglyph rocks (designated as Feature 2 and Feature 3) that were identified during the current survey. All three features occur outside the project area, in the extended survey area. Feature 1 consists of a large boulder with petroglyphs that was previously identified. Feature 2 is either exposed bedrock or a buried boulder with two petroglyphs visible located 20 m southeast from, and in the same clearing as Feature 1. Feature 3, which was identified by the SHPD-Kaua‘i representative during a field visit in 2014, is located approximately 70 m to the northeast of Feature 1, and is at the base of the wooded slope in the extended survey area.

The area surrounding Feature 1 is currently covered by tall grasses (Figure 60). Excavation of test trenches during this AIS showed that the ground east, north, and west of Feature 1 had been plowed for the cultivation of sugar cane. To the south, however, the test trench exposed intact natural stratigraphy. The area south from the boulder extends to one branch of the southward flowing Māhā‘ulepū Stream. This confined area, the absence of disturbed soils, and the absence of any signs of impact by machinery on the boulder suggest that care had been taken not to disturb the boulder.

Feature 1 measures 4.0 m long by 3.8 m wide, with the long axis north to south. The boulder is 1.1 m high at its northern end, 1.3 m at its center, and ranges from 0.6 to 0.8 m high at the southern end. The eastern, northern and southern faces are vertical, while the southern end slopes steeply in the ground surface. The ground to the south is at a slightly higher elevation than the boulder, and the ground slopes away from the boulder in the other directions. The high center of the boulder is an east to west extending ridge across the top of the boulder. From this crest, the top surface of the boulder is smooth and descends gradually northward. On the east and northwest sides of the surface, the surface slopes slightly before turning into vertical faces. The remaining sides of the boulder are all vertical to the top surface. South from the crest, the slope is shorter, steeper, and the surface is rough and pockmarked from natural causes.

At the crest of the ridge is a pecked cup or basin measuring 0.1 m in diameter and 0.1 m deep. From this cup is a pecked groove approximately 0.03 m wide and approximately 0.01 m deep that descends northward in a gradual curve across the surface of the boulder, ending at the northwest side. Parallel to this groove is a natural bifurcated fissure that descends with one branch ending at the northwest end of the boulder next to the groove and the other branch ending at the northeast end (Figure 61).
Figure 60. Plan view of Site -3094, Feature 1 overview.
Petroglyphs representing human figures are pecked into four vertical faces, two sloped faces, and the top surface of the north end of the boulder. On the top surface, there are figures on either side of the groove, and all sides of the fissure, and one is placed between the groove and the fissure. These were documented and illustrated as separate panels but the panels are regarded as being part of the whole entity of the boulder (Figure 62 through Figure 72).

The vertical and sloped panels each have between one and three figures, while the top surface has a total of seven figures. Some panels have pecked areas and/or lines as well. What these pecked areas represent is not currently understood. The petroglyphs are stick figured and limbed, with round heads. There are figures with extensions at the ends of limbs and at least one has male genitalia represented. The figures vary in size but do not exceed 0.3 m in length or width.

There are no figures on the slope south from the crest but there is a second pecked basin or cup, this one at the base of the slope. It has the same dimensions as the one at the crest, but there are no associated figures, grooves, or fissures.

The meaning of these petroglyphs and their placements on the boulder is open to interpretation. One interpretation is that, despite being oriented in the opposite direction, the crest represents Ha'upu Ridge, and Mount Ha'upu, and the groove represents Māhā'ulepū Stream as it descends and curves to the coast (Ching et al. 1974). The basins may represent head waters to streams. The petroglyphs may represent population centers, chieftains or the divine. The fissure, being natural, may represent either another stream course, or perhaps a ridgeline. Another interpretation is that these are all representing someplace on Kaua'i where a stream actually does flow north. It may be that all of this represents some facet of navigation, ceremony, cosmology, or documentation of events which we do not as of yet understand.

During the current AIS, a second feature with petroglyphs was identified (N457372, E2423831). Feature 2 was identified by the backhoe driver as he was clearing grasses in the area to conduct trenching around the Feature 1 boulder. Feature 2 is located 20 m (at 140 degrees) from Feature 1. This second “boulder” is only slightly exposed at ground surface and may actually be a natural basalt outcrop. Feature 2 measures 1.5 m in diameter and rises only 0.2 m above the current ground surface. The exposed rock measures 1.72 m (north flank) by 1.98 m (east side). The figures on Feature 2 are different, and not as clearly defined, as those on Feature 1. There is a stick-figured human standing legs apart and wide-armed, holding what appears to be a spear upright in his right hand. Perpendicular to this is a three-leafed image on a staff, possibly a kahili image. Neither of these are as clearly defined as those on the larger Feature 1.
boulder, which is not surprising considering it occurs on the surface of the fields. Other scratches on the surface of Feature 2 are indistinct (Figure 71).

Because Feature 2 is at ground surface level, and because there are fewer, less distinct images, it appears that the markings on Feature 2 were etched for a different purpose than those on Feature 1. If the figure is a kahili, then this could indicate the area being decreed kapu. A kapu could be seasonal, periodical, or eternal. This may explain why the main boulder was left intact and in situ throughout the Kingdom and the modern era. The figure that appears to be holding a staff or spear is not as distinct as those figures on Feature 1. None of the Feature 1 figures appear to be holding anything.

Feature 3 is located 70 m to the north/northeast of Features 1 and 2, in the extended survey area. This boulder measures 2.5 m by 2.1 m by 1.7 m tall, with its long axis northeast to southwest (Figure 72). Feature 3 contains etchings of several human figures with stick torsos and limbs. These are located on the mauka face of a large, slab-like boulder. The figures of Feature 3 are slightly larger than those of Feature 1. The meaning and purpose of Feature 3 is open for interpretation, but likely represents individuals of the area.

STRATIGRAPHIC TRENCH EXCAVATIONS

Stratigraphic trench excavations were conducted mechanically with a backhoe in areas within and around historically interesting areas, one known site (Site -3094), and proposed effluent ponds along the western flank of the project area (Figure 73). Several of the trenches were concentrated near the cluster of LCA’s located on the east side of the Main East Ditch. These LCAs were awarded during the Great Māhele in 1848 and were occupied and/or utilized until approximately the 1880s, when individual ownerships passed over to group and corporate development for the Koloa Sugar Cane Plantation.

A total of nine (9) trenches were mechanically excavated within the exact location of the former LCA cluster area. The trenches, designated Stratigraphic Trenches (ST), were numbered sequentially and excavated in rows of three. The southernmost row, ST-1 to ST-3 was excavated east to west. The middle row, ST-4 to ST 6, was excavated west to east. The northernmost row, ST-7 to ST-9, was excavated east to west. This area is identified on the soils map as P-131 through P-134. To the east from this point, P-135 to P-137 is currently marshland and an excavator could not safely be brought in to excavate. The previously noted soils map identified the soils exposed by ST-1 through ST-9 as KavB or Kaena Clay, Brown Variant.

The next area of excavation occurred around Feature 1 of Site -3094, the previously-identified petroglyph boulder. Four (4) trenches were mechanically excavated here. This area is identified on the soils map as P-120. The soils map identified the soils exposed by ST-10 through ST-13 as HsD or Hanamaulu Silty Clay.

A single trench was excavated east of the -2254 retaining wall in an attempt to find remnants of a historic household that is shown on older maps of the area. This area is identified on the soils map as P-161 and P-162. The soils map identified these soils as KavB or Kaena Clay, Brown Variant.

Trenches were desired on a small knoll at the northwest turn of Māhā’ulepū Road. On older maps of the area, this location is designated as “Camp”, but no further explanation is provided. However, a trench with water lines is present alongside the road and prevented access to this area. Alternatively, two trenches were excavated to the southeast of the knoll, in the fields south of existing pump station structures. These structures service a series of wells known as Māhā’ulepū 14, drilled during the 20th century to service irrigation for the plantation. This area is identified on the soils map as P-103. The soils map identified the soils as KavB or Kaena Clay, Brown Variant.
Figure 73. USGS Map depicting stratigraphic trench locations.
A final trench was excavated within the area of the Effluent Ponds and other infrastructure proposed to be constructed for the project. This area is identified on the soils map as P-201 and soils are also identified as KavB or Kaena Clay, Brown Variant.

**SPECIFIC TRENCHING METHODS**

All trenches were excavated with use of a small, tracked, excavator. Each trench was 10.0 m long (9.14 m being the average open space, the remaining 0.86 consisting of the ramp into the trenches) and the width of the bucket, 0.75 m wide. Depth of the trenches varied, depending on the water table. If the table was encountered, excavation was halted. If the water table was not encountered, excavation extended to 2.0 m below the ground surface for the first 2.0 m of the trench, and then was reduced to 1.5 m for the remainder. In every trench, the uppermost 0.2 to 0.8 m below ground surface was composed of grey brown loam with fine grass roots. This was identified as a disturbed plow zone. The trenches excavated in rows in the LCA area were 20 m apart and the rows were approximately 40 m apart. Each trench was documented with soil descriptions, profiles, written descriptions, and photographs.

At each trench location, an area approximately 15 m wide and long was cleared by the excavator down to the ground surface. This was done to allow complete views of the interior of the trench, to expose areas around it in the event of additional excavations, and in order to facilitate greater ease and access when back filling was undertaken.

A total of seventeen (17) stratigraphic trenches were mechanically excavated. The greatest concentration of these was within the area identified as containing numerous LCA properties. The second largest concentration was around Site 3094. No cultural materials or features were exposed during any of these excavations. Appendix A provides stratigraphic profiles and representative photographs of the trenches.

**PROJECT AREA**

**Stratigraphic Trench 1 (ST-1)**

ST-1 measured 9.14 m long, 0.6 m wide, and was oriented at 120/300 degrees. The trench was excavated to a maximum depth of 1.52 m at the north end and 1.8 m at the south end. Three stratigraphic layers were identified. Layer I (0.0-0.16 mbs) is composed of dark brown (10YR 3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. Lower boundary was abrupt and wavy. Layer II (0.16-0.56 mbs) is a dark grayish brown (10YR 4/2) clay, structureless, plastic, less than 1% roots and gravel. Layer III (0.56-1.5/1.8 mbs) consisted of dark grayish brown (10YR 4/2) clay that was structureless, plastic, with no roots and no gravel. The water table was exposed at the base of the excavation. This
trench was located in the center of the project area, east of Māhā'ulepū Ditch, and south of Māhā'ulepū Road.

**Stratigraphic Trench 2 (ST-2)**

ST-2 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.52 m at the north end and 1.8 m at the south end. Three stratigraphic layers were identified. Layer I (0.0-0.16 mbs) is a dark brown (10YR 3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. Lower boundary was abrupt and wavy. Layer II (0.16-0.56 mbs) is a dark grayish brown (10YR 4/2) clay that is structureless, plastic, less than 1% roots and gravel. The lower boundary was clear and wavy. Layer III (0.56-1.5/1.8 mbs) consisted of dark grayish brown (10YR 4/2) clay that was structureless, plastic, with no roots and no gravel. The water table was exposed at the base of this excavation. This trench was located in the center of the project area, east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.

**Stratigraphic Trench 3 (ST-3)**

ST-3 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.52 m at the north end and 1.8 m at the south end. Three stratigraphic layers were identified. Layer I (0.0-0.16 mbs) is composed of a dark brown (10YR 3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. Lower boundary was abrupt and wavy. The lower boundary was clear and wavy. Layer II (0.16-0.56 mbs) was a dark grayish brown (10YR 4/2) clay that was structureless, plastic, less than 1% roots and gravel. The lower boundary was clear and wavy. Layer III (0.56-1.5/1.8 mbs) consisted of dark grayish brown (10YR 4/2) clay that was structureless, plastic, with no roots and no gravel. The water table was exposed at the base of this excavation. The trench was located in the center of the project area, east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.

**Stratigraphic Trench 4 (ST-4)**

ST-4 measured 9.14 m long and 0.6 m wide and was oriented at 20/160 degrees. The trench was excavated to a maximum depth of 1.52 m at the north end and 1.8 m at the south end. Three stratigraphic layers were identified. Layer I (0.0-0.16 mbs) is composed of a dark brown (10YR 3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II (0.16-0.56 mbs) is a dark grayish brown (10YR 4/2) clay that was structureless, plastic, less than 1% roots and gravel. The lower boundary was clear and wavy. Layer III (0.56-1.5/1.8 mbs) consisted of dark grayish brown (10YR 4/2) clay that was structureless, plastic, and with no roots and no gravel. The water
table was exposed at the base of this excavation. This trench was located in the center of the project area, east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.

**Stratigraphic Trench 5 (ST-5)**

ST-5 measured 9.14 m long and 0.6 m wide and was oriented at 90/270 degrees. The trench was excavated to a maximum depth of 1.52 m and exposed two stratigraphic layers. Layer I (0.0-0.3m) was a dark brown (10YR3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II (0.3-1.52m) was a dark brown (10YR 3/3) clay with no roots and no gravel. The water table was exposed at the base of this excavation. This trench was located in the center of the project area, east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.

**Stratigraphic Trench 6 (ST-6)**

ST-6 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.52 m and exposed five stratigraphic layers. Layer I (0.0-0.3m) was composed of dark brown (10YR3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II (0.3-0.6 m) is a dark brown (10YR 4/2) clay that was structureless, plastic and had no roots or gravel. The lower boundary was clear and wavy. Layer III (0.6-1.0 m) is a brown (10YR4/3) clay that was structureless, plastic, and had no roots or gravel. The lower boundary was clear and wavy. Layer IV (1.0-1.2 m) is a dark grayish brown (10YR 4/2) clay that was structureless, plastic, and had no roots and no gravel. The lower boundary was clear and smooth. Layer V (1.2-1.5 m) is a brown (10YR 4/3) clay that was structureless, plastic, and had no roots or gravel. The water table was reached at 0.9 m below the ground surface. This trench was located in the center of the project area east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.

**Stratigraphic Trench 7 (ST-7)**

ST-7 measured 9.14 m long and 0.6 m wide and was oriented at 90/270 degrees. The trench was excavated to a maximum depth of 1.52 m and exposed four stratigraphic layers. Layer I (0.0-0.2 m) is a dark brown (10YR3/5) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II (0.2-0.5 m) is a yellow brown (10YR 5/4) clay that was structureless, plastic, and had no roots and no gravel. The lower boundary was abrupt and wavy. Layer III (0.5-0.73 m) is a black clay that was structureless, plastic, and had no roots and no gravel. The lower boundary was abrupt and wavy. Layer IV (0.73-1.52 m) is a brown (10YR4/3) clay that was structureless, plastic, and had no roots or gravel. The water table was exposed at the base of the excavation. This trench was located in the center of the project area east of Māhā'ulepū Ditch and south of Māhā'ulepū Road.
Stratigraphic Trench 8 (ST-8)

ST-8 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed three stratigraphic layers. Layer I (0.0-0.2 m) is a dark brown (10YR4/3) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II is a yellowish brown (10YR5/6) clay that was structureless, plastic, and had no roots or gravel. The lower boundary was clear and smooth. Layer III was a bluish gray (Gley 2 5/1) clay exposed, with the water table, at the base of the excavation. This color clay was not exposed in any other excavation and simply represents water saturated soils. This trench was located in the center of the project area east of Māhā’ulepū Ditch and south of Māhā’ulepū Road.

Stratigraphic Trench 9 (ST-9)

ST-9 measured 9.14 m long and 0.6 m wide and was oriented at 90/270 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.2 m) is composed of dark brown (10YR4.3) silt that was structureless, slightly plastic, and includes roots, rootlets, and less than 1% gravel. The lower boundary was abrupt and wavy. Layer II (0.2-1.5 m) is a yellowish dark brown (10YR4/4) clay that was structureless, plastic and had no roots or gravel. The water table was exposed at the base of the excavation. This trench was located in the center of the project area east of Māhā’ulepū Ditch and south of Māhā’ulepū Road.

Stratigraphic trench 14 (ST-14)

ST-14 measured 9.14 m long and 0.6 m wide and was oriented at 20/200 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.4 m) was composed of dark brown (10YR4/3) silty clay that was structureless, slightly plastic, and included no roots and less than 1% gravel.. The lower boundary is abrupt and wavy. Layer II (0.4-1.8 m) is a dark yellowish brown (10YR3/6) clay that was structureless, plastic and contained no roots or gravel. The water table was not exposed in this excavation. This trench was located to the east of the fork in the Māhā’ulepū Ditch.

Stratigraphic Trench 15 (ST-15)

ST-15 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed three stratigraphic layers. Layer I (0.0-0.1 m) was composed of dark brown (10YR4/3) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 10% gravel. The lower boundary is abrupt and wavy. Layer II (0.1-0.46 m) is a dark grayish brown (10YR4/6) clay that was structureless, plastic, and had no roots and less than 1% gravel. The lower boundary is clear and wavy. Layer III (0.46-1.52 m) is a dark grayish brown (10YR4/2) clay that was structureless, plastic, and had
no roots or gravel. Layer III was moist but the water table was not exposed in this excavation. This trench was located immediately south of the pumping station of the “Māhā‘ulepū 14” wells at the northwest end of the property where Māhā‘ulepū Road turns to the east.

**Stratigraphic Trench 16 (ST-16)**

ST-16 measured 9.14 m long and 0.6 m wide and was oriented at 0/360 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed three stratigraphic layers. Layer I (0.0-0.16 m) was composed of dark brown (10YR4/3) silty clay that was structureless, slightly plastic, and included roots, rootlets, and less than 10% gravel. The lower boundary is clear and wavy. Layer II (0.16-0.82 m) is a dark grayish brown (10YR4/2) clay that was structureless, plastic, and had no roots and less than 1% gravel. The lower boundary is clear and wavy. Layer III (0.82-1.52 m) is a dark grayish brown (10YR4/2) clay that was structureless, plastic, and had no roots or gravel. The water table was not exposed in this excavation. This trench was located in the proposed Effluent Pond area along the western side of the project area.

**Stratigraphic Trench 17 (ST-17)**

ST-17 measured 9.14 m long and 0.6 m wide and was oriented at 0/360 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed four stratigraphic layers. Layer I (0.0-0.05 m) was composed of dark brown (10YR4/3) silt that was structureless, slightly plastic, and included grass roots and no gravel. The lower boundary was abrupt and smooth. Layer II (0.05-0.4 m) is a mottled gray (10YR5/2) and dark brown (10YR4/3) clay that was structureless, slightly plastic, and included roots, rootlets, and less than 10% gravel. The lower boundary is clear and wavy. Layer III (0.4-0.88 m) is a dark yellowish brown (10YR4/6) clay that was structureless, plastic, and had no roots or gravel. The lower boundary was clear and wavy. Layer IV (0.88-1.52 m) is a dark gray (10YR4/2) clay. The sediment was structureless, plastic, and included no roots or gravel. The water table was not exposed in this excavation. This trench was located in the proposed Effluent Pond area along the western side of the project area.

**EXTENDED SURVEY AREA**

**Stratigraphic Trench 10 (ST-10)**

ST-10 measured 9.14 m long and 0.6 m wide and was oriented at 100/280 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.4 m) is composed of a dark brown (10YR4/3) silt that was structureless, slightly plastic, and included grass roots and no gravel. The lower boundary was abrupt and smooth. Layer II (0.4-1.8 m) is a yellowish brown (10YR5/8) silt that was fine, slightly plastic, and had no roots or gravel included. The water table was not exposed in this excavation. This trench was located to the north of the petroglyph boulder at Site -3094, Feature 1.
Stratigraphic Trench 11 (ST-11)

ST-11 measured 9.14 m long and 0.6 m wide and was oriented at 180/360 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.4 m) was composed of dark brown (10YR4/3) silt that was structureless, slightly plastic, and included grass roots and no gravel. The lower boundary was abrupt and smooth. Layer II (0.4-1.8 m) is a yellowish brown (10YR5/8) silt that was fine, slightly plastic, and had no roots or gravel included. The water table was not exposed in this excavation. This trench was located to the west of the petroglyph boulder at Site -3094, Feature 1.

Stratigraphic Trench 12 (ST-12)

ST-12 measured 9.14 m long and 0.6 m wide and was oriented at 100/280 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.4 m) was composed of dark brown (10YR4/3) silt that was structureless, slightly plastic, and included grass roots and no gravel. The lower boundary was abrupt and smooth. Layer II (0.4-1.8 m) is a yellowish brown (10YR5/8) silt that was fine, slightly plastic, and had no roots or gravel included. The water table was not exposed in this excavation. This trench was located to the south of the petroglyph boulder at Site -3094, Feature 1.

Stratigraphic Trench 13 (ST-13)

ST-13 measured 9.14 m long and 0.6 m wide and was oriented at 40/220 degrees. The trench was excavated to a maximum depth of 1.8 m and exposed two stratigraphic layers. Layer I (0.0-0.4 m) was composed of dark brown (10YR4/3) silt that was structureless, slightly plastic, and included grass roots and no gravel. The lower boundary was abrupt and smooth. Layer II (0.4-1.8 m) is a yellowish brown (10YR5/8) silt that was fine, slightly plastic, and had no roots or gravel included. The water table was not exposed in this excavation. This trench was located to the east of the petroglyph boulder at Site -3094, Feature 1.

DISCUSSION AND CONCLUSIONS

IDENTIFIED SITES

A total of sixteen (16) sites were identified within the project area and extended survey area. As shown in Table 1 above, six sites occur within the project area (Sites -2254, -2255, -2256, -2257, -2263, and -2264) and ten sites occur outside the project area (Sites -2250, -2251, -2252, -2253, -2258, -2259, -2260, -2261, -2262, and -3094).

Fifteen (15) of the sites were newly identified during the current survey; and one site, a boulder with petroglyphs designated State Site 50-30-10-3094, was re-located in the extended survey area. During pedestrian survey of the extended survey area, a buried boulder or exposed
bedrock outcrop with petroglyphs was identified 20 m to the southeast of the primary boulder (Site -3094, Feature 2). During survey of the extended survey area, approximately 70 m northeast of the primary boulder, a third feature (Site -3094, Feature 3), a large boulder with vertical faces and petroglyphs of human figures was found by the SHPD. These two new features are added to Site -3094 to form the petroglyph complex. All three features occur outside the project area.

**PRE-CONTACT/EARLY HISTORIC PERIOD SITES**

Sites 50-30-10-2250 (enclosure) and -3094 (petroglyphs), both occurring outside the project area, are believed to be associated with pre-Contact and/or early historic occupation. Site 50-30-10-2250 has been identified as an agricultural *heiau*. Multiple test units were placed at this site. No cultural materials were found within the enclosure. However, excavations at several locations along the north and west walls did expose what appear to be foundations for the walls at these locations. Built of sub-angular gravel and cobble sized basalt, these foundations were directly associated with the walls. Excavations within the interior of the enclosure exposed no such deposit, so it is thought that rather than a paving, the deposit represents a construction or engineering component of the *heiau*. Given the location of Site -2250, at the base of Ha'upu ridge, where rain water runoff would have flowed, it would be necessary for walls to have a foundation base course component. One artifact, a lithic chopping tool, was recovered from 20 meters to the east of the enclosure but interpreted as an isolated find with no connection to Site -2250.

Site -2250 has been interpreted herein as an agricultural *heiau* due to its size, construction (uprights, paved foundation), location, and lack of cultural materials normally indicative of a *kau hale* or community *hale*. An agricultural *heiau*, also referred to as *mapele* or Hale O Lono (the god of fertility) is directly associated with ceremonies to insure the fertility of the crops (Handy 1972:386). These *heiau* are often utilized for prayer and meditation, which could explain the lack of cultural materials recovered during excavations of the site.

Examples of other agricultural *heiau* include Kaneaki Heiau in Makaha (O'ahu) and Pahua Heiau in Hawaii Kai (O'ahu). The differences between these agricultural *heiau* and the one documented herein are quite vast though, in terms of monumental construction. While the size of each may be similar, the actual construction was vastly different. Many *heiau*, including the ones mentioned for O'ahu above, often consist of massive amounts of rocks, multiple courses of rocks piled many meters high, and which stand out in complexity and breadth. However, there are many exceptions as *heiau*, in the broader sense, can encompass smaller structures such as small agricultural *heiau* and *ahu*. The current Site -2250 enclosure fits more into this latter
category as it is only monumental in size, not construction, is rather compact, and its outline is clearly defined. The north, east and west walls are two to three courses wide and two to three courses high. Located at the north corner entrance and the bend in the western wall both are upright, small boulders. In terms of energy expenditure, what is viewed today would not have taken much labor to create. However, the structure is solidly constructed and is at present in good condition. The walls are too low for this to have served as an animal pen. Heiau in the area, as noted above, were deconstructed to create cattle pens, pens with much higher walls and greater enclosure space. A cluster of LCA settlements were located several hundred meters to the south of the heiau. It is possible that Site -2250 is associated with some activity from those households. However, Site -2250 is placed at the base of the slope off the ridge, amidst a scattering of boulders that may have been too numerous to move, or that moving them was unnecessary as they were located within a woodland valued for its resources. The structure being built in this location, where it was unnecessary and impractical to dismantle, as well as a healthy respect by residents for something built by their ancestors, may have led to the preservation of this site. That the archaeological record of the site did not allow for dating, due to the lack of cultural materials, charcoal, coral, or midden, will undoubtedly ensure some conversation on the chronology of the site.

Site -3094 consists of a previously identified petroglyph rock, with two other petroglyph rocks (designated as Feature 2 and Feature 3), having been identified during the current survey. Feature 1 is a large petroglyph boulder. Feature 2 is either exposed bedrock or a buried boulder with two petroglyphs visible located 20 m southeast from, and in the same clearing as Feature 1. Feature 3 is located approximately 70 m to the northeast of Feature 1, and is at the base of the wooded slope, with several pecked figures. The petroglyphs are interpreted to be pre-Contact features. Feature 1 is perhaps the most interesting, having a large number of petroglyphs around the rock faces, as well as mortars and carved lines on the top of the rock. During a community site visit in February 2105, a gentleman (K. Pike) noted that the curved lines on the top of the rock, leading from a circular mortar, could indeed be a map of a water spring in the area, with the curved lines representing a drainage. He stated that it could also be that offerings were placed in the mortar, and would “flow” down the curves and back into the lands. Both were viable interpretations and could be equally appropriate.

HISTORIC PERIOD SITES

The remaining sites documented during this AIS within and outside the project area formed an interesting network of features, all associated in some manner with the intensive cultivation of sugar cane in the valley. For example, the two retaining walls, Sites -2254 and -
supported the stream banks so water could continue to flow unimpeded, and are located within two different stream bed branches upstream of where the two braid together forming the main course of Māhā‘ulepū Stream. Both are walls constructed of dry stacked sub-angular basalt cobbles and boulders built into the face of the stream bank and upon earthen terraces at the base of slope into their respective stream beds. Site -2254 appears to be primarily intact. Site -2257 has partially collapsed at its western end but the remainder appears solid. These walls have weathered the course of time well. Of note is that the stream bed containing Site -2254 has been modified in recent years by the construction of Site -2255, four culvert bridges for the conveyance of agricultural equipment. This stream bed was nearly empty of gravels, cobbles, or boulders.

The stream bed containing Site -2257 had an associated historic-era feature, Site -2256, a concrete bridge with retaining walls of boulder sized quarried basalt blocks mortared together with concrete. These retaining walls appear to be contemporaneous with the bridge but appear to post-date Site -2257. Additionally, the stream containing Sites -2256 and -2257 has an abundance of water worn gravels and cobbles, and sub-angular basalt cobbles and boulders strewn along the bed, from where the stream enters the valley to its junction with the other branch of the stream. The mixture of water worn and sub-angular basalt suggests that this stream bed was not so thoroughly modified during plantation operations. It is possible that the function of both of these retaining walls may be related to mid-19th century LCA activities in the valley. The remaining sites consist of features also constructed during various phases of the development of sugar cane cultivation within Māhā‘ulepū Valley. State Site 50-30-10-2261 is a good example of this. The northern component of the bridge is constructed of boulder sized quarried basalt blocks, with an inscription into its concrete surface giving the date “1908”. The southern component is constructed of concrete, with an inscription on the southern face of the curb giving the date “1951”. Furthermore, this southern curb has a metal rail constructed of a narrow gauge rail road rail. A similar rail is affixed to Site -2260, a bridge that also has the date “1951” inscribed into face of its concrete curb. As stated above, Site -2257 has two components, retaining walls of boulder sized quarried basalt blocks mortared together, and a concrete bridge mounted upon them.

All of these are examples of development of the plantation infrastructure proceeding through phases. Quarried basalt walls mortared together post-date traditional dry stacked construction utilizing sub-angular basalt cobbles and boulders. These walls built of quarried basalt in turn pre-date infrastructure built of concrete, but could, as in the case of Sites -2257, and more dramatically, Site -2261, be incorporated into more recent efforts to update the infrastructure of the plantation. Similarly, the utilization of rail road rails into these updates is
telling. The steam driven sugar cane railroads were utilized during the late 19th and early 20th centuries, post-dating the use of draft animals. The rail road lines were designed to be transported and laid into fields where needed during harvest. The use of the rail coincided with the use of steam-powered tractors, which also took over from draft animals. The age of steam came to an end in the third decade of the 20th century, and was replaced by gas, diesel and oil powered vehicles. The use of trucks required the improvement of the infrastructure, in the form of more bridges and roads. As the 20th century proceeded, so too did the improvement in size and power of these vehicles, once again requiring the improvement of the infrastructure. While rail roads were no longer necessary, the rails could still be used in new ways.

The date “1951” inscribed on two bridges is another indicator of change. The plantation flourished with the world economy, doing well in the early 20th century up until The Great Depression. Followed by the tumult of World War II, it would have been a leaner decade for landowner Koloa Plantation than hoped for. This may have led to the sale of the plantation from Koloa Plantation to Grove Farm in 1948. Improvement of the infrastructure by the new owners is marked by the inscription of the date, “1951” during which some of these improvements occurred.

The development of fuels for engines beyond steam power also allowed for improvements to irrigation. Not having to rely on gravity, rainfall, wind power or steam engines, wells could be drilled and the water pumped from well stations into places such as Site -2258, the Māhā'ulepū Reservoir. From the Reservoir, ditches, probably existing from earlier phases, were improved to carry increased flow along the valley edges and directed into desired areas.

That the valley was intensively transformed for the industrial-level of sugar cane cultivation is well documented. The many bridges, culverts, ditches, and sluice gates all speak to the incredible management, especially of water to the thirsty sugar cane, needed to produce such a crop. While the landscape contains such infrastructure, it was also destructive to the earlier archaeological record. Such massive landscape changes often results in the destruction of earlier sites, such as kuleana walls, mounds, enclosures, and other residential structures. Such is the tide of change. The importance of the Plantation era to the economics and lifestyle of the 19th and 20th centuries in Māhā'ulepū and the greater Kōloa region is vastly important to understanding the entire chronology and land use of the area.

The primary 20th century modification to the valley was the drilling of wells to feed the Māhā'ulepū Reservoir. Ditches discovered during the AIS led to and from the northern and southern ends of the reservoir, with pipelines extending to the ditch that paralleled the Māhā'ulepū stream course. Clearly, the reservoir was taking water out of the valley to other fields of the Kōloa area plantation. There is no evidence that these modifications were built on
the backs of historic or traditional irrigation systems. It must be kept in mind that the intensity of sugar cane cultivation operations erased a great deal of evidence of previous occupation.

Sugar cane cultivation required plowing operations that could reach depths of up to 1 meter below ground surface. Nearly one hundred years of these operations have scoured the Māhāʻulepū Valley floor. No cultural materials of any era were found during pedestrian survey of the valley floor. Areas identified on historic maps as having been wells and pumping stations, as well as LCA settlements had no materials or artifacts which could be attributed to the former occupants.

However, it has been borne out by the current research, in some areas, the deeper past is preserved, both within the fields and on their outer reaches. Site -3094 and Site -2250 remain intact and are thought to represent pre-Contact ceremonial pursuits. That Feature 1 of Site -3094 boulder was preserved, when all around it sugar cane was cultivated, speaks to its importance. Intensive transformation occurred in the valley, which is why Feature 2 of Site -3094 was such an interesting find: it occurred beneath the grasses, in the only location which mechanical stratigraphic test trenching showed not to have been impacted by sugar cane cultivation.

TRAILS

The Kaua‘i lead archaeologist (SHPD) and community emphasized the need to consider potential trails in the area, particularly those that would lead to the top of the ridgeline to the east. Given reports of Keolewa Heiau possibly located atop Mount Ha‘upu, and the former Hanakalauea Heiau within the valley (outside the current project area), this could suggest that pre-Contact/Historic era trails may have once connected the project area to the upper ridgeline. The ridgeline itself has also been considered as culturally significant by some. Despite ethnographic accounts of Keolewa Heiau, there are no direct observations of such a religious structure; and it may be that the crest of the mountain was regarded as holy but no structure was ever constructed and sanctified through ceremony to make it so. A limited field inspection by SCS crew to the summit in December 2015 did not discover any definitive structural elements typically associated with heiau construction.

Formal survey was conducted of the extended survey area, and informal survey was also conducted along the base of the valley's slopes and up toward the ridgeline to the north and east to ascertain the presence/absence of trails to the ridgeline. The crew hiked to just below the summit of the northern and eastern ridgelines, which proved to be inaccessible from this location. Although a modern trail can be observed in Google Earth imagery (2014) from the summit proceeding down the southern ridge, it is likely that the trail continues south along the eastern ridge of Māhāʻulepū Valley towards Puʻu Keke and does not connect to the project area.
An SCS crew field visit was completed on June 19, 2015 to the location where the word “Path” was marked on Registered Survey Map #1898. Given that the possible path shown in the survey map was marked slightly on the mauka side of a land division which still exists today, the map was georeferenced to existing TMK and physical landscape features and the path location was exported to a GPS for relocation in the field.

Upon arriving at the precise georeferenced location, it was apparent that the possible path was situated directly on the uphill side of a former historic period agricultural ditch. Both flume and lock components which functioned to control the flow of water into the field were visible in the vicinity of the possible path. On the uphill side of the ditch is a fence and on the uphill side of the fence, and following it, is a flattened area which served the maintenance of the fence. The flume, fence, and maintenance path continue northwest towards the former reservoir and southeast towards Pu'u Keke. Mauka (east) of the agricultural infrastructure the land becomes rapidly and increasingly steep and is crisscrossed with informal game trails and erosional gullies. No evidence was found that a path or any other cultural feature was located above the area where the agricultural infrastructure flanks the field.

Finally, SCS had the pleasure of sitting down and listening to Mr. James Case, born and raised in Kōloa and now 95 years of age. The extremely sharp Mr. Case presented a fascinating background of the Kōloa area, from his birth in 1920 through the plantation days and into the present. Of particular interest was a focus on his knowledge of trails in the area. Mr. Case, who was born on Grove Farm and grew up in Kōloa across the street from Wilcox Dairy, and had walked all over Kōloa and beyond as a child/teenager, and later, as a professional surveyor (prior to getting into law). He explored all the reaches of Māhā'ulepū Valley and even swam in the reservoir as a young boy.

Per trails in the Māhā'ulepū area, Mr. Case emphatically stated that he was unaware of any formal trails in or out of the valley. He reasoned that a) during the early days, it was easier to move by canoe on the ocean than by foot through the mountains; and b) all folks ascending the mountains would have used the Kōloa Gap, and not attempted to climb the ridges of Māhā'ulepū and beyond. He knew of many trails from Kipukai to Nawiliwili but none in Māhā'ulepū. He noted that, to his knowledge, there was no trail on top of the ridges around Māhā'ulepū as the east-west transition for all was indeed the Kōloa Gap.

Of additional interest, Mr. Case talked with SCS about land use through time and was not surprised that mainly historic sites were documented. He reasoned that sugar cultivation utilized a ratoon system for sugar cane cultivation, with deep excavation (to 4-5 feet below surface) and raising of furrows and mounds c. 6 feet apart across the surface. He noted that every 6 years the
land was plowed for new crops, inferring that after so many decades of doing this intrusive work, it was unlikely any traces of former activities would be present.

Overall, there was no empirical evidence on the ground for any trails connecting the project area or the extended survey area to the eastern or northern ridgelines, especially the former, which would be a direct route to Mount Ha'upu. Only sporadic pig trails were present. These animal trails lead to dead ends below steep cliffs and slopes. However, there are easier ways to gain the heights of the ridge, and traditional occupants may not have found it necessary to access the steep eastern and northern valley walls to gain access to the ridgelines above.

Older maps also do not show access routes up to the ridgeline (see above). It is worth noting that when a prior survey was conducted of the ridgeline itself, no trails were evident and archaeologists had to be dropped by helicopter and cleared their way through the survey area (McMahon 1996). The only sign of any possible trail was found in Registered Survey Map #1898 which noted the presence of a “Path.” This may simply have referred to a survey point on the ditch and not an actual trail.

Another line of evidence was that older generations may recall trails in the area. An interview with Mr. James Case, formerly born and raised in the area, substantiated that he had no knowledge of any trails or paths in the Māhā'ulepū area. Similarly, none of the other parties that were consulted in connection with the AIS provided any information about any trails (nor has any such information been discovered through the interviews conducted for the Cultural Impact Assessment).

In total, the findings of the AIS were as somewhat predicted, given the intensive land use during the 19th and 20th centuries in the project area. It was also interesting to note that the heiau was identified, and occurred in non-cleared areas above the project area flat lands. Plantation-era features dominate the current landscape, as expected, given the industrial nature of the cultivation and process. It is within this vein that the proposed project would move forward, also potentially utilizing the soils and infrastructure (ditches, etc.) created during this large-scale land alteration period.

**ASSESSMENT OF PROJECT EFFECT ON HISTORIC SITES**

In total, none of the 16 sites will be adversely affected by the proposed project, but safeguards will be in place. Those sites related to historic era sugar cane activities will not be adversely affected by the proposed project but may be adaptively re-used. These are presented in Table 2, as well as avoidance measures to minimize negative impacts to the sites.
SIGNIFICANCE ASSESSMENTS AND RECOMMENDATIONS

All sixteen (16) sites documented (and re-identified) during the current AIS have been evaluated for significance according to the criteria established for the State and National Register of Historic Places. The five criteria are listed below:

**Criterion A:** Site is associated with events that have made a significant contribution to the broad patterns of our history;

**Criterion B:** Site is associated with the lives of persons significant to our past;

**Criterion C:** Site is an excellent site type; embodies distinctive characteristics of a type, period, or method of construction, or represents the work of a master, or possesses high artistic values, or represents a significant and distinguishable entity whose components may lack individual construction;

**Criterion D:** Site has yielded or has the potential to yield information important in prehistory or history;

**Criterion E:** Site has cultural significance; probable religious structures or burials present (State of Hawai‘i criteria only).

Table 2 summarizes descriptive information on the sites, their significance, and recommendations. The sixteen historic properties have been assessed for significance and recommendations for mitigation. Two of the sixteen sites have been evaluated as significant under multiple criteria but occur outside the project area. Neither site will be adversely affected by the current proposed project. No further work is recommended for the rest of the sites as all relevant information has been drawn from these sites. Finally, as no anticipated project effects are postulated, no further mitigation is recommended for the project area.

INTRODUCTION

At the request of Hawaii Dairy Farms LLC, Scientific Consultant Services, Inc. prepared a Cultural Impact Assessment (CIA) of a 557-acre property in advance of proposed improvements for a proposed dairy farm property located within Māhāʻulepū Valley, Māhāʻulepū Ahupuaʻa, Kōloa District, Island of Kauaʻi. The property is owned by Mahaulepu Farms LLC and comprises TMK: (4) 2-9-003-001 por. & 006 por. and (4) 2-9-001:001 por. (Figures 1 and 2).

The Constitution of the State of Hawaiʻi clearly states the duty of the State and its agencies is to preserve, protect, and prevent interference with the traditional and customary rights of Native Hawaiians. Article XII, Section 7 (2000) requires the State to “protect all rights, customarily and traditionally exercised for subsistence, cultural and religious purposes and possessed by ahupuaʻa tenants who are descendants of Native Hawaiians who inhabited the Hawaiian Islands prior to 1778.” In spite of the establishment of the foreign concept of private ownership and western-style government, Kamehameha III (Kauikeaouli) preserved the peoples traditional right to subsistence. As a result in 1850, the Hawaiian Government confirmed the traditional access rights to Native Hawaiian ahupuaʻa tenants to gather specific natural resources for customary uses from undeveloped private property and waterways under the Hawaiian Revised Statutes (HRS) 7-1. In 1992, the State of Hawaiʻi Supreme Court, reaffirmed HRS 7-1 and expanded it to include, “native Hawaiian rights…may extend beyond the ahupuaʻa in which a Native Hawaiian resides where such rights have been customarily and traditionally exercised in this manner” (Pele Defense Fund v. Paty, 73 Haw.578, 1992).

Act 50, enacted by the Legislature of the State of Hawaiʻi (2000) with House Bill (HB) 2895, relating to Environmental Impact Statements, proposes that:

…there is a need to clarify that the preparation of environmental assessments or environmental impact statements should identify and address effects on Hawaiʻi’s culture, and traditional and customary rights… [H.B. NO. 2895].

Articles IX and XII of the State constitution, other state laws, and the courts of the State impose on government agencies a duty to promote and protect cultural beliefs and practices, and resources of Native Hawaiians as well as other ethnic groups. Act 50 also requires state agencies and other developers to assess the effects of proposed land use or shoreline developments on the “cultural practices of the community and State” as part of the HRS Chapter 343 (2001) environmental review process.
Figure 1: USGS Quadrangle (Lihue 1996; 1:24,000) Map Showing Project Area Location.
Figure 2: Tax Map Key [TMK: (4) 2-9-003] Map Showing Project Area Location.
It also redefined the definition of “significant effect” to include “...the sum of effects on the quality of the environment, including actions that irrevocably commit a natural resource, curtail the range of beneficial uses of the environment, are contrary to the State's environmental policies . . . or adversely affect the economic welfare, social welfare or cultural practices of the community and State” (H.B. 2895, Act 50, 2000). Cultural resources can include a broad range of often overlapping categories, including places, behaviors, values, beliefs, objects, records, stories, etc. (H.B. 2895, Act 50, 2000).

Thus, Act 50 requires that an assessment of cultural practices and the possible impacts of a proposed action be included in Environmental Assessments and Environmental Impact Statements, and to be taken into consideration during the planning process. As defined by the Hawaii State Office of Environmental Quality Control (OEQC), the concept of geographical expansion is recognized by using, as an example, “the broad geographical area, e.g. district or ahupua’a” (OEQC 2012:12). It was decided that the process should identify 'anthropological' cultural practices, rather than 'social' cultural practices. For example, limu (edible seaweed) gathering would be considered an anthropological cultural practice, while a modern-day marathon would be considered a social cultural practice.

Therefore, the purpose of a CIA is to identify the possibility of ongoing cultural activities and resources within a project area, or its vicinity, and then assessing the potential for impacts on these cultural resources. The CIA is not intended to be a document of in-depth archival-historical land research, or a record of oral family histories, unless these records contain information about specific cultural resources that might be impacted by a proposed project.

According to the Guidelines for Assessing Cultural Impacts established by the Hawaii State Office of Environmental Quality Control (OEQC 2012:12):

The types of cultural practices and beliefs subject to assessment may include subsistence, commercial, residential, agricultural, access-related, recreational, and religions and spiritual customs. The types of cultural resources subject to assessment may include traditional cultural properties or other types of historic sites, both manmade and natural, which support such cultural beliefs.

The meaning of “traditional” was explained in National Register Bulletin:

"Traditional” in this context refers to those beliefs, customs, and practices of a living community of people that have been passed down through the generations, usually orally or through practice. The traditional cultural significance of a historic property then is significance derived from the role the property plays in a community's historically rooted beliefs, customs, and practices. . . . [Parker and King 1990:1]
This CIA was prepared as much as possible in accordance with the suggested methodology and content protocol in the Guidelines for Assessing Cultural Impacts (OEQC 2012:11-13). In outlining the “Cultural Impact Assessment Methodology,” the OEQC (2012:11) states that:

…information may be obtained through scoping, community meetings, ethnographic interviews and oral histories…

This report contains archival and documentary research, as well as communication with organizations having knowledge of the project area, its cultural resources, and its practices and beliefs. An example of the letters of inquiry is presented in Appendix A. Copies of the posted newspaper notice and the affidavit are presented in Appendix B. An example of the follow-up letter of inquiry is presented in Appendix C. The signed information release form is presented in Appendix D. This CIA was prepared in accordance with the suggested methodology and content protocol provided in the Guidelines for Assessing Cultural Impacts (OEQC 2012:13), whenever possible. The assessment concerning cultural impacts may include, but not be limited to:

A. Discussion of the methods applied and results of consultation with individuals and organizations identified by the preparer as being familiar with cultural practices and features associated with the project area, including any constraints or limitations which might have affected the quality of the information obtained.

B. Description of methods adopted by the preparer to identify, locate, and select the persons interviewed, including a discussion of the level of effort undertaken.

C. Ethnographic and oral history interview procedures, including the circumstances under which the interviews were conducted, and any constraints or limitations which might have affected the quality of the information obtained.

D. Biographical information concerning the individuals and organizations consulted their particular expertise and their historical and genealogical relationship to the project area, as well as information concerning the persons submitting information or interviewed their particular knowledge and cultural expertise, if any, and their historical and genealogical relationship to the project area.

E. Discussion concerning historical and cultural source materials consulted, the institutions and repositories searched and the level of effort undertaken. This discussion should include, if appropriate, the particular perspective of the
authors, any opposing views, and any other relevant constraints, limitations or biases.

F. Discussion concerning the cultural resources, practices and beliefs identified, and, for resources and practices, their location within the broad geographical area in which the proposed action is located, as well as their direct or indirect significance or connection to the project site.

G. Discussion concerning the nature of the cultural practices and beliefs, and the significance of the cultural resources within the project area affected directly or indirectly by the proposed project.

H. Explanation of confidential information that has been withheld from public disclosure in the assessment.

I. Discussion concerning any conflicting information in regard to identified cultural resources, practices and beliefs.

J. Analysis of the potential effect of any proposed physical alteration on cultural resources, practices or beliefs; the potential of the proposed action to isolate cultural resources, practices or beliefs from their setting; and the potential of the proposed action to introduce elements which may alter the setting in which cultural practices take place.

K. A bibliography of references, and attached records of interviews which were allowed to be disclosed.

If ongoing cultural activities and/or resources are identified within the project area, assessments of the potential effects on the cultural resources in the project area and recommendations for mitigation of these effects can be proposed.

ARCHIVAL RESEARCH

Archival research focused on a historical documentary study involving both published and unpublished sources. These sources included legendary accounts of native and early foreign writers; early historical journals and narratives; historic maps; land records, such as Land Commission Awards, Royal Patent Grants, and Boundary Commission records; historic accounts; and previous archaeological reports.
INTERVIEW METHODOLOGY

Interviews are conducted in accordance with Federal and State laws and guidelines when knowledgeable individuals are able to identify cultural practices in, or in close proximity to, the project area. If they have knowledge of traditional stories, practices and beliefs associated with a project area or if they know of historical properties within the project area, they are sought out for additional consultation and interviews. Individuals who have particular knowledge of traditions passed down from preceding generations and a personal familiarity with the project area are invited to share their relevant information concerning particular cultural resources. Often people are recommended for their expertise, and indeed, organizations, such as Hawaiian Civic Clubs, the Island Branch of Office of Hawaiian Affairs (OHA), historical societies, Island Trail clubs, and Planning Commissions are depended upon for their recommendations of suitable informants. These groups are invited to contribute their input and suggest further avenues of inquiry, as well as specific individuals to interview. It should be stressed again that this process does not include formal or in-depth ethnographic interviews or oral histories as described in the OEQC's Guidelines for Assessing Cultural Impacts (2012). The assessments are intended to identify potential impacts to ongoing cultural practices, or resources, within a project area or in its close vicinity.

If knowledgeable individuals are identified, personal interviews are sometimes taped and then transcribed. These draft transcripts are returned to each of the participants for their review and comments. After corrections are made, each individual signs a release form, making the interview available for this study. When telephone interviews occur, a summary of the information is usually sent for correction and approval, or dictated by the informant and then incorporated into the document. If no cultural resource information is forthcoming and no knowledgeable informants are suggested for further inquiry, interviews are not conducted.

HAWAII DAIRY FARMS PROJECT DESCRIPTION¹

Hawai‘i Dairy Farms, LLC (HDF) was formed as a positive step toward the island state’s food security, economic diversity, and sustainability. Experimental trials were conducted to determine lands capable of growing nutritious forage for dairy cows, and lands meeting the operational requirements for a dairy operation were identified. Kaua‘i was determined to best meet the operational requirements, and Māhā‘ulepū Valley was found to provide ideal growing conditions.

At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually at market price. HDF will reduce

¹ Text for this section provided by Group 70 International.
Hawaii's reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawaii. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows' health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State Department of Health is required. The application process for a National Pollutant Discharge Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

**LANDFORM, SOILS, AND VEGETATION**

The mountain range that flanks the surveyed area to the north and northeast are composed of the most ancient volcanic series in the high islands, the Waimea Canyon Basalts (NPS 2008:11). These formed during the shield-building stage of the Kaua'i volcano, as eruptions gradually built up its sides and widened its base. Most of the range is part of the ancient Napali member of the Waimea series, dating from 4.35 to 5.1 million years ago. The caldera of Mount Ha'upu is a separate geological feature from the rest of the range and remains undated (Blay and Siemens 2004).

Māhā'ulepū lands below Ha'upu ridge are part of the Kōloa series that cloaks most of the eastern half of Kaua'i. The series formed as the Kaua'i volcano ceased major eruption and began to erode, with occasional small eruptions at lava domes, cinder cones, and spatter cones. These produced a layer of lava that, though not large in mass, nevertheless covered a large area. Kōloa volcanics within the study area at Māhā'ulepū include both underlying lava and visible vents, ranging from 0.5 to 2.0 million years in age (Blay and Siemens 2004).

Portions of the valley's slopes have been identified as Rockland (rRK; Foote et al. 1972: Sheet 32). This is composed of areas where exposed rock covers 25 to 90 percent of the surface.
Rock outcrops and very shallow soils are the main characteristics. The rock outcrops are mainly basalt and andesite. Elevations range from near sea level to more than 6,000 feet, with annual rainfall amounts between 15 to 60 inches. The vegetation at lower elevations consists mainly of *kiawe*, *klu*, *piligrass*, Japanese tea and *koa haole*.

Soils on the slopes of the valley are also associated with the KEHF series or Kalapa very rocky silty clay (Foote *et al.* 1972: Sheet 32). This is a well-drained soil that occurs at the base of slopes and is associated with moderately sloping to very steep topography. Elevations range from 200 to 1,200 feet above sea level, with annual rainfall amounts between 60 to 100 inches. Associated vegetation consists of guava, *lantana*, sensitive plant, *pilipiliula*, *ohia*, Japanese tea, and ferns.

Soils within the valley have been classified as LPE or Lualualei Series, composed of extremely stoney clay (Foote *et al.* 1972: Sheet 32). This series consists of well-drained soils on the coastal plains, alluvial fans, and on talus slopes. They are nearly level and gently sloping. Elevations range from 10 to 125 feet above sea level, with annual rainfall amounts to 50 inches per year. There is a prolonged dry spell during the summer. These soils are associated with sugarcane, truck crops, pasture, wildlife habitat, urban development, and military installations on Kaua’i. Associated vegetation consists of *kiawe*, *koa haole*, bristly foxtail, *uhaloa*, and fingergrass. This soil type, extremely stoney clay, was identified in several trenches during the AIS, with most stratigraphic trenches excavated on the valley floor being composed of a shallow O-horizon overlaying brown/yellow clays. In other words, there are exceptions to the general soil survey.

Twelve different soils within Māhā’ulepū Valley are identified on a USGS/USDA Soil Map kindly provided to the field crew by HDF (NRCS 2014). The soils map depicts the various soil regimes across the valley floor; these soil differences are most likely a product of water, whether through transport, ground water, or run-off deposition. During pedestrian survey of areas with sparse or no ground vegetation, the transition of soils was visibly recognizable.

The project area has been utilized for commercial sugar cane cultivation and/or livestock pasturage since the middle of the 19th century and is fairly clear of vegetation. Most of the project area lies fallow with the soils exposed. Some of the areas are covered with grasses up to 0.3 m tall, and smaller areas at the northeast and northwest ends of the valley are 100% covered by grasses up to 2.0 m tall. Within the surveyed area are few scattered *koa haole* and java plum trees. These occur outside the main valley footprint/project area, which has been extensively cleared for well over a hundred years. The slopes of the valley outside the project area are forested.
TRADITIONAL AND HISTORIC SETTING

Early settlement and agricultural development is thought to have first occurred on the windward sides of the Hawaiian Islands, including Kaua‘i, sometime in the A.D. 900-1000 range during what is known as the Colonization Period (Kirch 2011:22). Most likely arriving from east Polynesia, these early inhabitants brought with them a variety of tools, fishing gear, and household goods. Dogs, pigs and chickens were brought by these Polynesian voyagers for food. The Polynesian rat also arrived with the voyagers, but whether these were intentionally transported as a food source is unclear. Considering that every food crop cultivated by the Polynesians arrived with them, it is evident that these people had considerable knowledge not only regarding how to plant and harvest these crops, but also how to transport the crops' seeds, cuttings, and roots.

Prior to European Contact in 1778, Hawaiians cultivated taro in both irrigated and dry fields. Other dryland agriculture crops included ‘uala (sweet potato), uhi (yams), maia (bananas), ipu (gourds), and ko (sugar cane). Grasses were utilized for thatching the roofs of structures and covering floors, which were then covered by hala (pandanus) mats. Hala was also used in the making of matting and sails. Important arboreal crops included niu (coconut) and ulu (breadfruit). Other trees were utilized for the construction of canoes, house frames, tools, and weapons. Kapa cloth from wauke (paper mulberry) was also tended. There were a variety of medicinal plants utilized and plants, such as olona, grown to provide fibers for making cordage (Handy and Handy 1972).

Hawaiian aquaculture was extensive, and included the construction and maintenance of coastal and riverine fish ponds. Fishing ranged from shoreline to pelagic, with different strategies for each. In order to maintain and benefit from all of these resource zones, Hawaiian polities were organized into ahupua‘a, which gave residents access to a wide array of resources extending from mountain top forests to deep sea fishing zones. An ahupua‘a was an ancient land division that ran from the ocean to the mountains and allowed those living there to proffer from all the different environmental zones of the land. Ahupua‘a boundaries could expand, contract, appear, and disappear, depending upon political events. Given the size of Māhā‘ulepū Valley, Māhā‘ulepū Ahupua‘a was highly valued.

PRE-CONTACT ERA

Initial Polynesian settlement of Kaua‘i occurred in the resource-rich regions surrounding Wailua River on the east coast; the equally verdant Waimea River region on the southern coast; and the Hanalei region on the north coast (Joesting 1984). As with all the Hawaiian Islands, each district and region was eventually settled. These settlements developed into polities which allied,
warred, and co-existed with one another until Kaua'i came under unified rule of a single king. This process occurred in different stages on different islands. Because of the relative distance of Kaua'i from O'ahu, Moloka'i, Maui, Lana'i, and Hawai'i Island, the polities of Kaua'i and her neighbor Ni'ihau became their own entity, while the other islands struggled first for internal control and later, for the conquest and rule of several, and ultimately all, the islands.

The primary residence of the high king was in the Wailua River region of Kaua'i, with miles of cultivated lands, mountain resources, religious sites, and shoreline to pelagic fishing. Broad stretches of beach allowed for canoe landings but there was no deep water anchorage, despite the presence of the Wailua River.

Initial settlement is presumed near the coastline in the A.D. 1000-1200 range, with expansion inland during the A.D. 1400-1600s, as was typical across the islands (see Kirch 1985). Agricultural field systems were created at these inland areas, closer to fresh water resources and soil more amenable to kalo and sweet potato production. Permanent habitation locales were present from the coast to this more inland area, with ceremonial sites, walls, and other associated structures being built. Within the mountainous areas, such as at the back of Māhā'ulepū Valley, temporary habitation loci such as rock shelters/caves or small enclosures (C-shapes) were utilized by those gathering upland resources. The middle zone, between the coastlines and mountains, such as Māhā'ulepū, was ideal for agriculture and homesteads, as witnessed by the numerous LCA's occurring in a small section of the valley later. However, historic land use obliterated much of the archaeological signatures for these settlements.

In early 1778 Captain James Cook and the two ships under his command, H.M.S. Resolution and H.M.S. Discovery arrived off of Kaua'i. Finding that they could not make landfall at Wailua, Cook continued westward until reaching Waimea. This would be the beginning of contact between Europeans and Hawaiians (Salmond 2003).

WAHI PANA (LEGENDARY PLACES)

Māhā'ulepū literally translates as “and falling together” (Pukui et al. 1974:138), a likely reference to the ridges flanking the sizable valley. Handy and Handy (1972:427) describe Māhā'ulepū as a

Broad, rich valley with a broad bottom, not planted with sugar cane but no doubt it was once had some lo'i. The area is in the lee of the …Waialeale mountain. Some inferior taro was grown in mounds (pu'epu'e) in semibrackish spring water in the lower valley.

According to Wichman (1998:47-48), the name “Māhā'ulepū” refers to a great battle that occurred in Māhā'ulepū in the 1300s. Kalaunuiohua, an ali'i from the island of Hawai'i, was
attempting to conquer all of the Hawaiian Islands. He had already succeeded in gaining control over the islands of Maui, Moloka'i, and O'ahu and was carrying the ruling ali'i from those islands with him as prisoners when he set sail for Kaua'i. Kūkona, the ruling ali'i of Kaua'i at that time, was aware of the coming invasion and placed his warriors in the mountain ridges above and his canoes in Hanapēpē Bay where they could not be seen. Wichman (1998:47-48) describes the battle as follows:

[Kūkona] allowed Kalaunuiohua to land unopposed and soon the Hawai'i canoes were drawn up on the beach, the royal prisoners safely housed, and all the invading warriors formed into their fighting order. Then Kūkona, dressed in full royal regalia of helmet and cloak and with his Kāhili towering above him, appeared on the ridge above. Kalaunuiohua hurried to meet his enemy, but when he arrived, no chief was there. Then, a shout was heard, and Kalaunuiohua saw Kūkona on the neighboring ridge. From ridge to ridge, Kūkona drew his invaders farther and farther from the beach, until they reached the plains of Wahiawa. Here Kūkona ordered his army to attack, and the invading army, stretched thinly over so many miles, was easily defeated.

Meanwhile, Kūkona's canoe fleet sped from Hanapēpē and caught the invading canoes before they even had time to launch them again. In the fierce battle between canoes, blood flowed freely. Only one enemy canoe managed to escape to bring the dreadful news back to their home island. By nightfall, Kalaunuiohua's was gone and he was a prisoner. The other royal prisoner's had been found, and Kūkona found himself in the position of being able to take command of all the islands. While he decided what to do, he took his captured chiefs on an extended tour of the island.

Subsequently, significant landmarks in the area were named after events from this battle. The ridge beneath which the invading canoes met their demise became known as “Kawelikoa” (terror of the warriors), the cape where the invading army beached their canoes and came ashore is now known as “Nā‘ākea” (starboard hulls of the double canoe), and the bay is known today as “Papamō‘i (platform of the king) in reference to the ruling ali‘i who encountered each other there.

Māhā‘ulepū Ahupua'a sits in the shadow of Mount Hā'upu (to recollect), a 2,297 foot peak within the Wai'ale'ale Mountain Range. Mount Hā'upu is associated with numerous legends and chants. According to Pukui et al. (1974:187) Mount Hā'upu was possibly named after a demigod. According to legend, there is a legendary stone at located at Ka'ena Point, O'ahu, that was thrown by an ali'i from Kaua'i named Hā'upu (Westervelt in Sterling and Summers1978:93-94). Hā'upu was a great warrior capable of great feats of strength. However, when he was angered he often acted rashly. One night while he was sleeping on the side of a mountain facing O'ahu, he was awakened by shouting. As he looked towards O'ahu he could see numerous lights
out on the water. As he had just awakened from a deep sleep, Hā'upu was not thinking clearing and thought a great fleet of enemy warriors was coming to attack Kaua'i. So, in an effort to defeat the enemy, Hā'upu tore loose a huge boulder and hurled it at the lights and voices killing, many members of a fishing party from O'ahu. The rock thrown by Hā'upu became embedded in the ocean, but as it was so large, the upper portion rose far out of the water. Later, when the demo-god Māui attempted to unite the islands of O'ahu and Kaua'i together, “sea goddesses snagged his hook on this rock.”

Oral traditions reflect the beauty and the prominent role of Mount Hā'upu. The following Hawaiian proverbs, collected, translated, and interpreted by Mary Kawena Pukui (1983) refer to Mount Hā'upu:

Hā'upu mauna Kilohana i ka la'i.
Hā'upu, a mountain outstanding in the calm.

Said of a person of outstanding achievement. Also used in praise of Hā'upu, Kaua'i (Pukui 1983:59).

Ka'i ka pua'a i luna o Hā'upu e au ana.
When the pigs move around the summit of Hā'upu, it is going to rain.

When puffy “pig” clouds encircle the top of Hā'upu, above Kīpū, on Kaua'i, it is a sign of rain (Pukui 1983:151).

Ka'ohu wānana ua o Hā'upu.
The mist of Hā'upu that foretells rain.

When clouds circle the peak of Hā'upu. Kaua'i, it is sure to rain.

**EUROPEAN CONTACT AND THE KAMEHAMEHA DYNASTY**

The third voyage commanded by Captain Cook was undertaken primarily to discover the fabled Northwest Passage, which supposedly linked the Pacific, Arctic, and Atlantic Oceans. As he had during previous journeys, Cook visited Tahiti and it was from there that he set out for the northern Pacific coast of North America.

The voyage put him within sight of the island of O'ahu, but adverse winds prevented his arrival. Continuing on to Kaua'i, he sighted Wailua, but could not make landfall. The ships continued southwest and then westward, past Mount Ha'upu and Māhā'ulepū Valley. Both were sketched and drawn by expedition artist John Webber, the first European artwork to depict a Hawaiian Island.
Cook found a manageable anchorage at the mouth of Waimea River. Several trips ashore by him and a select group of his officers, marines, and crew led to generally good relations with the Hawaiians. It is unclear what Cook and the others learned about the politics of Kaua'i and her eastern neighbor. It is probable that at this time (1778) Kaeokulani was ruler of Kaua'i. He was of high rank, a chief born on Maui, and the half-brother of the paramount king of Maui, Kahekili.

After a short time on Kaua'i in the early months of 1778, Cook departed to continue the search for the Northwest Passage. A year passed after which Cook returned to the Hawaiian Islands. This time, Maui was sited and briefly visited, but the island of Hawai'i became the focus of the remainder of the voyage of Cook and ultimately of his demise, at Kealakekua Bay (Salmond 2003).

After the death of Cook, the journey continued, now under the command of Captain Clerke. The ship passed O'ahu, and returned to Waimea, Kaua'i. After their departure a short time later, it would not be until 1786 that Europeans returned to the Hawaiian Islands, with Waimea (Kaua'i) receiving her share of British and American vessels focusing on the lucrative fur trade in the Pacific Northwest. These visits coincided with, and perhaps accelerated, the growing conflict for control of the eastern islands.

Beginning in approximately 1790, battles on and around Maui, Moloka'i, and Hawai'i Island between several rulers occurred with increasing ferocity. Safely in control of Kaua'i, Kaeokulani became a participant, bringing fleets of warriors to assist his half-brother on Maui. Many European and American ship captains had contact with all the rivals, and a fairly coherent chronology of events is known. What certainly is known is that Kaeokulani was killed during a battle in Honolulu in 1794 while fighting his nephew Kalanikupule, who had taken rule of Maui and O'ahu upon the death of his father Kahekili in Waikiki, several years earlier in 1791 (Ridley 2010).

The son of Kaeokulani was Kaumuali'i. Born around 1780, the young king went through a period where a Regent (an older relative) made the decisions, but Kaumuali'i eventually came to rule on his own. The remainder of his days was spent trying to keep Kamehameha, who had consolidated the rule of the other islands, from bringing Kaua'i in as well.

Kamehameha had difficulty solidifying his rule. Rebellions, plague, and appeasing subordinates all kept him from mounting more than two serious efforts at physical conquest of Kaua'i. The first effort to fail occurred in 1796 when Kamehameha sailed with an invasion fleet for Kaua'i. Hit by a heavy storm, the fleet turned back to O'ahu (Kamakau 1961). The second effort failed in 1804 when Kamehameha mustered his forces on O'ahu, but the army fell victim to *oku'u*, a smallpox epidemic. Kamehameha himself almost died, and far too many of his troops,
counselors, and their families did succumb (Kamakau 1961). In 1810 Kamehameha used diplomacy, suggesting that he rule the eastern islands in name and deed, while Kaumuali'i acknowledge his suzerainty but continue to rule Kaua'i and Ni'ihau. It was agreed that the arrangement would end with the death of Kaumuali'i and that rule would then pass to the heirs of Kamehameha. It was an arrangement that Kamehameha and Kaumuali'i would honor, but that the heirs of Kamehameha would not (Joesting 1984).

This arrangement lasted between 1810 and 1822. It endured the death of Kamehameha the Great in 1819. During these 12 years, Kaumuali'i solidified rule of his kingdom and engaged in efforts to gain foreign weapons and support from the Russian Fur Company (Mills 2002). Also during this time, the trade in sandalwood flourished. Harvested in the Hawaiian Islands, traded for goods to European and American captains, and sold in the Chinese trade ports of Macao and Canton, sandalwood became the first Hawaiian cash crop (Ridley 2010). The Hawaiians called it laau ala (sweet wood) or iliahi (fiery surface) for its reddish blooms. They used this wood for scenting bark cloth, making dyes, and for medicinal purposes (Ridley 2010).

At first, the sandalwood revenue went solely to the paramount chiefs, Kamehameha and Kaumuali'i. However, with the death of Kamehameha, nearly all of his chiefs called upon the young heir, Liholiho, and the Regents, among whom was Ka'ahumanu, the favorite wife of Kamehameha but not mother of his heirs, to allow the chiefs to harvest sandalwood for their own profit. This practice would affect and disrupt the rule of Hawai'i and the welfare of the common people for decades.

The upland forests were scoured, crops were neglected, commoners suffered malnutrition and disease, chiefs went into debt to foreigners, and Liholiho was hard pressed to find new resources for his chiefs to exploit. Kaua'i appeared to be the answer. While continuing to honor the arrangement made by his father, Liholiho arrived on Kaua'i in 1822, visited with Kaumuali'i, and then kidnapped him, returning to O'ahu with his captive. In order to secure the rule of Kaua'i, Kaumuali'i was forced to marry not an heir of Kamehameha, but his wife, Ka'ahumanu. To ensure her hold, she also wed her new husband's son, Keali'iiahonui. This second marriage was later dissolved. However, ties between dynasties stayed strong as Keali'iiahonui married a granddaughter of Kamehameha, named Kekauōnohi (Mills 2002).

Ka'ahumanu had been instrumental in the overthrow of the kapu system of Hawaiian governance and social behavior, as well as one of the earliest and most prominent proponents of conversion to Christianity. That she utilized polyandry to achieve control of Kaua'i is just one example of her abilities to utilize both traditional and introduced ways of life to achieve her goals (Joesting 1984).
While still titular ruler, Kaumuali‘i did not exercise any power. Governors were appointed by the Regents, the first of these being the brother of Ka‘ahumanu, named Kahekili Ke‘eaumoku. Beginning with this Governor, land acquisitions beneficial not just to the Kamehameha line but to their powerful subordinates started.

The practice of allowing individual chiefs to harvest sandalwood was carried over to Kaua‘i. How many Kaua‘i chiefs retained their lands during this time is not certain. What was certain is that the mountains of Kaua‘i, including Ha‘upu, yielded the valuable resource. And practically the only place that it could be shipped was from the only secure anchorage at Waimea River. Waimea also served as a provisioning port of call to the growing number of whaling ships that began to appear in the Pacific.

The independent rule of Kaua‘i came to an end in 1824 with the death of Kaumuali‘i. This same year, the heir of Kamehameha, Liholiho Kamehameha II also died. The kingdom of Hawai‘i would now be ruled by a queen.

THE REGENCY OF KA‘BAHUMANU

Ka‘ahumanu was one of Kamehameha's primary wives, his favorite in fact, but not of sufficient rank to be mother of his heirs. It appears she never bore the king, or anyone else, any children. From her actions following his death in 1819, it is apparent that Ka'ahumanu considered herself Kamehameha's heir. The mother of the heirs, Keopuolani, died in 1823. Her first son was Liholiho, born in 1796, made king in 1819, and died visiting London in 1824. Her second son was Kauikeaouli Kamehameha III, born in 1813. Her daughter, Nahienaena was born in 1815 (Day 1984). With the death of Liholiho and his mother, Ka'ahumanu became Regent of the kingdom until Kauikeaouli would come of age. Her rule of Hawai‘i in general, and Kaua‘i specifically, was adroit, intelligent, and shrewd.

George Kaumuali‘i and a number of Kaua‘i chiefs forcefully resisted the rule of the Kamehameha line, and their revolt was crushed. As with many Byzantine events in Hawaiian history, some Kaua‘i chiefs stood with the old, while others stood with the new. In this case, as with any other, people chose who they thought would benefit them most. Those who rebelled had their lands and lives taken, while those who did not, benefitted.

The first long term governor during the regency was Kaikioewa, a high chief born at Waimea, Kaua‘i. He was a first cousin and brother-in-law of Kamehameha, a guardian of Kamehameha III, and a principal leader in crushing the 1824 rebellion (Mills 2002). He reigned as governor from 1825 until his death in 1839. During his tenure, we know of at least one konohiki, or land manager, for Māhā‘ulepū. Documents show that in 1826, Hukiku was konohiki. He was in attendance that year during a visit by the governor. Kaikioewa was accompanied by
missionary Samuel Whitney of Waimea, who left an account of this event. It is unknown if Hukiku was Kaua'i born, or one of the conquerors invested with this stewardship. He may be the chief Kukiku, who Kaikioewa named commander of Paulaula o Hipo, also known as “The Russian Fort” (Mills 2002).

During his term as governor, Kaikioewa claimed Ha'upu Ridge, to the east/northeast of Māhāʻulepū, as his personal sandalwood reserve. One of the duties Hukiko performed may have been overseeing the efforts to harvest sandalwood from the ridge and transport it to foreign ships at Waimea or Kōloa. Eventually, as did so many other aliʻi, the governor would go into debt to foreign captains and merchants. When the sandalwood ran out, it is not clear how Kaikioewa paid his bills (Joesting 1984).

Kaʻahumanu ruled as Regent until her death in 1831. A daughter of Kamehameha, Kīnaʻu, took over as Regent until 1834, at which time Kauikeaouli Kamehameha III took the throne. He had lived on Kaua'i as a boy under the protection of Kaikioewa but had spent the majority of his youth on Oʻahu. Ruling until his own early death in 1854, his reign was admirable for its civil rights, efficiency, and the creation of the Great Māhele, by which land awards to commoners and granting ownership to the disenfranchised was achieved. In Māhāʻulepū, there were many Land Commission Awards (LCA), discussed below, but the majority of the acreage was retained by the government. During his reign, there was an increase in the number of immigrants from Europe, the United States, and China. Missionaries, merchants, laborers, and farmers of multiple nationalities added to the diversity and complexity of the Kingdom.

LAND COMMISSION AWARDS

The Great Māhele was yet another drastic change in the lives of Hawaiians. Commoners, also known as makaʻainana, had for centuries been allowed use, but denied ownership of the lands they worked. This changed in the late 1840s when private ownership of lands was made into law. Certainly aliʻi, or nobles, had the better of the deal, but commoners were allowed to claim, through right of labor and longevity of occupancy, Land Commission Awards (LCA). King Kauikeaouli Kamehameha III was a sovereign brought up in the old ways who saw that some things must change, and orchestrated this new policy. A legal process was established, in which land claimants testified, and had others support their testimony, before a Commission appointed by the king. Traditional land use was communal and land use was often dendritic, following the course of streams and occupation zones from the coast to the mountains. Claimants were often related and the lands they claimed were as varied in their usage as they were in their location. For a traditional ahupua'a to work, those mauka (towards the mountains) had to work with those makai (towards the ocean). The private ownership offered through the Māhele,
however, created new risks for landowners. A commoner who did not own the land could not go into debt; but, one who did could achieve profit or debt.

Land claim testimonials are complex documents. Boundaries are defined in a variety of ways. Land divisions descend in size from *ahupua'a* to *kuleana* to *'ili*, thence *apana*, and finally *mala*, which are individual garden plots, fields, and/or *lo'i* (Pukui 1957). Other boundaries are defined by names of neighboring occupants or by use of the land. Testimonies were given regarding which chief had granted the occupant use of the land. This is compelling, because occupants claimed title based on grants from Kaumuali'i, last independent king of Kaua'i, to Kaikioewa, governor from 1824 to 1839 for the Kamehameha Dynasty, to his *konohiki* for Māhā'ulepū, Hukiki. They invoked the names of Ka'ahumanu, the Regent for nearly a decade, to Kīna'u, Regent and half-sister to King Kauikeaouli Kamehameha III until he took the throne. Some claims were contested, others were not, and some were won on appeal. When one studies the LCAs of Māhā'ulepū, it can be seen that claims of land, in a variety of places, for a variety of uses, were made by individuals throughout the *ahupua'a*. With modern ownership, a traditional lifestyle could be maintained, but once individual plots began to be sold, and relationships were sundered, life for the commoners and nobles alike began to change drastically.

On Kaua'i, and in Māhā'ulepū Valley specifically, a number of land claims were made by residents who had been allowed use of the land during the reign of the previous king. In the valley, LCA 5080 to Kiko, LCA 4767 to Napaliala, and LCA 4769 to Nahuma, for example, were all claimants who had tenure from Kaumuali'i. It is presumed that their neighbors had similar histories (Ching 1974). That these residents all received their awards is notable because their claims were based on the right of use granted by the former ruler, and not by permission of the Kamehameha Dynasty. An 1896 map of the valley, depicts a “house” and “cattle pen” in the northern part of the valley and the LCA's just below, in what today is the mid-section of the valley (Figure 3). The 1896 map also shows the word “Path”, far above the LCA area. This “path” was fully investigated during the AIS (2016) and shown not to exist (see below). An 1897 survey map by Monsarrat (Figure 4) shows a better view of the LCAs.

Many of LCAs for Māhā'ulepū are tightly clustered within the 'ili of Kawaiola (Figure 5). There is a cluster east of Māhā'ulepū Ditch near the center of the valley. The remainder of the valley was deemed government land. Thus, no LCAs occur elsewhere in the project area or the extended survey area. It is interesting to note the estimated population of this portion of Māhā'ulepū Valley at this time. In 1848, 46 male names appear in genealogical records (M. Ching, LDS Records). If one were to reasonably add one wife and at least one child per household, the population would have been 138 persons. In 1855, a total of 36 male names occur in the Māhā'ulepū records. Using the same figures, the total would have been 108 persons. This
represents a fairly sizeable population for this upper valley at that time, all likely associated with the LCAs.

The following provides a representative sample of names and LCAs that are both present on the LCA map within the project area and are described in previous literature (Ching 1974). Claimants used owners of adjacent lands as boundary references and/or supporters of their claims. Many claimants were related in some way. The claimants of LCAs within the project area often also had additional claims downstream of Māhā'ulepū Ditch on the coast or elsewhere. Thus, only some of the claims discussed (kula lands, etc.) may actually be in the project area. A good example is LCA 5080, where a salt pan is discussed. Such claims related to salt pans would have occurred far outside the current project area near the coastline. In addition, some of the claims also include information about other LCAs claimed by the same person. While somewhat confusing, the summary of records are presented in full here in order to get a clearer picture of the LCAs in and around the surveyed area:

**LCA 4767** Napaliala received his lands in the days of Kaumuali'i, who died in 1824. This was waste land when Napaliala took it over, occupied it, and developed it. He died in the late 1840s and his wife then possessed the land.

**LCA 4769** Nahuma was another native who occupied lands prior to 1824. One piece was waste land when he took it over, built on it, and fenced it with stone. In addition he received on the death of relatives other lands occupied previous to 1824: two (2) lo'i in the 'Ili of Kauki'i, which had belonged to his wife through her parents; 7 dry taro patches in Kioea received through his father-in-law, kula land at Waipa which his brother had taken possession of, planted orange trees and cultivated; and two salt ponds. Nahuma appears to have been an affluent native.

**LCA 4910** Kahee claimed property in the 'Ili of Kapakalehu; this property in the late 1840s had one orange tree. The konohiki contested the title of this property, claiming that Governess Kekaonohi had given it, and two more, to him and that he had cared for them, harvesting the fruit. Kahee never collected the oranges but contends that the governess had no right to give the trees to the konohiki as they had belonged to Kahee's parents, who had planted them and he was the rightful heir. That was the foundation of his claim.

**LCA 5080** Kiko took over waste land, built his own fences and dug his own salt pond in the 'Ili of Kawaiola (Note: the salt pond would be outside the project area, near the coastline). The date of occupancy is not given but it probably was later than Kaumuali'i, for Kiko's lo'i came from Kīna'u's time. Kīna'u was a daughter of Kamehameha, mother of the kings Kamehameha IV and V, and was Regent between the death of Ka'ahumanu and the ascendency of Kamehameha III, her half-brother.

Ching (1974) argues the recovery of waste land mentioned in LCA records was the clearing of previously untouched lands for cultivation. However, Putzi (2014) argues that these
were previously cultivated areas left unattended due to a declining native population, but were brought back into production because of the incentive of individual ownership. It may be that ownership, as well as the threat of feral cattle and pigs, led to the construction of fences of either stone or wooden posts to delineate property boundaries. Other claimants shown on the LCA map were identified in the Mahele Database:

**LCA 4770** Naahuao. The land came to Naahuao through his father, who was granted the land by Hukiku, the konohiki of Māhā'ulepū during the reign of Governor Kaikioewa. He gives his testimony as follows:

Greetings to the Land Commissioners: Be it known to you, the ones who quiet land titles, that I, Naahuao, a man living at Māhā'ulepū, island of Kaua'i have a claim for land, and the kula. The genuine land is 56 fathoms long by 26 fathoms wide. The mala of noni is 26 fathoms long by 13 fathoms wide. The salt land is 6 fathoms long by 4 fathoms wide. Another salt land is 10 fathoms long by 7 fathoms wide. A house lot is 28 fathoms on the long sides and 25 fathoms on the wide side. My message is ended. A respectful farewell to you, Naahuao.

**LCA 6667** Mika received lands from Ahukai (owner of LCA 4543) on the LCA map, but no further information has been gained. Mika received lands from Kaikioewa in the days of Kinau. His testimony reads:

The Land Commissioners, greetings: I, Mika, a Hawaiian subject living in Māhā'ulepū, hereby state my claim for 4 lo'i, 5 sweet potato enclosures, 4 mala of noni, and 3 orange trees. However, these claims are not situated together, but are in various cultivated places of Māhā'ulepū, also 1 mala of uhī/yam/ a kula planting of wauke and one other lo'i. 1 loko/ either fish pond or taro pond/ and 13 lo'i are bounded 80 fathoms on the east, 80 fathoms on the south, 20 fathoms on the west and 10 fathoms on the north. That is my claim which was received from Ahukai. There is also a kula named Hoopouliloa. Respectfully, Mika.

The testimony of Mika says much about how Hawaiians utilized the Māhā'ulepū landscape and environs. Parcels were utilized for the cultivation of several food crops, for raising fish, and the growth of wauke for the production of kapa cloth. Except for the orange trees, this is a classic example of traditional Hawaiian life. The mention of sweet potato enclosures is interesting because 'uala were traditionally raised in long rows of intermittent mounds. It may be that these fields were fenced in to protect them from pigs or cattle, or that land ownership required definitive boundaries.

It is worthy to note that all the LCAs in the Māhā'ulepū project area are confined to a central area, on the east side of Māhā'ulepū Stream, with the remainder of the valley claimed as government lands. These LCAs form a tight cluster. Of additional interest is that during the
height of the sandalwood trade the adjacent Ha'upu Ridge was claimed by Kaikioewa. It would appear that after his death in 1839 these mountain claims would revert to government control.

The Governor of Kaua'i in 1842 was Kekauonohi, the granddaughter of Kamehameha who had wed Keli'ialohi after having been a wife to her uncle Liholiho Kamehameha II. During her governorship, Kekauonohi partook in land exchanges, consolidating her grants in Māhā'ulepū and Kōloa. These consolidated lands would become the basis for the next cash crop – sugar, which, unlike sandalwood, could be rejuvenated and continued. From the 1830s until the 1980s, sugar would be the economic focus of Māhā'ulepū. Remnants of industrial-level sugar cane cultivation in the area represent the greatest number of historic properties documented during the current AIS.

Figure 3: Registered Survey Map #1898 showing location of “House”, “Cattle Pen”, and LCAs in mid-valley. Note: “Path” in map center.
Figure 4: Registered Survey Map #1900 (1897) of LCAs in Māhā'ulepū Valley.
Figure 5: Modern TMK map of Māhā'ulepū Valley depicting LCAs.
The testimony of Mika says much about how Hawaiians utilized the Māhā'ulepū landscape and environs. Parcels were utilized for the cultivation of several food crops, for raising fish, and the growth of wauke for the production of kapa cloth. Except for the orange trees, this is a classic example of traditional Hawaiian life. The mention of sweet potato enclosures is interesting because 'uala were traditionally raised in long rows of intermittent mounds. It may be that these fields were fenced in to protect them from pigs or cattle, or that land ownership required definitive boundaries.

It is worthy to note that all the LCAs in the Māhā'ulepū project area are confined to a central area, on the east side of Māhā'ulepū Stream, with the remainder of the valley claimed as government lands. These LCAs form a tight cluster. Of additional interest is that during the height of the sandalwood trade the adjacent Ha'upu Ridge was claimed by Kaikioewa. It would appear that after his death in 1839 these mountain claims would revert to government control.

The Governor of Kaua'i in 1842 was Kekauonohi, the granddaughter of Kamehameha who had wed Keli'i'ahonui after having been a wife to her uncle Liholiho Kamehameha II. During her governorship, Kekauonohi partook in land exchanges, consolidating her grants in Māhā'ulepū and Kōloa. These consolidated lands would become the basis for the next cash crop – sugar, which, unlike sandalwood, could be rejuvenated and continued. From the 1830s until the 1980s, sugar would be the economic focus of Māhā'ulepū. Remnants of industrial-level sugar cane cultivation in the area represent the greatest number of historic properties documented during the current AIS.

**SUGAR AND THE HISTORIC ERA OF KŌLOA AND MĀHĀ'ULEPŪ**

The sugar cane history of Māhā'ulepū is intricately tied with the history of Kōloa. Sugar cane began to be grown and milled commercially in Māhā'ulepū Valley and around Kōloa in the 1820s, one of the first places in Hawai'i where sugar was commercially grown (Donohugh 2001). Some of the earliest efforts were undertaken by Chinese immigrants (post 1820s-30s) who had a small mill in Māhā'ulepū, as well as in Kōloa and other parts of the island. The mills were small, producing raw sugar and molasses for local consumption. By 1835, however, many of these farmers were out of business and were later employed by new plantation owners.

In 1835, a sugar cane plantation owned by Ladd and Company was located to the west of the surveyed area. This was the first attempt at producing sugar cane at an industrial scale. The land was leased for a fifty year period from Kaua'i Governor Kaikioewa and King Kamehameha III. Importantly, the lease was the first of its kind in Hawai'i and represented the first formal recognition that someone other than a chief could control land use. Kōloa Plantation, formally established in 1841, is universally known to be the first commercial sugar plantation in the
islands. Ladd and Company was the first owner of the plantation but financial difficulties caused them to sell in 1845. Robert Wood and his brother-in-law bought the plantation and kept the plantation going until 1899 when the Koloa Agricultural Company, the McBryde family, bought the plantation. The Koloa Plantation merged with Grove Farm in 1948 and continued operations through 1996.

The sugar industry grew sporadically between 1845 and 1875. At this latter date, the Hawaiian government scored a coup of its own when a reciprocity treaty with the United States was negotiated. This allowed all unrefined Hawaiian sugar to be admitted into the United States duty free. The cultivation of sugar was going to become profitable (Alexander 1985:74).

Koloa Plantation commenced growing sugar cane in Māhāʻulepū Valley in 1878, having focused more on lands to the west near Kōloa. A total of 875 acres of the flat valley floor was made available. The land was level, sheltered, and had a good underground water supply. However, there was an initial problem with the ground water as some of the valley was saturated and other areas were dry. Accordingly, Koloa Plantation undertook efforts to build infrastructure that would drain waters from the saturated areas, and divert that water to irrigate drier fields (Alexander 1985). Sugar cane requires much water so in 1897, the Koloa Plantation also excavated several wells to irrigate the cane in Māhāʻulepū Valley (see Donohugh 2001).

By 1897, the main source of irrigation water for the valley came from the ground water. At the northwest end of the valley, six wells were drilled and the water was pumped approximately a quarter mile to the north into the recently constructed Māhāʻulepū Reservoir (Figure 6). The area of the wells was known as “Māhāʻulepū 14”, probably because that was the number of wells eventually drilled and/or in service. The primary source of irrigation water for Māhāʻulepū appears to have been the six wells drilled in 1897. Four more were drilled later and all were located near the western side of the valley. These wells pumped water to Māhāʻulepū Reservoir, where it was stored and released, when needed, to various parts of the valley via the irrigation ditch.

Irrigation ditches at both the north and south ends of the Māhāʻulepū Reservoir served to transport water to the crops and to receive water from existing streams descending from Haʻupu Ridge (Alexander 1985:97-98). A pumping station was built and manned with full-time resident staff who lived with their families in a camp here. The larger north to south, excavated irrigation ditch that extends the length of the valley was excavated but does not appear on the 1935 Koloa Plantation map (Figure 7). Intensification of irrigation efforts, which added to the waters provided by Māhāʻulepū Ditch, began after this date.
The thick clay soils of the Valley were difficult to till using plows pulled by teams of oxen. However, with the introduction of steam powered tractors, more land began to be put into production. Development thus began to escalate at the start of the 20th Century. The number of laborers increased from 430 in December, 1900 to 769 in July, 1901. In February, 1904 it was reported that 600 out of 730 men were “working on permanent improvements.” (Ibid.) Infrastructure modifications in Māhā’ulepū Valley also intensified at the start of the 20th Century, with the excavation of canals, reservoirs, and wells. A narrow gauge railway was also constructed in the valley. The railway extended from Koloa Mill to “Māhā’ulepū 14”, the series of wells on the valley floor at the northwestern end of the valley itself. The railway tracks were movable, but SCS found no evidence of them in the valley during the current AIS. Other portable narrow gauge rail systems were utilized to facilitate the harvest.

In 1904, $16,420.81 was spent on additions to the plantation railroad system, including “a three-mile addition to the Puuhi railroad and a short cut road to Maha'ulepu” (Ibid.). Considering a laborer in the fields made about $17 per month, this was quite an expenditure at the time (Alexander 1985:122).

While the Plantation owned all the land, they contracted with groups of approximately a dozen men to manage parcels of fifty to one hundred acres. Koloa Plantation “…furnish[ed] land, seed-cane, water, fertilizer, and tools, and perform[ed] such portions of the work as require[d] expensive machinery, such as plowing, furrowing and hauling the cane to the mill” (Ibid, 97-98). The contractors, however, otherwise took care of their parcels from planting to harvest, selling the cane to the Plantation at a set price. This method kept the land under one owner, but provided the contractors incentive to raise a bountiful crop (Ibid. 123).

Early 20th century maps document the extent of the fields throughout the Kōloa and the Māhā’ulepū Valley areas. The fact that Māhā’ulepū Valley was used for extensive sugar cane cultivation is also evidenced by the infrastructure developed within the valley over time. Thus, the available information demonstrates that HDF's project area consists of lands that were previously used for sugar cultivation.
Grove Farm continued to produce sugar cane in the greater Kōloa area, including Māhā'ulepū, until 1974, when it leased its Kōloa lands and mill to McBryde Sugar Company (Donohugh 2001). Sugar production continued under McBryde until September, 1996 when the mill officially closed.

The Wilcox Family sold Grove Farm to S. Case in 2000. From the early cultivation times until then, the lands extending from Māhā'ulepū Valley to the sea were extensively modified for the cultivation of sugar. Fields were plowed, streambeds cleared, irrigation ditches excavated, reservoirs created, roads built, and wells drilled.

During the remainder of the Kingdom, then the Republic, through the Territorial Period, and into Statehood, sugar cultivation and Māhā'ulepū would be synonymous. More recently, since sugar cane cultivation operations ceased, Māhā'ulepū Valley has been the location of cattle ranching (2002) and taro cultivation (2007), the latter being done through lease to W.T. Hara.

**PREVIOUS ARCHAEOLOGY**

There have been numerous archaeological studies along the coast of Māhā'ulepū, but archaeological studies within Māhā'ulepū Valley and nearby inland environs have been limited. Figure 8 shows the location of relevant studies both within the current project area and close to the project area. The reader is also referred to a National Park Service (NPS; 2008) regional study for a praxis of the projects conducted along the coastline. A sampling of other studies that are further removed from the Māhā'ulepū project area are also briefly described below to provide additional context on a regional scale. Studies performed in areas closer to the ocean include those conducted by Farley (1898), Thrum (1907), Bennett (1931), Kikuchi (1963, 1980, 1981, 1988-d), Ching et al. (1974), Neller (1981), Rosendahl (1988, 1989), Hammatt (1979, 1989a, b, 1990 a, b) Pietrusewsky (1990), Walker and Rosendahl (1991) and Firor and Rosendahl (1994). Four projects were conducted directly with the current project area: Thrum (1907), Kikuchi (1963), Ching et al. (1979), and NPS (2008). The studies described below are listed in chronological order, not by geographic location, and provide both a regional and local context to previous archaeological work in the Māhā'ulepū area.

The earliest study was by F.K. Farley in 1898. During this study, petroglyphs were discovered beneath sand dunes at Keoneloa Beach, to the southeast of the current project area near the Hyatt hotel. According to Farley, local residents knew of the petroglyphs and reported that they had been exposed previously.
Figure 6: Koloa Plantation infrastructure (1912 USGS Territory of Hawai‘i Quadrangle portion).
The antiquarian T.G. Thrum documented two heiau on Kauai'i named Weliweli and Waiopili (Thrum 1907). The former was not accurately plotted on any map, while the latter was located along the stream of the same name that descends from Māhā'ulepū Valley. Waiopili Heiau was formerly just south of the current project area, near the present-day quarry.

Within the valley itself, but outside of the project area, Thrum identified the possible location of a large heiau named Hanakalaua. This heiau was reported to have been dismantled in the 1860s by a gentleman named Fredenberg and the stones then used to build cattle pens (Thrum 1907). Thrum also reports a fourth heiau, named Keolewa, on the crest of Mount Ha'upu (Thrum 1907; see also Bennett 1931, Site 90). It is not certain if Thrum or Bennett actually visited the site, but both noted that it was a small heiau dedicated to a goddess named Laka (Thrum 1907; Bennett 1931). A cursory field inspection of the summit by SCS archaeologists in December 2015 did not note any definitive structural remnants of this heiau.

During an archaeological survey conducted in 1928-1929, Bennett (1931) located or re-located the heiau at Weliweli and Waiopili. The Keoneloa Beach petroglyphs were not exposed during this visit but he collected information about them from local residents. Bennett also recorded human burials within the sand dunes at Makahuene Point.

According to Bennett (1931:46), at Waiopili Heiau, “a tower of stone stands in one corner. It is solid enough to climb upon and an excellent view is afforded from the top. It is a unique feature for Kauai heiau, and if modern, defies conjecture as to the reason of its construction.” According to Ching (1974), “Waiopili Heiau is a rectangular walled enclosure, which lies on a smooth pahoehoe lava bed. The limestone cliff which forms a natural boundary between Māhā'ulepū and Pa'a lies almost directly to the south of this temple.” Chang (1974) further states that Kapunekea Pond is nearby and that the walls were large, 2.5 m wide and 2.0 m high, constructed of pahoehoe slabs. The heiau was still mostly visible in 1974. By 2006, only a very small portion of the southern wall of the heiau was visible, near a spring pump house. The heiau has been mostly destroyed by quarrying activities, as well as by the quarry road which runs along the southern boundary of the former structure.

Kikuchi (1963) conducted an archaeological investigation of coastal Kōloa. In addition to identifying new sites near the coast, he re-located several sites described by Farley, Thrum, and Bennett: Site 96 (Kane'aukai Heiau); Site 97 (dune burials); Site 98 (Keoneloa Beach Petroglyph Field); Site 99 (Weliweli Heiau); Site 100 (Keoneloa Beach Walls); Site 101 (Makaweki Point petroglyphs); and Site 102 (a structure).
Figure 7: Distribution of Koloa Plantation lands (1935).
Kikuchi also documented the only previously identified site within the surveyed area, Site -3094. This site is composed of a large boulder sitting in a pasture at the northern end of the valley. Kikuchi (1963) notes this boulder as occurring some 2 miles inland. Some twenty anthropomorphic figures, two pecked cups (4 inches deep), and a long groove are etched on the surface (Ching et al. 1974; McMahon 2007; see also Cox and Stasack 1970). The groove may represent a stream, but interpretation is uncertain. As discussed below, this site was fully recorded and mapped during the current project. In addition to the one boulder previously identified by Kikuchi (1963), two additional petroglyph rocks associated with this site were also documented during the current AIS (see Results section below). Thus, Site -3094 now consists of three features.

During surface survey of 1,100 acres along the coastal lands of Weliweli, Paa, and Māhā'ulepū Ahupua'a, Ching et al. (1974) wrote of Weliweli Heiau: “no actual alignments or other features were noted at the reported location of this temple. This site has either been completely destroyed or is located elsewhere” (Ching et al. 1974:81). During the Ching study, the archaeologists found and sketched the petroglyphs at Keoneloa (Site 84), found sand dune burials (Sites 3096, 3097 and 3024) and re-located Waiopili Heiau (Site 87). They also located Waiopili Pond and Kapunakea Spring, but these were not given site designations (Firor and Rosendahl 1994).

Kikuchi (1984) continued archaeological investigations along the coastline of Keoneloa Beach. Kikuchi documented numerous sites and at least one, but possibly two, cultural layers that extended along the length of Keoneloa Bay (Kikuchi 1998a). This was the beginning of an era of extensive archaeological excavations and monitored construction excavations in this area. Work by Neller (1981), Rosendahl (1988, 1989), Hammatt (1979, 1989a, b, 1990 a, b) Pietrusewsky (1990), Walker and Rosendahl (1991) and Firor and Rosendahl (1994) followed.

McMahon (1996) conducted an archaeological field inspection of a circa 25,000 sq. ft. area on the southeast flank of Ha'upu ridge for the proposed installation of a radio tower. The project area for that study was located at 1,500 ft. asl. No sites were identified, nor were any trails observed along the ridgeline; the area was, as McMahon notes (1996), only accessible by helicopter.
Figure 8: Previous archaeological studies in the Māhā'ulepū area.
Following this study by McMahon (1996), a letter was submitted by the Office of Hawaiian Affairs (OHA) in March 1998 to the Federal Communications Commission opposing the construction of a radio tower on Mount Ha'upu. The letter stated that the mountain is of special significance to Native Hawaiians as a wahi kapu (sacred place): “Ha'upu is our kin, descendent of Papa [Earth mother] and Wakea [Sky father], and older sibling of the Hawaiian people. This is the main reason why we, as Hawaiians, hold Ha'upu sacred in our hearts”.

According to the OHA (1998) document, Ha'upu was named after a demi-god/warrior who took a large boulder from Kaua'i and threw it across the Ka'ie'ie Waho Channel, where it killed an enemy chief on O'ahu. The small heiau atop Mount Hā'upu is dedicated to the goddess of hula (Laka). Both the heiau and the wooded areas at Hā'upu Summitt are known as keolewa, a word common in Hawaiian oral traditions. In addition, Ku and Hina, the first Hawaiian god and goddess, live on Ha'upu Ridge. Mount Ha'upu was also an important navigational landmark for traditional Native Hawaiian fishermen, and Hawaiians today still view the mountain with reverence (OHA 1998).

Beginning in the 1990s, Burney and Kikuchi began excavating the Makauwahi Cave and Sinkhole. They stated that within the cave “in a single stratigraphic sequence and encapsulated view of the full span of human occupation, including the millennia preceding human arrival, earliest human evidence, subsequent population increased and cultural change, European contact, and modern transformation” (Burney and Kikuchi 2006). Amongst the many discoveries from this study are bones of a Polynesian rat, which dated to 1039-1241 A.D. Because the rats were in the canoes with Polynesian voyagers, this is some of the earliest evidence for human occupation of this area. Excavations also exposed intact cultural layers, as well as culturally sterile deposits. Artifacts such as files, picks, scrapers, adzes, fish hooks, octopus lures, game stones, sling stones, and hammer stones were recovered. The preservative qualities of the deposits in the sinkhole were excellent. Fiber cordage, wooden fragments from canoes, paddles, and tool handles were also recovered. These materials came from three excavations. There is much potential for more information to be gained from this site (Burney and Kikuchi 2006).

Archaeological surveys and field work were conducted farther to the southwest along Waikomo Ditch by Cultural Surveys, Hawaii, Inc. (Hammatt, et. al. 2004). The terrain this ditch flows through is different from the terrain that the stream which flows out of Māhā'ulepū Valley travels through. Features originating during the pre-Contact era include agricultural terraces, habitation terraces and platforms, and irrigation auwai along both crests and bases of long, low ridges were observed (Hammatt, et. al. 2004). This complex of sites is designated the Kōloa Field System.
The most recent comprehensive effort at documenting the biology, botany, geology, ecology, and archaeology of the region is that compiled by the National Park Service (NPS; 2008). “The Māhā'ulepū, Island of Kaua'i Reconnaissance Survey” published in 2008 consists of an effort by the NPS to re-identify multiple natural and cultural features in the Māhā'ulepū Valley and environs. The goal was to argue for the importance of conducting a more thorough natural and cultural study of the area along the southeast coast of Kaua'i from Kōloa to Poipū, and northward along Māhā'ulepū, Kīpū Kai, Niumalu, Nawilili Harbor and then to Līhu'e. Included in the study is Mount Ha'upu and the ridgelines extending from it (NPS 2008). The study presents a summary of the natural and cultural features for the area and effectively argues for additional research.

**CONSULTATION**

Consultation was conducted via telephone, e-mail, personal interviews, and the U.S. Postal Service. Consultation was sought from Dr. Kamana'opono M. Crabbe, Chief Executive Officer, Office of Hawaiian Affairs; Vincent H. Rodrigues, Cultural Historian, State Historic Preservation Division; Missy Kamai, Na Kuleana o Kanaka Oiwi; Teddy Blake, Kōloa Community Association; Randy Wichman, President Kaua'i Historical Society; Jane Kamahaoakalani Gray, Director of the Kaua'i Museum; Office of Hawaiian Affairs, Kaua'i Branch; Sherri “Puni” Patrick, kupuna; Rupert Rowe, community member, and proficient fisherman; Beryl Blaich, Executive Director of Malama Maha'ulepu; Bridget Hammerquist, Friends of Maha'ulepu; Kalanikumai (aka Branch Harmony), traditional cultural practitioner and member of Malama Maha'ulepu; Terrie Hayes, community member; Llewelyn “Billy” Kaohelaui'i, community member; Ali'i Nui Aleka Aipolani, Polynesian Kingdom of Atooi; Gordon Higa, community member; David Chang, long-time resident, founder of Ohana o Maha'ulepu, and founder of Malama Maha'ulepu; Napua Wong Romo, Vice-President Malama Maha'ulepu; Kunane Aipoalani; Leinaala Pavao Jardin, Kumu Hula; Aletha "Puna" Kaohi; Scott Sagum, Vice President of the Royal Order and President of the Ho'ola Lahui Hawaii Board of Directors; David Burney, steward of Makauwahi Cave; Lida Burney, steward of Makauwahi Cave; Catherine Lo, community member; Karl Lo, community member, Reverend Doctor Alan Akana, community member, and Reverend of Kōloa Union Church; Kaulilani Kahalekai, community member and cultural practitioner; William Ho'ohuli, community member; and Jim Case, longtime resident.

In addition, a Cultural Impact Assessment Notice was published on October 24, 25, and 28, 2012, in *The Honolulu Star-Advertiser* and in *The Maui News*, which published on the same dates on Maui, and the January 2015 issue of the OHA newspaper, *Ka Wai Ola* (see Appendix B). These notices requested information of cultural resources or activities in the area of the
proposed project, stated the Tax Map Key (TMK) number, and where to respond with pertinent information. Based on the responses, an assessment of the potential effects on cultural resources in the project area and recommendations for mitigation of these effects can be proposed.

**CULTURAL IMPACT ASSESSMENT INTERVIEWS AND CONCERNS**

Analysis of the potential effect of the project on cultural resources, practices or beliefs, the potential to isolate cultural resources, maintain practices or beliefs in their original setting, and the potential of the project to introduce elements that may alter the setting in which cultural practices take place is a requirement of the OEQC (2012:13). As stated earlier, this includes the cultural resources of the different groups comprising the multiethnic community of Hawai‘i.

Initially, Mr. Kawika McKeague, Group 70 Cultural Liaison, planned to sit in on the interviews. However, due to health reasons, Mr. McKeague was unable to attend either session. Due to a family emergency, Missy Kamai was unable to attend either interview session. David Chang planned on attending the April 17, 2015 interview session, but called Friday morning to say he was not feeling well. Scott Sagan, also, planned on attending, but health issues prevented kept him away, as well.

Consultation was conducted in person on April 16 by SCS Senior Archaeologists Ms. Dagher and Jim Powell, B.A. These semi-private interviews were hosted by Mr. and Mrs. Hammerquist and with the permission of those in attendance; the interviews were conducted on the Hammerquist's lanai. Those interviewed on April 16, 2015 included:

- Rupert Rowe
- Kalanikumai
- Reverend Doctor Alan Akana
- Llewelyn “Billy” Kaohelauli‘i
- Terrie Hayes
- Kaulani Kahalekai
- Bridget Hammerquist

**RUPERT ROWE**

Rupert Rowe explained that this area has three springs set up to feed taro patches so that water is filtered on its journey to the ocean. Big land owners, in Hawai‘i, are able to colonize the islands because there is no treaty between the Kingdom and the United States. As wards of the State, which is based on a liquid measurement, Native Hawaiians really do not have the
resources to fight the corporations that occupy Hawai'i. When asked by one of the interviewers if he knew the names of the springs, Mr. Rowe answered that he could not reveal their names because a lot of the secrets about the culture are being invaded by people who try to do what they want to do. There is no place in the world where the culture is second best to the citizens of America. By becoming wards of the United States, Native Hawaiians are totally dysfunctional under the puppet government of the State of Hawai'i because as the host culture, they can never protect their assets of the past, the future, and the present. Archaeologists and consultants conducting research try to document the mystical part of Hawaiian culture, but it can't be understood by outsiders “it's like talking bubbles under water.”

As a kanaka maoli, Mr. Rowe can only speak of the culture and its unique situation as it applies to this [Māhā'ulepū] valley. Native Hawaiians are the only people in Hawai'i who do not have a say in what happens. Everyone else is just interested in making money, but what they are really doing is stealing the treasury of the Kingdom of Hawai'i. You cannot buy land in Hawai'i and come out with a valid deed. In order to own the land out right, you have to have clear title to the land, which is a treaty between two states. When the time came for Hawai'i to become a part of the United States, the native people didn't want to become American because they saw it as a country without a culture (i.e., as a country without a race). They saw the moral values of the Americans as based on the face of the dollar that says “In God we trust.” The people wondered what does god have to do with a piece of paper? Native people understand that energy is within a person and when you talk of a spiritual bond between native cultures and the land, it is understood that all people have a great bond between the land and their souls (i.e., they intuitively understand the uniqueness of what is there).

When asked by one of the interviewers if he was from the Maha'ulepu area, Mr. Rowe responded that his 'ohana where from Māhā'ulepū and Kōloa. Mr. Rowe added that, as had said earlier, the outside people want to know the genealogies of the people from a particular area, but culturally, the ranking ali'i did not disclose their identity to their enemies. Kalanikumai interjected that Rupert's family, in Kōloa and, Māhā'ulepū goes back many, many, many generation before western contact and that Rupert's family name appears on the roles and on the records. Mr. Rowe believes that letting his cultural and familial secrets out to the westerner world is a violation of his human and civil rights.

Concerns

Mr. Rowe is concerned that the proposed dairy will disturb the bond between the soul and land. He strongly believes that it's important for native people to have a voice in what happens to the land. Mr. Rowe's opinion is that the native person really loses out when the western mentality of taking “what is yours to be theirs.”
KALANIKUMAI

Kalanikumai Ka Mak'ul'uli 'O Na Ali'i Hanohano: Representing the 7th generation of aboriginal descendants of Kōloa District since Western contact, Kalanikumai stated that his Mo'okuauhau [genealogy] goes back many generations before western contact. Kalanikumai knows of two of the springs in the area. One spring is currently owned by the County and there used to be a habitation site built there located above the road. Title to this Spring site is clouded as the County contacted and obtained a signature from one member of the Kekauoha family [Vice-Principal at Hanalei School 1940's post-war], while seven other brothers and sisters held equal claim unsettled. (source: Samuel Kekauoha/ family Elder & Genealogist).

Another spring is located in Hidden Valley (also known as 'Aweoweonui). Kalanikumai's great-great-great grandfather (Nakapa'ahu, [1798-1895] son of Nahinu, a grand-nephew of Kaumuali'i, and first-cousin to the Kamehameha regime, who was principal Ali'i Nui of Kōloa prior to the overthrow, and later the superintendent (Ilāmuku) of Kōloa under the Kingdom, built and occupied a Kauhale by the Spring through the auspices of Hannah Moore, who had adopted Nakapa'ahu's daughter and encouraged Nakapa'ahu to live on the property and work the land. Nakapa'ahu developed the Hidden Valley spring, on land given to him by Mika who had acquired the land through a trade. Mika was tax collector for the Kingdom, and first Lay Teacher at the Catholic “San Rafael” Parish School operated by the Belgian “Sacred Heart” Order. Mika's mother, Hannah Moore, negotiated the transfer of land from Mika to Nakapa'ahu, as documented in the records. Mika married Nakapa'ahu's daughter Rose. Trained by her husband, Rose became the second Lay Teacher at San Rafael's. Rose, in turn, trained her elder sister Halieta's daughter [Rebecca] as the third, and final Lay Teacher at that school. The two families were closely intertwined.

Nakapa'ahu built up the spring, established a home there, with cultivated lo'i, garden, and raised his daughter there for the last twenty-six years of his life. He fostered a relationship with a haole named William Brown, who organized the kalo farmers in the Māhā'ulepū Valley, who were at odds with Koloa Sugar over the kalo lands. There was a case where Mr. Brown got Koloa Sugar to pay a settlement to him (Nakapa'ahu), which he distributed among the tenant kalo farmers, for violations and intrusions that Koloa Sugar had been doing on the kalo lands. Two years after Nakapa'ahu died, in 1897, Knudsen Estate and Koloa Sugar tried to claim the land. Mr. Brown helped Nakapa'ahu's daughter, got legal counsel, organized a defense against Knudsen Estate and Koloa Sugar. Knudsen Estate and Koloa Sugar tried to exclude Brown from representing Nakapa'ahu's daughter, as he was no relation to her. So, William Brown married Nakapa'ahu's daughter, in order to be able to speak for her. In 1899, the Kauai District Court ruled that the land belonged to Nakapa'ahu's heirs fee simple, under the right of Adverse
Possession. In 1991, Kalanikumai discovered documentation indicating Grove Farm had acquired quiet title to the land in 1976. Kalanikumai states he has direct Kuleana claim to land at 'Aweoweonui and that Mika had registered LCAs in Māhā'ulepū to which Kalanikumai has kuleana rights. Court documentation demonstrates that some 300 acres of Māhā'ulepū Valley land was in tenant Kalo cultivation as late as 1899.

Kalanikumai collects 'aweoweo (*Chenopodium oahuense*), herbals, botanicals, and vegetation; has documentation to show that he has repeatedly used trails in Māhā'ulepū since returning to Kauai in 1989. He frequents Hau'ula, the 'Aweoweonui Burial Dunes, "Hidden Valley", the "Petroglyph field"; Unu Heiau; Plateau; Bamboo groves and Waterfall above the Plateau; and the Pa’a- Māhā'ulepū Alahele, as well as the coastal & beach shoreline. As Kalanikumai believes there are post-Contact burials in Māhā'ulepū near the LCAs, he would like further archaeological work conducted in this area. According to Kalanikumai, it was a common practice to bury infants, less than 1 year old, in lo'i with the kalo, so as to be absorbed by Haloa and nourishing successive generations. He has first-hand experience with this practice. When his infant sister died, his family buried her in the lo'i with the kalo that was his sustenance until seven years of age.

During the post-Contact Period, family burials were customarily interred within the LCA awarded plots containing habitations near the house site. Subsequent surface clearing activities removing signs of habitation for agricultural repurposing obscures, but fails to remove the presence of burials.

Kalanikumai mentioned that there was a habitation and ceremonial site on the plateau, above Māhā'ulepū Valley, used from the pre-Contact Period into the post-Contact Period. Kalanikumai also said that there were salt pans located down in the conservation zone outside of project area that are hydrologically linked to the valley's drainage as well as from Ditch 1, Ditch 2, and Waiopili Ditch. Restoration of this culturally significant unique practice, exclusive to Hawai‘i, limited to few environmentally suited locations, would be irrevocably precluded by the inevitable seepage of soil contaminants resulting from the Dairy installation. According to Kalanikumai, the heiau (State Site 50-30-10-2250) was of the Unu type or classification of the heiau (i.e., a low circular structure, with northern and southern doorways). The heiau was an agricultural heiau associated with the god Lono, but was also associated with other ceremonies, including the ceremony of the First Fruits and Makahiki. Kalanikumai stated that he is planning on conducting a First Fruits Ceremony at State Site 50-30-10-2250 in the near future. The unu 'unu is not separate from the petroglyph heiau or the petroglyph boulders in the back of the valley, which are associated with the god Kāne and Lono; “…they are all part of one… different practices were conducted at the different areas there.”
Kalanikumai also stated that he recently conducted two ceremonies in Māhā'ulepū Ahupua'a [February and March 2015] during New Moon at State Site 50-30-10-2250. Māhā'ulepū is also associated with the goddess Laka. There is a burial cave on the plateau and two sacred bamboo groves are located above the plateau, between 800 and 900 feet above the valley floor, that are associated with the legendary demi-god (Kupua) Palila of the House of Moana. The legend of Pele's sister Hi'iaka-I-Ka-Poli-'O Pele recounts how Hi'iaka addressed prayers of supplication toward the Heiau of Laka, positioned in the meadow sheltered in the lee of Hā'upu's prominent knoll. There is a Lele (a jumping off space or portal) known as Ke O Lewa, located in the atmosphere, suspended in the heights, above Mount Hā'upu.

Kalanikumai stated that pre-Contact Period burials are located all along the mountain and coastal cliffs, in crevices and in caverns. During the post-Contact Period, people would inter their dead near their homes. Kalanikumai believes that the historic burials on the valley floor, in the LCAs, were not impacted by the commercial production of sugar, as only the ground surface was graded and scraped. So, Kalanikumai believes there may still be Historic burials there. Prior to WWII there was a village at Māhā'ulepū. After the WWII, the people were displaced from the valley.

Kalanikumai confirmed that the plateau, located approximately 450 to 600 feet above the valley floor, was designated as a pu'u honua (see Kauelani Kahalekai testimony below). He has collected herbs, flowers, plants, spring-water, calcite minerals and other native resources in Maha'ulepu Ahupua'a for over 25 years, following in the footsteps of his Kupuna Kaluhimoku Nakapa'ahu, a Kahuna La'a Lapa'au (son of the Ali'i Nui), whose practice in this area has been documented.

**Concerns**

Kalanikumai is concerned with access to the valley, highlands and natural resources; that seepage and discharge from the dairy will contaminate the Kalo Lo'i, the salt pans, the Makauwahi Cave Complex, Wetlands and near-by Waiopili Heiau. He believes there may still be Historic burials in the LCAs and would like to see additional archaeological work in this area. Kalanikumai would like to see Māhā'ulepū Ahupua'a preserved in vegetative and biodiverse crops.

Kalanikumai believes that vegetative crop cultivation is the best and highest use of this environmentally sensitive and fragile area. Kalo and Pa'akai cultivation and production are cultural priority crops. Historic uses have demonstrated success with 'Uala (Sweet Potato), Oranges, 'Ulu, and other dioecious crops. Introduction of associated airborne, water, and soil contamination on a scale of magnitude such as is inevitable with this project will produce a
devastating effect, not only upon the environment and shoreline, but accordingly, upon the economy; businesses; tax base; tourism; residents; health and welfare of the community. Ignoring facts, dissembling or prevarication thereof, misrepresentation or promotion of inaccuracies, distorting information revealed thru Community scrutiny in examination of the impact and details of this intended operation is morally reprehensible. The continuation of presenting slanted distortions of fact that fly in the face of reason only prolong the inevitable, and display corporate consumptive greed over public welfare, besmirching the character of those who would continue to deny the devastating effect this would have upon our Island.

Kalanikumai Ka Maka'uli'uli 'O Na Ali'i Hanohano
Waiuka Poele'ele, Awawa Lawa'i, i Kona Kaua'i. 18 Aukake [August] 2015.

REVEREND DOCTOR ALAN AKANA

Reverend Doctor Akana has family roots on Hawai‘i and Kaua‘i Islands, now lives on Kaua‘i, and is the pastor of Kōloa Union Church. Reverend Akana hikes, runs, and swims in Māhā'ulepū. He has visited the Makauwahi Cave Reserve on several occasions and is aware of its rich cultural importance. Although he knows of no other specific cultural sites, he feels the importance of the area. Reverend Doctor Akana said that Māhā'ulepū feels like a special place to him, he sees Māhā'ulepū as a “cultural kipuka” (i.e., an old growth area surrounded by more recent lava flow), and as a place for Hawaiian people to gather. Reverend Akana understands the importance of being connected to an area and believes it is important to have a “sense of place.” He also stressed the importance of having undeveloped areas as nature reserves for people to be able to retreat, away from modern development. Reverend Akana also stressed the importance of people who are connected to the land to have a say in what happens to land and how it is used. He believes it is important that “sacred places” are preserved for the people, regardless of who owns the land. He comes from farming and agricultural family and is not opposed to agriculture or dairy. Per se, Reverend Doctor Akana understands the importance of “sustainable agriculture,” but is not convinced that it applies to the proposed dairy at Māhā'ulepū.

Concerns

Mr. Akana is concerned that the people culturally connected to the land have a say in how it is used. He believes that it is important that some areas remain pristine, undeveloped, and available to the public, in order for people to have a place to go to feel connected to the land, to a place, to each other, and to their history. Mr. Akana is not convinced that the plan for the planned dairy at Māhā'ulepū is good for the Hawaiian people, nearby residents, the water table or shoreline.
LLEWELYN “BILLY” KAOHELAULI'I

Mr. Kaohelauli'i is the Moku for the Kona District, one of the six and the largest of the Moku Districts on the Island of Kaua'i. Within the Kona Moku, there are 11 Ahupua'a, one of which is Māhā'ulepū. As the Moku for this District, it is his duty to work with the Ahupua'a representative of Māhā'ulepū (among others) and do whatever he can to communicate with the Department of Land and Natural Resources. In his position as the appointed Hawaiian representative, he is committed to protecting and preserving the water and other environmental resources of the areas of his District.

Mr. Kaohelauli'i was born in Waimea Hospital (Kaua'i) in 1950. He has lived all his life in Kōloa, and is the fourth generation fisherman in a family who's initial roots were at Māhā'ulepū. The most important things to him are fishing and farming, which he sees as providing sustainability for the people of the ahupua'a. He has spent his life helping the people of the Kona District, teaching youth how to fish and gather opīhi and limu. His ancestral background and life's activities were a likely influence in his selection by more than 200 Kupuna as the Moku for the Kona District.

Mr. Kaohelauli'i has fished every bay from Po'ipū all the way to Līhu'e, the whole coast, and all the way down to the west side of the island. He has fished/gathered for limu, opīhi, wana, loli, uhu, manini, kala, menui, weke, moi, aholehole. Mr. Kaohelauli'i stated that fishponds and fishing grounds are located along the coastline of Māhā'ulepū and that one of the fishing areas is located near “kitchen rock.” Mr. Kaohelauli'i's parents used to go back by the heiau in Māhā'ulepū (State Site 50-30-10-2250) to collect plants including, maile, mokihana, and the seeds of black eyed susans for lei making.

The main thing they used to gather was the water from Hidden Valley ('Aweoweonui) - from the fresh water spring, which is located “high up” in the valley. Hidden Valley is located on the other side of Māhā'ulepū Ridge. In Hidden Valley ('Aweoweonui) there is a spring and a grove of Java plum where the cows, horses, and pigs gather. (Kalanikumai interjects that this is where Nakapa'ahu's residence was – on a 9 acre parcel in 'Aweoweonui/Hidden Valley). All the local people went there to collect the fruits and water, which was known for being clean and pure. Mr. Kaohelauli'i's grandfather used to own 100 acres of land in the Valley. The land was given to Mr. Kaohelauli'i by Eke Opunui, the ali'i of Po'ipū.

The area can still be accessed by trails which are currently used by hunters. When Mr. Kaohelauli'i used to hunt, he would climb up the mountain, from Māhā'ulepū side, down the ridge, to a road going across and to another trail that goes to Black Mountain. Trails go across to Kīpū Kai, and back by Makawehi Cave. When Mr. Kaohelauli'i was a boy, even when his father
was alive, they used to go to an area of Makawehi Cave to gather Hawaiian herbs, including pilo, for medicinal use. Back in the day, the area was very spooky. No one wanted to go there at night because it was a known Hawaiian burial area and people were said to see spirits walking. When Mr. Kaohelauli'i was young, he used to walk trail from Po'ipū to Māhāʻulepū, as this area was the family gathering area. Mr. Kaohelauli'i has lived on fish all his life and still engages in subsistence fishing today. He is a strong believer in sustainability so that the resources will be available for future generations.

**Concerns**

Mr. Kaohelauli'i expressed concerns about the negative impacts the dairy will have on contaminating the streams, ponds, wells, and the ocean, all fish, the reef and fishing. It will adversely impact Kauai's resources, such as the reef, the fish, the drinking water, and fishing. As a strong proponent of sustainability, Mr. Kaohelauli'i favors a balanced ecosystem and wants fish and lands for farming to be available for future generations.

Mr. Kaohelauli'i was recently denied access to the heiau at Māhāʻulepū for cultural practices by Grove Farm, because of the lease with Hawaii Dairy Farms. This is a violation of the State Constitution and the Hawaii Revised Statutes, which provide access for ongoing traditional uses and cultural practitioners.

Mr. Kaohelauli'i is also concerned that there are Hawaiian families still in the area with unresolved LCA (Land Commission Awards) Claims in the very area where the Dairy is planned to be. Mr. Kaohelauli'i is worried that although many of the families still live in the area, they were not contacted for their cultural input or to find out about their sustenance fishing, hunting, and gathering practices in this area. He believes a more in-depth study of the ongoing use of this Valley and its waters and coastline should be conducted.

**TERRIE HAYES**

Ms. Hayes visited the islands for 30 years before coming to live here over 13 years ago. Ms. Hayes, a teacher and educator by trade, has now been living with Mr. Kaohelauli'i on the Kaohelauli'i family property in Kōloa for twelve years. Ms. Hayes stated that Mr. Kaoheluli'i also fishes in Pāʻa Ahupua'a, which is where the fishponds are. Ms. Hayes is familiar with native plants and understands farming. Ms. Hayes explained the Aha Moku system of resource management, which utilizes traditional native knowledge of agriculture and fishing as a method of preserving natural resources. Ms. Hayes stated that the Aha Moku system of management, which was enacted by the legislature as SB 288 in 2012, empowers the kanaka maoli and gives them a voice.
Concerns

Ms. Hayes' greatest concerns are the potential impacts the dairy will have on the environment, specifically to the drinking water, groundwater, ocean, and reef. She is also very concerned about the kanaka maoli being kept from their customary access – access is imperative to maintain their traditions. Ms. Hayes stated that tests have shown that the soils in Māhā'ulepū are clay based and while suitable for some agriculture like Taro, they are poorly draining which will increase the risk of Waste runoff. Historically, the sugar plantation put in a large network of ditches to carry the excess water that collects on the soil surface, to the ocean. Ms. Hayes explained that the dairy representatives told them that they have restored the ditch network and intend to use it, admitting that they still drain to the ocean. The ditch system running through the dairy property increases the risk of contamination of all waters in Māhā'ulepū.

In addition, the roads to Māhā'ulepū are now gated and locked making accessibility very difficult to impossible. Ms. Hayes believes it is also extremely important to preserve the cultural resources for future generations.

The proposed HDF Plan claims that there will be zero discharge of waste, stating no waste will leave their farm. They seem only to have considered runoff in that statement; because there is no way that they can prevent groundwater contamination in the areas where the soil is well draining. According to their Plan, they need to pump and empty the effluent ponds when there is a hurricane. They also say that this process takes approximately 96 hours to empty the ponds. Thus far this hurricane season would have forced the emptying of effluent ponds six times in the past three months. This is an impending disaster that the sacred Māhā'ulepū Valley could not endure. Dairy representatives told us that each mature Dairy cow will produce approximately 143lbs. of wet manure and 8-10 gallons of urine per day. Even their starting herd of 699 pregnant cows will add more than 100,000 lbs of waste per day. As Poipu and Kōloa drinking water wells are also contained within the valley, contamination would be unavoidable. Ms. Hayes feels strongly that the proposed dairy would be terrible for the people of Kaua'i and in the future.

BRIDGET HAMMERQUIST

Mrs. Hammerquist is kama'aina, born in Hilo, Hawai'i prior to Statehood. She grew up on Sugar Plantations on the Big Island, as her father, Frank Sweeney, worked for Sugar Companies from the time she was born. She believes in agriculture and has many fond memories of her time on the Sugar Plantation, remembering issues about water in years that were dry and the effect on Sugar content when the cane was harvested. She and her brothers had a favorite pastime of sitting out on the porch when fields near the house were being burned, enjoying the ash that fell on their clothing. She knows that sugar companies didn't do everything right but she
learned a genuine concern for the environment. As a young person, attending Paauhau School, she raised a garden, an option to P.E. that Paauhau students were offered. She enjoyed selling the vegetables in the village and really believes in the importance of locally produced food.

When she was in high school, her father was transferred to Olokele Sugar Company, at Kaumakani Kaua’i. On weekends, it was a favorite pastime of her family to picnic, swim, and hike the trails in Māhā’ulepū. At the time, Grove Farm issued a car pass which she recalls was necessary for their entrance. For her, the treasures of Māhā’ulepū are the memories of the cultural treasures as well, including the petroglyph boulders, that she visited with her family when she was growing up. Now, Mrs. Hammerquist is raising her three grandchildren and resides full time in Kōloa on Kaua’i. Not only did she take her own children to Māhā’ulepū when they were growing up, often staying with her parents who lived in Weli Weli track, but she continues to share the joys of Māhā’ulepū Valley with her grandchildren. They have hiked, snorkeled, ridden horses, and all have enjoyed multiple visits to the Makauwehi Cave.

Mrs. Hammerquist became concerned about the impact of the proposed Dairy when she read the Dairy’s plan and learned about the amount of waste that would be produced and the amount water that would be consumed, 2.93 million gallons daily (MGD) from the Waita Reservoir for irrigation. In addition, the dairy intends to draw potable water for the cows to drink and for washing their udders, all from the Māhā’ulepū Wells. She is also very worried about the amount of biting flies (already on Kaua’i at some farms) that will breed and multiply in the large waste deposits from the proposed dairy herd. From her background as a nurse, she fears the spread of Zoonotic diseases by the flies. She also feels the flies will be very damaging to the South Shore visitor population. She explained that the Dairy representatives have stated their goal is for a 2,000 cow dairy, starting with 699 pregnant cows. On page 42 of their plan, the dairy states that each cow will produce at least 143 pounds of wet manure per day not including 8-10 gallons of hormone and ammonia laden urine daily. Mrs. Hammerquist says, when you do the math, there will be more than 100,000 lbs. of waste per day of waste from the start up herd, and more than 300,000 lbs. per day once the herd is expanded to 2,000 cows. When she attended Hawaii Preparatory Academy on the Big Island, she regularly rode with Mr. Samulsen on Parker Ranch pastures. She recalls that cow manure remains on the ground for a long time. As a result, she is very concerned about the massive accumulation of waste over time, even when it falls on grass, increasing the risk of further contamination of the ditches, Waiopili Stream, groundwater, and nearby coastal waters.

On review of their plan, Mrs. Hammerquist read that there is to be an 81 acre manure and sludge pad that the Dairy plans to locate approximately 750 to 1,000 feet from three existing County wells that currently supply drinking water for all of Pō’ipu and much of Kōloa. She
became more concerned after reading the soils study and learning that the soils of the valley are primarily poorly draining, with one of the exceptions in the 81 acre proposed manure and sludge pad (their block H). The Dairy's plan calls for pumping the effluent pond contents onto the 81 acre pad every 5 weeks, the area closest to the County Wells. The sludge pumped from the effluent ponds to Block H, will be an addition to any manure deposited by the cows that graze on that same area. Thus, she is concerned that the sludge will percolate down into the water table and the well capture zone, contaminating the drinking water. She has read numerous reports of communities in the Mainland United States (New Mexico, New York, Washington, Wisconsin, Iowa, and others) that have lost wells due to nitrate infiltration. She reported that in Des Moines, Iowa, a city of 504,000, they are projecting a cost of $100 million to purchase, install, and operate a plant to extract the unsafe nitrates from their potable water.

**Concerns**

Mrs. Hammerquist has expressed deep concerns about manure and sludge seepage from the dairy contaminating drinking water, making it very difficult for residents of Pō'i-pu and Kōloa to continue who have to rely on the County Wells as their sole source of drinking water. She is also concerned that the runoff from the dairy will flow into the ocean and contaminate the coastal area and marine resources, which will negatively affect the people who use those resources for subsistence. Mrs. Hammerquist is also concerned about access, as the gates into the valley area are now gated and locked. With access now denied, she fears that this rich cultural experience, enjoyed by many and the site of a routine, third grade field trip for Kōloa School (among others), is now lost. She views the valley as a local environmental and cultural treasure that is important for the people of Kaua'i now and for the future generations to experience.

The April 17, 2015 interviews were held at Kōloa Neighborhood Center Annex, former judge's chambers, and conducted, in person, by Ms. Dagher. Initially, the April 17, 2015 interviews were slated to be private, individual, interviews. However, as all in attendance were in agreement, the private interview organically morphed into a group conversation. Those interviewed on April 17, 2015 included:

- Teddy Blake
- Napua Wong Romo
- Catherine Lo
- Karl Lo
TEDDY BLAKE

Mr. Blake was raised from birth to third grade in Ho’ai, Kualu, Kōloa, his house was right next to Kūhiō Park. When he was in third grade, his family moved to the present family residence on Waikomo Road, in Kōloa. Long time Kōloa residents refer to the entire area from Waitā Reservoir all the way down to Māhā'ulepū as one area. So, when facing the Kōloa Mill, everything before you was Māhā'ulepū. Mr. Blake spent a lot of time growing up in Māhā'ulepū, as did Napua Wong Romo and David Chang. Growing up, weekdays, after the chores were finished; weekends; vacations; and holidays were spent exploring the Māhā'ulepū area.

Waita Reservoir, the largest man-made reservoir in the State of Hawaii, was built in 1906 by Grove Farm. The water from Waita Reservoir was a source of irrigation water for the entire south side of the island. Following the construction of the reservoir, the production of sugar cane increased dramatically. When Mr. Blake was growing up, Māhā'ulepū, in its entirety, was in sugar cane, while approximately ¾ of the ahupua’a of Weliweli and Pāʻā were under the commercial production of sugar cane. Waita Reservoir was a source of recreation and his friends played there throughout their childhood. At the reservoir, they fished for blue gills and encountered native plants, including mokihana (Rutaceae Melicope anisata), maile oli (Alyxia sp.), and introduced plants such as tapioca root, coffee, cacao. Coffee and cacao were planted by the plantation as possible cash crops. A mud slide at Watagi Falls was another area of recreation frequented by Mr. Blake and his childhood friends.

Mr. Blake’s childhood treks to Māhā'ulepū were for camping, swimming, and fishing at Kawailoa Bay, now referred to as Māhā'ulepū. The Vasconcellos family raised cattle in the area. Although the Vasconcellos sons were older than Mr. Blake, he knew who they were: “Blondie” Vasconcellos and his brother David worked for Grove Farm, where Blondie ran the quarry and David was a mechanic at the shop.

Although he was not interested in cultural sites when he was growing up, Mr. Blake had seen petroglyphs in Māhā'ulepū and an agricultural heiau at Ka Lae o Kahonu, a promontory on the west side of Māhā'ulepū. The next point of importance was a small heiau called Keolewa (Keonelewa), which was dedicated to the goddess Laka, located on top of Mount Ha'upu. The floor of Keolewa is covered in ocean sand. The agricultural heiau, Waiopili, is also close by.

Two to three hundred years before Kamehameha I attempted to conquer Kaua‘i, the battle of Kaweliweli‘iwi occurred. The king of Kaua‘i, at that time was Kukona, his son was Manokalanipo. Kalaunuiohua, a chief from the west side of Hawai‘i Island, had set his eyes on Maui, and when he felt the time was appropriate, he brought his forces together and conquered the king, who was Kamaluahua. From Maui, he went to Moloka‘i and conquered the king there.
With the two conquered kings with him, Kalaunuiohua traveled to O'ahu and conquered the ali'i (chief) of the west side of the island, before heading for Kaua'i. However, Kukona had heard that Kalaunuiohua was coming and was prepared for him. All of the Kaua'i chiefs united under Kukona and decimated Kalaunuiohua when he and his fleets came ashore along the Kōloa coast, at Kīpū. Mr. Blake believes that most of the human skeletal remains in the beach sands of Māhā'ulepū are from this battle.

Mr. Blake states that in his lifetime, there were no communities at Māhā'ulepū. No one lived there because it was all in sugar. Mr. Blake is the limu (algae) gatherer of his family. His favorite is limu kohu (Asparagopsis taxiformis), which is hard to find as it does not grow prolifically along the coast as other limu do. Limu kohu is high in iron and is good for the blood, so and he often was sent out by his father to Māhā'ulepū to collect it for his mother and sister to give them another boost of iron. Na'akea is the first bay you come to when coming around Kawelikoa Point. Although it was a long walk from his house and not easy to get to, Mr. Blake would often collect the limu kohu from Na'akea Bay (also known by its popular name, Second Ha'ula), because he knew that if it couldn't be found at the regular spots, it could always be found there, as it could be at Ha'ula. Ha'ula is a type of limu, but Mr. Blake has never eaten it, doesn't know how it can be used, nor does he remember hearing his parents or grandparents talk about it. Fishermen caught 'ulua and other fish by shoreline cast fishing on the points.

Continuing along the coastline to the south, you come to Kawaiola Bay, which is sandy and where people liked to camp. Mr. Blake would come to spend the weekends there fishing, swimming, and camping and end up spending the whole summer. From Kawaiola Bay, the sandy beach extended all the way to Waiopili Stream. This is presently called Māhā'ulepū Beach, as Kawaiola is also called Māhā'ulepū Beach today. The proper name is Kāmala and it extends a point to the north a short distance past Waiopili Stream. Just west of Waiopili Stream is the seaside border of Māhā'ulepū Ahupua'a and Pā'ā Ahupua'a.

Waiopili Stream started from the Kapunakea Spring, located near Waiopili Heiau. The spring was named for the white coral walls of the spring. Mr. Blake believes that there are no archaeological sites on the Māhā'ulepū Valley floor, he believes they were destroyed by the commercial production of sugar cane. He is not sure when sugar cane came to Māhā'ulepū, but the commercial production of sugar cane started on Kaua'i in 1835. The valley floor was deep-plowed twice every two years, which would have destroyed any archaeological sites that were there.

Mr. Blake says the clayey soils of Māhā'ulepū make it one of the best places to grow taro. As the sub-soils were comprised of clay, very little water was lost because the water could not permeate through the soil. Mr. Blake said that he had been told that the entire Māhā'ulepū
Valley, approximately 400 acres, had been in taro at one time. Mr. Blake goes on to say that none of the pesticides used by the plantation have impacted the ground water Māhā’ulepū, because the soil is impermeable.

Concerns

Mr. Blake doesn't believe the proposed Māhā’ulepū dairy will have a negative impact on the environment or on traditional cultural practices, previously or currently, conducted in Māhā’ulepū Ahupua'a.

Catherine and Karl Lo

Mrs. Lo first was not born here. The first time she came to hear about Māhā’ulepū was when Charles Tanimoto wrote the book “Return to Māhā’ulepū, which was published in 1982. At that time she and her husband, Karl, went to the library to borrow the book. Mrs. Lo is writing a book about New Mill Camp and one of the things she noticed was that the people she is interviewing keep going back to their childhood days when they were fishing and picnicking.

There was a Māhā’ulepū Camp, where Mr. Tanimoto was born and lived with his family, that dates back to the turn of the 19th century. The plantation had wells in Māhā’ulepū and Mr. Tanimoto's father was one of the mechanics that maintained the power plant that pumped out water to irrigate the cane fields. When Mr. Tanimoto was 75 he returned to Māhā’ulepū see where he grew up. He remembered the fishing; he looked for the wells, etc.

There was a small camp located in the shadow of Mount Hā'upu, near Koloa Mill, called New Mill Camp, where workers and their families lived. Many of former residents of New Mill Camp remember hiking to and overnight fishing at Black Mountain and picnicking, fishing, and camping at Māhā’ulepū’s Kawaiola Beach. They also remember going to Gillin's Beach during the 1950s and 1960s, when Māhā’ulepū was pristine.

Mrs. Lo recalls that after the hurricane of 1992, she and Karl went to Māhā’ulepū see the petroglyphs which had been exposed for the first time in years. By the time they got to the site, a day or two after they learned about it, sand had covered the petroglyphs.

Concerns

Catherine and Karl Lo submitted a letter, via e-mail dated April 17, 2015, which expresses their concerns about the dairy (Appendix E).

James (Jim) H. Case

In 1918, Mr. Case's father graduated from the University of Hawai‘i and joined the Hawaii National Guard. Soon after graduation, the Hawaii National Guard was mobilized, and Mr. Case's father was immediately assigned to the North Shore of O'ahu to guard Hawai‘i from
attacks by Germans and Austrians. That same year, Mr. Case's mother graduated from the University of California, Los Angeles. Mr. Case's mother's roommate was from Honolulu. So, following graduation, Mr. Case's mother went to Honolulu to visit her roommate. She liked it there, got a job, and met Mr. Case, Sr. Along the way, his parents married and Mr. Case was born on April 10, 1920, on Grove Farm. The house Mr. Case grew up in was located right in the middle of Grove Farm Plantation, about 200 yards away from G.N. Wilcox's house and office.

In 1920, following the end of World War I, Mr. Case, Sr., was hired by Grove Farm. According to Mr. Case, Grove Farm was started on the site of a huge kukui grove, and that is how Grove Farm came to be named. George N. Wilcox [owner of Grove Farm] acquired all of the land on the west side of a stream, which was located within a deep gulch, which emptied into Nāwiliwili Bay. Lihue Plantation is located on the east side of the stream. Mr. Wilcox gradually acquired all of the land on the west side of this stream up to the Kōloa Gap, with the exception of the Kīpū Ahupua'a, which was acquired by the Rice family a long time ago. The main valuable lands were located on the east side of Ha'upu Ridge. This area consisted of nice flat land that was good for the cultivation of all types of crops. This area includes Hulē'ia River, which flows along the bottom of the ridge, a large fishpond that is still there, but not Kīpū Kai (the seaward portion of Kīpū Ahupua'a).

Jim Case was born in 1920 at Grove Farm. The family home was 200 yards away from George N. (G.N.) Wilcox's house and office. As a boy, Mr. Case would go down on his bicycle to the (12 to 15 acre) Grove Farm dairy every morning, at 6 am, with a pale, to get milk. Jim Case went to elementary school at the Līhu'e Grammar School until the age of 13. His classmates included Elizabeth Knudsen, whose family owned a huge swath of land in the Kōloa/Po'iipi'i area. The Knudsen family home was at a place called Waiohai, on the beach at Po'iipi'i. Mr. Case visited there frequently throughout his youth, where he played polo with them. Outside of the plantation, the Knudsen family was one of the largest land owners in the area and very knowledgeable about the area. Mr. Case learned about the Kōloa area through his childhood friend, Elizabeth Knudsen.

Another one of Mr. Case's classmates was John Troop Moir, III, the son of the Koloa Plantation manager. As a boy, Mr. Case spent a lot of time at the Moir's house. He and John Troop Moir, III, went swimming at the beach, swam and fished at the [Waitā] reservoir, and drove around the fields.

Mr. Case got to know the Kōloa area even better through G.N. Wilcox's nieces, Ethel and Mabel Wilcox. They owned a beach home overlooking Brennecke's Beach, one of the best body surfing spots at the time. Every summer Ethel and Mabel loaned this house to Mr. Case's family. Mr. Case spent his childhood summers in this portion of Po'iipi'i, where he and his family often
drove the family car on a dirt road along the length of Māhā'ulepū Beach, stopping to swim and picnic along the way. Mr. Case stated that he and his family saw [human] bones, which were extruded out of the ground, in the sand dunes at the main beach. Some say there was a huge battle there. Mr. Case believes that Native Hawaiians lived near the beach and buried their dead close to where they lived and that it is not likely that the Native Hawaiians buried their dead in their taro patches.

Mr. Case stated that during his youth he saw no evidence of any habitation or of Hawaiian trails during his youthful driving excursions along the dirt roads within the sugar plantation. Although, he did observe Hawaiian trails on the sand dunes. He never climbed Mount Ha'upu Ridge, as "it was a long way up." He has hiked all over the Nāwiliwili side of Ha'upu Ridge from Kīpū Kai to Nāwiliwili Bay along ancient Hawaiian Trails. Of note, in this area is a ledge overlooking the entrance into Nāwiliwili Bay. The konohiki would climb to this ledge to sight schools of fish. When the konohiki sighted a school of fish he would blow his conch shell to notify the fishermen. This was still occurring during Mr. Case's childhood. As a boy, Mr. Case knew a konohiki there whose daughter was a few years ahead of Mr. Case in school and whose son played tennis with Mr. Case.

According to Mr. Case, no one he knew would go from Kōloa to Līhu'e over the mountain because Kōloa Gap was right there. Mr. Case believes the Hawaiians did go through Kōloa Gap because the only alternative route was by boat and the ocean was rough. Mr. Case said it was possible to travel by boat from Kōloa to Nāwiliwili Bay in order to access Kīpū Kai. Based on Mr. Case's knowledge of Hawaiian history, there would have been trails from the beach and lowlands up the mountain that the Hawaiians used to access areas for gathering flowers and plants for food and medicinal purposes. However, he never heard of any trails in the dairy area. Mr. Case stated that there are other ways to access the mountain without going through the dairy.

Mr. Case's knowledge comes from growing up on Grove Farm, spending a lot of time visiting with his classmates in Kōloa and spending summers in Po'ipū. Most of Mr. Case's information, in terms of what went on the old days," was learned from Elizabeth Knudsen's father, Erik, whose family had lived on Kaua'i for many years. Mr. Case and his friends did not spend much time in Māhā'ulepū because the area was covered in sugar cane fields, although they did go through the sugar cane fields to access Waitā Reservoir.

In 1948, G.N. Wilcox acquired Koloa Plantation and incorporated it into the Grove Farm Plantation. Prior to 1948, Grove Farm and Koloa Plantation were entirely separate operations. In 1948, Mr. Case was in law school and his father was the chief financial officer, for Grove Farm, where he was responsible for all of the plantation operations, with the exception of the
agricultural operations. Mr. Case Sr. negotiated this acquisition from the owners of the Koloa Plantation from AMFAC. As Mr. Case was studying corporate law, his father sent him copies of all the paperwork associated with this acquisition, which allowed him to go through the acquisition process as a law student.

**Concerns**

Mr. Case doesn't believe the proposed Māhā'ulepū dairy will have a negative impact on the environment or on traditional cultural practices, previously or currently, conducted in Māhā'ulepū Ahupua'a.

**SUMMARY**

The “level of effort undertaken” to identify potential effect by a project to cultural resources, places or beliefs (OEQC 2012) has not been officially defined and is left up to the investigator. A good faith effort can mean contacting agencies by letter, interviewing people who may be affected by the project or who know its history, researching sensitive areas and previous land use, holding meetings in which the public is invited to testify, notifying the community through the media, and other appropriate strategies based on the type of project being proposed and its impact potential. Sending inquiring letters to organizations concerning development of a piece of property that has already been totally impacted by previous activity and is located in an already developed industrial area may be a “good faith effort.” However, when many factors need to be considered, such as in coastal or mountain development, a good faith effort might mean an entirely different level of research activity.

In the case of the current undertaking, letters of inquiry were sent to individuals and organizations that may have knowledge or information pertaining to the collection of cultural resources and/or practices currently, or previously, conducted in close proximity to the proposed dairy to be located on an 557-acre property within Māhā'ulepū Valley, Māhā'ulepū Ahupua'a, Kōloa District, Island of Kaua'i. The property is owned by Mahaulepu Farms, LLC and comprised of TMK: (4) 2-9-003-001 por. & 006 por. and (4) 2-9-001:001 por.

Historical and cultural source materials were extensively used and can be found listed in the References Cited portion of this report. Such scholars as Samuel Kamakau, Martha Beckwith, Jon J. Chinen, Lilikalā Kame'eleihiwa, R. S. Kuykendall, Marion Kelly, E. S. C. Handy and E.G. Handy, and Mary Kawena Pukui and Samuel H. Elbert continue to contribute to our knowledge and understanding of Hawai‘i, past and present. The works of these and other authors were consulted and incorporated in this report where appropriate. Land use document research was supplied by the Waihona ‘Aina Database (2014).
CULTURAL ASSESSMENT

Analysis of the potential effect of the project on cultural resources, practices or beliefs, its potential to isolate cultural resources, practices or beliefs from their setting, and the potential of the project to introduce elements which may alter the setting in which cultural practices take place is a suggested guideline of the OEQC (2012). As indicated by the responses received from the community, the broad area constituting Māhā‘ulepū Ahupua‘a, has been, and is currently, used for traditional cultural purposes. However, the project area itself is not being utilized for these activities. The areas used to gather plants and marine resources; the plateau; the coastal petroglyphs; the trails; State Site 50-30-10-2250 (the agricultural heiau); and State Site 50-30-10-3094, Feature 3 (a petroglyph boulder), are all located outside of the project area.

Of the eleven individuals interviewed, two individuals believed that the dairy would not have an impact on traditional cultural practices or to the environment. The remaining individuals expressed a variety of concerns about impacts the proposed dairy may have which are indirectly and directly related to traditional cultural practices. The indirect negative impacts would affect:

- The environment (i.e., seepage, discharge, and runoff would impact the groundwater, drinking water, and the watershed, the reef, the ocean and marine resources, and the smells will pollute the air);
- Activities the interviewees enjoyed as children would not be experienced by future generations (i.e., camping, hiking, swimming); and to
- Archaeological/cultural features and sites located along the coast (i.e., the salt pans, the “kitchen” or “kitchen rock”, Makawehi Cave, and Waiopili Heiau, and the coastal petroglyphs).

Many the interviewees go to Māhā‘ulepū Ahupua‘a to conduct traditional cultural activities. These individuals expressed concerns regarding restricted access to Māhā‘ulepū Ahupua‘a and to the adjacent coastal area, restricted access to the trails within the ahupua‘a, which are utilized to gather natural resources for cultural purposes, and restrictions on conducting traditional ceremonies within the ahupua‘a. Concerns were also expressed in regards to impacts to the natural resources gathered and collected from the area resulting from the proposed dairy polluting the air, land, and the water. The traditional cultural activities include collecting specific terrestrial and marine resources and conducting ceremonies.

- Native plants gathered from Māhā‘ulepū Ahupua‘a, for traditional use include; ‘aweoweo, maile, mokihana, ‘ohi‘a ’ai, pilo, hinahina, limu kohu, mokihana, maile oli, and various native fruits and limu. Non-native plants collected from Māhā‘ulepū Ahupua‘a for traditional use include the seeds of black eyes susans, cat’s claw, and Java plum. These plants are used as medicines, in lei making, in ceremonies, traditional dance, and as food resources
• At least one traditional ceremony was recently conducted in Māhā'ulepū Ahupua'a;

• Native fish, used as food resources, caught from the waters of Māhā'ulepū Ahupua'a include ʻulua, opihi, wana, loli, uhu, manini, kala, menui, weke, moi, aholehole.

• The spiritual connection between the people and the land;

CONCLUSION

While some members of the community expressed concern about impacts from the dairy, others did not. Given the ability of the Environmental Impact Statement to address these impacts, it seems reasonable to conclude that, pursuant to Act 50, the exercise of native Hawaiian rights, or any ethnic group, related to numerous traditional cultural practices including, gathering, access, cultivation, the use of traditional plants, and the use of trails, will not be adversely impacted by the proposed dairy.

APPENDIX A: EXAMPLE LETTER OF INQUIRY
In compliance with the State of Hawai‘i Revised Statute (HRS) Chapter 343 Environmental Impact Statements Law, and in accordance with the State of Hawai‘i Department of Health’s Office of Environmental Quality Control (OEQC) Guidelines for Assessing Cultural Impacts as adopted by the Environmental Council, State of Hawai‘i on November 19, 1997, Scientific Consultant Services, Inc. (SCS) is in the process of preparing a Cultural Impact Assessment (CIA) in advance of proposed improvements for a proposed dairy farm property located within Māhā‘ulepū Valley, Māhā‘ulepū Ahupua‘a, Kōloa District, Island of Kaua‘i. The property is owned by Māhā‘ulepū Farms, LLC. [TMK: (4) 2-9-003-001 por. & 006 por. and (4) 2-9-001:001 por.] (Figures 1 and 2)

Scientific Consultant Services has conducted an Archaeological Inventory Survey of the proposed project area (Putzi et al. 2014, in prep.) in order to determine the presence of archaeological cultural materials. During the survey, one previously identified historic property, a carved petroglyph boulder (State Site 50-30-10-3094), was re-identified and 15 historic properties were newly identified and documented (Putzi et al. 2014, in prep.).

According to the Guidelines for Assessing Cultural Impacts (Office of Environmental Quality Control, Nov. 1997):

The types of cultural practices and beliefs subject to assessment may include subsistence, commercial, residential, agricultural, access-related, recreational, and religious and spiritual customs. The types of cultural resources subject to assessment may include traditional cultural properties or other types of historic sites, both man made and natural which support such cultural beliefs...

We are seeking any information that you or other individuals have which might contribute to the knowledge of traditional cultural activities that were, or are currently, conducted in the vicinity of the proposed project area. We are also asking for any information pertaining to traditional cultural activities or traditional rights which may be impacted by the construction of the proposed dairy improvements. The results of the cultural impact assessment are dependent on the response and contributions made by individuals and organizations such as yours.

Enclosed are maps showing the proposed project area. Please contact me at the Scientific Consultant Services, Honolulu, office at (808) 597-1182 or via e-mail (cathy@scshawaii.com) with any information or recommendations concerning this Cultural Impact Assessment.

Sincerely yours,

Cathleen Dagher
Senior Archaeologist

12/24/2014
Dear:

This is our follow-up letter to our December 23, 2014 2 letter which was in compliance with the statutory requirements of the State of Hawai‘i Revised Statute (HRS) Chapter 343 Environmental Impact Statements Law, and in accordance with the State of Hawai‘i Department of Health’s Office of Environmental Quality Control (OEQC) Guidelines for Assessing Cultural Impacts as adopted by the Environmental Council, State of Hawai‘i, on November 19, 1997.

Scientific Consultant Services, Inc. (SCS) is in the process of preparing a Cultural Impact Assessment (CIA) in advance of improvements to a dairy farm located within Māhā‘ulepū Valley, Māhā ‘ulepū Ahupua‘a, Kōloa District, Island of Kaua‘i [TMK: (4) 2-9-003-001 por. & 006 por. and (4) 2-9-001:001 por.]. The 580-acre property is owned by Māhā‘ulepū Farms, LLC.

In 2014, SCS (Putzi et al. 2014, in review) conducted an Archaeological Inventory Survey of the proposed project area in order to determine the presence, or absence, of historic properties. During the survey, one previously identified historic property, a carved petroglyph boulder (State Site 50-30-10-3094), was re-identified and 15 historic properties were newly identified and documented.

According to the Guidelines for Assessing Cultural Impacts (Office of Environmental Quality Control, Nov. 1997):

The types of cultural practices and beliefs subject to assessment may include subsistence, commercial, residential, agricultural, access-related, recreational, and religious and spiritual customs... The types of cultural resources subject to assessment may include traditional cultural properties or other types of historic sites, both man made and natural which support such cultural beliefs...

We are seeking any information that you or other individuals have which might contribute to the knowledge of traditional cultural activities that were, or are currently, conducted in the vicinity of the proposed project area. We are also asking for any information pertaining to traditional cultural activities or traditional rights which may be impacted by the construction of the proposed dairy improvements. The results of the cultural impact assessment are dependent on the response and contributions made by individuals, such as you.

Please contact me at the Scientific Consultant Services, Honolulu, office at (808) 597-1182 or via e-mail (cathy@scshawaii.com) with any information or recommendations concerning this Cultural Impact Assessment.

Sincerely yours,

APPENDIX E: CATHERINE AND KARL LO'S CONCERNS
Subject: April 17, 2015: CIA Interviews
From: Karl & Catherine Lo <cp1123@hawaiiantel.net>
Date: Fri, Apr 17, 2015 5:41 pm
To: Cathleen Dagher <cathy@scshawaii.com>
Cc: Beryl Blaich <blaich@aloaha.net>, tony_napua <tony_napua@msn.com>, Ted Kawahinehelelani Blake <tktlake@mac.com>

Aloha, Cathy:

It was a pleasure meeting you today and listening to Teddy Blake and Napua Romo share their personal knowledge on Maha‘ulepu.

We regret that David Chang is ill and couldn’t be at the meeting.

We await to see your notes on today’s sharing.

As to Hawai‘i Dairy Farms at Maha‘ulepu, here are our thoughts:

The dairy should be situated elsewhere away from homes, beaches and resorts.

Our concerns are based on experience, not fear. We remember Waimea Dairy, which in more recent years was owned by Meadow Gold Dairies. From the Westside, Meadow Gold moved to the North Shore and operated a dairy in Moloka‘i until 2000. Unpleasant odors during visits to the Westside and North Shore always assaulted our olfactory organs as we approached and passed the dairies.

Remembrance of the dairies always bring back memories of noxious odors. Cow manure is cow manure! They all have very unpleasant, harmful and poisonous fumes that pollute the environment and the air we breathe and compromise human comfort and well-being. Also, cow manure is breeding ground of bacteria and viruses that can cause disease making public health a concern.

With the dairy located so close to the ocean, it’s hard to convince the community that dairy waste will not create in some way runoff that will pollute Kawaiola Bay. Also, swimming and picnicking at Kawaiola Beach, fishing at Black Mountain, walking along the shore and enjoying a leisurely day at Maha‘ulepu may become the joys of yesteryears with the dairy taking over the valley.

Equally important to us as supporter of Malama Maha‘ulepu is our concern that a dairy at this pristine valley will destroy the natural, cultural and historical heritage for which Maha‘ulepu is appreciated and loved by residents and visitors alike.

Malama Maha‘ulepu’s mission is to take care of Maha‘ulepu, educate the public about it and preserve it for future generations. The question is: Is Hawai‘i Dairy Farms putting an end to this mission?

We hope that our paths will cross again. Until then....

Mahalo nui loa,
K & C

1 Introduction

Hawaii Dairy Farms LLC (HDF) intends to develop a dairy with up to 2,000 cows in the Maha‘ulepu Valley on the island of Kaua‘i. The project will utilize a pastoral-based rotational grazing system. To demonstrate the sustainability of the dairy, HDF is committed to establishing a herd of 699 cows. HDF will contemplate the possibility of expanding the herd up to 2,000 cows. Both herd sizes are analyzed in this report. This air emissions and odor evaluation report presents the analysis used to determine the potential impacts of odors from both herd sizes and fugitive dust concentrations for the larger contemplated herd size of the proposed dairy facility at off-site receptors. In addition, to evaluate the potential impact of particulate matter (PM) and greenhouse gas (GHG) emissions, the report evaluates the annual emissions from the project for these constituents of concern.

2 Project Site

The project area has historically been used for sugar cane production as part of the Koloa Plantation until the late 1990s when the Koloa Mill closed. Since the mill closed, the project area and its surrounding has been leased to various tenants for ranching and diversified agricultural operations. A small plot of land in the lower center of the valley is currently used for taro lo‘i and will continue to be leased and farmed after the dairy and related pastures are in full operation. Recreational land use such as golf courses and hotels are located approximately 0.9 miles to the south and residential properties are located more than 1.5 miles to the southwest and west. Figure 1 presents a project location map showing the project site and surrounding land use.

The total dairy farm area inclusive of pasture and dairy facility, but excluding the existing taro farm, is 556.8 acres. For the purposes of this evaluation, the dairy project site was divided into two land use areas: Field 1, 547.1 acres of pasture; and Field 2, 9.7 acres containing the dairy facility. Field 1 is broken up into paddocks of approximately 4 to 5 acres in size.

3 Air Dispersion Modeling Methodology

3.1 Model Selection

Computer-based air dispersion models can be used to determine the concentration and frequency of odors and fugitive dust at specific locations around a source using local weather data. The AERMOD modeling system (AERMOD (version 15181) and its pre-processing programs, AERMAP and AERMET) were used for the analysis. AERMOD is a steady-state Gaussian plume model that requires four general types of input data: emission source information, receptor locations, meteorology, and model specific control options.
3.2 Receptors\(^1\)

Fenceline (boundary) receptors and one Cartesian grid of receptors extending out to 4.5 km from the site were used for the modeling analysis. Fenceline receptor spacing was 25 meters while the Cartesian receptor grid spacing is 100 meters between receptors. All receptors were placed at ground level in the model based on standard modeling protocol.

3.3 Terrain

The project site is situated in the Maha‘ulepu Valley on the island of Kaua‘i. The valley is on the leeward side of the Ha‘upu mountain ridge, which runs in the east-west direction, and the valley is also flanked by ridge lines on both sides. Mt. Ha‘upu is the highest point on the ridge line at the back of the valley with an elevation of 2,297 feet. From this point, the ground drops very quickly down to the bottom of the valley to about an elevation of 150 feet. The base of the valley itself is somewhat gradually sloped from an elevation of 150 feet to an elevation of 60 feet along Maha‘ulepu Road on the makai side of the project site near the taro farm.

Terrain elevations were obtained from National Elevation Dataset (NED) digitized terrain data from the United States Geological Survey (USGS), and processed using AERMAP.

3.4 Meteorological Data

One year (2014) of AERMET-ready meteorological data for the project site was obtained from Lakes Environmental. The meteorological data were derived from the NCAR MM5 (5th-generation Mesoscale Model) prognostic meteorological model. The data were used to develop the necessary surface and upper air files for the project's location and modeling domain. These files were used as inputs into the AERMET pre-processing software. The final AERMOD-ready meteorological data file was processed using estimated surface characteristics in the project vicinity with AERMET. The surface characteristics were estimated from available aerial photos for the project location. A wind rose plot of meteorological data is presented in Figure 2. This figure shows that the predominant wind direction is towards the southwest.

\(^1\) Receptors are defined as locations at which odor or particulate concentrations are estimated and do not necessarily denote where a person is located.
3.5 Model Control Options

The analysis included the use of selected model control options that allow the model to be made more site and project specific. These model options include land use classification, incorporation of building wake information, averaging time, and regulatory control options. The modeling used the AERMOD regulatory default option. This option includes elevated terrain algorithms, the effects of stack-tip downwash, missing data routines, and calm wind processing. In addition, rural boundary layer effects were incorporated into the model.

3.6 Emission Sources

3.6.1 Odors

Odor emissions are generated during incomplete anaerobic decomposition of organic matter in manure. Potential sources at the facility would include the effluent ponds, the irrigation system which utilizes effluent, manure from pasture fields, and the dairy buildings. These sources are described in detail in the sections below.

Odor refers to the combined effect of a mixture of gases on the sense of smell. For livestock sources, it may contain hundreds of trace compounds including ammonia (NH₃) and hydrogen sulfide (H₂S). Instead of measuring the individual components of an odor, as is done in standard air concentration modeling, odor concentration is reported in odor units per cubic meter (OU/m³), and odor emissions are reported in units of OU/s (for point sources) and OU/s/m² (for area sources). An odor concentration of 1 OU/m³ is defined as the threshold where the odor of a sample has a 50 percent probability of being perceived by a trained odor specialist.

3.6.1.1 Effluent Ponds

The effluent pond design includes two ponds: a settling pond and storage pond. The settling pond allows for the settlement and accumulation of solids with the overflow of liquid effluent entering the storage pond. The effluent ponds are open to the atmosphere. The top of the settling pond is 87 feet by 133 feet with a total depth of 17 feet with side slopes not steeper than 2 horizontal to 1 vertical. Effluent from the settling pond overflows through overflow pipes and into the storage pond. The top of the storage pond is 215 feet by 133 feet with a total depth of 17 feet. However, it is not likely the effluents would reach the top of the ponds as it is designed for a 25-year flood level. Based on a normal 30-day period of rain and effluent storage, the settling pond would be 12 feet deep and the storage pond would be 10.75 deep. The corresponding widths and lengths are 67 feet by 113 feet and 190 feet by 108 feet for the settling pond and storage pond, respectively. The effluent ponds were modeled at ground level.
Each pond was modeled in AERMOD as an area source with dimensions of the anticipated 30-day period of rain and effluent storage effluent surface. Odor emission rates were taken from Feitz 2002 (Dairy Australia, December 2008) which measured 30 ponds over 12 months in Australia. These results were selected over other data presented in Dairy Australia (2008) as it was measured using a wind tunnel apparatus as opposed to isolation flux hoods. According to Dairy Australia, most research shows that isolation flux hoods under-predict odor emissions relative to wind tunnels.

3.6.1.2 Irrigation

Odors from the irrigation process will be based on the odors volatilizing from effluent water mixed with irrigation water. This water will be applied through two center pivots and released approximately one meter from the ground surface. Irrigation droplets are typically large (200 µm or larger) in order to prevent droplets from evaporating before hitting the ground (Hardy et al., 2006). These larger sized aerosols also limit the physical dispersion of the water droplets used in the center pivot. Therefore, the evaluation of the irrigation droplets as particulates is not considered. Irrigation pivot #1 will be a full circle pivot and irrigation pivot #2 will be a ¾-circle pivot. The ¼ circle not reached by irrigation pivot #2 will receive water through a hard-hose gun irrigation system.

The odor emissions associated with the effluent ponds were reduced by a factor of 12 to account for dilution of the effluent for irrigation. The diluted effluent will be quickly absorbed into the ground and the odor will be short-lived. Therefore, the area covered in an hour (1/40 of a complete rotation) was modeled as an area emission source. As a worst case scenario, the section closest to the southern boundary was used in this evaluation.

3.6.1.3 Pasture

The cows will be maintained in six mobs of animals. At the committed herd size of 699 cows, mobs will contain up to 115 animals and for the contemplated herd size of up to 2,000 cows, mobs will contain up to 334 animals. The cows graze for one day per paddock and will produce the majority of the manure in that one paddock as they graze. Each mob will graze in a separate paddocks of 27 to 81 acres, and
adjacent to paddocks with other mobs. Paddock blocks that would be occupied on a given day were selected based on a typical scenario and were modeled as an area source.

Odor emission rates were based on a study by Topper et al. (2008) which evaluated odors from manure of dairy heifers. Various diets were evaluated in the Topper et al. (2008) study. The odor emissions used for this odor evaluation was for high concentrate (HC) and 20% corn silage. Although this diet does not necessarily coincide with the project (pasture fed cows were not evaluated in Topper et al., 2008), the HC; 20% silage resulted in the highest percentage of urine in the manure which is consistent with the anticipated manure. The samples used in the Topper et al study were 200 grams in weight placed in a 3.8-liter glass jar. The odor emission rate used in this report was adjusted from the sample size used in Topper et al. (2008) (Appendix A).

3.6.1.4 Slurry

Solids collected from the settling pond will be applied on designated areas through a “gun type” application system to areas outside the liquid effluent application. The slurry consists of three components; 1) liquid effluent, 2) settled solids from the liquid effluent, and 3) irrigation/collected rain water. The settled solids will be mixed with liquid (effluent or irrigation and/or collected rain water) to create a solids suspension slurry, which can then be pumped to the hydrants. The ratio of liquid to solids will be 20:1 (mixing volume to solids volume). Since the liquid will consist of either effluent or irrigation/collected rain water, it is conservatively assumed that all the liquid will be effluent. The slurry will be pumped through underground pipes to hydrants which have a “gun sprinkler” with a 65 foot radius. The planned location of the application (the “sludge delivery area”) is anticipated to be on the east portion of the site between the area that is covered by the irrigation two center pivots for the committed herd size of 699 cows and anywhere within the site. As a worst case scenario for the contemplated herd size of up to 2,000 cows, the section closest to the southern boundary not occupied by cows (since sludge is not applied to occupied areas) was used in this evaluation.

The odor emissions associated with the slurry were based on undiluted effluent and pasture manure, described in Sections 3.6.1.2 and 3.6.1.3 in a ratio of 20:1 effluent to manure. An area covering a circle with a 65-foot radius, consistent with the gun sprinkler reach was modeled with a ground level release height.

3.6.1.5 Dairy Facility

The dairy facility is contained within an approximately 10-acre area in Field 2. The corresponding building areas are under 0.1% of the total farm area. The dairy buildings include the milking parlor, an implement shed, and calf sheds. The milking parlor contains an automated 60-stall rotary which is approximately 256 feet by 88.5 feet by 33 feet tall. Two open bay calf sheds will be constructed to provide safe housing
to newly born calves. Each shed will be approximately 81 feet by 26 feet by 15 feet tall. The feeding area will be washed daily and the wastewater transferred to the effluent ponds.

Dairy facility odor emissions were modeled as area sources with dimensions of the building footprint. Emission rates consistent with free stall dairy buildings from Jacobson et al. (2001) were used.

Table 1 summarizes the emission fluxes used in the evaluation and the area of the emission source. The emission flux estimates are detailed in Appendix A.

Notes:
All sources were modeled as area sources with a ground level release (i.e., release height = 0) with the exception of irrigation which was modeled with a release height of 1 meter (the height of the effluent water from the center pivots).
3.6.2 Fugitive Dust

Fugitive dust emissions, measured as particulate matter (PM), are generated from the movement of cows along the walkways and races that connect the paddocks together and provide access to and from the dairy facility. The cow races allow twice daily movement of the cows from the paddocks to the Milking Parlor and are not irrigated. Figure 4 shows the cow walkways and races. Emission rates, in mass of PM per time, were estimated using USEPA AP-42 emission factors. These emission factors were developed from literature sources from a number of dairy farm sources including scrape freestall barns, drylots, liquid manure land application activities, and solids storage. The only source with measurable PM emissions was from drylots. Drylots are confined areas where animals are walking over dirt and dried manure throughout the day. In the project scenario, cow movement along the walkways and races would occur for brief periods of time during the day. Therefore, use of the PM emission factor from AP-42 will overestimate PM emissions associated with cow movement along the cow walkways and races.

Calculated emission rates were then used in the AERMOD model to estimate downwind concentrations in micrograms per cubic meter (µg/m³). Emissions were evenly distributed throughout the cow walkways and races and assumed to occur between the hours of 6 am and 9 pm. Figures 3 and 4 show the locations of the modeled odor emission sources and particulate matter sources, respectively.

3.7 Thresholds

3.7.1 Odor

The development of a target odor criteria is complicated by the difficulties in odor sampling and measurement combined with a lack of suitable data on odor levels associated with annoyance and complaint. Mahin (2003) presented regulatory off-site limits based on levels predicted by dispersion modeling in the U.S. range from 1 OU/m³ to 50 OU/m³ for a variety of averaging times.

</tr>
</tbody>
</table>

3 As discussed in Section 3.6.1.2, irrigation droplets are typically large (200 µm or larger) and are therefore not included in PM₁₀ (particulate matter 10 µm or less) and PM₂.₅ (particulate matter 2.₅ µm or less) analyses.
Many of these values are for wastewater treatment plant or composting facilities, but none of the regulatory standards are specific to dairy farms. However, an Australian study by Wang and Feitz (2004) suggested 6.5 OU/m³, 1-hour averaging and 99.5th percentile at receptor as appropriate criteria for the assessment of dairy farm odors. Based on the source of the odor, this odor threshold was selected for this analysis. These criteria represent the extent of the 6.5 OU/m³ level that could be expected to be reached only 0.5% of the time (1 – 99.5%), or once per 200 hours, or 44 hours per year. In other words, 99.5% of the time the odor threshold of 6.5 OU/m³ is less than the extent shown, and only 0.5% of the time is it at or beyond the extent shown.

3.7.2 Fugitive Dust

Fugitive dust was modeled as PM₁₀ (respirable dust particles of less than 10 microns) and PM₂.₅ (fine dust particles less than 2.5 microns). Modeled PM₁₀ and PM₂.₅ concentrations were added to background concentrations and compared to State and Federal ambient air concentration standards. The standards are presented in Table 3.

3.8 Results

3.8.1 Odor

Odor isopleths were created using the results of AERMOD modeling. The odor modeling analysis and isopleths indicate that the 99.5th percentile of 6.5 OU/m$^3$ odor threshold extend beyond the dairy farm boundary, however it does not reach recreational nor residential areas. Figures 5 and 7 illustrate the extent of the odors for both herd sizes, respectively. Figures 6 and 8 show close-up views of the same odor extents. It should be noted that the parameters used in this analysis were intentionally very conservative and the impacts shown depend on an unlikely confluence of worst-case meteorological data, irrigation location, and grazing location; thus, actual offsite odor impacts are likely to be much lower and/or less frequent than shown.

3.8.2 Fugitive Dust

Fugitive dust concentrations from the contemplated herd size were estimated using the results of AERMOD modeling. The fugitive dust concentration from the dairy farm was added to the background concentration and compared to the state ambient air quality standards. All of these concentrations were less than the applicable state and federal standards. Because of the relatively low impact even at the contemplated herd size, fugitive dust modeling was not conducted for the committed herd size.

3.8.3 Overall

Based on the air dispersion modeling conducted for both committed and contemplated herd sizes development, neither the odor nor fugitive dust emissions from the dairy farm would exceed applicable thresholds. In addition, aerosols from irrigation water would not extend across the facility boundary.
4 Annual Emissions from Potential Constituents of Concern

In addition to modeling concentrations of odors and particulate matter (PM), total annual emissions (in tons per year) were estimated for PM and greenhouse gases (GHGs). Total annual emissions are typically estimated for potential Hawaii Department of Health (DOH) Clean Air Branch (CAB) permitting applicability. The minimum annual emission threshold for regulated pollutants emitted from regulated sources are given in Hawaii Administrative Rules (HAR) Chapter 11-60.1. For GHGs, the threshold is 3,500 tons per year, and for PM is 2 tons per year. However, for the dairy project, the sources of GHGs and PM (enteric fermentation by cattle, manure application, and fugitive dust from cattle raceways) are not considered regulated sources by CAB standards. Therefore, total annual emissions are estimated only for comparison purposes.

4.1 Emission Sources

4.1.1 Particulate Matter

Fugitive dust emissions, measured as PM, are generated from the movement of cows along the walkways and races that connect the paddocks together and provide access to and from the dairy facility.

4.1.2 Greenhouse Gases

Dairy cows can result in methane (CH$_4$) emissions from enteric fermentation and both CH$_4$ and nitrous oxide (N$_2$O) emissions from manure application. Manure application includes direct deposition from cows and application of slurry and irrigation water containing manure.

4.2 Emission Factors

4.2.1 Particulate Matter

Emission rates, in mass of PM per time, were estimated using USEPA AP-42 emission factors from the Emissions from Animal Feeding Operations Report. A PM emission rate of 2.3 pounds per year per “animal unit” (where 1 cow equals 0.7 animal units [AU]), was obtained for dairy cattle from drylots. Specific parameters are presented in the attached Table A-3.

4.2.2 Greenhouse Gases

GHG emission rates were calculated using IPCC’s Guidelines for National Greenhouse Gas Inventories (IPCC 2006). Specific parameters were selected for Oceanic dairy cattle in warm climates to most accurately represent conditions at the Hawaii Dairy Farms. CH$_4$ and N$_2$O emissions were converted to
carbon dioxide equivalents (CO$_2$e) using the IPCC’s AR4 global warming potential (GWP) that relates the GHG to CO$_2$. Specific parameters are presented in the attached Tables A-4 to A5.

4.3 Results

For the committed and contemplated herd sizes, GHG emissions were estimated to be 2,693 and 7,705 CO$_2$e metric tons per year, respectively. The total annual PM for the committed and contemplated herd sizes is 0.6 and 3.3 tons per year. Detailed calculations are provided in Appendix A.

**DIRECT N2O EMISSIONS FROM MANAGED SOILS (TIER 1)**

\[
N_{2O_{Direct}} = N_{2O-N_{input}} + N_{2O-N_{OS}} + N_{2O-N_{PRP}}
\]

Where:

\[
N_{2O-N_{input}} = \left[ \left( F_{IN} + F_{DN} + F_{CR} + F_{OM} \right) \cdot EF \right]
\]

\[
N_{2O-N_{OS}} = \left( F_{OS\_CG\_Temp} \cdot EF_{CG\_Temp} \right) \left( F_{OS\_F\_Temp\_NR} \cdot EF_{F\_Temp\_NR} \right)
\]

\[
N_{2O-N_{PRP}} = \left( F_{PRP\_CPP} \cdot EF_{PRP\_CPP} \right) \left( F_{PRP\_SO} \cdot EF_{PRP\_SO} \right)
\]

Where:

- \(N_{2O_{Direct}}\) = annual direct \(N_2O-N\) emissions produced from managed soils, \(kg\ N_2O-N\ yr^{-1}\)
- \(N_{2O-N_{input}}\) = annual direct \(N_2O-N\) emissions from inputs to managed soils, \(kg\ N_2O-N\ yr^{-1}\)
- \(N_{2O-N_{OS}}\) = annual direct \(N_2O-N\) emissions from managed organic soils, \(kg\ N_2O-N\ yr^{-1}\)
- \(N_{2O-N_{PRP}}\) = annual direct \(N_2O-N\) emissions from urea and dung inputs to grazed soils, \(kg\ N_2O-N\ yr^{-1}\)
- \(F_{IN}\) = annual amount of synthetic fertilizer N applied to soils, \(kg\ N\ yr^{-1}\)
- \(F_{DN}\) = annual amount of animal manure, compost, sewage sludge and other organic N additions applied to soils (Note: If including sewage sludge, cross-check with Waste Sector to ensure there is no double counting of \(N_2O-N\) emissions from the N in sewage sludge), \(kg\ N\ yr^{-1}\)
- \(F_{CR}\) = annual amount of N in crop residues (above-ground and below-ground), including N-fixing crops, and from forage/pasture renewal, returned to soils, \(kg\ N\ yr^{-1}\)
- \(F_{OM}\) = annual amount of N in mineral soils that is mineralised, in association with loss of soil C from soil organic matter as a result of changes to land use or management, \(kg\ N\ yr^{-1}\)
- \(F_{OS}\) = annual area of managed/drained organic soils, ha (Note: the subscripts CG, F, Temp, Trop, NR and NP refer to Cropland and Grassland, Forest Land, Temperate, Tropical, Nutrient Rich, and Nutrient Poor, respectively)
- \(F_{PRP}\) = annual amount of urea and dung N deposited by grazing animals on pasture, range and paddock, \(kg\ N\ yr^{-1}\) (Note: the subscripts CPP and SO refer to Cattle, Poultry and Figs, and Sheep and Other animals, respectively)
- \(EF_{IN}\) = emission factor for \(N_2O-N\) emissions from N inputs, \(kg\ N_2O-N / (kg\ N\ input)^{1}\) (Table 11.1)
- \(EF_{PRP}\) = emission factor for \(N_2O-N\) emissions from N inputs to flooded rice, \(kg\ N_2O-N / (kg\ N\ input)^{1}\) (Table 11.1)
- \(EF_{OS}\) = emission factor for \(N_2O-N\) emissions from drained/managed organic soils, \(kg\ N_2O-N / ha^{-1}\ yr^{-1}\) (Table 11.1) (Note: the subscripts CG, F, Temp, Trop, NR and NP refer to Cropland and Grassland, Forest Land, Temperate, Tropical, Nutrient Rich, and Nutrient Poor, respectively)
- \(EF_{PRP}\) = emission factor for \(N_2O-N\) emissions from urine and dung N deposited on pasture, range and paddock by grazing animals, \(kg\ N_2O-N / (kg\ N\ input)^{1}\) (Table 11.1) (Note: the subscripts CPP and SO refer to Cattle, Poultry and Figs, and Sheep and Other animals, respectively)
**Equation 11.5**

**N in urine and dung deposited by grazing animals on pasture, range and paddock (Tier 1)**

\[ F_{PRP} = \sum_{T} \left( N_{T} \cdot N_{e}(T) \cdot MS_{T,PPP} \right) \]

Where:

- \( F_{PRP} \) = annual amount of urine and dung N deposited on pasture, range, paddock and by grazing animals, kg N yr\(^{-1}\)
- \( N_{T} \) = number of head of livestock species/category \( T \) in the country (see Chapter 10, Section 10.2)
- \( N_{e}(T) \) = annual average N excretion per head of species/category \( T \) in the country, kg N animal\(^{-1}\) yr\(^{-1}\) (see Chapter 10, Section 10.5)
- \( MS_{T,PPP} \) = fraction of total annual N excretion for each livestock species/category \( T \) that is deposited on pasture, range and paddock\(^{12}\) (see Chapter 10, Section 10.5)

**Equation 10.20**

**Annual N excretion rates**

\[ N_{e}(T) = N_{e}(T) \cdot \frac{TAM}{1000} \cdot \frac{365}{TAM} \]

Where:

- \( N_{e}(T) \) = annual N excretion for livestock category \( T \), kg N animal\(^{-1}\) yr\(^{-1}\)
- \( N_{e}(T) \) = default N excretion rate, kg N (1000 kg animal mass\(^{-1}\)) day\(^{-1}\) (see Table 10.19)
- TAM\(_{T}\) = typical animal mass for livestock category \( T \), kg animal\(^{2}\)

\[ N_{2}O = N_{2}O-N \cdot \frac{44}{28} \]

EXECUTIVE SUMMARY

1. PROPOSED DAIRY

In 2013, Ulupono Initiative funded Hawai‘i Dairy Farms (“HDF” or the “Dairy”). The Dairy was formed to increase Hawai‘i’s supply of milk and thereby reduce dependence on imported milk, bolster food security for the islands with a sustainable supply of milk, and help diversify the economy.

The Dairy will be located in Māhā‘ulepū Valley in Kōloa, Kaua‘i because the site meets the operational requirements for a dairy, and the Valley was found to provide ideal growing conditions for grass feed and dairy cows. Based on the most successful island dairy models in the world, the Dairy will be the first in Hawai‘i to use rotational pasture-grazing. The two existing dairies in Hawai‘i and most dairies on the mainland use feedlots. Also, the Dairy will use the most advanced dairy-farming techniques, including: (1) precision monitoring of the health of the cows; (2) technology to determine the productivity of the land and, ultimately, its carrying capacity; (3) effluent management to ensure environmental health and safety; and (4) other best management practices.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating that rotational pasture-grazing is an economically and environmentally sustainable model for Hawai‘i. With proven success, HDF may expand the herd up to the carrying capacity of the land, which is currently estimated to be up to 2,000 productive milking dairy cows. For dairy operations with 700 or more milking cows, additional regulatory review and permitting by the State Department of Health will be required. The process for the additional approvals, including public notification and input, will be followed if and when HDF decides to pursue an expanded operation.

2. SOCIO-ECONOMIC CONDITIONS

The Dairy site is located in the Kōloa-Po‘ipū region. This region has socio-economic conditions similar to those of the entire island except for the following:

— Demographic
  • Slower population growth.
  • During the previous decade, a slight decline in the male population and a significant increase in the female population (evidently, many males left due to more attractive opportunities elsewhere).
  • A slightly older population, with fewer school-age children and more retirees.
EXECUTIVE SUMMARY

- More whites and fewer Asians and Native Hawaiians/Other Polynesians.
- More residents born in another state.
- Smaller households.
- More homes for seasonal, recreational or occasional use.

— Income and Education
- Higher per-capita incomes.
- Less poverty.

— Property Values
- Higher average values for both single family homes and condominiums.

It should also be noted that the economy of the region and the entire island depend heavily on tourism, with about 36% of the visitor units located in the Poʻipū area.

3. AGRICULTURAL BENEFITS

a. Increased Food Self Sufficiency

Milk

The Dairy will increase Hawaiʻi’s milk self sufficiency and reduce fluid milk imports. At full steady-state operations achieved after the pasture matures, the Dairy will produce about 1.5 million gallons of milk per year for a 699-cow dairy. Should HDF decide, in the future, to expand the herd up to 2,000 milking cows, milk production could reach 4.4 million gallons. This compares to about 4 million gallons produced in Hawaiʻi in 2015. Production was down from a peak of about 18.3 million gallons in 1988 when Hawaiʻi dairies supplied nearly all of the milk consumed in the state.

Livestock

In addition, the Dairy will increase the supply of livestock, including female calves for other dairies, male calves for beef ranching, and culled cows and heifers for beef or dairy operations.

b. Open Space

The Dairy’s irrigated pasture will provide about 470 acres of well-maintained grassland divided into 119 fenced paddocks. The herd will be split into 6 groups, each of which will be rotated among the paddocks. Thus, at any given time, about 5% of the pasture land will be occupied by cows (6 of 119 paddocks), and about 95% will be unoccupied green open space. In addition, about 77 acres will be used for cow raceways, internal roads, and setbacks along drainage ditches.
4. Employment Benefits

a. Construction and Related Employment

Development of the Dairy and related processing facilities will employ an average of about 12 construction workers during the 2-year construction period for the dairy. Indirect employment related to Dairy development is expected to average about 16 jobs on Kaua‘i and 8 jobs on O‘ahu. Thus, total direct-plus-indirect employment associated with Dairy development will average about 36 jobs, of which about 28 jobs will be on Kaua‘i. The actual job counts will fluctuate over time, depending on the pace of construction.

b. Operating Employment

At full operations, the 699-cow dairy will provide about 11 jobs on Kaua‘i, including about 5 farm jobs and about 6 indirect jobs. About 3 indirect jobs will be on O‘ahu.

Corresponding employment figures for the 2,000-cow dairy are about double.

5. Fiscal Benefits

a. County

Development of the Dairy is expected to have a negligible impact on County finances inasmuch most taxes on construction activity is collected by the State, and HDF will provide needed infrastructure (interior roads, water distribution, drainage, etc.). Also, most construction workers are expected to be from Kaua‘i, so they already pay taxes and will not require additional services from the County.

At full operations, the Dairy is expected to generate net income to the County of about $51,000 for the 699-cow Dairy. Should HDF decide, in the future, to expand to a 2,000-cow Dairy, net income to the County would be about the same. Most of the taxes will come from property taxes on improvements.

Dairy workers and their families will pay a variety of taxes to the County, while also requiring County services. For these workers and families, the resulting net revenues are expected to be near zero but positive since the County budget is structured to break even, and most Dairy workers will earn wages higher than the County average.

b. State

Unlike the County, the State will derive significant revenues from development activity: a cumulative total of about $650,000 for both the 699-cow dairy and the 2,000-cow dairy. However, the revenues will be offset by the $1 million tax credit for improvements on land designated by the State Land Use Commission as Important Agricultural Lands. Most construction workers are expected to be from Hawai‘i, so they already pay taxes and will not require additional services from the State.
When the Dairy is operational, net income to the State is expected to exceed $60,000 per year for the 699-cow Dairy, and exceed $170,000 per year should HDF decide, in the future, to expand to a 2,000-cow Dairy.

6. Nuisance Issues and Impacts

Given the important economic, residential, and recreational role of the Kōloa-Poʻipū region, the Dairy must be compatible with, and not cause adverse impacts on regional resorts, commercial areas, homes, recreational activities, etc.

The Dairy will feature modern facilities and practices, and will comply with all applicable Federal and State environmental standards. Considerable distances will separate the Dairy from the resorts, commercial areas, homes and recreational areas. The nearest resort units are about 1.5 miles from a Dairy paddock and about 2.4 miles from the Dairy milking parlor. For the Kōloa town center, the distances from the closest paddock and dairy facilities are about 2.2 and 2.8 miles, respectively. For homes, the distances are about 1 and 2 miles away, respectively. And for recreational activities, the distances are about 0.6 mile and 1.3 miles, respectively.

The environmental studies indicate that no noticeable noise, dust, odors, flies, runoff, or other nuisance impacts will extend to resort, commercial, residential or recreational areas. Noticeable nuisance impacts occurring outside the Dairy property will be limited to the abutting farm and ranch lands which are owned by Māhāʻulepū Farm, lessor of the Dairy property. These abutting lands are designated Important Agricultural Lands, so they will remain in agriculture for the foreseeable future.

In view of these findings, the Dairy will not adversely affect:

— Guests of resorts in the Kōloa-Poʻipū region.
— Recreational activities in the region.
— The regional economy (number of visitors, visitor expenditures, retail sales, employment, incomes, etc.)
— Residents when at home in the region.
— Property sales in the region (single-family homes, condominiums, second homes, time-share units, etc.).
— Values of properties in the region.
— County or State taxes derived from residents, resorts, or commercial activities in the region.

From a broader perspective, the Dairy will help maintain the existing rural character and ambience of the Kōloa-Poʻipū region.
HAWAI‘I DAIRY FARMS:
SOCIO-ECONOMIC CONDITIONS,
ECONOMIC IMPACTS, AND FISCAL IMPACTS

PART I: INTRODUCTION AND PROPOSED DAIRY

1. INTRODUCTION
   a. Content and Purpose

      In 2013, Ulupono Initiative funded Hawai‘i Dairy Farms (‘’HDF’’ or ‘’Dairy’’). The Dairy will be located in Kōloa, Kaua‘i.

      This report addresses the socio-economic conditions on Kaua‘i and the Kōloa-Po‘ipū region, plus the economic and fiscal impacts of the Dairy. The purpose is to provide the community and State and County officials with relevant information about planned development and operations.

      Socio-economic conditions includes information about the population, housing, incomes, education, economic activities, employment, labor force, and property values on Kaua‘i and in Kōloa-Po‘ipū.

      Economic impacts cover sales and expenditures, profits, employment, and payroll related to (1) construction and related activities, and (2) full operations of the Dairy. Also covered is the impact of the Dairy on property values.

      Fiscal impacts address the impact of the Dairy on County and State revenues and expenditures. The material covers the increase in County and State tax revenues, the increase in government support expenditures, and the resulting net revenues to the County and State.

   b. Methodology

      Socio-economic Conditions

      Demographic data for this report was gathered from the U.S. Census Bureau. Data is presented for Kaua‘i County and the Kōloa-Po‘ipū Census Subdivision. Population counts are provided for 2000 and 2010 from the decennial census. Demographic, social, household and economic characteristics of the population were obtained from the 2000 decennial census and the American Community Survey (‘’ACS’’) for 2009-2013. The ACS is an ongoing survey that provides up-to-date information about the nation’s population. The ACS includes
questions that were not included in the 2010 decennial census (but, historically, were included in the 2000 census). The ACS releases data every year in the form of estimates. The most up-to-date available data from the ACS are five-year estimates from 2009-2013. In addition to providing population counts for 2000 and 2010, this report provides an analysis of population characteristics for 2000 and an estimate for the period covering 2009-2013.

Additional information on socio-economic conditions and projections for the County and Kōloa-Po'ipū was obtained from the County of Kaua‘i, State Department of Labor and Industrial Relations (“DLIR”), the Hawaii Tourism Authority, and the State Department of Business, Economic Development and Tourism.

Residential sales price data was obtained from Locations Hawai‘i, while assessed property value information for individual properties located nearest to the proposed Dairy were gathered from RealQuest Professional, a private data service that compiles local real property tax data.

**Economic and Fiscal Impacts**

**Multipliers**

The proposed development and operations are translated into economic and fiscal impacts based on a number of multipliers (for example, indirect sales as a percentage of direct sales, construction jobs per $1 million in expenditures, indirect jobs per direct jobs, and tax rates). These multipliers reflect the professional judgment of the consultant, and were derived based on information from the following sources: U.S. Census data; the State of Hawai‘i Data Book; The Hawai‘i State Input-Output Study: 2007 Benchmark Report (I-O Model); employment and labor rates from DLIR; County and State tax rates; and revenue and expenditure data from the County and the State.

**2015 Dollars**

For the economic and fiscal impacts (Part III), dollar amounts are expressed in terms of 2015 purchasing power and market conditions. Values, prices, costs and dollar amounts for prior years are adjusted for inflation to 2015 dollars based on the Honolulu Consumer Price Index (CPI) for Urban Consumers. Dollar amounts after 2015 are not increased to account for inflation, appreciation in property values, changes in labor rates, changes in building costs, or other changes in market conditions.

**Accuracy of Estimates**

Much of the analysis contained in this report is quantitative in nature, where numbers are used to help communicate anticipated impacts. However, these numbers should not be interpreted as precise predictions. Rather, they represent the best estimates of what is expected to occur based on available information about planned development and operations,
market conditions, and tax rates. As a general rule, economic and fiscal impact estimates in this report are accurate within about 25%.

c. **Organization of the Report**

The report is divided into three Parts:

— Part I: Introduction and Proposed Dairy
— Part II: Socio-Economic Conditions
— Part III: Economic and Fiscal Impacts

All Figures in this report are embedded in the text, while all tables are at the end of the report. Socio-economic conditions for Kaua‘i and Kōloa-Po‘ipū are presented in Tables II-1 to II-9. Economic and fiscal impacts are presented in Tables III-1 to III-5: In these tables, the quantities appearing in **bold** highlight the most significant impacts.

d. **Economic Consultant**

The analysis was conducted by Plasch Econ Pacific LLC, a Hawai‘i-based economic-consulting firm specializing in economic development, land and housing economics, feasibility studies, valuations, market analysis, public policy analysis, and the economic and fiscal impacts of projects.

2. **Dairy Acreage and Location**

The Dairy will occupy about 557 acres in Māhā‘ulepū Valley in Kōloa, Kaua‘i (see Figure I-1). The Tax Map Keys (TMKs) for the property are: (4) 2-9-003:001 (portion), (4) 2-9-003:006 (portion), and (4) 2-9-001:001 (portion). The land is being leased from Māhā‘ulepū Farm, LLC.

This site was chosen for the Dairy for the following reasons:

— Kaua‘i Island was determined to best meet the operational requirements for the Dairy.

— Māhā‘ulepū Valley has ideal conditions for the Dairy, including favorable soils, high solar radiation, and other agronomic conditions for growing nutritious forage; a sufficient supply of water for cows and for irrigating pastures; minimally sloped terrain with few stones, allowing safe navigation by cows; sufficient contiguous land to support an economically viable pasture-based dairy; long-term availability of the land; and good access.

— The site is sufficiently removed from resorts, residential communities, and recreational areas so as to avoid potential nuisance impacts (noise, dust, odors, flies, runoff, etc.).
Figure I-1. Hawai‘i Dairy Farms Map
Māhāʻulepū Valley has been used for commercial agriculture for over 140 years, notably for cultivating sugarcane as part of the Kōloa Plantation, then by McBryde Sugar Co. which ceased operations in 1996. Ranching began in the valley in 1986, and taro cultivation was introduced on an adjacent parcel in 2007.

In response to a petition by Māhāʻulepū Farm, the State Land Use Commission designated in 2011 about 1,533 acres in Māhāʻulepū as Important Agricultural Lands (“IAL”). This designation, which includes the Dairy site, ensures that the land will remain in agriculture for the foreseeable future.

3. Plans for the Dairy

a. Contributions

Until 1984, a number of local dairies throughout Hawaiʻi produced all of the milk consumed in Hawaiʻi. But by 2008, most of them had closed due to the high cost of imported feed and competition from low-cost mainland milk imports. Currently, the two remaining dairies, both of which are located on the Big Island, supply only about 10% of the fresh milk consumed in Hawaiʻi, while imports supply about 90%.

The proposed Dairy will reverse this decline. It will increase the supply of local milk and thereby reduce imports, bolster food security for the islands with a sustainable supply of milk, and help diversify the economy.

b. Land Use

The 557-acre Dairy site will include: (1) about 10 acres for farm structures and related facilities; (2) about 470 acres for pastures; and (3) about 77 acres for cow raceways, internal roads, and setbacks along drainage ditches.

c. Rotational Pasture Grazing

The Dairy will be the first in Hawaiʻi to employ rotational pasture-grazing. A herd of up to 699 milking cows will be divided into six mobs, each of which will be rotated systematically through about 119 fenced paddocks to feed on locally grown pasture grass, supplemented with other feeds and vitamins as needed. Kikuyu grass was selected as the most productive and nutritious grass for rotational grazing. About every 12 to 18 hours, each mob of cows will be moved from one paddock to another in order to prevent overgrazing of the pastures within paddocks, and to allow the pastures to recover between grazings. This approach optimizes grass growth, cow health, and milk production; facilitates even deposits of manure for fertilization; and reduces erosion and runoff. The Dairy will use the most advanced dairy-farming techniques, including: (1) precision monitoring of the health of the cows and the productivity of the grass; (2) technology to determine the productivity of the land and, ultimately, its carrying capacity; (3) effluent management to ensure environmental health and safety; and (4) other best management practices.
In contrast to the Dairy’s rotational pasture-grazing approach, traditional dairies enclose their milking cows in feed lots where the cows feed on grains, hay and/or silage. In Hawai‘i, however, this approach requires farmers to import expensive feed for their animals. The alternative to importing feed is to produce it locally. This has been attempted many times over the past 40 or more years. Problems have included grain-eating birds; humidity that is too high to dry forage crops for hay; occasional high winds or heavy rains which damage feed crops; the high cost of harvesting, processing, and transporting grass to produce silage; etc. The rotational pasture-grazing approach eliminates many of these problems.

d. Cow Breed

The Dairy will use Kiwi-cross cows, which are a cross breed of Friesian-Holstein and Jersey milking cows. They are small in stature, bred to produce milk from grass, and their milk has a high butterfat and protein content, which allows for a wide variety of added-value dairy products such as yogurt and cheese.

e. Milking

The cows will be moved via a system of raceways (aka walkways) to the milking parlor where they will be milked twice a day. The milking will take place on a highly automated 60-stall rotary, which completes one rotation every 9 minutes or so. With this system, the maximum milking time is 10 minutes, and the maximum time off-pasture per milking is 1 hour.

f. Calves

Newborn calves will stay in single crates for up to 10 days, after which they will be transferred to pens that will hold 20 calves each. At age 3 to 4 weeks, calves will transition to pasture. At about 90 days of age, the calves will be transferred to another ranch (see next subsection).

g. Related Ranch Operations

Dry cows, heifers, and calves older than 90 days will be managed off-property on existing ranches that are owned and operated by other local ranchers.

h. Products

The Dairy will produce raw milk that will be sold in bulk to a dairy processor who will process and package the milk and related products for sale to consumers.

Additional revenues will be derived from the sale of female calves to other dairies, male calves for beef ranching, and culled cows and heifers for beef or dairy operations.
i. **Reuse of Nutrients**

Manure captured during the milking process will be transferred via underground pipes to two nearby effluent ponds (about 7,600 sq. ft. and about 20,500 sq. ft.), where solids will settle out and the remaining fluid stored for application to the pasture via the irrigation system. When applied to the pasture, this nutrient-rich fluid will be mixed with non-potable irrigation water.

The effluent ponds will be constructed within a secondary containment berm, and the ponds be lined with a flexible membrane of synthetic material.

j. **Improvements**

In converting former sugarcane fields to pastures, the existing infrastructure will be reused where possible. This will include gravel access roads, field roads, reservoirs, pipelines, irrigation ditches, drainage-ways and culverts. Field improvements will include a livestock water-distribution system, two pivot irrigation systems, cow raceways, perimeter and paddock fencing, and additional culverts.

Dairy buildings and related facilities will occupy approximately 10 acres along the western boundary of the farm. The milking parlor (about 22,700 sq. ft.) will be the largest structure on the property, and will include the rotary milking system, a covered milk loading area, holding pens, supplemental feeding facilities, a mechanical room, a pump room, office space, veterinary space and storage, staff restrooms, and containers for milk storage and cooling.

Two calf sheds (each about 2,100 sq. ft.) will provide safe housing for newly born calves. The sheds will have feeding and bedding areas, and one shed will have a milk kitchen and 30 single calf crates.

An implementation shed (about 1,700 sq. ft.) will provide space for storing equipment, tools and farm machinery. This shed will also include a workshop.

Additional improvements will include paved access roads, a paved turnaround area for milk tanker trucks, parking for employees, feed silos, milk storage tanks, a paved holding pen (about 12,300 sq. ft.) for mobs waiting to enter the milking parlor, effluent ponds for manure, a potable water system for both humans and cows, electrical power, communications, a septic system for waste disposal, and photovoltaic panels on roofs for solar power generation.

An existing on-site well will supply potable water, and Waitā Reservoir will supply non-potable irrigation water.

Equipment will include the milking system, tractors, trucks, other farm equipment, mobile tankers, refrigeration, heating, freight containers, office furniture and equipment, etc.
k. Future Plans

HDF is committed to demonstrating that the rotational pasture-grazing approach is an economically and environmentally sustainable model for Hawai‘i. In the future, HDF may expand the herd to the maximum carrying capacity of the land—estimated by HDF to be up to 2,000 productive cows. Additional regulatory review and permitting would be required by the State Department of Health (“DOH”) for 700 or more milking cows. The process for the additional approvals, including public notification and input, will be followed if and when HDF decides to pursue an expanded operation.

Eventually, a milk processing plant might be built in an existing industrial area on Kaua‘i or O‘ahu if warranted. The plant would produce finished milk packaged for consumers, and possibly some milk-related products (e.g., yogurt and cheeses).
PART II: SOCIO-ECONOMIC CONDITIONS

1. SOCIO-ECONOMIC CONDITIONS, KAUAI

Tables II-1 to II-9 summarize socio-economic conditions for Kaua‘i County, as well as Kōloa-Po‘ipū which is discussed in the next section. Kaua‘i County includes two populated islands: Kaua‘i and the small nearby island of Ni‘ihau. The data reflect almost entirely the population and economy of the island of Kaua‘i because the privately owned island of Ni‘ihau contains only 0.3% of the County’s population and supports an even smaller percentage of the County’s economic activity.

a. Population

In 2010, Kaua‘i County had a population of about 67,100 residents, up 14.8% since the 2000 U.S. census (see Table II-1). Residents include those who live full-time or permanently on Kaua‘i, and exclude visitors and part-time residents (i.e., those who reside most of the time in a primary home located elsewhere).

The total County population amounted to only 4.9% of the State population—the smallest of the four counties. Only 170 of the residents, primarily Native Hawaiians, lived on Ni‘ihau.

Most Kaua‘i residents live in towns around the perimeter of the island, primarily along the east and south shores, with smaller populations living in towns on the north shore. There are no towns on the northwest side of the island or in the mountainous interior.

b. Population Characteristics and Distribution

Kaua‘i’s population is racially diverse (see Table II-1). For the period spanning 2009 and 2013, Asians comprised 35.7% of the County’s population, while people of two or more races made up 19.8% and Native Hawaiian and Other Pacific Islanders represented 9.9%. Kaua‘i County has a slightly higher proportion of white residents compared to the State as a whole; 33.4% of County residents were white compared to 25.0% in the State as a whole. Approximately 55.9% of Kaua‘i County residents were born in Hawai‘i. The median age of Kaua‘i residents was 41.6 years old between 2009 and 2013. Consistent with national demographic trends, Kaua‘i County’s population is aging. In 2000, the median age was 38.4 years old.

c. Households

The average household size in Kaua‘i County was 2.99 people per household between 2009 and 2013, a slight increase from 2.87 people per household in 2000 (see Table II-1).
Approximately 62.6% of Kaua'i households are homeowners—a percentage that has not changed significantly over the past decade.

d. **Housing**

Between 2009 and 2013, Kaua'i County had an estimated 29,972 housing units, up 18.3% from 2000 (see Table II-1). This figure includes resort/residential units that are used as second homes, or are available for visitors, or are vacant. Approximately 25.3% of housing units in the County were vacant, including 14.4% that were for seasonal, recreational, or occasional use. Kaua'i County has a higher proportion of vacant resort/residential units compared to the State as a whole. Between 2009 and 2013, just 13.8% of housing units in Hawai'i were vacant, including 6.1% that were for seasonal, recreational, or occasional use.

e. **Income and Education**

Table II-2 provides information on income levels and education for the residents of Kaua'i. The median household income between 2009-2013 is estimated at $62,052—an increase of 37.8% since 2000. An estimated 11.2% of the County population was living below poverty level; 90.1% had a high school degree or higher; and 92.1% spoke English well or very well.

f. **Primary Economic Activities**

The principal economic driving forces for the economy of Kaua'i County are tourism, agriculture, and technology and defense. Table II-3 summarizes key economic characteristics for Kaua'i County.

*Tourism*

Kaua'i hosted over 1.11 million visitors in 2014, and visitor expenditures totaled approximately $1.47 billion, making tourism the dominant industry in the County. Visitors to Kaua'i in 2014 represented 13.6% of the State’s visitor arrivals by air, and 10% of Statewide visitor spending.

Figure II-1 presents the annual number of visitor arrivals to Kaua'i County since 2000. As shown, visitor arrivals have been on the rebound since 2009, when the County had less than 1 million visitor arrivals annually. Since that time, visitor arrivals increased steadily.

There were 8,582 visitor units on the island of Kaua'i in 2015, including 1,387 condominium hotel units, 2,667 hotel units, and 2,632 timeshare units (see Table II-4).
Figure II-1. Visitor Arrivals, Kaua‘i: 2000 to 2015
**Defense and Technology**

Located in the southwest corner of Kaua'i, the Pacific Missile Range Facility (PMRF) is the world’s largest instrumented multi-environment range to support surface, subsurface, air and space operations. PMRF also provides fleet training for the U.S. Navy and the navies of allied nations and plays a significant role in the testing and evaluation of future systems, including the AEGIS ballistic missile defense system and upcoming THAAD (Terminal High Altitude Air Defense) system. Operations vary from small, single-unit exercises to large, multiple-unit battle-group scenarios. Also, the research and testing operations conducted at PMRF have spawned branch operations on Kaua'i of a number of high-technology companies.

PMRF is a major contributor to the economy of Kaua'i County, particularly on the west side of the island. PMRF is one of Kaua'i’s largest employers with nearly 1,000 active duty Navy, government, civil service and contract civilians, and Hawai'i Air National Guard members. PMRF’s prime contractor is ITT Services, with approximately 500 employees, providing base support as well as high-tech range safety and scheduling operations. Numerous other contractors, both on and off Kaua'i, are associated with PMRF.

**Agriculture**

For more than a century, sugarcane was the economic mainstay on Kaua'i. In 1980, about 53,600 acres were used for growing sugarcane (see Table II-5). However, the industry suffered major contractions starting in the 1980s, and the last sugar plantation on Kaua'i (Gay & Robinson, Inc.) closed in 2010.

Some of the former sugarcane fields are now used for diversified crops (crops other than the plantation crops of sugarcane and pineapple)—principally coffee (about 3,800 acres) and seed corn (about 13,300 acres). The seed companies reduced their use of land on Kaua'i in 2015 by over 3,000 acres. Furthermore, they cultivate only about 25% of the land they use and fallow about 75%. Since 1980, the amount of land used for other diversified crops and intensive livestock operations (dairy, hog, and poultry) declined by nearly 500 acres and over 250 acres, respectively. Also, about 1,700 acres of farmland are now used for commercial forests, and about 13,000 additional acres are used for grazing cattle. Cattle grazing is a comparatively low-value use of farmland.

Finally, some of the former farmlands are now used for residential communities and other urban development.

Despite the contraction in the sugar industry, revenues from crops grown on Kaua'i increased from $42.4 million in 2000 to $74.6 million in 2008, the latest year data is available for the County. The increase in revenues can be attributed largely to seed operations. Revenues from livestock and aquaculture sales, however, declined from $6.0 million in 2000 to $3.3 million in 2008.
g. Labor Force and Employment

In 2014, Kaua‘i County’s civilian labor force numbered 34,600 workers, up 14.4% since 2000 (see Table II-3). Employed civilians totaled 42,950 workers. The unemployment rate in 2014 was 4.9%. Unemployment in the County fluctuated over the 14 years, peaking at 9.8% in 2009 when the national economy was in a recession. Since that time, the County’s unemployment rate has gradually decreased each year as the economy recovered and the tourism industry strengthened.

There were 29,400 jobs in Kaua‘i County in 2014, an increase of 10.7% from 2000. The leisure and hospitality industry represents the largest proportion of jobs in the County, accounting for 9,300 jobs or 31.6% of countywide jobs. Other industries comprising a large portion of jobs in the County include: Trade, transportation & utilities (5,800 jobs, 19.7%), government (4,600 jobs, 15.6%), professional and business services (2,800 jobs, 9.5%), and educational & health services (2,700 jobs, 9.2%).

Table II-6 also includes job counts for Kaua‘i, but for 2011. This table also includes counts for Kōloa-Po‘ipū which is discussed in the next section.

h. Home Prices

Table II-7 presents home sales prices for 2013 to 2015. The median sales price for single-family homes on Kauai in 2015 was $615,000, 15.4% higher than the median price in 2014. Condominium sales prices have also trended upwards in 2015. The median sales price for condominiums on Kauai was $365,000, a 5.5% increase over the 2014 median price.

i. Projected Growth

As part of the Kaua‘i General Plan Update, consultants for the County of Kaua‘i Planning Department prepared socio-economic forecasts for the County. Table II-9 summarizes past growth for the 10-year period from 2000 to 2010, and future projected growth for the 20-year period from 2010 to 2030. Continuation of growth at about the same average rate would result in a percentage change for the future 20-year period that is about double that of the past 10-year period.

As shown, Kaua‘i’s resident population is projected to grow from about 67,100 residents in 2010 to about 83,300 residents 2020. This reflects a slight deceleration of growth: from about 14.8% over the past 10 year period to about 24.2% for the future 20-year period. Consistent with this projection, slower growth is projected in the number of households on Kaua‘i as well as the number of housing units.

Kaua‘i’s average visitor census is expected to grow to from about 19,500 visitors in 2010 to about 25,700 visitors in 2030. This reflects an acceleration of growth: from about 8.4% over the past 10-year period to about 31.7% for the future 20-year period. Correspondingly, faster growth is projected for the de facto population (residents plus visitors less absent
residents), wage and salary jobs (largely tied to tourism growth), and the number of visitors arriving by air. In spite of faster growth in the number of visitors on Kaua‘i, slower growth is projected in the number of visitor units on the island: that number is projected to increase 20.2% from 9,345 units in 2010 to 11,230 units in 2030. For the previous 10-year period, the increase was 30.5%.

2. SOCIO-ECONOMIC SETTING, KÔLOA-PO‘IPŪ

The proposed Hawai‘i Dairy Farm is located within the Kôloa-Po'ipū District (defined as the Kôloa-Po'ipū Census Subdivision as shown in Figure II-2). This district includes the coastal communities of Po'ipū and Kukui'ula.

a. Population and Distribution

In 2010, the Kôloa-Po'ipū District had a resident population of approximately 5,700, or 8.4% of the County population. The population in Kôloa-Po'ipū grew at a slower rate than the County as a whole, increasing by 5.2% from 5,400 residents in 2000. During the previous decade, the male population declined by 1.4% while the female population increased 20.9% (See Table II-1). Evidently, many males left due to more attractive opportunities elsewhere.

Similar to Kaua‘i County as a whole, the resident population of the Kôloa-Po'ipū region is racially diverse. Between 2009 and 2013, white residents comprised a slightly higher proportion of the Kôloa-Po'ipū population compared to the County as a whole; 42.1% of residents were white compared to 33.4% of residents in the County (Table II-1). A slightly lower proportion of the Kôloa-Po'ipū population was born in the State of Hawai‘i; an estimated 51.6% of the region’s population was native born to the State compared to 55.9% for the County as a whole.

The resident profile of the Kôloa-Po'ipū region is slightly older than that of Kaua‘i County. The median age in Kôloa-Po'ipū was 44.8 years old between 2009 and 2013, compared to 41.6 years old in the County. The Kôloa-Po'ipū region is characterized by a higher proportion of retirement age residents (65 years and older) and a lower proportion of school age children.

b. Households

The average household size in the Kôloa-Po'ipū region was 2.68 people per household between 2009 and 2013—a decrease from 2.71 people per household in 2000 (Table II-1). On average, households in Kôloa-Po'ipū are smaller than households in the County as a whole (2.99 people per household between 2009 and 2013). The smaller household size combined with the higher median age in Kôloa-Po'ipū is indicative of a higher proportion of older residents and households without children.
Figure II-2. Kōloa-Poʻipū Census Subdivision
c. **Housing**

Between 2009 and 2013, the Kōloa-Po'ipū region had an estimated 3,704 housing units—an increase of approximately 3.1% since 2000 (Table II-1). Consistent with the population growth parameters, the region experienced a slower housing unit growth rate than the County, where the number of housing units increased by 18.3% during the same time period. Kōloa-Po'ipū has a higher proportion of vacant housing units than Kaua'i County as a whole due to the number of second homes. Approximately 36.8% of housing units were vacant for seasonal, recreational, or occasional use between 2009 and 2013 in Kōloa-Po'ipū, compared to 14.4% Kaua'i County.

d. **Income and Education**

The median household income in Kōloa-Po'ipū between 2009 and 2013 was estimated at $62,083, similar to the County as a whole (Table II-2). However, Kōloa-Po'ipū has a higher per-capita income and a lower proportion of residents living in poverty. An estimated 7.5% of residents were living in poverty in the region, compared to 11.2% for the County. A slightly higher proportion of residents in Kōloa-Po'ipū completed some secondary education compared to the County as a whole. An estimated 66.7% of Kōloa-Po'ipū residents attended some college or received a higher education degree, compared to 61.1% of County residents.

e. **Primary Economic Activities**

As with Kaua'i County, the primary economic activities in the Kōloa-Po'ipū District are tourism and, to a much lesser extent, agriculture. Defense is not a primary economic activity in the Kōloa-Po'ipū District since it has no military installations.

**Tourism**

The largest share of visitor units on Kaua'i is located in the Po'ipū/Kukui'ula area. Of the 8,582 visitor units on Kauaʻi, 3,058 (36%) units were located in Po'ipū/Kukui'ula (Table II-4). Hotels in the area include the Grand Hyatt Kaua'i Resort & Spa, Koa Kea Hotel & Resort, and the Sheraton Kaua'i Resort. The Grand Hyatt Kaua'i Resort & Spa is the closest hotel to the proposed Dairy—about 2.4 miles from the Dairy facilities. This resort provides 602 visitor units, and is the largest employer on Kaua'i—in 2014, it employed 941 workers.

Major timeshare properties in Po'ipū/Kukui'ula include the Lawai Beach Resort, Marriott Waiohai Beach Club, Nihi Kai Villas, and The Point at Po'ipū. There are also 11 condominium hotel properties in Po'ipū/Kukui'ula providing 608 units.
**Agriculture**

Hawai‘i’s sugar industry began in Kōloa in 1835, and sugarcane cultivation continued in the district until 1996 when the last plantation (McBryde Sugar Co.) finally ceased operations.

Of the 12,000+ acres that were planted in sugarcane, some of it has been or will be urbanized (e.g., the Kukui‘ula development); about 3,100 acres are planted in coffee (most of which is in the adjacent region of ‘Ele‘ele-Kalāheo); about 1,200 acres were in seed corn until 2015; about 1,200 acres are in commercial forest; and some is in other diversified crops (vegetables, tropical fruits, taro, flowers). Most of the remainder is used for low-value cattle grazing or is fallow. Figure II-3 shows agricultural activities in Kōloa and Po‘ipū in 2015.

**f. Labor Force and Employment**

As noted above, tourism is the primary industry in the Kōloa-Po‘ipū region. This is reflected in the employment distribution. In 2011—the most recent year jobs data is available at the Census Subdivision level—there were 3,752 jobs in Kōloa-Po‘ipū (see Table II-6). This accounted for 13.2% of the 28,300 County-wide jobs in 2011. The leisure and hospitality industry accounted for the vast majority of jobs in Kōloa-Po‘ipū at 69.8%. In comparison, leisure and hospitality jobs represented 29.3% of total countywide jobs during the same year. Trade, transportation & utilities jobs represented another 12.2% of jobs in Kōloa-Po‘ipū.

**g. Home Prices**

Sales prices for homes in Kōloa-Po‘ipū are significantly higher than County-wide prices. In 2015, the median sales price for single-family homes in Kōloa-Po‘ipū was $1,070,000, compared to $615,000 County-wide. The median sales price for condominium units was $425,000 in Kōloa-Po‘ipū compared to $365,000 County-wide.

Home prices for Kōloa-Po‘ipū can be monitored over time to verify that the Dairy will not adversely impact prices—see Part III, Section 7.

**h. Assessed Property Values**

Figure II-4 shows distances of various properties and designated areas in Kōloa and Po‘ipū that are closest to the Dairy. An analysis of the County’s 2016 assessed property values for those properties and areas is summarized in Figure II-5 and in Table II-8. Assessed property values (land and improvements) are the County’s estimates of market values.
Figure II-3. Agricultural Activities in Kōloa-Poʻipū: 2015
For specified properties and designated areas, Figure II-5 includes: the distance to the nearest pasture, the distance to the Dairy facilities, and the assessed values for vacant and developed properties. For designated areas with multiple properties, median values are shown. Table II-8 lists assessed values by: designated area, TMK, type of property, lot acreage, the year a home on the property was built, square footage, number of bedrooms, and number of bathrooms. For designated areas with multiple properties, median values are shown for vacant and developed properties.

Seven residential and agricultural areas and four resort properties were identified as being the closest to the proposed Dairy. In 2016 the Grand Hyatt Kauai had an assessed value of $212.8 million while the neighboring Poipu Bay Golf Course was valued at $16.3 million.

As shown in Figure II-3, many of the homes in the region are also close to existing beef-cattle operations. The values shown in Figure II-5 and Table II-8 apply also to properties near grazing operations. In addition, Figure II-6 and Table II-8 show values of select properties on the west side of Kōloa nearest grazing operations.

The properties listed in Table II-8 can be monitored over time to verify that the Dairy will not adversely impact property values—see Part III, Section 7. Ideally, just land values should be tracked since property values can change significantly with changes in the improvements on a parcel. However, for each property, Kauaʻi County combines land and improvement values into a single value—other counties separate the two.

i. Projected Growth

The socio-economic projections prepared for the County also include projections by District Planning Areas. The one that includes Kōloa and Poʻipū is the Kōloa-Poʻipū-Kalāheo District. In Figure II-2, this District includes the areas labeled (1) Kōloa-Poʻipū and (2) the adjoining ʻEleʻele-Kalāheo.

In addition to the projections for the County, Table II-9 also summarizes the projections for the combined areas of Kōloa-Poʻipū and ʻEleʻele-Kalāheo. For the most part, this Planning District is projected to grow at about the same rate or faster than that of the entire County. However, slightly slower growth is projected for the average visitor census, wage and salary jobs, and the number of visitor units.
Figure II-4. Hawai‘i Dairy Farm and Nearby Properties
Figure II-5. Assessed Values of Nearby Properties: 2016
(Assessed values from Table II-8)
Figure II-6. Assessed Values of Other Properties: 2016
(Assessed values from Table II-8)
PART III: ECONOMIC AND FISCAL IMPACTS

1. PLANS FOR THE DAIRY

Plans for the Dairy are summarized in Part I, Section 3 as well as in Table III-1. This table provides information on the Initial Dairy (up to 699 mature milking cows), a Potential Increase in the size of the Dairy (an additional 1,301 milking cow) sometime in the future, and the Potential Dairy (up to 2,000 mature milking cows).

As indicated, both the Initial Dairy and the Potential Dairy will cover about 557 acres, including (1) about 10 acres for farm structures and related facilities; (2) about 470 acres for pastures; and (3) about 77 acres for cow raceways, internal roads, and setbacks along drainage ditches.

The cows will be grouped into 6 mobs, and the pasture will be divided into about 119 fenced paddocks ranging in size from 3 to 5 acres.

This table also lists the farm improvements for (1) the pasture, (2) farm structures and related improvements, and (2) major dairy equipment.

2. ECONOMIC IMPACTS OF DEVELOPMENT ACTIVITIES

The development of the Dairy will involve installing perimeter and paddock fencing, building cow raceways and internal roads, installing an irrigation system, installing a potable water system, preparing sites for buildings, constructing buildings, installing an effluent system, installing equipment, etc. Table III-2 summarizes the direct and indirect economic impacts of these development activities. The material in the table gives the development period, construction expenditures, indirect sales generated by the construction activity, profits, employment and payroll, and the number of residents and houses supported by the development activities.

a. Development Period

As indicated in Section 2.a of Table III-2, the assumed development period is about 2 years. However, development could require more or less time, depending on future market conditions and property sales.

b. Construction Expenditures

Over the 2-year development period, total construction expenditures for the Dairy are estimated at about $7.5 million, plus or minus $1.5 million (see Section 2.b of Table III-2). This translates into average construction expenditures of about $3.75 million per year. In practice, construction expenditures will vary from year to year.
c. Equipment Expenditures

Total equipment expenditures for the Dairy are estimated at about $2 million, plus or minus $0.5 million, or about $1 million per year over the development period (see Section 2.c of Table III-2).

d. Indirect Sales Generated by Construction Activity

In addition to construction expenditures, development activities will generate indirect sales associated with supplying goods and services to construction companies and to the families of their construction workers. In turn, the companies supplying goods and services, and the families of their employees, will purchase goods and services from other companies, and so on. These indirect sales will include sales by companies supplying building materials (fencing, cement, steel, lumber, roofing materials, plumbing equipment, electrical equipment, hardware supplies, lighting, flooring, etc.); rental of construction equipment; equipment repair; warehousing services; shipping and trucking services; etc. Indirect sales also include sales by grocery stores, drug stores, restaurants, service stations, beauty salons, medical providers, accountants, attorneys, insurance agents, etc.

Based on State economic multipliers, these indirect sales are expected to average about $4.4 million per year, of which about $2.9 million will be on Kaua‘i and about $1.5 million on O‘ahu (see Section 2.d of Table III-2.).

e. Summary of Expenditures and Sales

Section 2.e of Table III-2 summarizes anticipated expenditures and sales. As indicated, construction expenditures, equipment expenditures, indirect sales related to construction, are expected to average about $9.1 million per year. About $5.7 million per year will be subject to the State 4% excise tax on final sales, while about $3.4 million per year will be subject to the 0.5% excise tax on intermediate sales.

f. Profits

Profits on direct and indirect sales generated by construction of the Dairy are estimated at about $1 million per year (see Section 2.f of Table III-2). This includes estimated profits of: construction companies, subcontractors, the companies supplying goods and services in support of construction activity and to the families of workers, etc.

g. Employment

During the 2-year development period, construction employment is expected to average about 12 jobs (see Section 2.g of Table III-2). These jobs will include supervisors, equipment operators (grading, roads, etc.), cement workers to lay foundations, metal workers,
carpenters, plumbers, electricians, roofers, glass and window installers, painters, equipment installers, etc. Other jobs related to construction will include architects, civil engineers, draftsmen, government inspectors, etc. These jobs will range over a variety of skill levels, including entry-level, semiskilled, skilled, management, and professional positions.

As with indirect sales, development activities will generate indirect jobs associated with supplying goods and services to construction companies and to the families of construction workers. In turn, the companies supplying goods and services, and the families of their employees, will purchase goods and services from other companies, and so on. Indirect jobs will include those at companies supplying building materials (fencing, cement, steel, lumber, roofing materials, plumbing equipment, electrical equipment, hardware supplies, lighting, flooring, etc.); rental of construction equipment; equipment repair; warehousing services; shipping and trucking services; etc. Other indirect jobs will include those involved with supplying goods and services to employees and their families: grocery workers, store clerks, restaurant workers, service-station workers, beauty technicians, barbers, bankers, pharmacists, veterinarians, computer technicians, medical workers, accountants attorneys, etc. The jobs will range over a variety of skill levels, including entry-level, semi-skilled, skilled, and management positions.

Based on State employment multipliers, indirect employment related to Dairy development is expected to average about 16 jobs on Kaua‘i and 8 on O‘ahu.

Thus, total direct-plus-indirect employment associated with Dairy development activities will average about 36 jobs, of which about 28 jobs will be on Kaua‘i.

h. Payroll

Development activities are expected to generate a total annual payroll of about $1.7 million per year for the Dairy, of which about $640,000 million will be for construction workers, about $690,000 for indirect employment on Kaua‘i, and about $390,000 for indirect employment on O‘ahu (see Section 2.h of Table III-2). These estimates are based on the average number of direct and indirect jobs multiplied by average wages as reported to the DLIR.

Wages will range from less than $30,000 annually to over $100,000, and are expected to average about $53,500 per year for construction jobs, about $42,900 for indirect jobs on Kaua‘i, and about $48,500 for indirect jobs on O‘ahu.

i. Sources and Training of Construction Workers

As noted above, construction employment is expected to average about 12 jobs during the 2-year development period. This is about 0.8% of the County’s 1,540 construction jobs in 2014 (DLIR). In view of this small percentage, it is expected that the construction jobs for the Dairy will be filled by workers already living on Kaua‘i. As other construction projects
are completed on the island, Kaua‘i construction workers will be hired to work on the various components of the Dairy infrastructure and buildings, and then move on to other projects. Thus, the Dairy will help keep a small number of Kaua‘i’s existing construction workers employed.

Special programs to train additional construction workers on Kaua‘i appear to be unwarranted since a sufficient number of workers are already available.

j. Supported Population and Housing

During the 2-year development period, direct and indirect jobs provided by Dairy construction will support about 79 residents housed in about 26 homes (see Sections 2.i and 2.j of Table III-2). Most of the residents supported by the direct-plus-indirect jobs are expected to live on Kaua‘i: about 63 of them housed in about 21 homes.

3. Economic Impacts at Full Operations

Table III-3 summarizes the estimated economic impacts of the Dairy at full steady-state operations achieved after about 5 to 10 years. Included are estimated milk production direct and indirect sales, profits, direct and indirect employment, payroll, and population and housing supported by Dairy operations.

a. Milking Cows

The economic impacts are estimated for two scenarios: the Initial Dairy of 699 milking cows, and a Potential Dairy of 2,000 milking cows (see Section 3.a of Table III-3).

b. Production

Raw Milk

The Dairy will increase Hawai‘i’s milk self-sufficiency and reduce fluid milk imports. At full operations with 699 cows, the Dairy will produce about 1.5 million gallons of raw milk per year, and will produce about 4.4 million gallons with 2,000 cows (see Table III-3, Section 3.a). This compares to about 4 million gallons produced in Hawai‘i in 2015. Production was down from a peak of about 18.3 million gallons in 1988 when Hawai‘i dairies supplied nearly all of the milk consumed in the state.

Livestock

In addition, the Dairy will increase the supply of livestock, including female calves for other dairies, male calves for beef ranching, and culled cows and heifers for beef or dairy operations.
c. Sales

At full operations of the 699-cow Dairy, annual direct-plus-indirect milk sales are estimated at about $10.1 million, of which about $8.1 million will be on Kaua‘i and about $2 million on O‘ahu (see Table III-3, Section 3.c).

Should HDF decide, in the future, to expand the herd up to 2,000 cow, annual sales are estimated as follows: about $23.3 million in direct and indirect sales on Kaua‘i, and about $5.7 million in indirect sales on O‘ahu, for a total of about $29 million.

d. Profits

At full operations, profits on direct and indirect sales are estimated at about $1 million per year for the 699-cow Dairy, and $2.9 million per year for the 2,000-cow Dairy (see Table III-3, Section 3.d). This includes estimated profits of: the Dairy, its subcontractors, companies supplying goods and services to the Dairy and to the families of Dairy workers, etc.

e. Employment

At full operations, the 699-cow Dairy will provide about 11 jobs on Kaua‘i, including about 5 farm jobs and about 6 indirect jobs (see Table III-3, Section 3.e). About 3 indirect jobs will be on O‘ahu. Thus, the Dairy will generate about 14 direct-plus-indirect jobs. Corresponding employment figures for the 2,000-cow Dairy are about double.

Dairy employment will include a farm manager, a marketing/community relations person, supervisors, and skilled and semi-skilled workers.

The employment figures are relatively low because the Dairy will be a modern facility with labor-savings devices which are needed to achieve profitable operations.

f. Payroll

Section 3.f of Table III-3 addresses payroll at full operations of the Dairy, although estimates are not shown in order to avoid disclosure.

For the Dairy jobs, annual salaries and wages will be competitive, and are expected to range from less than $40,000 to $115,000 or more. Because of the skill requirements for a modern dairy, the average wage for the Dairy is expected to exceed County-wide and State-wide averages. For the indirect jobs, wages will range from less than $30,000 annually to over $100,000.

g. Sources and Training of Farm Workers

As noted above, farm employment is expected to be relatively small: about 5 jobs for the 699-cow Dairy at full operations, and about 10 jobs for a 2000-cow operation. It is expected that most workers will be recruited from Kaua‘i. New workers will be trained by the Dairy.
h. Supported Population and Housing

At full operations, the 699-cow Dairy will provide about 31 direct-plus-indirect jobs for Hawai‘i residents who will live in about 11 homes (see Sections 3.g and 3.h of Table III-3). It is expected, that most of the workers will be Kaua‘i residents (about 25 residents in 9 homes). Corresponding figures for a 2,000-cow Dairy are about twice those of the 699-cow operation.

4. IMPACTS ON COUNTY REVENUES AND EXPENDITURES

The impact of the Dairy on County revenues and expenditures is shown in Table III-4. This table summarizes: (1) changes in the County’s tax and expenditure base, which is used to calculate revenues and expenditures; (2) revenues and expenditures related to Dairy development activities; and (3) revenues and expenditures related to full operations of the Dairy.

a. Development Activities

As shown in Table III-4, Section 4.b, development of the Dairy will result in a negligible impact on County finances. Unlike the State, County taxes on development activity are insignificant. Furthermore, the developer (not the County) will provide the required infrastructure: water, interior roads, waste disposal, drainage, etc. Also, construction companies provide their own security, sanitation, transportation, etc. Thus, few on-site services will be required from the County. And for the most part, construction workers already pay various County taxes, and already receive various County services.

b. Operations at Full Development

At full operations, the Dairy is expected to generate a net income to the County of about $51,000 for both the 699-cow Dairy and the 2,000-cow Dairy (see Table III-4, Section 4.c.). Most of the taxes will derive from property taxes on improvements. County property taxes on land—which are low when dedicated to agriculture—are already being paid, and are not expected to change significantly.

The Dairy will pay a variety of minor taxes and fees to the County (e.g., fuel and vehicle taxes), while requiring few County services.

Dairy workers and their families will pay a variety of taxes to the County, and will require County services. For these workers and families, the resulting net revenues are expected to be near zero but positive since the County budget is structured to break even and, on a per-capita basis, most Dairy workers will pay higher than average taxes since they will earn higher than average wages.
5. **Impacts on State Revenues and Expenditures**

The impact of the Dairy on State revenues and expenditures is shown in Table III-5. This table summarizes: (1) changes in the State’s tax and expenditure base which is used to calculate revenues and expenditures; (2) revenues and expenditures related to development activities; and (3) revenues and expenditures related to full operations of the Dairy.

**a. Development Activities**

Unlike the County, the State will derive significant revenues from development activity: a cumulative total of about $650,000 for both the 699-cow Dairy and the 2,000-cow Dairy (see Table III-5, Section 5.b). However, the revenues will be offset by the $1 million tax credit for improvements on land designated by the State Land Use Commission as Important Agricultural Lands.

Other than the IAL tax credit, State expenditures to support the development of the Dairy are expected to be negligible. As mentioned previously, HDF will provide the infrastructure for the Dairy. Also, construction activities require few on-site services from the State. And for the most part, construction workers already pay various State taxes, and already receive various State services.

**b. Operations at Full Development**

At full operations, the Dairy is expected to generate net income to the State that will exceed $60,000 per year for the 699-cow Dairy. Should HDF decide, in the future, to expand to a 2,000 cow Dairy, net income to the State would exceed $170,000 per year (see Table III-5, Section 5.c). Most of the revenues will derive from excise taxes on sales.

Similar to that for the County, the Dairy will pay a variety of minor taxes and fees to the State, while requiring few State services.

Also, Dairy workers and their families will pay a variety of taxes to the State, and will require State services. For these workers and families, the resulting net revenues are expected to be near zero but positive, since the State budget is structured to break even and, on a per-capita basis, most Dairy workers will pay higher than average taxes since they will earn higher than average wages.

6. **Other Benefits**

**a. Open Space**

The Dairy’s irrigated pastures will provide about 470 acres of well-maintained grassland divided into 119 fenced paddocks. The herd will be split into 6 groups, each of which will be rotated among the paddocks. Thus, at any given time, about 5% of the pasture land will be occupied by cows (6 of 119 paddocks), and about 95% will be unoccupied green
open space. In addition, about 77 acres will be used for cow raceways, internal roads, and setbacks along drainage ditches.

b. Potential Educational Tours

Although not currently planned, potential exists to add educational tours of the Dairy for school children, residents and visitors. This would provide an interesting learning experience about raw milk production, and possibly offer an additional activity for visitors to Kaua‘i. However, some additional building improvements would be required to accommodate tour groups.

7. Nuisance Issues and Impacts

Given the important economic, residential, and recreational role of the Kōloa-Poʻipū region, the Dairy must be compatible with, and not cause adverse impacts on regional resorts, commercial areas, homes, recreational activities, etc. If nuisance impacts were to occur—which is not expected—it could result in reduced tourism, sales, employment, salaries and wages, property values, personal wealth, State and County tax revenues, enjoyment of homes and recreational activities, etc. As mentioned previously, 36% of the island’s visitor units are in Po’ipū and Kukui‘ula, including the Grand Hyatt Kaua‘i Resort & Spa which is the largest employer in the County. Nuisance impacts on the economy, including property values, are addressed below.

a. Impacts of Concentrated Animal Feeding Operations on Property Values

A number of mainland studies have addressed the impact of large concentrated animal feeding operations (“CAFOs”) on property values of nearby homes (see listing in References). These operations, which are often called feedlots, confine a large number of animals—hogs, chickens, sheep, or cows—in a small area. Correspondingly, a large volume of manure is generated in a small area, leading to waste-management challenges.

Most CAFOs generate significant odors and other nuisance impacts (flies, dust, noise, runoff, etc.) that can extend beyond the CAFO property boundaries, thereby affecting nearby and downwind properties. Usually, but not always, property values of homes near CAFOs are lower than those of similar homes that are not affected by nuisance impacts of CAFOs. Relevant findings of the various studies, some of which are contradictory, include the following:

— Distance
  • Significantly lower home values can be limited to less than 1 mile from a CAFO, but some studies have found that lower values can extend beyond 3 miles.
  • Adverse impacts on home values diminish rapidly with distance from a CAFO.
— Size and Concentration
  • In general, larger CAFOs have a more negative effect on home values.
  • However, one study found the opposite to be true, with the possible explanation being that larger CAFOs tend to be newer, so have better manure-management facilities and use better practices.

— Animal Species
  • Most studies found that hog operations have a significant adverse impact on the value of nearby homes.
  • The findings on dairy operations are mixed. Some studies found that dairies lower home values significantly, especially those within 1 mile of a facility. But other studies have found that dairy operations, or a combination dairy/beef-cattle operation, can increase home values by adding a rural-lifestyle amenity.

— Management Practices
  • CAFOs with conservation plans have less of an impact on home values than CAFOs without them.

— Home Values
  • One study found that the less-expensive homes are less impacted by CAFOs than the expensive ones. Another study found the opposite.

— Employment Effect
  • In some cases, homes near a CAFO may increase in value due to the increased demand for homes by CAFO employees.

The above findings about the impacts of CAFOs on home values do not apply to the proposed Dairy for the following reasons:

— The HDF pasture system differs from a conventional dairy where cows are confined to barns. Instead of storing manure in lagoons and feeding silage (fermented vegetation) as forage, the Dairy will use rotational pasture-grazing where the animals are dispersed over a large expanse of grassland.

— Home values will not be affected because no noticeable odors, noise, flies, dust, runoff, or other nuisance impacts from the operation will extend to residential areas (see Subsections 7.c and 7.d). Instead, any noticeable nuisance impacts occurring beyond the Dairy property will be limited to the abutting farm and ranch lands which are owned by Māhāʻulepū Farm, lessor of the Dairy property.

b. Nuisance Impacts of Past and Current Agricultural Activities in Kōloa-Poipu

Unlike urban Honolulu and Waikiki, most of Kauaʻi and its resort areas—including Kōloa and Poʻipū—have a rural ambience. Most homes and visitor units on the island are within one mile of some agricultural activity. This rural character contributes to the charm
and appeal of the island. Some agricultural activities generated or currently generate significant nuisance impacts.

Sugar

Po‘ipū and Kōloa grew and thrived near sugar operations, which continued until 1996. Sugarcane fields bordered Kōloa to the east, north, and west, and bordered parts of Poʻipū. The Grand Hyatt Kaua‘i opened in 1992 while sugarcane was still being grown just mauka of the hotel property.

Sugarcane caused a number of nuisance impacts, including but not limited to: smoke when cane was burned prior to harvest, dust and soil runoff after fields were plowed, noise when fields were harvested, and field mice.

The large canehaul trucks created considerable noise, dust and cane litter. And the Kōloa Mill emitted odors, smoke, and noise. The distance from this mill to the the nearest homes in Kōloa is about 0.8 mile (versus about 2.3 miles for the Dairy facilities). For the nearest visitor units (the Grand Hyatt Kaua‘i), the distance is about 1.6 miles (versus about 2.5 miles for the Dairy facilities).

The nuisance impacts of past sugar operations far exceed the impacts anticipated for the Dairy. Also, these impacts from sugar operations extended to the Kōloa and Poʻipū communities, which will not be the case for the Dairy (see Subsection 7.c).

Seed Crops

From 1996 to 2015, seed crops had a major presence in Kōloa-Poʻipū, with over 1,000 acres used by Dupont Pioneer in 2015 (see Figure II-3). This included land adjacent to the Poʻipū Bay Resort Golf Course, which is the golf course for the Grand Hyatt Kaua‘i. Pioneer recently returned its lease land to Māhāʻulepū Farm.

The seed companies generally farm plots of 1 to 5 acres surrounded by a buffer zone to protect planted areas from pollen drift. Cover crops are often planted to build soil fertility and reduce windblown dust.

Nevertheless, one of more significant nuisance impacts of seed crops is windblown dust. Dust from the Dairy’s pastureland will not be a problem since the fields will be kept in grass, won’t be plowed, and soil will not be left exposed even for short periods.

Beef Cattle

With the demise of sugar and seed crops in Kōloa and Poʻipū, the cattle grazing for the beef market is now the dominant use of agricultural land in the region (see Figure II-3). Grazing lands to the east, north and west of Kōloa total over 2,900 acres, which is reduced
from over 3,300 acres before Māhāʻulepū Valley was leased for the Dairy. In the near term, grazing is likely to expand onto most of the lands used recently for seed crops.

Grazing cattle for the beef market is known as cow-and-calf operations. When the calves reach about 500 pounds, most are shipped to the mainland for finishing. Over 700 cow-and-calf units graze on the land in the region, down from over 800 units before Māhāʻulepū Valley was leased for the Dairy.

Grazing of cattle for the beef market usually uses rotational pasture grazing similar to that planned for the Dairy, with the cattle rotated every 18 to 30 days, depending on the ranch and pasture. But because the pastures for beef cattle are not irrigated nor fertilized, the carrying capacity of the land is less than that for the proposed Dairy; the paddocks are larger; and the animal densities are less.

Grazing cattle near communities is common throughout Hawai‘i, including but not limited to the following:

— Kaua‘i: Hanalei, Hanapēpē, Kalâheo, Kapa‘a, Kukui‘ula, Wailuā
— O‘ahu: Ko ‘Olina, Makakilo, Lā‘ie, Waimānalo, Waipi‘o
— Moloka‘i: Kaunakakai, Maunaloa
— Maui: Hāna, Kīhei, Kula, Makawao, Mākena, Wailuā
— Big Island: Hawi, Honoka‘a, Laupāhoehoe, Mountain View, Nā‘ālehu, South Hilo, Waimea, Wood Valley

A number of these communities feature expensive homes, and some are resort or resort-residential communities (Kukui‘ula and Wailuā on Kaua‘i; Ko ‘Olina on O‘ahu; and Kīhei, Mākena, and Wailuā on Maui).

In Kōloa and Po‘ipū, grazing occurs less than 200 feet from some homes, less than 1 mile from some visitor units, less than one-third of mile to the east and west of the main commercial area of Kōloa, and less than 200 feet from a golf course.

Many of the homes in the region that are near cattle operations are in the northeast and eastern sections of Kōloa (Areas A, B and C in Figure II-5). As indicated in Table II-8, most of the homes are old (built before 1980), and most are of modest size (less than 1,200 sq. ft.). For these areas, the 2016 median assessed values are as follows:

— Area A: $567,500
— Area B: $406,100
— Area C: $471,100

Homes in West Kōloa are also near cattle grazing (Area H of Figure II-6). This neighborhood has a mix of older and smaller homes, and newer and larger homes (see Table II-8). The 2016 median assessed values are $464,150 for a residential lot and $788,200 for a single-family home.
At the western end of Po‘ipū is Kukui‘ula—a luxury residential community that abuts grazing land (Areas I, J and K in Figure II-6). Much of the grazing land is owned by the development company or an affiliated company. Most of the homes are new (built after 2012), and most are large (over 2,100 sq. ft.). For 2016, median assessed values of residential lots and homes are as follows:

- Area I: $1,297,150 for a lot and $2,462,400 for a home
- Area J: $641,400 for a lot and $2,582,000 for a home
- Area K: $2,893,100 for a home

Clearly, beef cattle operations are compatible with nearby homes, commercial areas, resorts, and recreational activities. Although stocking densities are lower for beef cattle on unirrigated pastures than they are for the proposed Dairy on irrigated pastures, the operations are similar: cattle are rotated among pastures as limited by the carrying capacity of the land for feed, reabsorption of nutrients, erosion control, etc.

**Feral Chickens**

Although few (if any) commercial poultry farms remain on Kaua‘i, former farms have left an impact in terms of feral chickens which are now ubiquitous on the island. While colorful and adding to the rural ambience, they create two nuisance problems: (1) the roosters start crowing about 2 hours before daybreak, and continue to crow occasionally during the day and into the night; and (2) chicken dung provides a breeding ground for flies.

The Dairy will not create animal noises that can be heard in resort, commercial, residential or recreational areas, and the flies will be controlled (see Subsection 7.c).

**Application of Reclaimed Wastewater and Nutrients**

Reclaimed wastewater is used for irrigating farmlands and golf courses throughout Hawai‘i, including golf courses in Po‘ipū. In 2013, the Limticao Consulting Group reported that the Po‘ipū Bay Resort Golf Course, which is the golf course for the Grand Hyatt Kaua‘i, uses a mix of 20% to 40% R-2 rated wastewater. However, a mix of up to 60% wastewater is used on the first three holes, resulting in a slight odor during spraying. For the Dairy, the mix will be less than 8%.

The Kiahuna Golf Course uses a mix of 40% to 60% R-1 rated wastewater, which is cleaner than R-2 rated water. The fairways of the course are lined with single-family homes which, for homes on the east side of the project, have a median assessed value exceeding about $1.16 million (see Figure II-X and Area D Table II-8).

The nutrients in the sludge from wastewater treatments plants may also be reclaimed. From 2003 to 2014, Aqua Engineers applied sludge to about 45 acres of forage grass in Māhā‘ulepū. The land bordered Po‘ipū Road about 1 mile northeast of the Grand Hyatt Resort, and within about 500 feet of the 12th green of its golf course. Aqua Engineers reports
that there were no complaints about odors or other nuisance impacts, and no adverse health or environmental impacts. Nevertheless, the operation was forced to close due to community concerns that it was contributing to high levels of *enterococci* bacteria in Waiopili Ditch which passes about a half-mile to the east of the former sludge-disposal site. In a 2016 report, the DOH found high levels of *enterococci* bacteria in the Ditch after the sludge operation ceased, and determined that the bacteria came from a number of upstream and in-stream sources (see Subsection 7.c below).

These examples indicate that properly managed reclaimed wastewater and nutrients can be compatible with high-end resorts, homes, and recreational areas.

c. **Nuisance Impacts**

This section summarizes the anticipated economic impacts of nuisance issues due to the Dairy. The information is based on the various environmental studies conducted in preparation of an Environmental Impact Statement.

**Overview**

The Dairy will feature rotational pasture-grazing along with modern facilities and practices, and will comply with all applicable Federal and State environmental standards. In addition, conditions at the Dairy will be monitored continually to ensure that adverse impacts will not occur, or will be mitigated to minimize adverse impacts.

Considerable distances will separate the Dairy from the resorts, commercial areas, homes and recreational areas. The nearest resort units are about 1.5 miles from a Dairy paddock and about 2.4 miles from the Dairy milking parlor (see Figure II-4). For the Kōloa town center, the distances from the closest paddock and dairy facilities are about 2.2 and 2.8 miles, respectively. For homes, the distances are about 1 and 2 miles away, respectively. And for recreational activities, the distances are about 0.6 mile and 1.3 miles, respectively.

Winds in the region are generally from the east-northeast (normal tradewinds) and range from 5 to 15 miles per hour. The tradewinds blow across the Dairy property and toward Poʻipū, but not toward Kōloa.

Given the plans for the Dairy and its location, environmental studies indicate that no noticeable noise, dust, odors, flies, runoff, or other nuisance impacts will extend to resort, commercial, residential or recreational areas. Noticeable nuisance impacts occurring outside the Dairy property will be limited to the abutting farm and ranch lands which are owned by Māhāʻulepū Farm, the lessor of the Dairy property.

**Noise**

Most of the noise from milking and related operations will be contained within the milking parlor and other buildings, while noise from tractors and other field equipment will
occur mostly during the daylight hours. Some farmers and ranch hands on abutting lands may hear noises from Dairy operations. But the resorts, stores, homes and recreational areas are too distant from the Dairy for visitors and residents to be adversely affected by the noise.

**Dust**

Dust will be generated as cows move along soft limestone raceways that connect the paddocks and lead to and from the milking parlor. As case with noise, resorts, stores, homes and recreational areas are too distant for visitors and residents to be adversely affected by dust from Dairy operations.

The Dairy will generate far less dust than was the case when sugarcane was grown in the Kōloa-Poʻipū region, and much less dust than typical field farming. Both of these agricultural activities generate considerable dust during plowing, followed by weeks or months of occasional dust when soils are left exposed. The Dairy pasture will not be plowed, and the soils will not be left exposed.

**Odors**

Potential sources of odor from the Dairy include (1) manure deposited by cows in the milking parlor and holding pens; (2) the two effluent ponds; (3) the irrigation system (which uses effluent); and (4) the manure deposited directly onto the pasture. The manure from the milking parlor and holding pen will be collected frequently and washed into a settling pond that will be aerated to reduce odors. The resulting effluent will be pumped into a storage pond and then used to irrigate the pasture diluted with water from the Waitā Reservoir. To further reduce odors from the Dairy effluent ponds and other facilities, ironwood trees will be planted along the east-southeast boundary of the property.

The majority of manure (about 90%) will be deposited directly onto the pasture where—with the help of cattle egrets and dung beetles—it will break down quickly and provide nutrients to the pasture.

Figures III-1 and III-2 show odor-detection limits for the 699-cow Dairy and the 2,000-cow Dairy, respectively. For people who are sensitive to odors, the limits indicate where 50 percent of them would detect an odor from the Dairy at an average rate of once every 200 hours. The figures are based on an unlikely confluence of worst-case weather conditions and other factors. Thus, in practice, the odor limits are likely to extend a shorter distance.

For the 699-cow Dairy, the odor detection limit extends about 1,670 feet (about one-third mile) outside the Dairy boundary, and about 2,780-feet (about half mile) for the 2,000-cow Dairy. All of the affected area occurs on land owned by Māhāʻulepū Farm.

As above, resorts, stores, homes and recreational areas are too distant for visitors and residents to be adversely affected by odors from Dairy operations.
**Flies**

Fly populations at the Dairy will be controlled through Integrated Pest Management whereby fly reproduction will be disrupted at key points in the life cycle. Cattle egrets break up the cow patties while searching for prey, and dung beetles bury cow patties in 1 to 3 days. This interrupts the egg-to-fly lifecycle, which ranges from 7 to 20 days depending upon the species of fly. Kauaʻi has 14 dung beetle species, some of which fly at night and some during the day, and some that prefer older manure over fresh.

Supplemental pest control may be used to prevent short-term spikes in fly populations. These could include: sticky tapes or ribbons in the milking parlor and covered areas, outdoor traps, non-toxic repellants, etc. Insecticides are non-discriminatory and kill beneficial as well as pest insects. Such control would only be used when needed by those qualified to apply chemicals, and in accordance with authorized procedures and regulatory labeling requirements.

The Dairy will not encourage or maintain any populations of dogs, cats or chickens at the Dairy because their dung would facilitate breeding of several species of flies that are not currently established on the property. While feral chickens are common throughout Kauaʻi, the Dairy will diligently clean up any spilled feed or other potential attractants to keep chickens away from the Dairy facilities.

In order to avoid rotting garbage that might provide attractive habitat for fly breeding, food waste of on-site workers will be disposed of in covered, lined containers and removed from the site often. Spilled or waste supplement foods for the cows will not be allowed to become wet and stay exposed. And Dairy workers will remove trash found on roads abutting or near the property so that flies do not breed in garbage, and migrate to the Dairy.

In Kōloa and Poʻipū, flies depend upon local food and breeding sources, such as dog, cat, and chicken dung; rotting fruits and vegetables; exposed garbage; and damp and decaying organic matter. Given the controls that are planned for the Dairy, it is not expected to add to existing fly problems in Kōloa and Poʻipū.

**Runoff**

Several intermittent streams drain the southern slopes of Hāʻupu Ridge and converge into man-made ditches that run through the Dairy property into the concrete-lined Waipōlī Ditch. This ditch parallels lower Māhāʻulepū Road and is fed by another ditch from the west. Waipōlī Ditch continues southward, terminating at a deep and muddy basin where the ditch water joins the ocean via a channel cut through the beach sand. Mixing of the ditch water with ocean water occurs rapidly just a short distance from the shoreline.

Waipōlī Ditch receives runoff from a 2,700-acre sub-watershed, including the runoff from lands mauka and makai of the Dairy. The Dairy property accounts for about 20% of the subwatershed.
Figure III-1. Odor Detection Limit for 699-cow Dairy
Figure III-2. Odor Detection Limit for 2,000-cow Dairy
Environmental sampling by DOH has identified high levels of *enterococci* bacteria in Waiopili Ditch, particularly near its ocean terminus. According to a 2016 report by DOH, the bacteria appear to originate upstream from feral animals (pigs and some cats and dogs), avian wildlife, domesticated sheep, beef cattle on the slopes of Hāʻupu Ridge, decaying organic matter, vegetation, soils and insects. Two conditions block ultraviolet light that would otherwise reduce bacteria levels: the dense canopy along the makai end of Waiopili Ditch, and the turbidity of the water. Also, the particles that cause turbidity help transport bacteria downstream.

The Dairy is expected to contribute little runoff of soil particles, nutrients, organic debris, pathogens, etc. Cow excretions in the pasture and the effluent applied to pasture will be absorbed quickly by a thick thatch of pasture grass—essentially an organic net. Due to the high moisture and moderate temperatures in the thatch, the microbial activity is very high, and most of the effluent will be broken down by microbial activity within one day, after which the pasture grass will absorb the released nutrients.

Additional measures to prevent or minimize runoff from the Dairy will include:

— Fenced 35-foot-wide vegetation buffers on both sides of drainage ditches to keep cows away from the ditches and to filter water draining into the ditches.
— No application of effluent within 50 feet of drainage ditches.
— No application of effluent to the pasture before or during rainstorms that could result in runoff, or when the soil is completely saturated.
— Ongoing monitoring of surface and coastal waters to gauge whether nutrients and pathogens are reaching levels of concern.

Compared to the current situation, the Dairy will result in a reduction in the runoff from the property of soil particles, nutrients, organic debris, pathogens, etc. In turn, this will result in improved water quality for the affected drainage ditches. However, during rainstorms, nutrient runoff could increase for the 2,000-cow Dairy, but this will not degrade nearshore waters significantly since the nutrients will be diluted with rainwater, then will quickly be dispersed by wave action and ocean currents. Also, the health risk of cattle-fecal contaminate is low, about 0.7% to 4% of that of human-fecal contaminate. In any case, substantial runoff will continue to occur for the 80% of the subwatershed not occupied by the Dairy.

The drainage ditches are not recreational resources used by the public, even near the terminus of Waiopili Ditch at the ocean. Thus, any change in water quality—either positive or negative—will affect neither residents nor visitors.

d. Economic Impacts from Nuisances

As summarized above, no noticeable noise, dust, odors, flies, runoff, or other nuisance impacts from the Dairy will extend to resort, commercial, residential or recreational areas. Noticeable nuisance impacts occurring outside the Dairy property will be limited to the
abutting farm and ranch lands which are owned by Māhāʻulepū Farm, the lessor of the Dairy property. These abutting lands are designated IAL, so they will remain in agriculture for the foreseeable future.

Consequently, the Dairy will not adversely affect:

— Guests of resorts in the Kōloa-Po‘ipū region.
— Recreational activities in the region.
— The regional economy (number of visitors, visitor expenditures, retail sales, employment, incomes, etc.)
— Residents when at home in the region.
— Property sales in the region (single-family homes, condominiums, second homes, time-share units, etc.).
— Values of properties in the region.
— County or State taxes derived from residents, resorts, or commercial activities in the region.

From a broader perspective, the Dairy will help maintain the existing rural character and ambience of the Kōloa-Po‘ipū region.

8. Summary of Significant Benefits and Impacts

The primary economic benefits of the Dairy will include:

— For Hawai‘i, increased milk self-sufficiency by about 1.5 million gallons per year for the 669-cow Dairy, and about 4.4 million gallons should HDF decide, in the future, to expand to a 2,000-cows Dairy.
— At full operations and depending on the eventual size of the Dairy, about 14 to 28 additional jobs, including about 5 to 10 well-paying farm jobs.
— Preservation of about 547 acres of well-maintained green open space.

No adverse economic impacts due to nuisance issues are anticipated.

### 2.a. CONSTRUCTION PERIOD
- **Years:** 2

### 2.b. CONSTRUCTION EXPENDITURES
- **Total Construction Expenditures:** $7,500,000
- **Annual Construction Expenditures (average):** $3,750,000

### 2.c. EQUIPMENT EXPENDITURES
- **Total Expenditures on Equipment:** $2,000,000
- **Annual Equipment Expenditures (average):** $1,000,000

### 2.d. INDIRECT SALES GENERATED BY CONSTRUCTION
- **Kauai:** 117% of const. exp. (117% of construction expenditures), $2,851,875 per year
  - 65% on Kauai, $1,535,625 per year
- **Oahu:** 117% of const. exp. (117% of construction expenditures), $1,535,625 per year
  - 35% on Oahu, $913,750 per year
- **Total Indirect Sales:** $4,387,500 per year

### 2.e. SUMMARY OF EXPENDITURES & SALES
- **Final Sales (taxed at 4%)**
  - **Construction Expenditures:** $3,750,000 per year
  - **Equipment Expenditures:** $1,000,000 per year
  - **Consumption Expenditures:** 55% of payroll, $944,548 per year
  - **Total Sales at 4%:** $5,694,548 per year
- **Intermediate Sales (taxed at 0.5%)**
  - **Indirect Sales Related to Construction:** $4,387,500 per year
  - **Less Consumption:** $944,548 per year
  - **Total Sales at 0.5%:** $3,442,952 per year
- **Total Sales (direct and indirect):** $9,137,500 per year

### 2.f. PROFITS
- **Profits on Total Sales (direct and indirect):** 10.0% of sales, $913,750 per year
- **Risk Premium for Construction:** 2.0% of construction, $75,000 per year
- **Total Profit from Construction & Related Activity:** $988,750 per year

### 2.g. EMPLOYMENT (on-site & off-site)
- **Kauai:**
  - **Construction Jobs:** 12 jobs
  - **Indirect Employment Generated by Construction:** 16 jobs
  - **Total Kauai Employment:** 28 jobs
- **Oahu, Indirect Employment Generated by Construction:** 8 jobs
- **Total Employment:** 36 jobs

### 2.h. PAYROLL
- **Kauai:**
  - **Construction Payroll:** $53,510 average per job
  - **Payroll for Indirect Employment:** $42,928
  - **Total Kauai Payroll:** $1,328,968 per year
- **Oahu, Payroll for Indirect Employment:** $48,540 average per job
- **Total Payroll:** $1,717,360 per year

1 INTRODUCTION

This assessment presents an overall hydrologic analysis for the existing and proposed conditions for the Hawai‘i Dairy Farms project, as well as the storm drainage design criteria which will be utilized for the design of facility and farm specific drainage infrastructure as part of the project’s Conservation Plan and farm construction plans.

1.1 Proposed Project

In late 2013, Ulupono Initiative made the investment to fund Hawai‘i Dairy Farms, the first pasture-based rotational-grazing dairy in the state. Hawai‘i Dairy Farms, LLC (HDF) was formed as a positive step toward the island state’s food security, economic diversity, and sustainability. At steady-state production with 699 milking cows, the farm will produce roughly 1.2 million gallons annually. HDF will reduce Hawai‘i’s reliance on imported milk from the mainland United States by increasing current fresh local milk production by approximately 33 percent. The farm will be based on the most successful island dairy models in the world, and will utilize a sustainable, pasture-based rotational-grazing system and 21st century technology. The farm will be very different from conventional feedlot dairy operations.

HDF is committed to establishing a herd of up to 699 mature dairy cows, and demonstrating the pasture-based system as an economically and environmentally sustainable model for Hawai‘i. With proven success at a herd size of 699, HDF will contemplate the possibility of expanding the herd in the future. Precision agricultural technology that monitors cows’ health, grass productivity, and effluent management will be used to ensure environmental health and safety, as well as best management practices, and help determine the ultimate carrying capacity of the land.

For dairy operations with 700 or more mature dairy cows, additional regulatory review and permitting by the State of Hawai‘i, Department of Health (DOH) is required. The application process for a National Pollutant Discharge Elimination System (NPDES) Concentrated Animal Feeding Operation (CAFO) permit includes public notification and input. At the discretion of HDF, management may choose to expand operations up to the carrying capacity of the land,
which is currently estimated to be up to 2,000 productive milking dairy cows. Permit process compliance would be followed at such time HDF may decide to pursue an expanded operation.

The project will be located in the Māhāʻulepū Valley on the island of Kauaʻi, exclusively within the approximate 556.8 acres of land leased by HDF from Mahaulepu Farm LLC. See Figure 1 – Vicinity Map.

Regardless of the amount of animals on the farm, the majority of infrastructure must be constructed prior to commencement of any dairy operations. The farm improvements discussed herein will be used to support the dairy, whether for the initial herd of 699 mature dairy cows, to up to 2,000 mature dairy cows.

1.2 Project Location and Land Use
The project site is situated in the Māhāʻulepū Valley on the island of Kauaʻi. The valley is on the leeward side of the Hāʻupu mountain ridge, which runs in the east-west direction, and the valley is also flanked by ridge lines on both sides. The project area has historically been used for sugar cane production as part of the Kōloa Plantation until the late 1990s when the Kōloa Mill closed. Since the mill closed, the project area has been leased to various tenants for ranching and diversified agricultural operations. A small plot of land in the lower center of the valley is currently used for taro loʻi and will continue to be leased and farmed after the dairy and related pastures are in full operation. See Figure 2 – Location Map

The original agricultural infrastructure from the sugar plantation is largely still in place and continues to be used for on-going agricultural activities. Much of this existing infrastructure will also be used for the dairy, but with a significant amount of upgrades and improvements. The existing infrastructure in the project area includes: gravel and dirt access roads, field roads, water wells, reservoirs, pipelines, pumps, irrigation ditches, drainage ways and culverts.

The project area is comprised of lands designated pursuant to the Hawaiʻi State Constitution as Important Agricultural Lands. Accordingly, the project is consistent not only with past agricultural use of the area, but with ongoing constitutionally recognized interest in maintaining and utilizing the area for agricultural purposes that promote agricultural self-sufficiency.
Unlike conventional feed lot dairies, in which mature dairy cows are confined and fed only hay and silages, the project will be the first dairy in the State to utilize rotational, pasture-based grazing. The rotational, pasture-based grazing approach is a system that involves regularly rotating cows through farm paddocks, where they will primarily feed on locally grown grass, supplemented with grain and vitamins as needed. This approach optimizes grass growth, cow health and milk production, facilitates even applications of waste products for fertilization, prevents over-grazing and over-application of fertilizers, and maintains erosion and runoff controls.

The initial herd of up to 699 mature dairy cows will be divided into groups and rotated through a series of paddocks over an 18-day period to access fresh grass and deposit manure throughout the area. Cows will move through a system of raceways to and from the milking parlor, where they will be milked twice a day for a total of two hours. The remaining dry cows, heifers and 90-day and older calves will be managed off-property on existing ranches that are owned and operated by other local ranchers. The project will be fully enclosed by perimeter fencing along the boundary of the leased premises, which will ensure that livestock and grazing activities are contained within the project area.
2 DESIGN CRITERIA

The project will utilize various design criteria due to the available design standards for agricultural operations within the United States, the State of Hawai‘i, and the County of Kauai. Drainage design criteria and considerations will be used from the following sources:

2.1 References:

4. All subsequent revisions and amendments for the above referenced standards.

2.2 Design Recurrence Interval (Tm):

Different recurrence intervals will be utilized for analyzing project site and tributary storm drainage flows, and for sizing of the drainage infrastructure on the farm, depending on the type of infrastructure improvements that are constructed and by the governing code and references listed above.

The drainage facility itself is located within 9.7 acres within the farm. Local drainage improvements such as catch basins, storm drain piping, downspouts, and other conveyance systems will be designed to meet the 2-year, 1-hour storm event per County requirements.

Farm-wide improvements will be designed to applicable NRCS Standards and Specifications. If improvements are not covered under applicable NRCS Standards and Specifications, improvements affecting drainage areas less than 100 acres in size will be designed to the 2-year, 1-hour event, and areas greater than 100 acres will be designed to the 100-year, 1-hour event.
Drainage improvements and best management practices will be installed at the guidance, direction, and approval of the NRCS, in accordance with standard practice for agricultural operations, as applicable. These improvements and best management practices will be shown on Hawai’i Dairy Farm’s Conservation Plan.

Such improvements are typically required to address stormwater management on farm and agricultural lands, and the County typically defers approval of the stormwater and runoff management improvements and best management practices to the local soils and water conservation district, so long as the improvements are constructed to NRCS standards and specifications. The following NRCS practice codes will be used for the site, and the appropriate design recurrence interval is noted.

*Standards and Specifications, Field Office Technical Guide (FOTG), Pacific Islands*

- **For stream/ditch crossings for animals/persons/equipment:**
  \[ T_m = 2\text{-year}, 24\text{-hour peak discharge} \]
  (Per NRCS Conservation Practice Standard Code 578)

- **For stream/ditch crossings for access roads:**
  \[ T_m = 10\text{-year}, 24\text{-hour peak discharge for frequent use for a farm headquarters} \]
  (Per NRCS Conservation Practice Standard Code 578)

- **For vegetated/grassed waterways:**
  \[ T_m = 10\text{-year}, 24\text{-hour peak discharge} \]
  (Per NRCS Conservation Practice Standard Code 412)

### 2.3 Runoff Quantity (Q\_peak):

Similarly, different methods of calculating peak flows will be utilized for analyzing the project site’s generated runoff as well as tributary storm drainage flows for sizing of the drainage infrastructure on the farm, depending on the type of improvements required and by the governing standard.
The drainage facility itself is located within 9.7 acres within the farm. Local drainage flows will be analyzed using the Rational Method, per the County of Kauai standard.

Farm-wide infrastructure improvements, affecting tributary areas greater than 100 acres, will be analyzed using TR-55 or TR-20 programs.

*Storm Water Runoff System Manual, Department of Public Works, County of Kauai*

- For drainage areas less than 100 acres
  
  Rational Method, \( Q = CIA \)

  Where \( Q = \) flow (cfs), \( C = \) Runoff Coefficient, \( I = \) Intensity (in/hr), and \( A = \) Area (acres)

- For drainage areas greater than 100 acres and less than 2,000 acres
  
  Utilize TR-55 or TR-20 Program

The NRCS Standards and Specifications defer to County requirements to determine peak flows.

*Standards and Specifications, Field Office Technical Guide (FOTG), Pacific Islands*

- Stormwater Runoff Control, per NRCS Conservation Practice Standard Code 570.
  
  Prepare a plan, design, and construct controls to comply with applicable federal, state, and local laws and regulations.
2.4 Runoff Coefficient (C) – For Use with the Rational Method:

*Storm Water Runoff System Manual, Department of Public Works, County of Kauai*

</tbody>
</table>

NOTE: (These Rational formula coefficients may not be valid for large basins. These coefficients are also average values and may require adjustments depending on the surface characteristics, soil type, slope, infiltration, evaporation, depression storage, etc. The Engineer shall use sound engineering judgment in selecting the proper coefficient(s).) For composite drainage areas compute "weighted" Rational formula coefficient(s). *Average impervious areas do not correlate directly to allowable impervious area.*

2.5 Runoff Curve Number (CN) – For use with TR-55 Program:

*TR-55, USDA, NRCS, Conservation Engineering Division*

- Land uses based on soils, plant cover, amount of impervious areas, condition, etc.:
  For drainage areas with more than one type of land use, a weighted value of the CN shall be computed.
2.6 **Time of Concentration (Tc):**

Similarly, different methods of the Time of Concentration (Tc) will be utilized for analyzing the project site’s generated runoff as well as tributary storm drainage flows, as required by the governing standard.

Local drainage flows at the facility will be analyzed using the Rational Method as flow paths will be less than 300 feet in length.

Farm-wide improvements will be analyzed using TR-55 or TR-20 programs and will use a summation of distinct, consecutive flow areas.

*Storm Water Runoff System Manual, Department of Public Works, County of Kauai*

- **For flow paths less than 300 feet:**
  - Use Plate 1

*TR-55, USDA, NRCS, Conservation Engineering Division*

- **For distinct consecutive flow areas:**
  - The summation of Tc shall be used. Beyond 100 feet, the flow is considered shallow concentrated flow.

2.7 **Rainfall Intensity (I):**

Similarly, different methods of determining the rainfall intensity will be utilized for analyzing the project site’s generated runoff as well as tributary storm drainage flows, as required by the governing standard.

Plate 2 and 3 of the County Code will be used to determine the appropriate rainfall intensity at the dairy facility, to be utilized with the Rational Method.

TR-55 or TR-20 programs, using NOAA 24-hour rainfall for select 24-hour events, will be used to determine rainfall intensity around the farm.
For 2-year, 1 hour event:
Use Plate 2 and 3 to determine intensity and correction factor

Based upon NOAA 24-Hour Rainfall for Select 24-hour Events
Type I Rainfall Distribution

2.8 NRCS Conservation Practice Standards and Best Management Practices Criteria:
Additional NRCS Conservation Practice Standards, used for specific infrastructure improvements to manage stormwater runoff, may be installed around the farm as needed and will follow the appropriate criteria.

Surface Cross Drains:
- Spacing for access roads: Based upon soil type and roadway grade. See Figure 1 of NRCS Conservation Practice Standard Code 560
- Spacing for animal trails and walkways: As required due to field conditions or as indicated. See NRCS Conservation Practice Standard Code 575

Waterway Setbacks and Filter Strips (393) / Buffer Plantings (390):
- Minimum Flow Length per NRCS Conservation Practice Standard Code 393: 10-year life span, with a minimum 20-foot filter strip length. Length shall be increased to 30 feet to provide additional capacity to reduce dissolved contaminants in runoff.
- Minimum Width of Buffer per NRCS Conservation Practice Standard Code 390: Buffer shall be 2.5 times the stream width from bank-full elevations or 35 feet to provide capacity to maintain or improve water quality and quantity
management. Concentrated flow erosion should be controlled up-gradient of buffer.

- Design Slopes per NRCS Conservation Practice Standard Code 393: Upstream drainage area should have minimum 1% slope. The maximum gradient along the leading edge shall not exceed 5%.

- **Grassed Waterway (412) / Field Ditch (607):**
  - Minimum Capacity per NRCS Conservation Practice Standard Code 412: Waterway shall convey the peak runoff from the 10-year, 24-hour duration event. Capacity shall be increased to account for potential high volumes of sediment. When the slope is less than 1%, out of bank flow is permitted so long as erosion is minor.
  - Minimum Capacity per NRCS Conservation Practice Standard Code 607: Application of locally tried and proven drainage coefficients, plus consideration for yield of groundwater or irrigation water.
  - Maximum Side Slope per NRCS Conservation Practice Standard Code 412: Flatter than 2 to 1 H:V slopes and should accommodate equipment needed for maintenance and tillage/harvesting.
3 EXISTING CONDITIONS

Since the sugar plantation closed, the project area has been leased to various tenants for ranching and diversified agricultural operations. A small plot of land in the lower center of the valley is currently used for taro lo’i and will continue to be leased and farmed after the dairy and related pastures are in full operation. Neighboring operators consist of beef cattle and banana crops.

Currently, the site is being used for grass trials in preparation of construction and establishment of the dairy facility and pastures. Irrigation systems for growing the grass, watering facilities, limited fencing, and monitoring wells have also been installed, though the site is largely vacant. Clearing and mowing has been taking place as part of ongoing maintenance.

3.1 Topography and Drainage Runoff Patterns

The project site is situated in the Māhāʻulepū Valley on the island of Kaua‘i. The valley is on the leeward side of the Haʻupu mountain ridge, which runs in the east-west direction, and the valley is also flanked by ridge lines on both sides. Mt. Haʻupu is the highest point on the ridge line at the back of the valley with an elevation of 2,297 feet. From this point, the ground drops very quickly down to the bottom of the valley to about an elevation of 150 feet. The base of the valley itself is somewhat gradually sloped from an elevation of 150 feet to an elevation of 60 feet along Māhāʻulepū Road on the makai side of the project site near the taro farm.

Runoff from the valley walls is generally conveyed via shallow concentrated flow which collects into cutoff ditches along the exterior of the boundary of the farm. The cutoff ditches are typically located on the uphill side of the proposed fence line for the dairy farm or of the farm roads, including Māhāʻulepū Road, preventing the run on of stormwater onto the farm property. These cutoff ditches then move along the fence lines or roadways and ultimately connect to two main ditches that convey water via channel flow from the upland area, through the farm, and then mauka to the ocean. The ditches were likely configured by historical agriculture uses, based upon their linear shape and as they follow two main roads on the farm site. The two ditches remain separate on the farm: Māhāʻulepū Ditch (East) which runs centrally through the farm, and Māhāʻulepū Ditch (West) which runs near the proposed facility.
location. Downstream of the farm site, the two separate ditches combine into Māhāʻulepū Ditch, before reaching the ocean.

Runoff from the farm area within the project boundaries itself generally sheet flows or flows in shallow concentration towards and into these ditches.

**See Figure 3 – USGS Map**

### 3.2 Existing Water Resources

The Māhāʻulepū Valley has been in agricultural use for a very long time and much of the water resources and infrastructure in the valley are man-made and were constructed to provide irrigation water to the sugar cane lands throughout the valley. Systems of ditches, reservoirs and irrigation pipes and pumps are still in place and are still used to irrigate fields and pasture. Some of these systems cutoff overland flow towards the project site, as they surround the farm. Much of this infrastructure is shown on the USGS maps. **See Figures 4 – Water Resources**

### 3.3 Soils Condition

According to the United States Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS) survey data, the project area consists of a variety of soils. Soil characteristics are summarized in the table below. **See Figure 5 – Soil Map**
Table 1 – Soil Characteristics Summary

3.5 Existing Hydrology

As previously noted, the site is currently utilized for diversified agriculture, though some of the site is used for grass trials for the proposed dairy. Therefore, the site is assumed to generally consist of grass, in “fair” condition, on a gentle to moderate sloping surface.

Because the entire farm site drains into two major ditches running mauka to makai, the runoff generated over the farm area is split into two drainage areas and drainage systems. Additionally, run-on onto the site and into the farm area must be considered from the upland areas and from the ridges which form Māhāʻulepū Valley, though the majority of run-on is diverted by cutoff ditches on the uphill side of the farm boundary.

Generally, runoff from the west side of the valley sheet flows or is conveyed via shallow concentrated flow through the various system of ridges and valleys along the west side of Māhāʻulepū Valley. Runoff concentrates into several ditches, cut from agricultural operations, before ultimately collecting into one of the major ditches that runs mauka to makai along the west side of the farm, and along the proposed location of the dairy facility. This ditch conveys both water collected from the various tributary ditches, but also sheet flow from the west side of the farm, to the makai boundary of the farm along Māhāʻulepū Road, before leaving the site and ultimate discharge into the ocean.
Runoff from the east side of the valley, similarly, sheet flows or is conveyed via shallow concentrated flow through the various system of ridges and valleys along the east side of Māhāʻulepū Valley. Runoff concentrates into several ditches, cut from agricultural operations, before ultimately collecting into one of the major ditches that runs mauka to makai along the central or east side of the farm. This ditch conveys both water collected from the various tributary ditches, but also sheet flow from the central and eastern areas of the farm, to the makai boundary of the farm along Māhāʻulepū Road, before leaving the site and ultimate discharge into the ocean.

The flows from these two ditches converge beyond the boundary of Hawaiʻi Dairy Farms before discharge to the ocean.

**See Figure 8 - Hydrology Exhibit - Existing Conditions**

Utilizing TR-55 for analysis of both ditches running through the valley (Māhāʻulepū Ditch East & Māhāʻulepū Ditch West), the following parameters were input into the TR-55 program to estimate the existing peak discharge from both reaches:
