Mr. Tom Eisen, Staff Planner
Office of Environmental Quality Control ("OEQC")
Department of Health
235 South Beretania Street, Room 702
Honolulu, Hawaii 96813

Dear Mr. Eisen:

SUBJECT: National Environmental Protection Act (NEPA) Environmental Assessment ("EA") Request Publication in the Environmental Notice

Project:	Halewai`olu Senior Residence
Applicant:	Halewai'olu Senior Development, LLC
Owner:	City and County of Honolulu
Agent:	R.M. Towill Corporation (Keith Kurahashi)
Location:	1331-1347 River Street – Downtown, Honolulu
Tax Map Key:	(1) 1-7-006:012
Proposal:	A new 201H affordable, rental housing residential facility for seniors aged 62 and over, with incomes at 80% and below of the Area Median Income. The new residential facility will include 156 one- and two-bedroom units (includes one resident manager's unit), commercial spaces, recreational amenities, and off-street parking.

Although not required by statute, on behalf of the City and County Department of Land Management, we respectfully request OEQC publish the Project summary of this Project's NEPA EA (not an HRS 343 HEPA) in the next edition of The Environmental Notice on **April 8, 2020.**

If you have any questions or need any additional information, please contact me at (808) 691-9446 or by email KSeddon@tmo.com.

Thank you for your assistance in this matter.

Very truly yours,

Karen Seddon

Karen Seddon
Vice President, Halewai'olu Senior Development
Regional Vice President, Michaels Development

Applicant:	Halewaiʻolu Senior Development, LLC Karen Seddon, Vice President Email: kseddon@tmo.com Phone: (808) 691-9446 737 Bishop Street, Suite 1520 Honolulu, Hawaiʻi 96813
Approving Agency:	City and County of Honolulu Department of Land Management Sandra S. Pfund, Director Email: spfund@honolulu.gov Phone: (808) 768-4277 558 South King Street Honolulu, Hawaii 96813
Consultant:	R. M. Towill Corporation Keith Kurahashi, Principal Planner Email: keithk@rmtowill.com 2024 North King Street, Suite 200 Honolulu, Hawaiʻi 96819 Phone: (808) 842-1133
Status:	30-day public and agency comment period starts. **Comments due by May 08, 2020.** Send comments to the Consultant.

Summary (Provide proposed action and purpose/need in less than 200 words. Please keep the summary brief and on this one page)**:**

Applicant proposes to demolish an existing vacant commercial building and parking lot on the Project Site and construct a new affordable rental housing facility for seniors aged 62 and over. The new 17-story residential facility will include 155, 1- and 2-bedroom units for seniors earning 80% and below of Area Median Income (AMI), and one resident manager's unit. Eight units will be designated for seniors earning 30% AMI or below; 131 units will be designated for seniors earning 60% AMI or below; and the remaining 16 units will be available for seniors earning 80% AMI or below. The residential facility will also include a multi-purpose room, social services office, property management offices, lobby, courtyard, and retail space. Project will remain affordable for a maximum term of 75 years. It will be about 174 feet tall with a 4-story podium. Various affordable housing and LUO exemptions under the City's HRS, 201H program are being requested.

PREFACE

The Applicant, Halewai'olu Senior Development, LLC (HSD), is developing a 0.6181-acre parcel identified as Tax Map Key (TMK) 1-7-006:012, located at 1331-1347 River Street in Honolulu, Island of O'ahu, State of Hawai'i ("Project Site"). This Halewai`olu Senior Residences ("Project") will include the demolition of an existing, vacant, commercial building and parking lot on the Project Site and construction of a new affordable, rental housing residential facility for seniors aged 62 and over, with incomes at 80% and below of the U.S. Department of Housing and Urban Development (HUD) Area Median Income (AMI). The new residential facility will include 156 one- and two-bedroom units (includes one resident manager's unit). The new residential facility will also include a multi-purpose room, warming kitchen, restrooms, storage rooms, utility rooms, computer room, social services activity rooms, social services office, property management offices, mail and package boxes, and elevator lobby on the ground level. On the ground level will also be a courtyard (plaza), retail space, and parking access, along with bicycle parking, the trash compactor room and loading area. Levels 2 -3 will include vehicle parking, a portion of the bicycle parking, a generator room, storage and utility rooms. Level 4 will include a recreation area, laundry room, and equipment rooms. The residential units will be on Levels 5- 17. The new residential facility's preliminary unit count and type are shown in **Table 1: Housing Unit Mix for Halewai'olu Senior Residences**.

Table 1: Housing Unit Mix for Halewai'olu Senior Residences

Unit Type	One-bedroom	Two-bedroom	Total
30% of AMI	8	0	8
60% of AMI	115	16	131
80% of AMI	7	9	16
Manager's Unit	0	1	1
Total:	130	26	156

The Project will revitalize a site that is currently blighted and underutilized. In addition to providing much-needed affordable housing for seniors within the Primary Urban Center (PUC), the Project will provide benefits for the community by providing multi-purpose and activity rooms for the senior residents and the surrounding neighborhood and will improve the urban streetscape through the provision of landscaping, street trees and a courtyard. The Project is located within the Downtown Neighborhood Transit-Oriented Development (TOD) Plan area ("Downtown TOD Plan"), and promotes the principles of a walkable, dense, mixed-use neighborhood where residents are located in close proximity to everyday needs and community activities in the Downtown-Chinatown neighborhood. Although the Project is in proximity to three transit stations (Iwilei, Downtown, and Chinatown), it is nearest to the Chinatown station (approximately 0.4 miles).

The Project Site is owned by the City and County of Honolulu (City). In 1992, the City purchased the property with funds from HUD's Community Development Block Grant (CDBG) program. The Project will be funded through the Internal Revenue Tax Code, Section 42, Low-Income Housing Tax Credit (LIHTC) program, along with funds from the State Hula Mae Multifamily Bond and Rental Housing Revolving Fund programs that were awarded by the Hawai'i Housing Finance and Development Corporation (HHFDC) to HSD in February 2019.

Due to the use of federal HUD CDBG funds for the initial land purchase, the Project is subject to the HUD environmental review regulations as stipulated in Title 24, *Housing and Urban Development*, Code of Federal Regulations (CFR) Part 58, *Environmental Review Procedures For Entities Assuming HUD Environmental Responsibilities*, the National Environmental Policy Act (NEPA) and its federal cross-cutter regulations.

HSD, has requested a determination from the Department of Land Management that the Halewai'olu Senior Residences ("Project") is exempt from HRS, Chapter 343, *Environmental Impact Statement Laws*, and HAR, Chapter 11-200.1, *Environmental Impact Statement Rules*.

Governor David Ige signed and adopted HAR, Chapter 11-200.1 on July 30, 2019, which took effect on August 9, 2019. The Project complies with the eligibility criteria listed in Chapter 11-200.1-15, which authorizes the exemption from the preparation of an Environmental Assessment. See the discussion below:

(c) The following general types of actions are eligible for exemption:

(10) New construction of affordable housing, where affordable housing is defined by the controlling law applicable for the state or county proposing agency or approving agency, that meets the following:

(A) Has the use of state or county lands or funds or is within Waikiki as the sole triggers for compliance with chapter 343, HRS;

Discussion: In accordance with HRS, 343-5(a), the trigger for this Project is the use of state funding, including Low-income Housing Tax Credits and funding from the Rental Housing Trust Fund.

(B) As proposed conforms with the existing state urban land use classification;

Discussion: The Project site is located within the "Urban" district, as classified by the State.

(C) As proposed is consistent with the existing county zoning classification that allows housing; and

Discussion: The Project is located in the "BMX-4" Central Business Mixed Use District, as classified by the City. This BMX-4 district permits the development of the new multi-family facility.

(D) As proposed does not require variances for shoreline setbacks or siting in an environmentally sensitive area, as stated in section 11-200.1-13(b)(11)."

Discussion: The Project does not require a variance for a shoreline setback or the siting in an environmentally sensitive area. Additionally, the Project is not located along coastal areas, nor is it within the 3.2-foot sea level rise exposure area. Further, the subject property is located in Zone X (areas outside the 0.2% annual chance floodplain), as classified by the Federal Emergency Management Agency.

The Project meets the requirements for exemption from HRS, Chapter 343, *Environmental Impact Statement Laws*, and HAR, Chapter 11-200.1, *Environmental Impact Statement Rules*

1.0 PROJECT SUMMARY

Project:	Halewai'olu Senior Residence Project
Applicant:	Halewai'olu Senior Development, LLC (HSD) 737 Bishop Street, Suite 1520 Honolulu, Hawai'i 96813 Contact: Karen Seddon, Regional Vice President Phone: (808) 691-9446
EA Accepting Agency:	City and County of Honolulu Department of Land Management 558 South King Street Honolulu, Hawaii 96813 Phone: (808) 768-4141
EA Preparation:	R. M. Towill Corporation 2024 North King Street, Suite 200 Honolulu, Hawai'i 96819 Contact: Keith Kurahashi, Principal Planner Phone: (808) 842-1133 Email: keithk@rmtowill.com
Project Location:	1331-1347 River Street Honolulu, Hawai'i 96817 Honolulu, Kona District, Island of O'ahu
Tax Map Key:	(1) 1-7-006: 012
Proposed Action:	HSD proposes to demolish an existing, vacant commercial building and parking lot on the Project Site and construct a new affordable rental housing facility for seniors aged 62 and over. The new 17-story residential facility will include 155 units for seniors earning 80% and below of the AMI, and one resident manager's unit. Eight units will be designated for seniors earning 30% or below of the AMI; 131 units will be designated for seniors earning 60% or below of the AMI; and the remaining 16 units will be available for seniors earning 80% or below of the AMI. The residential facility will also include a multi-purpose room, social services office, property management offices, lobby, courtyard, and retail space.
Land Area:	0.6181 acres (26,925 square feet)
Present Use:	Residential
State Land Use District (SLUD):	Urban
City Zoning District:	BMX-4 – Central Business Mixed Use
PUC Development Plan Land Use Map	Medium and Higher-Density Residential/Mixed Use
Special Management Area (SMA):	Not in SMA
Permits and Approvals Required:	Clearances and permits needed from the various Federal, State and City and County of Honolulu agencies include but are not limited to the following

	Federal • Section 106 National Historic Preservation Act (NHPA) **State** **Department of Health (HDOH)** • Community Noise Permit • Noise Variance Permit **HDOH, Disability and Communication Access Board (DCAB)** • HRS, §103-50 Accessibility Compliance **Department of Labor and Industrial Relations (DLIR)** • Dumb Lift Permit • Man Hoist Permit **City** **City Council** • Hawai'i Revised Statutes (HRS) Chapter 201H Exemptions • Development Agreement **Department of Planning and Permitting (DPP)** • Hawai'i Revised Statutes (HRS) Chapter 201H Exemptions • Building and Construction permits – Grading, Building, Demolition, Electrical, Plumbing, Stockpiling, Sidewalk/Driveway • Sewer Connection Permit • Park Dedication Requirement • Storm Drain Connection Permit • Certificate of Occupancy • Construction Plan Review and Approval **Honolulu Board of Water Supply (BWS)** • Water System Connection • Construction Plan Review and Approval **Honolulu Fire Department (HFD)** • Construction Plan Review and Approval • Fuel Tank Permit **Department of Environmental Services (ENV)** • Construction Plan Review and Approval **Department of Transportation Services (DTS)** • Street Usage Permit **Department of Facility Maintenance (DFM)** • Erosion and Sediment Control Plan • Clean Water Pollution Plan • Post-Construction Best Management Plan
Determination:	Finding of No Significant Impact (FONSI)

2.0 PROJECT DESCRIPTION

2.1 PROJECT BACKGROUND

The City, through its Department of Community Services and the Mayor's Office of Housing, published a Request for Proposal on July 3, 2014, with the intention to "realize the Chinatown community's need for a quality affordable senior housing development."[1]

Developer proposals were submitted on September 5, 2014, followed by developer presentations to the Selection Committee on November 10, 2014, and after Best and Final Offers were finalized on February 9, 2015. HSD was informed by the City via a letter dated April 4, 2015, that it had been selected as the developer for the Project.

After a presentation to Mayor Kirk Caldwell and the Administrative Staff on April 28, 2015, HSD and the City entered into negotiations on a Development Agreement until a final draft was completed on November 6, 2015, enabling the City to file Resolution No. 16-70 for City Council approval of the Development Agreement. Resolution No. 16-70 was introduced to the Honolulu City Council Budget Committee on March 16, 2016 and approved on March 30, 2016. Resolution No. 16-70, CD1, FD1[2] was approved by the full Honolulu City Council on May 4, 2016. The final Development Agreement based on the approved resolution was completed on May 17, 2016, with a first Amendment to the Development Agreement completed on August 16, 2016. Due diligence was performed, followed by partial acceptance of the Project by HSD on November 23, 2016, related to acceptance of the physical condition of the property but reserving other objections to the property. A second Amendment to the Development Agreement was completed on December 8, 2016. The Applicant will revise the Development Agreement, as required, after completion of the 201H Process, as this approval may require changes to the Development Agreement. In addition, a separate 201H Development Agreement will be prepared in consultation with the Department of Planning and Permitting (DPP).

The required documentation for the HHFDC Consolidated Application for Project funding, scheduled for February 2017, could not be adequately generated in time for submittal in 2017; therefore, the Project funding submittal was delayed to February 2018. HHFDC subsequently awarded the requested Project funding one year later, in February 2019.

Pursuant to the executed Development Agreement, HSD agreed to develop, construct, complete, manage and operate a senior affordable rental Project, for a term of 65 years (lease may be extended for a period not to exceed 75 years total).

DEVELOPMENT AGREEMENT

The Development Agreement will be revised after approval of the 201H Application is acted on (approved) by the Honolulu City Council, to be sure that all revisions needed to the Development Agreement related to the 201H Application approval can be requested.

Differences between the existing Development Agreement and the Project are discussed below:

[1] Request for Proposals, Halewai'olu Residences, Offered by: City, Kirk Caldwell, Mayor, July 3, 2014, p. 4

[2] http://www4.honolulu.gov/docushare/dsweb/Get/Document-179177/RES16-070.htm

1. "2.2.1 Residential Units: There shall be 150 affordable residential rental units for Qualified Tenants (the "Units") plus one unit for an on-site staff member ("Staff Unit")."
   The Project is planned with 155 affordable residential units with on-site staff unit (resident manager). The Applicant was able to increase the number of affordable rental units provided to seniors.

2. "2.2.3 Unit **Mix:**
   …..

Approx. No. of Units	Type of (No.) Bedroom Unit	AMI Levels, as determined by HUD
8	1	30%
117	1	60%
12	1	80%
10	2	60%
4	2	80%
Total 151"		

   The Project now proposes the following number of units at the listed AMI, increasing the total number of units and total number of larger, two-bedroom units:

Unit Type	***One-bedroom***	***Two-bedroom***	***Total***
30% of AMI	*8*	*0*	*8*
60% of AMI	*115*	*16*	*131*
80% of AMI	*7*	*9*	*16*
Manager's Unit	*0*	*1*	*1*
Total:	*130*	*26*	*156*

3. "2.2.4 Parking and Loading. A three-story parking structure, to include a total of 75 parking stalls, at least 1O of which shall be reserved for persons with disabilities in compliance with the Americans with Disabilities Act, as amended ("ADA"), and one (1) loading space (located on the ground floor), all in compliance with the LUO and other applicable law."

   The Project is planned with 51 parking stalls and as necessary, the number of accessible parking stalls provided will be based on the requirements of the HDOH, DCAB Interpretive Opinion 2014-05. DPP has recommended 25 parking stalls, since the Project Site is in walking distance to the future transit station and bus stops. The proposed 51 parking stalls represents a middle ground between the Development Agreement and DPP's recommendation.

4. "2.2.5 Resident Amenities. The following amenities shall be available exclusively for residents and their guests:

…..

2.2.5.2 An approximately 4,000 square foot rooftop garden on the rooftop of the Community Center."

The Project will now provide approximately 622 square feet rooftop garden due to required rooftop mechanical enclosure and other rooftop equipment for the multi-purpose room below

5. "2.2.6 Community Center. A community center of approximately 10,453 square feet (the "Community Center'') at the ground floor along the main entry to the residences. The Community Center will include a "Great Room" for events, a warming kitchen, and other activity and meeting spaces for small scale programs and services."

   The Community Center spaces total approximately 10,444 square feet, including the "Great Room" warming kitchen, and other activity and meeting spaces.

6. "2.2.7 Retail Space. Developer will provide retail shop space comprising an area of approximately 1,922 square feet configured as two to four small shops with rents to be offered at below-market pricing."

   Due to HECO requirements to locate transformers and the vault room close to the street, the retail space is reduced to approximately 618 square feet.

7. "2.2.1O Modifications. The exact number of Units, Unit mix, Unit affordability mix, square footages, amenities and mixed-use components may be adjusted upon the request of the Developer and reasonable approval of the City based upon the results of Developer's due diligence permitted under Section 4.1 of this Agreement, the requirements of Developer's lenders and investors, and feedback from governmental authorities, community groups and public stakeholders during the design, environmental review and entitlement process. By way of example only, the City and Developer hereby agree that it shall be reasonable for the parties to adjust the Project components as provided for in this Agreement, to the extent necessary to comply with any affordable housing regulatory agreement or similar restrictive conditions or covenants imposed by a governmental agency to be recorded against the Property. Any such modifications shall not significantly deviate from Developer's Proposal and shall be made prior to the submission of the Lease to the City Council for approval, and the final details of all Project components shall be incorporated into such Lease."

   All of these modifications represent not significant deviations from the Development Agreement and permitted without amending the Development Agreement. The number of parking stalls has decreased due to the Project's location within the Downtown TOD plan area and at the request of DPP. Notwithstanding, the Applicant intends to request a modification from the City Council, after action/approval of the 201H Application.

Proposed Change in Use Designation

In order to facilitate the development of the Halewai'olu Senior Residences Project, the City Is proposing to change the CDBG use restriction on the property to allow the construction of affordable rental housing. The rationale for the redesignation of use is as follows:

Redeveloping the vacant commercial building into affordable rental housing meets a CDBG national objective under which housing will be created which is 24 CFR 570.208(a)(3) Housing Activities and furthers the City's goal of creating and preserving affordable rental housing stock.

Accordingly, the following Public Notice was published in the Honolulu Star-Advertiser on Tuesday, March 31, 2020:

"PUBLIC NOTICE
Community Development Block Grant ("CDBGn) Program
Proposed Change in Use

"NOTICE IS HEREBY GIVEN that the City and County of Honolulu (the "City") is proposing to change the use of certain real property acquired with federal CDBG funds from a commercial property which met the national objective of removal of blight to affordable rental housing. The proposed use meets the national objective of a housing activity, carried out for the purpose of providing or improving permanent residential structures which, upon completion, will be occupied by low- and moderate-income households, set forth in 24 Code of Federal Regulations ("CFR") §570.208(a)(3). The change in use is being pursued pursuant to the provisions of 24 CFR §570.505 to the CDBG national objective of a housing activity under 24 CFR 570.208(a)(3) Housing Activities.

The real property ("Property") is known as the John R. Gilliland Sr. Building and is located at 1331-1347 River Street, Honolulu, Hawaii 96817. The property is identified as Tax Map Key 1-7-006:012 and contains 0.6181 acres (26,925 square feet) of land. The property was within the Urban Renewal Plan for the Queen Emma Project, which restricted the use to commercial uses for thirty-five (35) years. The commercial use restriction expired in 1997. However, in 1992, in order to preserve the commercial property, the City utilized CDBG funds to acquire the property in fee for $6,750,000 under the slum and blight national objective.

The City is now proposing to demolish the existing vacant two-story commercial building to construct the Halewai'olu Senior Residences Project, a new 17-story building, which will include one hundred and fifty-five (155) units for seniors earning 80% and below the Area Median Income ("AMI"), and one (1) resident manager's unit. Eight (8) units will be designated for seniors earning 30% or below the AMI; one hundred thirty-one (131) units will be designated for seniors earning 60% or below the AMI; and the remaining sixteen (16) units will be available for seniors. earning 80% or below the AMI. All 100% of the units created will meet the CDBG national objective at 24 CFR 570.208(a)(3) Housing Activities**.** The redevelopment will serve to provide much needed affordable rental housing for seniors and optimize an underutilized parcel in the Primary Urban Core. Community benefits will include a community room for residents and neighbors."

2.2 PROJECT LOCATION

The Project is located at 1331-1347 River Street in proximity to Chinatown in Downtown, Honolulu (Downtown-Chinatown) on TMK: (1) 1-7-006:012. See **Figure 1: Project Location** and **Figure 2: Tax Map Key**. The Project Site is owned by the City. The property is located in the 2019 Qualified Census Tract (QCT)

51.00 with a poverty rate of 22.5%. The Project Site is bounded by River Street to the northwest, Borthwick Mortuary to the south and east, and the Lum Sai Ho Tong temple to the southwest. The Project Site is currently accessed by two driveways along River Street. The Project Site is located within the Downtown TOD Plan area.

It is adjacent to (but not within) the Honolulu Chinatown Special District (SD) and Punchbowl SD, as it is located outside of the district boundaries as shown in Revised Ordinances of Honolulu (ROH), Chapter 21, *Land Use Ordinance* (LUO). See **Figure 3 – City & County of Honolulu Special Districts**. The Project is also not within the National Chinatown Historic District.

2.3 EXISTING AND SURROUNDING USES

The Project Site consists of an existing 35-foot tall, two-story, commercial building, which was constructed in 1958, and an asphalt-paved parking lot. The commercial building was occupied by various small office, restaurant, and commercial establishments; however, the building is now vacant and has become dilapidated over time. An asphalt-paved parking lot is located at the rear of the property behind the building and the Project Site includes a minor amount of peripheral landscaping.

The Project is located within the Downtown TOD Plan Area, and promotes the principles of a walkable, dense, mixed-use neighborhood where residents are located in close proximity to everyday needs and community activities in the Downtown-Chinatown neighborhood. Although the Project is in proximity to three transit stations (Iwilei, Downtown, and Chinatown), it is nearest to the Chinatown station

Northwest of the Project Site is River Street and the sidewalks along River Street serve as a promenade along the Nu‘uanu Stream called Sun Yat Sen Mall, located approximately 54 feet northwest of the Project Site. Further northwest and across the Nu‘uanu Stream are the Waena Apartments. The Izumo Taishakyo Mission of Hawai‘i, a Shinto shrine, constructed in 1968, is located approximately 322 feet northwest of and also across the Nu‘uanu Stream from the Project Site. College Walk promenade is on the northwest side of Nu‘uanu Stream.

The Lum Sai Ho Tong temple, constructed in 1953, is located directly southwest and adjacent to the Project Site. Approximately 254 feet further southwest of the Project Site is the Chinatown Cultural Plaza, a popular commercial center used for seasonal community events. Alongside the Chinatown Cultural Plaza, a portion of River Street by the Nu‘uanu Stream becomes a pedestrian-only promenade popularly used for recreation by seniors in the Downtown-Chinatown area.

The Borthwick Mortuary and Chapel are located directly adjacent and to the southeast of the Project Site. A portion of its surface parking lot extends north and directly borders the northeast portion of the Project Site. The Kuan Yin temple and Foster Botanical Garden are located approximately 246 feet further northeast of the Project Site across Vineyard Boulevard.

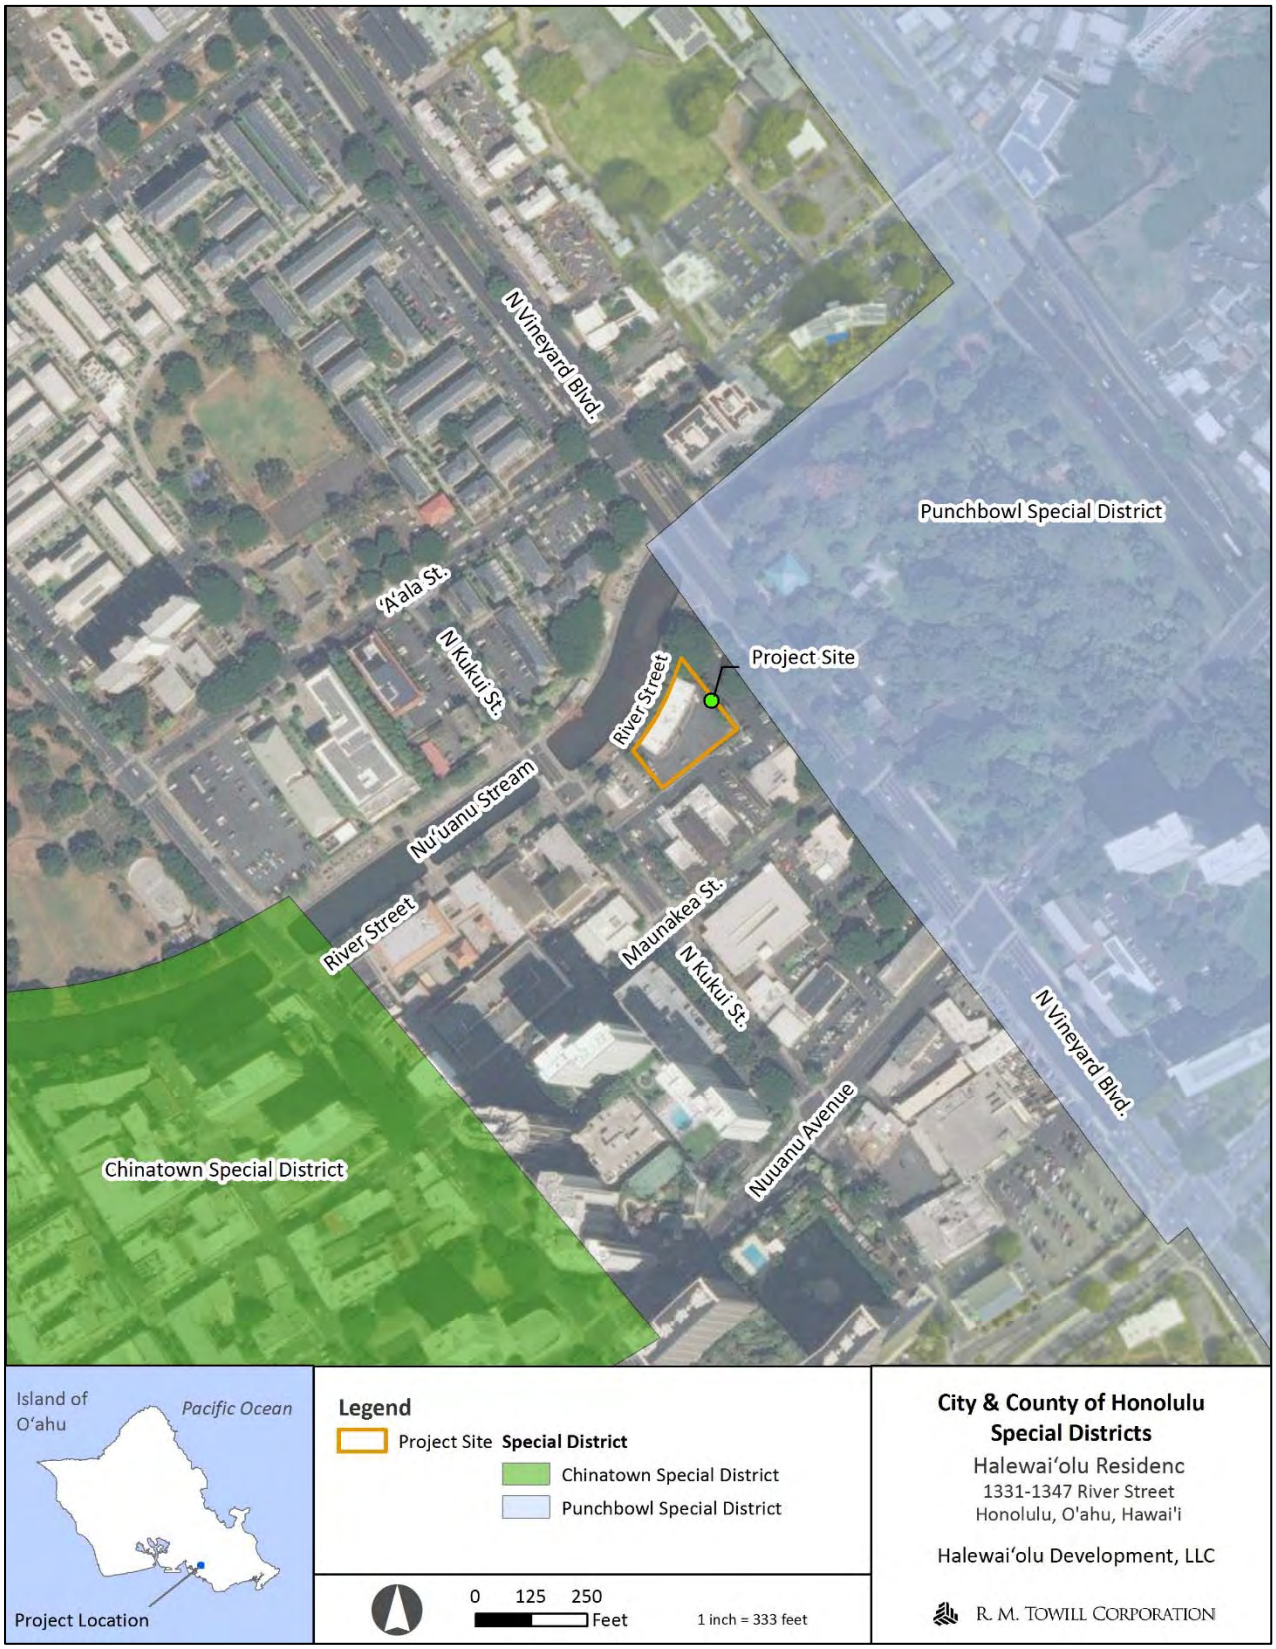

FIGURE 1 – PROJECT LOCATION

FIGURE 2 – TAX MAP KEY

FIGURE 3 – CITY & COUNTY OF HONOLULU SPECIAL DISTRICTS

2.4 DESCRIPTION OF THE PROPOSED PROJECT

The Project will include the demolition of the existing, vacant, commercial building and the surface parking lot on the Project Site and a new affordable housing facility for seniors aged 62 and over at 80% or below of AMI will be constructed. Units will remain affordable for a term of 65 years, with an option to extend to 75 years. The new facility will have 17 levels and be approximately 174 feet in height. The building will include 156 units (including one manager's unit), with one- and two-bedroom units. Five slightly different one-bedroom unit configurations will be offered and will range from about 456 to 478 square feet in floor area. Two types of two-bedroom units about 805 square feet will also be available. The proposed housing mix is presented in **Table 1**. See the preliminary floor plans on Sheets A-111 through A114 in **Appendix A, Drawings.**

The ground level will include a multi-purpose room, warming kitchen, restrooms, storage rooms, utility rooms, computer room, social services activity rooms, social services office, property management offices, mail and package boxes, and elevator lobby on the ground level. A courtyard, retail space, and parking access, along with bicycle parking, a trash compactor room and loading area are also on the ground level. The courtyard will have a large sliding gate to welcome visitors and residents during the day. At night, the sliding gate and courtyard fence will be locked to secure the premises. Stakeholders emphasized the need for a secure building in this area of Downtown-Chinatown. The courtyard tree and landscaping along the west property line will provide visual screening of the building façade and stormwater biofiltration. See Sheet A-111 – Floor Plan Level 1 in **Appendix A**.

The second floor includes vehicle and bicycle parking, storage, and utility rooms. The third level will be comprised of vehicle and bicycle parking, along with an emergency generator. Providing habitable space as a liner for the parking garage on the second, third and fourth levels would raise the cost of the Project and was not provided. The fourth level includes a covered recreation deck, dog area, laundry room, restroom, and maintenance and storage rooms. Residential units are on levels five through seventeen. Each residential level will include 12 units. All units will be Americans with Disabilities Act (ADA) compliant or adaptable to allow conversion to accessible units, and all public spaces and clearances will be ADA compliant. Level 18 is the roof where some mechanical equipment will be located. See **Appendix A.**

The proposed gross area of each floor is provided in **Table 2**: **Proposed Floor Area** below. The proposed floor area ratio (FAR) of the building is 5.9. In the interest of keeping seniors safe, there will be controlled access into the building, as well as a resident manager on-site. There will also be a social services coordinator.

Table 2: Proposed Floor Area

Level	Area
1: Ground Level	16,844 square feet
2: Lobby , Utility, and Stairs (Parking not counted)	1,864 square feet
3: Lobby, Utility, and Stairs (Parking not counted)	2,449 square feet
4: Recreation and Amenities	9,584 square feet
5 – 17: Residential (each floor)	9,785 square feet (each floor)
Total Floor Area:	157,946 square feet

2.5 PURPOSE AND NEED OF PROJECT

Affordable Senior Rental Units

The primary purpose of the Project is to provide much-needed affordable rental housing for seniors aged 62 and over. In July 2018, the State Department of Business, Economic, Development and Tourism (DBEDT), and Office of Planning (OP), published an *Affordable Rental Housing Report and Ten-Year Plan* (Ten-Year Plan), in accordance with Act 127 signed by Governor David Y. Ige on June 29, 2016, which established a goal of developing 22,500 affordable rental units statewide by December 31, 2026. The DBEDT-OP Ten-Year Plan further specified the housing production goals for each HUD income group. The goal stipulated that Honolulu is to develop 9,002 new affordable rental units, with 2,209 of those units targeted for households earning more than 50% but less than 60% of the AMI and 3,289 units targeted for those earning more than 60% but less than 80% of the AMI.

The following tables (**Tables 3** through **6)** show strong potential demand for one- and two-bedroom rental units, island-wide and within a 6-mile radius, amongst the senior demographic (age 62 years old and above) (Cassiday, 2019). The full Market Study that includes these tables is provided in **Appendix B, Halewai'olu Senior Residences 2019 Market Study (Ricky Cassiday, 2019)**.

Table 3: One Bedroom Share of Total Potential Market by AMI

ONE BEDROOM SHARE OF TOTAL POTENTIAL MARKET, BY AMI

Target AMI	Unit Supply	Potential Demand	Capture Rate 50%

60%	1,657
80%	2,298

Source: Cassiday, 2019

The Project will provide 1 resident manager's unit and 155 senior affordable rental units, with 8 units for seniors at 30% AMI, 131 units at 60% AMI, and the remaining 16 units at 80% AMI. The Project will utilize LIHTC, Hula Mae Multi-Family tax-exempt bonds (HMMF), and Rental Housing Revolving Fund (RHRF) funding, which is administered by HHFDC. The City's 2019 income limits for a one-person household is as follows:

- 30% of AMI: $25,320
- 60% of AMI: $50,640
- 80% of AMI: $67,520

See **Table 7: Honolulu County Income Schedule by Family Size (2019)** for the full income schedule published by HHFDC based on HUD income limits and U.S. Census Bureau data. The rental housing units to be developed as part of the proposed Project include one- and two-bedroom units. A mix of residential units is proposed in order to preserve the socioeconomic diversity of the people within the Downtown-Chinatown community. HSD has designated 90% of the units (139 units) as affordable for residents earning 60% or below of AMI and the remaining 16 units as affordable for residents earning 80% or below of AMI. See **Table 8: Proposed Rental Rates (2019)** for proposed rental rates and **Table 9: Proposed Utility Allowances** for an estimate of monthly utility allowances based on HUD and City standards. The resident rental rate is net of the utility allowance.

Table 7: Honolulu County Income Schedule by Family Size (2019)

HHFDC

HONOLULU COUNTY INCOME SCHEDULE BY FAMILY SIZE 2019

THE FOLLOWING TABLE PRESENTS INCOME LIMITS BY FAMILY SIZE AND BY PERCENTAGES OF THE VERY LOW INCOME LEVELS ESTABLISHED BY HUD. THESE INCOME LIMITS SERVE AS GUIDELINES TO ESTABLISH SALES/RENTAL PREFERENCES.

		LIMITS BY FAMILY SIZE							
MEDIAN $99,000		1 PERSON	2 PERSON	3 PERSON	4 PERSON	5 PERSON	6 PERSON	7 PERSON	8 PERSON
Adjustments for family size		0.7000	0.8000	0.9000	1.0000	1.0800	1.1600	1.2400	1.3200
% of Income	10%	$8,440	$9,640	$10,850	$12,050	$13,020	$13,980	$14,950	$15,910
	20%	$16,880	$19,280	$21,700	$24,100	$26,040	$27,960	$29,900	$31,820
	30%	$25,320	$28,920	$32,550	$36,150	$39,060	$41,940	$44,850	$47,730
	40%	$33,760	$38,560	$43,400	$48,200	$52,080	$55,920	$59,800	$63,640
	50%	$42,200	$48,200	$54,250	$60,250	$65,100	$69,900	$74,750	$79,550
	60%	$50,640	$57,840	$65,100	$72,300	$78,120	$83,880	$89,700	$95,460
	70%	$59,080	$67,480	$75,950	$84,350	$91,140	$97,860	$104,650	$111,370
	80%	$67,520	$77,120	$86,800	$96,400	$104,160	$111,840	$119,600	$127,280
	90%	$75,960	$86,760	$97,650	$108,450	$117,180	$125,820	$134,550	$143,190
	100%	$84,400	$96,400	$108,500	$120,500	$130,200	$139,800	$149,500	$159,100
	110%	$92,840	$106,040	$119,350	$132,550	$143,220	$153,780	$164,450	$175,010
	120%	$101,280	$115,680	$130,200	$144,600	$156,240	$167,760	$179,400	$190,920
	130%	$109,720	$125,320	$141,050	$156,650	$169,260	$181,740	$194,350	$206,830
	140%	$118,160	$134,960	$151,900	$168,700	$182,280	$195,720	$209,300	$222,740

The U.S. Department of Housing and Urban Development (HUD) sets income limits that determine the eligibility of applicants for its assisted housing programs. HUD typically uses the Very Low-Income Limit (VLIL) as the basis for deriving other income limits. The VLIL is calculated by taking the 4-person income limit equal to 50% of the estimated median family income (based on the U.S. Census Bureau's ACS median family income estimates) and making adjustments if this income is outside formula constraints. For example, the VLIL is increased for areas where rental housing costs are unusually high in relation to the median income or if it is less that the relevant State non-metropolitan median family income level. See "FY2019 Briefing Materials" at https://www.huduser.gov/portal/datasets/il/il19/IncomeLimitsMethodology-FY19.pdf

HHFDC uses the HUD income limits for households at the 50% and 60% income levels as calculated for the Multifamily Tax Subsidy Project (MTSP) charts. For HHFDC programs, the 80% income level is calculated as the Multifamily Tax Subsidy Project (MTSP) VLIL (for FY 2019, it is also the HUD Section 8 VLIL) multiplied by 1.6 (or 80/50). The limits for households at other income levels are calculated in the same way. For further information see "Multifamily Tax Subsidy Income Limits" at https://www.huduser.gov/portal/datasets/mtsp.html

NOTE: This chart is provided as a guide only. You are responsible to ensure the accuracy of the numbers.

Table 8: Proposed Rental Rates (2019)

HHFDC **AFFORDABLE RENT GUIDELINES*** **2019**

Affordable rents are based on 30% of income (including utilities)**

Area	$99,000	Studio	1 Bedroom	2 Bedroom	3 Bedroom	4 Bedroom
HONOLULU COUNTY						
30% of Median		$633	$678	$813	$940	$1,048
50% of Median		$1,055	$1,130	$1,356	$1,566	$1,747
60% of Median		$1,266	$1,356	$1,628	$1,880	$2,097
80% of Median		$1,688	$1,808	$2,170	$2,507	$2,796
100% of Median		$2,110	$2,260	$2,712	$3,133	$3,495
120% of Median		$2,532	$2,712	$3,255	$3,760	$4,194
140% of Median		$2,954	$3,164	$3,797	$4,387	$4,893

*Please note that area market rents may be lower than these rent guidelines.

**Monthly rent levels would include the cost of the following utilities: water, sanitary sewage services, electricity and gas (where applicable). Please refer to the Utility Allowance Schedule for each island.

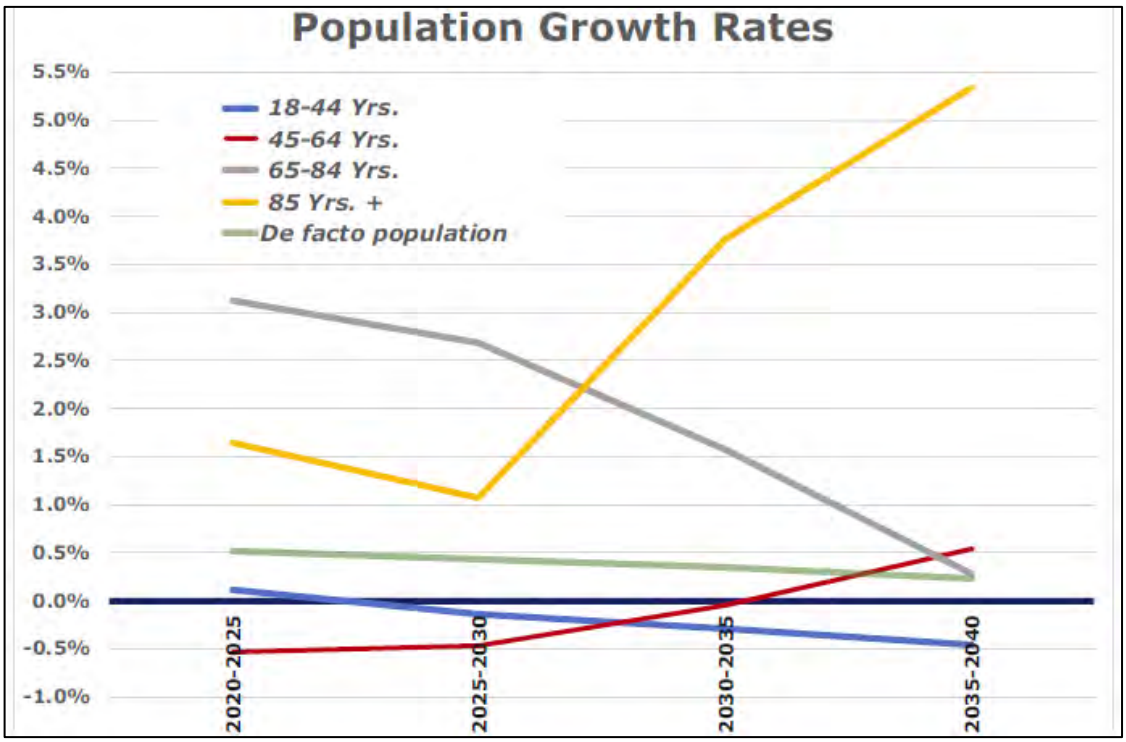

Table 9: Proposed Utility Allowances

Utility or Service	**Monthly Dollar Allowances**	
Utility	1 Bedroom	2 Bedrooms
Cooking –Electric	$15	$21
Other Electric	$60	$84
Total	$75	$105

Note: Utility allowances are based on HUD's "Allowances for Tenant-Furnished Utilities and Other Services" for the City, released January 1, 2019.

Current demographic trends for the City show that the general population as a whole, is aging as seen in **Figure 4: Population Growth Rate** below (Cassiday, 2019). See **Appendix B, Market Study** and **Section 5.1** for further discussion on demographics in the neighborhood and the market demand for affordable housing for the proposed Project.

Figure 4: Population Growth Rates

Source: Cassiday, 2019

Transit-Oriented Development and Multi-Modal Design

In addition to providing much-needed affordable housing for seniors, the Project is located near employment, shopping, and public services/amenities and is intended to meet the needs of seniors who prefer not to own and operate a vehicle to access necessary services while aging in place. The Project is located within the Downtown TOD Plan area that promotes the principles of a walkable, dense, mixed-use neighborhood where residents are located in close proximity to everyday needs and community activities in Downtown-Chinatown. The Project Site is located approximately 0.4 miles northeast of the proposed Chinatown Rail Station, at the intersection of Nimitz Highway and Kekaulike Street, which will have connections to the City bus system and Handi-Van pick-up and drop-off. Due to its proximity to existing public transportation, the future rail system and its central location, the Project offers residents an opportunity to reduce their transportation costs. The Project will also optimize an underutilized parcel in the Primary Urban Core. Community benefits will include a multi-purpose room and activity rooms available to residents and neighbors, street trees to improve the urban streetscape, and a transparent façade to help activate River Street.

During community and stakeholder outreach in preparation of the Downtown TOD Plan, adopted in September 2017, the City, DPP found that "additional housing options are needed for a range of income levels, including . . . senior low-income housing," as discussed further in **Section 7.3.4**. The Downtown TOD Plan acknowledges the high population of seniors and prioritizes housing, in addition to services and pedestrian amenities, as essential to ensuring a high quality of life for residents. The proposed Project would be a direct fulfillment of the needs expressed by the Downtown TOD Plan by providing senior affordable rental housing and improving non-automobile travel for seniors that may not drive or own cars.

Overall, the Project will contribute to a lively social environment by enhancing the pedestrian experience and reducing vehicular traffic.

Mobility trends are changing, and on-site parking will be sized to reflect the downscaled use of vehicles by residents in an urban setting. The convenient location of the Project places seniors near necessary services and will encourage residents to walk or utilize public transit. Reductions to parking requirements for elderly units and the Project's location in the proposed Downtown Neighborhood TOD Special District (SD) ("Downtown TOD SD") will result in approximately 51 off-street parking stalls that will include stalls to meet ADA requirements (the Development Agreement which projected 75 parking stalls and 10 ADA stalls for the Project will need to be modified, after the parameters of the 201H Approval by City Council, which may involve other changes to the Project described in the Development Agreement). One off-street loading area will be provided. DPP has recommended 25 parking stalls, since the Project Site is in walking distance to the future transit station and bus stops. The proposed 51 parking stalls represents a middle ground between the Development Agreement and DPP's recommendation. As necessary, the number of accessible parking stalls provided will be based on the requirements of the HDOH, DCAB Interpretive Opinion 2014-05.

2.6 ALTERNATIVES CONSIDERED

Based on an email from Mr. G. Morgan Griffin, Regional Environmental Officer for the U.S. Department of Housing and Urban Development, Region–IX - Office of Environment and Energy, "Only the preferred alternative must be evaluated for each law/authority and EA factor." As such, the impact and mitigation in future sections will be reviewed just for the preferred alternative.

2.6.1 No Action Alternative

Under the "No Action" Alternative, the 155 affordable housing units for seniors and one resident manager's unit would not be constructed. Additionally, community amenities would not be developed and no enhancement to the streetscape would occur. Under this alternative, environmental effects resulting from development activities would be averted and project costs would be spared. However, the No Action Alternative would render the property underutilized with a dilapidated, deteriorating building. The property would continue to remain inconsistent with the PUC DP and Downtown TOD Plan, which recommends development within the PUC and compact, affordable housing within walkable neighborhoods near future transit stations. The No Action Alternative would not meet the neighborhood needs and would not meet the goals and objectives of City plans. Therefore, this alternative was eliminated from further consideration.

2.6.2 Housing First Alternative

In 2010, the City considered developing the property as a "Housing First" project. Housing First is a national practice aimed to assist people experiencing chronic homelessness through the provision of permanent supportive housing and access to service providers who offer mental illness and substance abuse counseling, job training and placement, and other life skills. The City's initial proposal included the development of 100 residential units and counseling services. This "Housing First" Alternative was projected to cost $10.6 million (in 2010 dollars). However, due to overwhelming Downtown-Chinatown community opposition to the proposal, the City did not move forward with this alternative. Therefore, this alternative was eliminated from further consideration.

2.6.3 Preferred Alternative – Halewai'olu Senior Residence Project

The Downtown-Chinatown community is in support of the development of senior housing at the Project Site, in-lieu of the Housing First Alternative that was initially proposed by the City. Therefore, the Preferred Alternative involves the development of a new affordable housing residential rental facility for seniors aged 62 and over. The Preferred Alternative would result in an advantageous utilization of the property and would address the City's goals and objectives for the Downtown TOD Plan, to increase affordable rentals for seniors. Considering the well-documented need for senior affordable housing on O'ahu; the development potential of the property; and the location of the property within the urban core of Honolulu and near mass transit; the Applicant is seeking to undertake the proposed development as the Preferred Alternative. The Preferred Alternative is put forth as the proposed Project and is further described in **Section 2.4 and is further evaluated in this EA**.

2.7 OWNERSHIP, FINANCING, ESTIMATED COSTS, AND DEVELOPMENT SCHEDULE

In 1992, the City purchased the property on River Street with funds from the HUD CDBG program, supplemented with a City contribution to the total purchase price $6,751,700.00. While Project funding does not include HUD funds, the use of the federal HUD CDBG funding for the initial land purchase subjects the Project to HUD CDBG environmental review regulations as stipulated in 24 CFR Part 58, "Environmental Review Procedures For Entities Assuming HUD Environmental Responsibilities" and compliance with 40 CFR Parts 1500-1508, "Regulations for Implementing the Procedural Provisions of National Environmental Policy Act" and its federal cross-cutter regulations.

The Project is expected to cost approximately $85.6 million, subject to review of the final construction budget. Project construction will be funded with private equity through the LIHTC program, which was awarded by HHFDC to the developer in 2019. Other funding sources include the use of HMMF tax-exempt bonds, RHRF loan, and developer equity. HSD expects construction to begin in 2020.

2.8 PURPOSE OF THE ENVIRONMENTAL ASSESSMENT

This NEPA Environmental Assessment (EA) discloses the environmental and cultural impacts that may result from the project's implementation and commits to specific mitigation measures. This EA has been prepared to satisfy the requirements of NEPA as set forth in 40 CFR Parts 1500-1508, HUD environmental review compliance pursuant to 24 CFR 58, and, other environmental compliance requirements and implementing regulations. HSD will use this document to evaluate the possible environmental effects of the proposed action. This EA evaluates alternatives to the proposed Project and describes measures proposed to minimize potential impacts. The potential for direct, indirect, and cumulative impacts of the proposed action are also described.

Although not a requirement of NEPA as set forth in 40 CFR Parts 1500-1508, HUD environmental review compliance pursuant to 24 CFR 58, and, other environmental compliance requirements and implementing regulations, the Applicant will extend the NEPA EA process to include a public and agency 30-day review period.

The Applicant will request that the OEQC (Office of Environmental Quality Control) publish in their Environmental Notice the availability of the NEPA EA for review and comment and the deadline for comments. We will have a 30-day comment period.

After receipt of comments, relevant comments will be addressed in the NEPA EA prior to finalizing.

If the Department of Land Management determines that the Project will not have a significant environmental impact, it will issue a FONSI that will allow the Project to proceed. The public will have 15 calendar days after publication of the FONSI in a local newspaper to comment.

2.9 REQUIRED PERMITS AND APPROVALS

A list of permits and approvals that may be required is provided in **Table 10**: **Required Permits and Approvals** below:

Table 10: Required Permits and Approvals

Permit / Approval	Responsible Agency / Organization
Section 106, NHPA Consultation	State Historic Preservation Division (SHPD)
HRS, Chapter 201H, Affordable Housing Exemptions	City, DPP and City Council
201H Development Agreement	DPP and City Council
Development Agreement	City Council
Community Noise Permit Noise Variance Permit	State, HDOH
Park Dedication Requirement (ROH, 1990, Chapter 22, Article 7, Parks and Playgrounds)	City, DPP
Permits for Construction, including Building, Electrical, Plumbing; Grading/ Trenching Permits; Clearing and Grubbing Permit; Stockpiling Permit; Sidewalk/Driveway Permit; Demolition Permit, Street Usage Permit	City, DPP
Sewer Connection Permit	City, DPP
Water Connection	City, BWS
Plan Review	City, HFD
Certificate of Occupancy	City, DPP
HRS, §103-50 Accessibility Compliance	State, HDOH, DCAB
Street Usage Permit	City, DTS
Dumb Lift Permit Man Hoist Permit	State, DLIR
Fuel Tank Permit	City, HFD

Erosion and Sediment Control Plan Clean Water Pollution Plan Post-Construction Best Management Plan	City, DFM
Street Tree Permit	City, DPR

2.10 REGULATORY COMPLIANCE AND COMMUNITY CONSULTATIONS

The Project has been reviewed with appropriate government agencies to solicit input and provide a meaningful discussion about potential impacts and mitigations for the Project. Further, the Project will comply with City, State and Federal permits and approvals, which are discussed in **Section 6.1**.

HSD began conducting community outreach in August 2014 with various Downtown-Chinatown community stakeholders. Community input was also included in developing the Community Provisions section of the Development Agreement between HSD and the City, and in development of the Project design. Between August 2014 and May 2019, HSD has conducted 20 total community meetings and revised the Project to reflect feedback received at each meeting, as much as feasible. Feedback regarding massing, height, adjacency, unit sustainability, color and cultural references, green space, and Feng Shui were all taken into consideration for the Project design. Further discussion on public outreach, including a list of all meetings, is provided in **Section 7.7**.

Meetings related to the NEPA process have been conducted, as per **Section 2.8**.

Although not a requirement of NEPA as set forth in 40 CFR Parts 1500-1508, HUD environmental review compliance pursuant to 24 CFR 58, and, other environmental compliance requirements and implementing regulations, the Applicant will extend the NEPA EA process to include a public and agency 30-day review period.

The Applicant will request that the OEQC publish in their Environmental Notice the availability of the NEPA EA for review and comment and the deadline for comments. We will have a 30-day comment period.

After receipt of comments, relevant comments will be addressed in the NEPA EA prior to finalizing.

If the Department of Land Management determines that the Project will not have a significant environmental impact, it will issue a FONSI that will allow the Project to proceed.

The filing and publication of a notice of the FONSI with the Star Advertiser and OEQC will be followed by a 15-day public comment period. See **Section 7.0** for a complete list of agencies, organizations, and individuals consulted during the EA process. See also **Sections 5.2 and 5.3** for further discussion of the communication consultation for the preparation of the Draft Archaeological Inventory Survey (AIS) and Draft Cultural Impact Assessment (CIA) and **Section 6.1.12** for further discussion of NHPA Section 106 consultation to-date.

Once the Project is constructed, the proposed multi-purpose and activity rooms will be available for use by residents and the neighborhood community. In an effort to continue communication and include the surrounding community, an Advisory Committee will be established by HSD, property management its social services coordinator that may include committee members from the Downtown-Chinatown Neighborhood Board (NB) No. 13, United Chinese Society, Chinese Chamber of Commerce, and Chinatown Community Center Association, along with a cross section of other neighborhood organizations.

3.0 ENVIRONMENTAL SETTING

3.1 CLIMATE AND CLIMATE CHANGE

3.1.1 Existing Environment

The climate of the Honolulu District is typically warm and dry. Prevailing trade winds arrive from the northeast. According to the National Weather Service Honolulu Office, over a period of 30 years, normal monthly high temperatures range from 80 degrees in January to a high of 89 degrees in August for an annual average of 84 degrees. Normal month low temperatures range from a low of 65 degrees in February to 74 degrees in August for a monthly average of 70 degrees. Precipitation typically ranges from 0.44 inches in August to a high of 3.8 inches in December. The annual average rainfall in Honolulu is 17.05 inches per year.

Climate change is considered a threat to all coastal areas. Planning for climate change and sea level rise (SLR) is challenging as there are multiple variables and changing and unknown factors. Research indicates that greenhouse gas (GHG) emissions, including carbon dioxide, methane, nitrous oxide, and fluorinated gases, are a key contributor to the unprecedented increases in global atmospheric warming over the past century (USEPA, 2011 and IPRC, 2013). University of Hawai‘i (UH) researchers have documented the effects of climate change in Hawai‘i, as air temperatures have risen; rain intensity has increased while total rainfall has decreased; stream flows have decreased; sea surface temperatures and sea levels have increased; and the ocean is becoming more acidic (IPRC, 2013, var. and SB No. 2745, 2012). These trends are projected to continue to increase in the future, which poses unique and considerable challenges to Hawai‘i. It is estimated that sea level has risen in Hawai‘i by approximately 0.6 inches per decade (1.5 millimeter per year) over the past century (SOEST, 2012). The estimates point to a potential aggregate SLR of 1.3 feet (40 centimeter) by the year 2060 and a rise of 3.3 feet (100 centimeter) by 2110 (SOEST, 2012).

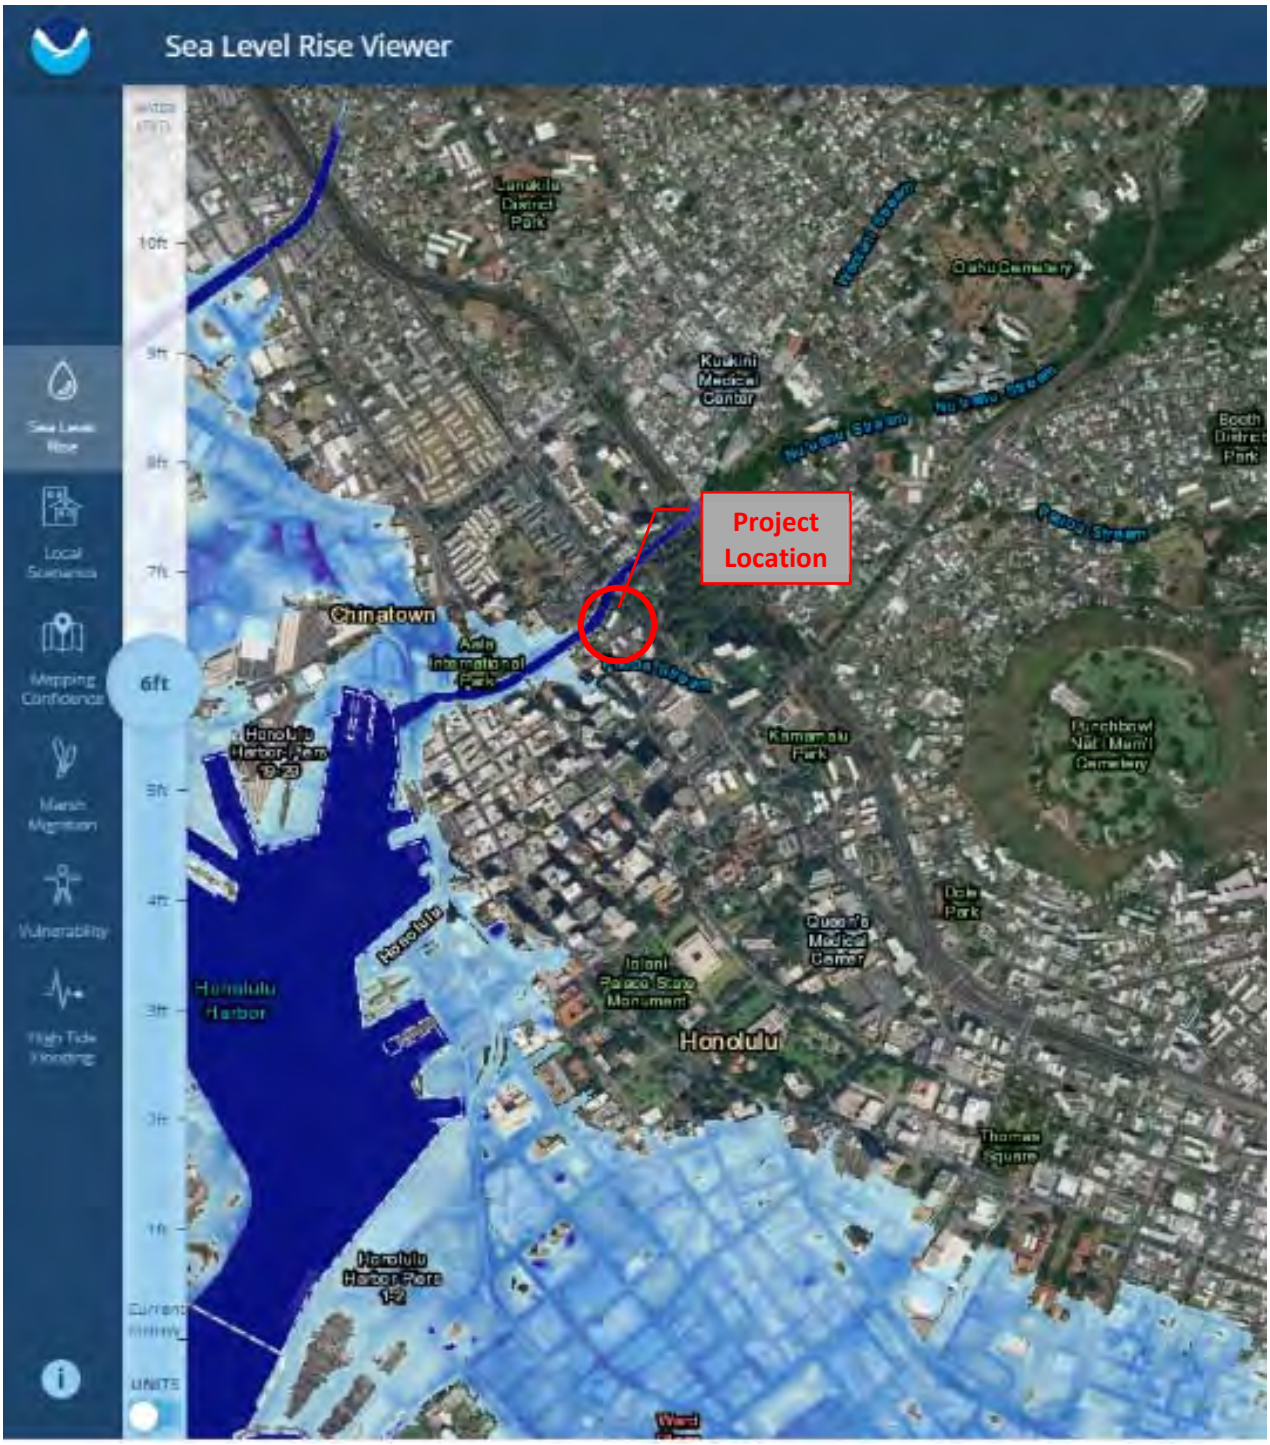
The Hawai‘i State Legislature passed a law (SB 2745) in 2012 that amended the State Planning Act to include climate change as one of the State’s priority guidelines. In 2014, the Hawai‘i State legislature passed the *Hawai‘i Climate Adaptation Initiative Act* (Act 83, 2014), codified as HRS, Chapter 225P, which established an Interagency Climate Adaptation Committee (ICAC). The purpose of Act 83 is to address the effects of climate change by implementing a climate adaption plan. On June 6, 2017, Governor David Ige signed Act 32, Session Laws of Hawai‘i, which amended HRS, Chapter 225P by renaming the ICAC to the Hawai‘i Climate Change Mitigation and Adaptation Commission (“Commission”). The Commission published the *Hawai‘i Sea Level Rise Vulnerability and Adaptation Report* (“SLR Report”) in December 2017, which included recommendations on how to reduce exposure and increase adaptability to the impacts of SLR. Research within the SLR Report notes that the intensity and frequency of natural disasters have increased and will continue to do so, and further provides technical projections of areas along the coast that are vulnerable to SLR based on the latest available science. The SLR Report includes recommendations to address risks associated with climate change. The SLR Report found that a SLR of 3.2 feet and the associated erosion, flooding, and waves inundation, will have significant impacts to O‘ahu’s building and land values, residents and infrastructure. Portions of O‘ahu that are vulnerable to the SLR are illustrated on the Hawai‘i Sea Level Rise Viewer (“Viewer”), an online interactive map created in conjunction with the SLR Report. Specifically, the Viewer defines an area called the SLR exposure area (SLR-XA), which is the projected extent of chronic flooding due to SLR (PacIOOS, 2018). The Project Site is not located in a coastal area (located 0.4 miles from the shoreline), nor is it located within the 3.2 feet SLR-XA.

Based on Guidance from the Honolulu Climate Change Commission, the City and County of Honolulu has found that a planning benchmark of six feet of sea level rise (SLR) is appropriate for projects with a life span

beyond mid- century, and for critical infrastructure. High tide flooding and nuisance flooding may be present and precede global mean SLR by decades. The National Oceanic and Atmospheric Administrators (NOAA) have come up with a viewer to view impacted areas at different levels of sea level rise. At six feet, the Project Site will not be affected by sea level rise. See **Figure 5: Sea Level Rise Exposure Area.**

3.1.2 Potential Impacts

An Air Quality Impact Assessment (AQIA) was prepared by Trinity Consultants in November 2019 for the Project to assess its impact on climate and climate change. See Appendix C, Air Quality Impact Assessment. The adverse impacts of GHG emissions are inherently indirect and cumulative, in that the consequences of climate change are removed in time and space from the boundaries of the Project Site but are arguably foreseeable. According to the AQIA, the Project will result in the creation of short-term GHG emissions due to the use of fossil-fuel based construction equipment. Construction-related activities may include demolition, grading, excavation, concrete work, stockpiling, transport of building materials and spoils, and the construction of the residential facility (Trinity, 2019a). The AQIA estimates that the Project will result in approximately 1,338 metric tons of carbon dioxide equivalent (CO_2e)[3] during construction. However, these emissions are expected to be minimal, temporary and will cease once construction is completed (Trinity, 2019a).



Once construction is complete, the Project will result in the creation of GHG emissions due to transportation to and from the Project Site and the use of natural gas, electricity, wastewater, potable water use and solid waste disposal. The AQIA estimates that the Project will result in approximately 4 tons per day of CO_2e due to vehicle miles travelled or 0.04% of total countywide CO_2e from motor vehicles. Insignificant amounts of GHG emissions are anticipated to result from residents' use of natural gas, electricity, water, wastewater and solid waste disposal (Trinity, 2019a). The Project is not anticipated to have a significant long-term contribution to total GHG emissions or a cumulative adverse impact on the regional or global climate conditions.

3.1.3 Avoidance, Minimization, and/or Mitigation Measures

The Project will be designed to attempt to meet Leadership in Energy and Environmental Design (LEED) Silver standards. LEED-certified buildings are recognized as saving energy, water, and resources and generating less waste than buildings that are not designed and built to LEED standards, reducing the Project's potential environmental impact and enhancing its sustainability (Trinity, 2019a). Additionally, the Project will provide more vegetation than what currently exists, which will result in carbon sequestration and lower the carbon footprint of the Project. Further mitigation measures are not anticipated to be required.

[3] The effect each GHG has on climate change is measured as a combination of the quantity of its emissions and its global warming potential and is expressed in terms of how much warming would be caused by the same mass of CO_2. Thus, GHG emissions are typically expressed in terms of pounds or tons of CO_2e (Trinity, 2019a).

Figure 5: Sea Level Rise Exposure Area

3.2 AIR QUALITY

3.2.1 Existing Environment

The Federal Clean Air Act (CAA), as amended, is the primary federal law that governs air quality, while the Hawai'i Air Pollution Control Act is its companion state law. These laws and related regulations by the United States Environmental Protection Agency (EPA) and the HDOH, Clean Air Branch, set the standards for the concentration of pollutants in the air. At the federal level, these standards are called National Ambient Air Quality Standards (NAAQS). NAAQS and State ambient air quality standards have been established for six transportation-related criteria pollutants that have been linked to potential health concerns: carbon monoxide (CO), nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM), which is broken down for regulatory purposes into particles of 10 micrometers or smaller (PM) and particles of 2.5 micrometers and smaller ($PM_{2.5}$), and sulfur dioxide (SO_2). The NAAQS and State air quality standards are set at levels that protect public health with a margin of safety and are subject to periodic review and revision.

O'ahu is in attainment of both NAAQS and State air quality standards. Readings at the Honolulu monitoring station operated by the HDOH, located approximately 6.5 miles southeast of the Project area, show that criteria pollutants were below the NAAQS and State air quality standards, as shown in **Table 11: Air Quality in the Project Area: 2015 – 2017**.

Table 11: Air Quality in the Project Area: 2015 – 2017

Parameter	Statistic	2015	2016	2017	Strictest Standard
24-hour PM_{10}	Maximum	36	29	31	150 µg/m3
Annual PM_{10}	Annual average	11.5	13.8		50 µg/m3
24-hour $PM_{2.5}$	3-yr avg 98th percentile	10.4	10	10	35 µg/m3
Annual $PM_{2.5}$	3-yr avg Annual average	3.7	3.4	3	12.0 µg/m3
8-Hour O_3	4th highest daily value	0.051	0.048	0.046	0.070 ppm
1-Hour NO_2	3-yr avg 98th percentile	23	29	33	100 ppb
Annual NO_2	Annual average	0.004	0.004	0.004	0.053 ppmc
1-Hour CO	2nd high	1.4	1.5	1.4	9 ppm
8-Hour CO	2nd high	1.0	1.1	0.9	4.4 ppm
1-Hour SO_2	3-year avg 99th percentile	8	7	4	75 ppb
3-Hour SO_2	2nd high	0.007	0.006	--	0.5 ppm
24-Hour SO_2	Maximum	0.003	0.002	0.002	0.140 ppm
Annual SO_2	Annual average	0.000	0.000	0.0044	0.03 ppm
3-month lead	Maximum	0.002	0.002	0.04	0.15 µg/m3
1-Hour hydrogen sulfide	2nd high	0.003	0.002	--	0.025 ppm

Source: Trinity Consultants, 2019

3.2.2 Potential Impacts

The Project will result in the generation of dust and exhaust from construction-related activities, including demolition, grading, excavation, concrete work, stockpiling, transport of building materials and spoils, and the construction of the residential facility. However, these dust and exhaust emissions will be temporary and are not anticipated to have a significant long-term impact on air quality (Trinity, 2019a).

Once the Project is constructed, the primary impact on air quality will result from motor vehicle trips to and from the proposed residential facility. The AQIA analyzed the Project's projected motor vehicle emissions, based off of an estimated 310 daily vehicle trips, as stated in the *Focused Mobility Analysis Report for the Proposed Halewai`olu Senior Residences* (MAR), prepared in August 2019 by Fehr and Peers. See **Appendix E**, **Focused Mobility Analysis Report**. The AQIA assumed an average, conservative length of 30 miles per trip, generated by the proposed Project. Utilizing the existing traffic levels indicated in the MAR and existing ambient air quality monitoring data from the HDOH's monitoring station, the AQIA determined that the Project is not anticipated to cause or contribute to violations of the NAAQS or State air quality standards or have a significant long-term or a cumulative adverse impact on the regional air quality (Trinity, 2019a).

South of the Project is the Borthwick Mortuary, which includes a crematorium with two incinerators. Pursuant to Hawai'i Administrative Rules (HAR), Chapter 11-60.1, Borthwick Mortuary has obtained and is in compliance with Noncovered Source Permit No. 0422-01-N. An *Odor and Other Impacts Assessment* (OONIA) was conducted by Trinity Consultants in November 2019 (Revised March 2020) to assess if construction of the Project would change the wind flow in the Project area, which might increase odors to certain neighbors in the surrounding community. See **Appendix D, Odor and Other Nuisance Impacts Assessment.** Six locations adjacent to the Project area and the Project Site were assessed for odor impacts – the Lum Sai Ho Tong, Mun Lun School, Chinese Cultural Plaza, Izumo Taishakyo Mission, Kuan Yin Temple and Foster Botanical Garden. The OONIA found that potential odors for properties adjacent to the Project Site were reduced at four locations and were unaffected at two locations. Future occupants of the Project site should not be adversely affected by the crematorium's operation, provided that the Borthwick facility continues to operate as permitted by the HDOH. The Project is expected to have an overall long-term net benefit to odor nuisance in the area (Trinity, 2019b).

3.2.3 Avoidance, Minimization, and/or Mitigation Measures

To minimize the potential adverse impact on air quality due to fugitive dust, the General Contractor will limit the amount of grubbing, grading, and vegetation removal, disturbing only the minimum area required, an estimated 0.6 acres. Additionally, construction work will be in conformance with air pollution control standards contained in the HAR, Title 11, Chapter 60.1, *Air Pollution Control*. Standard mitigation measures to contain fugitive dust and minimize engine exhaust may include the following:

- Maintain all construction equipment in accordance with manufacturer's specifications;
- Minimize the extent of disturbed area as much as possible;
- Use water trucks as needed to minimize the amount of airborne dust leaving the site;
- Cover or continuously wet dirt stockpile areas containing more than 100 cubic yards of material to minimize the formation of windblown dust;
- Install construction fencing to minimize the transmission of windblown dust onto roadways and adjacent properties;
- Implement permanent dust control measures identified in the Project plans as soon as possible following completion of any soil disturbing activities;

- Limit vehicle speed for all construction vehicles moving on any unpaved surface at the construction site; and
- Cover all trucks hauling dirt, sand, soil, or other loose materials (Trinity, 2019a).

Once construction is completed, the Project is not anticipated to have a significant, long-term adverse impact on air quality or odors in the surrounding community since the increase in motor vehicle traffic related to this Project versus the former commercial use will likely be negligible. Further mitigation measures are not anticipated to be required.

3.3 GEOLOGY, TOPOGRAPHY, AND SOILS

3.3.1 Existing Environment

The island of Oʻahu was formed by two major shield volcano formations, the older Waiʻanae Range to the northwest and the younger Koʻolau Range to the east. Both are remnants of shield volcanoes, but the term "range" indicates that they have lost most of their original shield outlines and are now long, narrow ridges shaped largely by erosion. Waianae Volcano is estimated to be middle to late Pliocene in age and forms the bulk of the western one-third of Oʻahu. The Koolau Volcano is estimated to be late Pliocene to early Pleistocene (Ice Age) in age and forms the majority of the eastern two-thirds of Oʻahu (Geolabs, 2017). The Waiʻanae and Koʻolau ranges were further transformed during the Pleistocene period through significant erosion cycles in which great amounts of material were removed by rainfall, stream and marine erosion.

The Project Site is located adjacent to River Street (northwest of the Project Site) and beyond that is the southwest bank of Nu'uanu Stream on the Honolulu Coastal Plain, a low-lying coastal plain along Oʻahu's southern coast. The Honolulu Coastal Plain is composed of interbedded marine, terrestrial, and volcanic deposits on the southwest side of the former Koʻolau Volcano (Geolabs, 2017).

A *Geotechnical Engineering Exploration* ("Geotechnical Report") was prepared by Geolabs, Inc. in 2019. See **Appendix F, Geotechnical Engineering Exploration**. The Geotechnical Report found that the base of the Project Site consists of basaltic lava flow from the Honolulu Volcanic Series, which was deeply scoured by stream erosion at a time when the sea level approximately 300 feet below its present elevation. As sea level rose due to the continental glaciers of the Ice Age melting, erosion of the basalt ceased, and subsequent extended periods of alluvium and ash deposition were transported from Nuʻuanu Valley upstream of the Project Site. Sandy beach deposits and coralline reef formation then covered the alluvium when the sea level rose above its present elevation. As sea level rose to its present level, the Nuʻuanu Stream channel was filled with fine-grained organic soils deposited in a lagoonal environment. Alluvial deposits continued to accumulate over the lagoonal sediments. In the past centuries, the area was filled for development (Geolabs, 2019).

The Project Site is approximately trapezoidal in shape and relatively flat, with existing ground elevations ranging from +8 to +10 feet above mean sea level (MSL) (Geolabs, 2017). See .

According to the U.S. Department of Agriculture (USDA), Soil Conservation Service's *Soil Survey of the Islands of Kauai, Oʻahu, Maui, Molokai, and Lanai, State of Hawaiʻi, 1972*, the Project Site is entirely comprised of 'Ewa silty clay loam (EmA), which occur on moderately shallow, 0 to 2% slopes. EmA soil is characterized by very slow runoff and an erosion hazard that is no more than slight. This soil was historically used for sugarcane, truck crops, and pasture.

Six subsurface borings were conducted, Boring Nos. 1 and 2 extended to approximate depths of 86 and 121.2 feet below the existing pavement surface, while Boring Nos. 101 through 104 extended to approximate depths of 79 to 152.5 feet below the existing pavement surface . Boring No. 1, 101 and 103 on the southern portion of the Project Site, encountered a thin layer of surface fills overlying a highly compressible layer of recent alluvium and lagoonal deposits extending to depths of about 25 to 38 feet below the existing pavement surface. Stiff to very stiff alluvial deposits interbedded with very dense cobbly boulders were the encountered and extended to the maximum depth explored of about 121.2 feet below the existing pavement. Boring Nos. 2, 102 and 104 were conducted on the northern portion of the Project Site, and encountered a highly compressible layer of recent alluvium and lagoonal deposits between depths of about 1 and 19 feet below the existing pavement surface. Below that, dense cinder sands and very stiff alluvial clays interbedded with basalt formation were encountered to a depth of about 98 feet below the ground surface. A hard to very hard basalt formation was encountered between depths of about 48 to 86 feet below the existing pavement surface (Geolabs, 2017). See Error! Reference source not found..

3.3.2 Potential Impacts

Due to the existing topography at the site, the Project will involve minimal site grading work. Areas within the grading limits will be cleared and grubbed thoroughly. Based on the subsurface conditions and structural load demands on the new high-rise building foundations, the Project will use a deep foundation system consisting of micropiles with a diameter of 7.625 inches (same as the grout bulb size), and the permanent casing should extend 3 feet into the alluvial clay deposits. These micropiles will extend about 75 to 120 feet below the bottom of the foundation cap elevations. A micropile consists of a small diameter (usually less than 12 inches) drilled and grouted pile with a center reinforcing steel bar. The micropile foundation typically is constructed by drilling a borehole, placing reinforcing steel in the hole, and grouting the borehole. In order to eliminate the chance of differential movement between two structures supported on different foundation systems, micropiles will be used on the minor structures as well. Micropiles are desirable because they can be installed readily in access restrictive environments and in numerous soil types and ground conditions. In addition, installation of the micropiles generally causes minimal disturbance to adjacent structures, the adjacent soils, and the environment. (Geolabs, 2019).

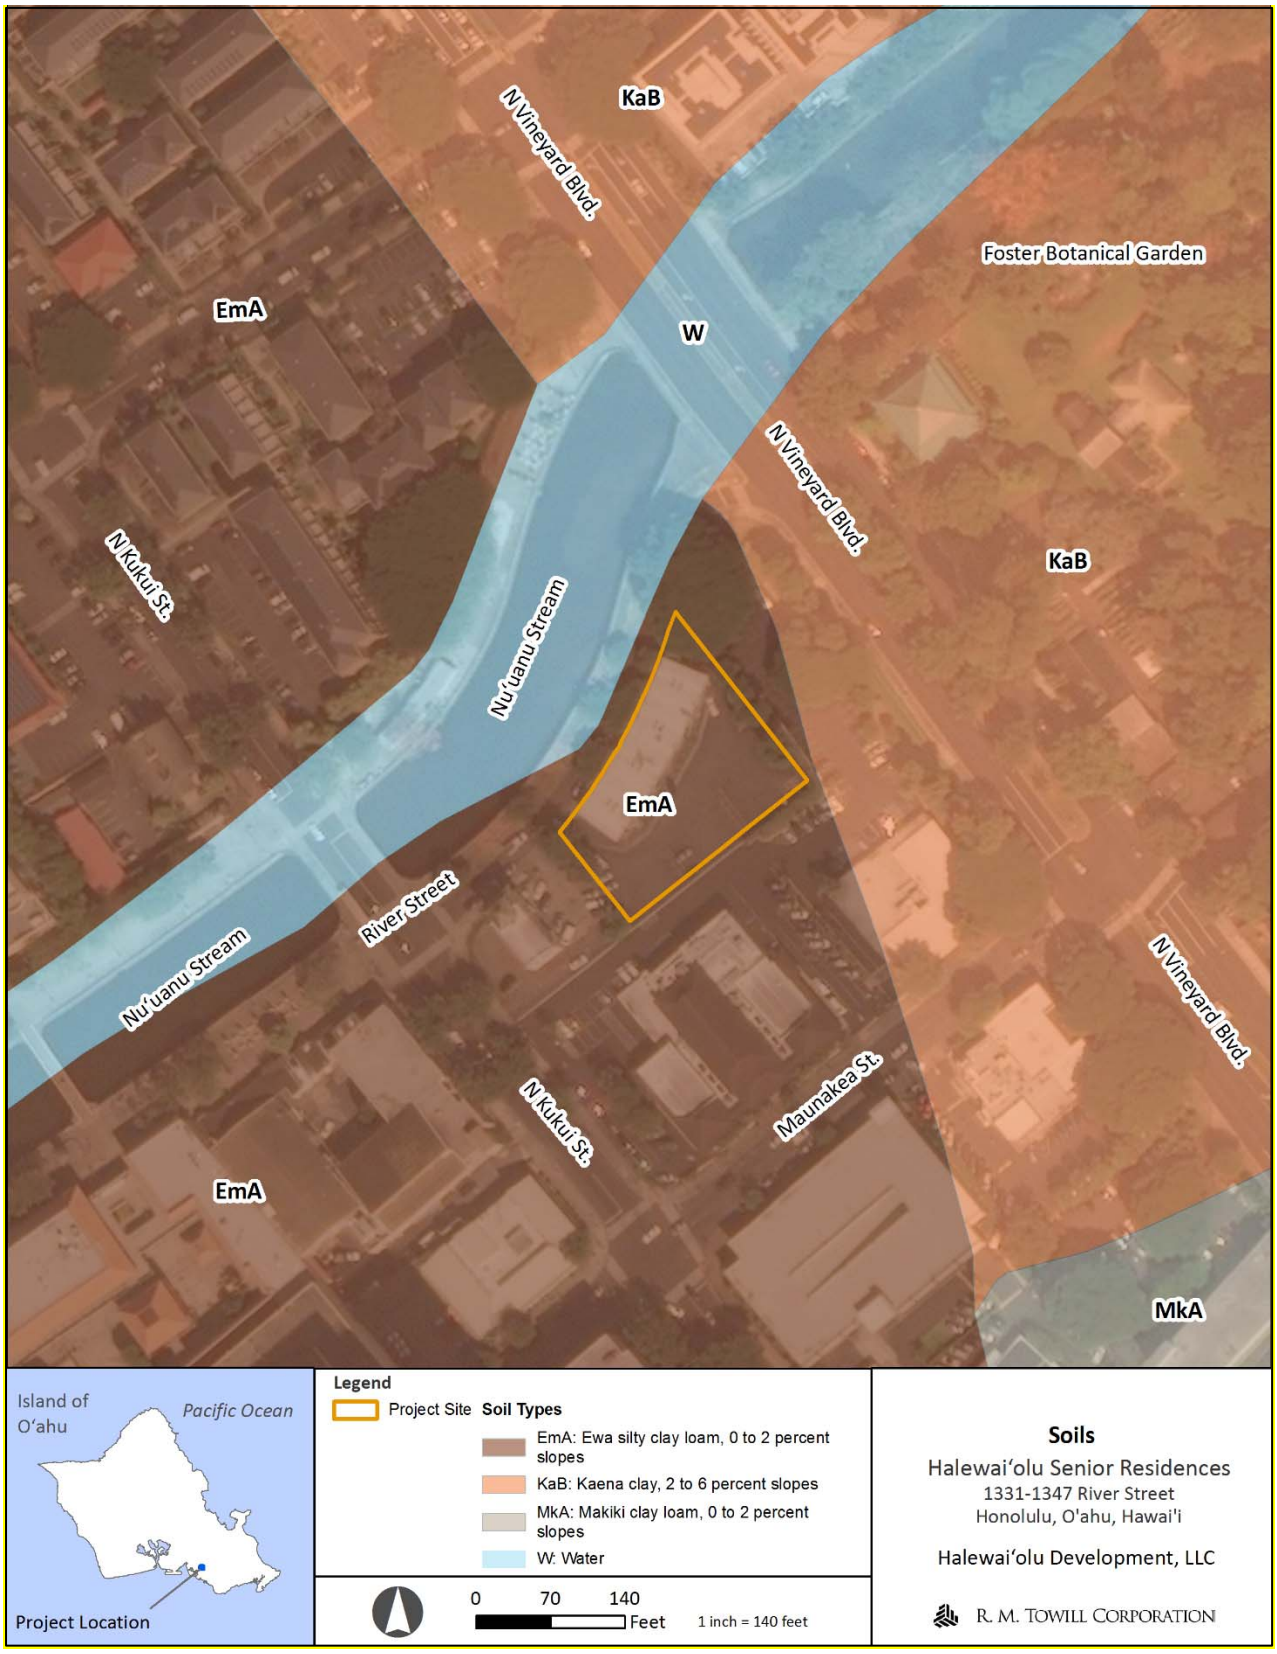
Compared to a dilled shaft foundation, micropiles will require less concrete material and will create a smaller amount of spoils that need to be disposed of off-site.

The Project is not anticipated to have a significant, adverse impact on geology, topographic landforms or soils on the Project Site or in the near vicinity. The Project will not alter the existing topographic in a manner that adversely impacts views or drainage patterns. The Project will not reduce the stability of surface features or underground utilities through alteration of the underlying soils. The Project will not involve excavation or disturbance of soils containing hazardous contaminants in such a manner that public health and safety are compromised.

3.3.3 Avoidance, Minimization, and/or Mitigation Measures

The Geotechnical Report included recommendations and mitigation measures that should be adhered to by the General Contractor during construction, including, but not limited to the following:

- Vegetation, debris and existing structures will be removed and disposed of properly to reduce the potential for contaminating excavated materials.
- The clayey silt soils encountered near the surface during the two borings may be used as general fill, provided that the maximum particle size is less than 3 inches in largest dimension.



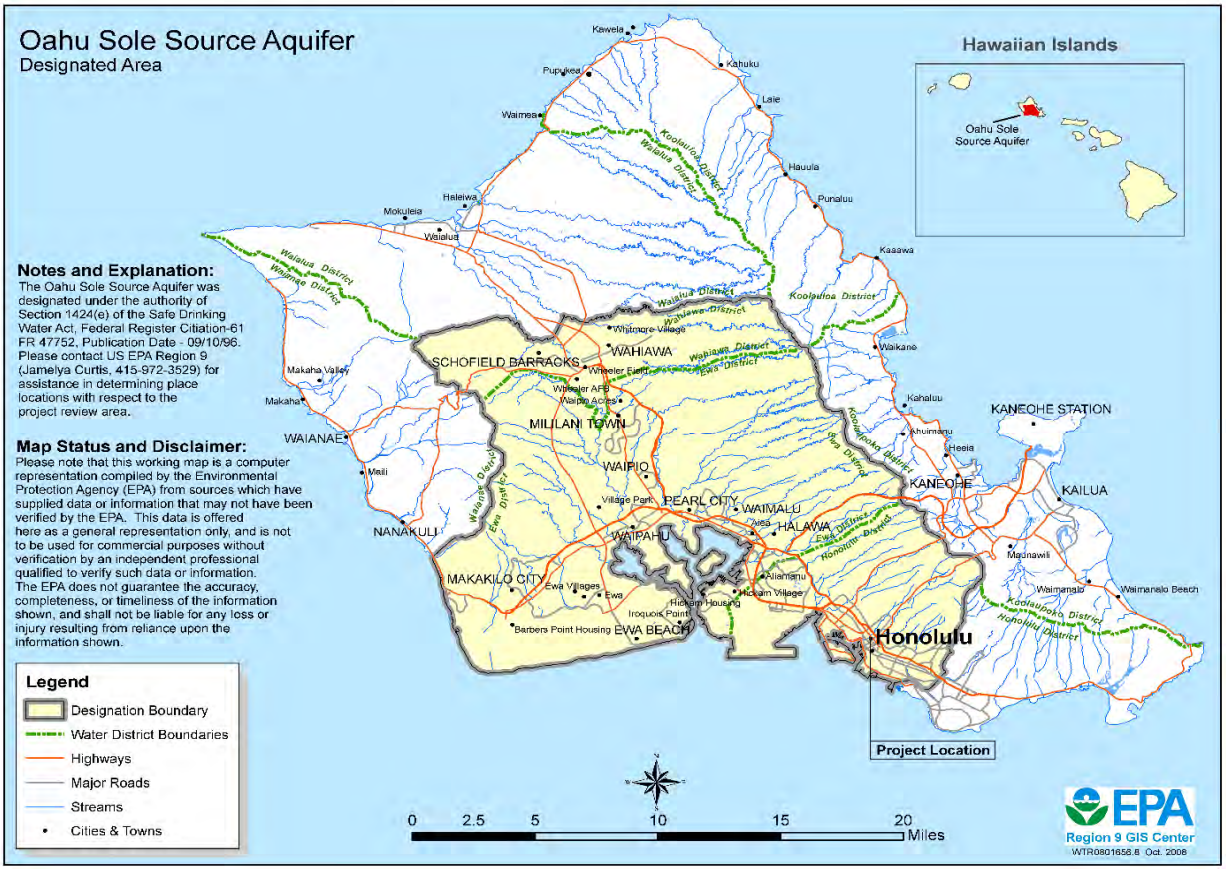
- Imported materials that are used as select granular fill should be non-expansive granular material, such as crushed coral or basalt.
- During excavations, if groundwater is encountered, backfill materials should consist of free-draining granular materials, such as No. 3B Fine gravel, wrapped on all sides with non-woven filter fabric.
- A Geolabs representative should monitor the grading operations to observe whether undesirable materials are encountered during the excavation and scarification process, and to confirm whether the exposed soil conditions are similar to those encountered in our field exploration (Geolabs, 2019).

The proposed Project will be designed in accordance with the requirements of the International Building Code (IBC), 2006 edition. Further the recommendations that are provided here and in the Geotechnical Report in **Appendix F** will be followed. Grading, excavation, and other construction activities required for the Project will be in accordance with City and State regulatory requirements. See preliminary plans on Sheets C002, C005, and C006 in **Appendix A**. Further mitigation measures are not anticipated to be required.

Figure 6: Topography

Figure 7: Soils Map

3.4 WATER RESOURCES AND HYDROLOGY



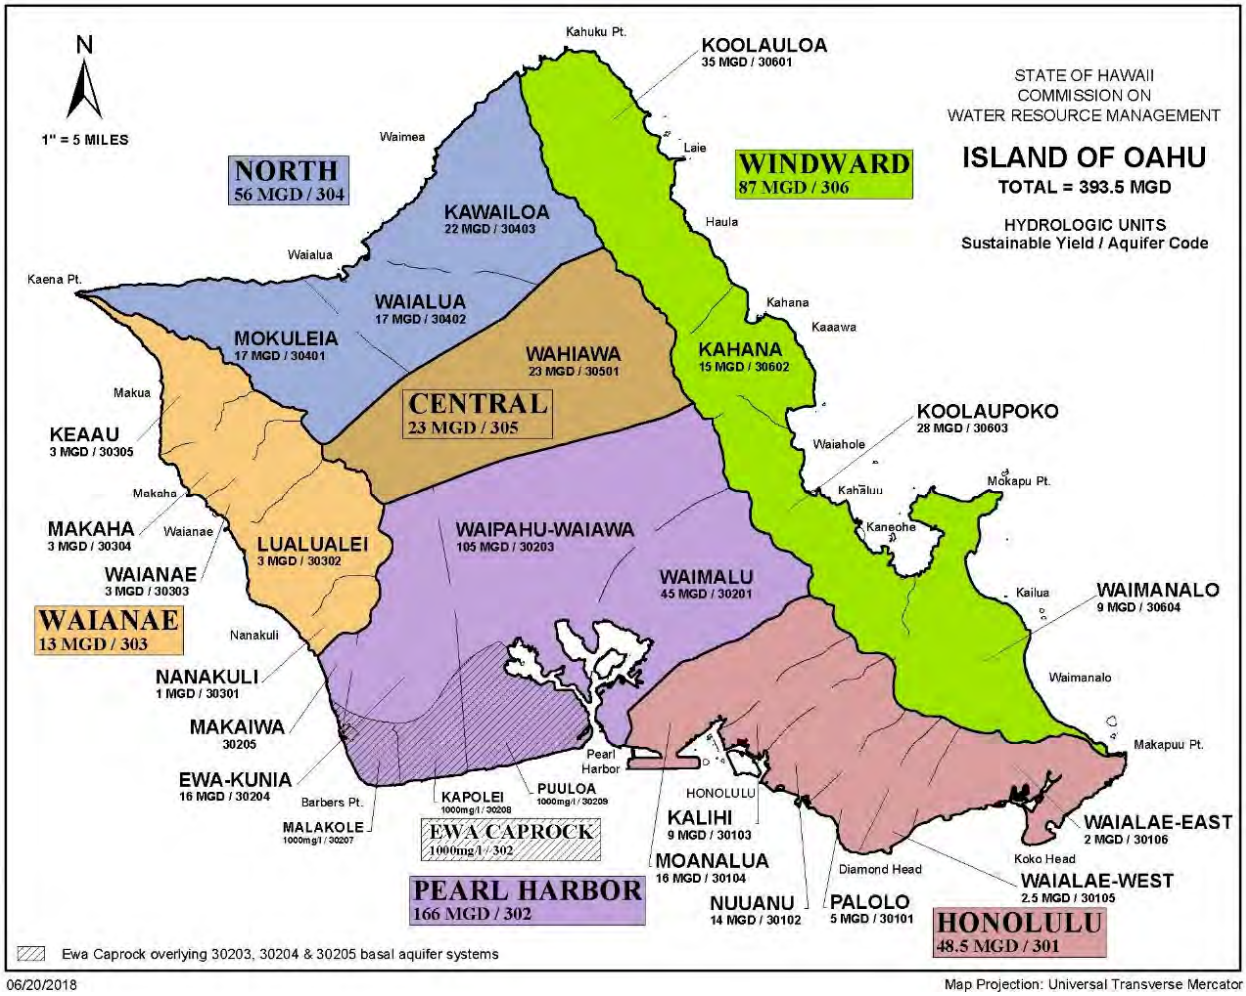
3.4.1 Existing Environment

Groundwater

Approximately 50% of Hawai'i's water supply is sourced from groundwater. An important source of groundwater supply for O'ahu is derived from the Southern O'ahu Basal Aquifer (SOBA), a basal aquifer underlying southern O'ahu, which extends from the Mō'ili'ili and Makiki region of O'ahu to the southern end of the Wai'anae Range. Rainfall in the Ko'olau Range is the principal source of the fresh groundwater recharge in the SOBA.

The SOBA is designated a Sole Source Aquifer (SSA) by the EPA. A SSA is defined as an aquifer that supplies at least 50% of the drinking water for a community. the U.S. EPA's Sole Source Aquifer Program was established under Section 1424(e) of the U.S. Safe Drinking Water Act (SDWA). The purpose of the program is to help prevent contamination of groundwater, by requiring all federally-funded projects above a SSA to consult with the EPA. See **Figure 8: O'ahu Sole Source Aquifer** below. See **Section 6.1.14** for further discussion.

Figure 8: O'ahu Sole Source Aquifer



Source: EPA, 2009

The State Department of Land and Natural Resources (DLNR), Commission on Water Resource Management (CWRM) has divided and defined O'ahu into five groundwater management areas/sectors: North, Windward, Honolulu, Pearl Harbor and Central. The boundaries of the SOBA cover a vast majority of the Central, Pearl Harbor and Honolulu sectors. The Honolulu Sector is further divided into six aquifer subsystems: Pālolo, Nu'uanu, Kalihi, Moanalua, Wai'alae-East and Wai'alae-West. The Project is located within the Kalihi aquifer subsystem. The CWRM also established an aquifer coding system used to describe the groundwater hydrologic units for each aquifer subsystem, in an attempt to manage groundwater resources. See **Figure 9: Hydrologic Unit Map** below.

According to the HDOH, Safe Drinking Water Branch, Groundwater Protection Program's Groundwater Contamination Maps, there are no public drinking or non-drinking water wells, such as irrigation and industrial wells, on or near the Project Site, nor are there any sites that were flagged for potential groundwater contamination.

Figure 9: Hydrologic Unit Map

Source: DLNR, CWRM 2018

Borings performed for the Geotechnical Report (**Appendix F**) found groundwater at depths of about 7.2 to 7.9 feet below the existing pavement surface. Groundwater levels can fluctuate depending on surface water runoff and seasonal precipitation, due to the proximity of the Project Site to the Nu'uanu Stream and groundwater withdrawal and/or injection.

Surface Water

The Nu'uanu Stream is located approximately 54 feet northwest of the Project Site. See **Figure 10: Surface Waters.** The Nu'uanu Stream is located in the Nu'uanu Watershed and is a perennial stream, flowing continuously throughout the year. Nu'uanu Stream channel has been modified and begins about 0.5 miles mauka of the Nu'uanu Reservoir No. 4 and flows through Nu'uanu Valley and Downtown Honolulu before reaching the Honolulu Harbor near Piers 15 and 16.

In the vicinity of the Project site, the Nu'uanu Stream is designated as a "Class 2" inland water by the HDOH, Clean Water Branch (CWB). According to HAR, Chapter 11-54, *Water Quality Standards*, "Class 2" waters are to be protected for recreational purposes, the support and propagation of aquatic life, agricultural and industrial water supplies, shipping, and navigation.

Figure 10: Surface Waters

The Nu'uanu Stream is listed on the §303(d) list in the HDOH's *2018 State Water Quality Monitoring and Assessment Report* (HDOH, 2018). During the dry season, Nu'uanu Stream does not meet the State's water quality standards for the following parameters: enterococcus, total nitrogen, nitrate + nitrite (NO3+NO2), total phosphorus (TP), turbidity, total suspended solids (TSS), trash, dieldrin, and chlordane. During the wet season, the Nu'uanu Stream does not meet the State's water quality standards for TP and TSS. Water bodies on the §303(d) list require HDOH to develop a Total Maximum Daily Load (TMDL), to assist bringing that water body into compliance with State water quality standards. The Nu'uanu Stream is currently listed as a "Low" priority for HDOH to initiate the development of a TMDL within the current monitoring and assessment cycle.

3.4.2 Potential Impacts

Groundwater

The Project involves excavation for the construction of the residential facility. Generally, the depth of excavation will be approximately 12 feet below the existing ground levels, for the construction of the building foundations and elevator pits. Additionally, the residential facility be supported on a deep foundation system consisting of micropiles with a diameter of 7.625 inches. These micropiles will extend about 75 to 120 feet below the bottom of the foundation cap elevations. Based on the subsurface soil conditions (e.g. soft and loose lagoonal deposits) and limited working space, temporary shoring (e.g. using interlocking steel sheet pilings) of some of the deeper excavations, especially where dewatering may be required. Excavation with backhoe excavator will likely be utilized. The Contractor and geotechnical engineer will be responsible for dewatering during construction, and for the selection of dewatering equipment and methods, to ensure there is minimal impact on the groundwater table.

The Project is not anticipated to have a significant, long-term or cumulative adverse impact on the SOBA, or SSA or groundwater resources in the Project vicinity. Ground-altering activities that threaten SSAs are typically associated with the installation of an injection well drilling or detention / infiltration basin; and/or a release of toxic chemicals (e.g. oil, grease, pesticides) which pollutes groundwater.

Surface Water

During construction, there is the potential that sediment and pollutants from construction storm water discharges may enter Nu'uanu Stream. However, pollution control measures and best management practice (BMPs) will be installed by the General Contractor to ensure short-term adverse impacts to water quality of the Nu'uanu Stream are avoided.

Permanent post-construction BMPs will be installed when the Project is complete to minimize long-term impacts to water quality. Additionally, the Project and associated landscaping will pre-treat storm water runoff and beautify River Street along this portion of the Nu'uanu Stream; therefore, increasing its attractiveness as a recreational resource and encouraging maintenance of the stream for residents and the community to enjoy. The Project is not anticipated to have a significant, long-term or a cumulative adverse impact to Nu'uanu Stream or other nearby surface waters. The Project does not involve permanent alteration, excavation or filling of a surface water.

3.4.3 Avoidance, Minimization, and/or Mitigation Measures

Groundwater

If groundwater is encountered during construction, the General Contractor and geotechnical engineer will be responsible for the selection of dewatering methods and equipment, to shore and seal excavated work areas in a manner that will minimize the potential for ground water infiltration into active work areas and to prevent the infiltration of pollutants into the groundwater table. If construction dewatering is required, a National Pollutant Discharge Elimination System (NPDES) permit for construction dewatering will be obtained from the DOH, CWB, in accordance with HAR, Chapter 11-54 and 11-55.

Surface Water

As previously stated, pollution control measures and BMPs will be installed by the General Contractor to prevent soil loss and sediment discharges into Nu'uanu Stream and to ensure short-term adverse impacts to Nu'uanu Stream are avoided. The Project is not likely to require an NPDES permit for construction storm water runoff, as the project size is less than 1.0 acre. BMPs will be employed in all phases of the Project. BMPs will be installed prior to the start of construction, will be maintained throughout the construction period, and permanent BMPs will be installed once construction is complete. BMPs will generally include a stabilized construction ingress/egress, catch basin inlet protections, and temporary filter sock perimeter controls. In addition to the BMPs described above, good housekeeping mitigation measures, may include the following. For additional details, see Sheets C002, C005 and C006 in **Appendix A**:

- When cleared and grubbed areas are not to be graded or disturbed for 14 days or more, seed, plant, or hydroseed temporary vegetation or use other temporary stabilization methods, unless remaining vegetation provides adequate protection.
- The General Contractor shall employ dust control measures, including keeping the Project Site and surrounding area free from dust nuisance. The work shall be in conformance with HAR, Chapter 11-60, Air Pollution Control. Measures may include but not be limited to the installation of dust screens, watering of the Project Site and fill material being placed.
- All pollutants discharged from the construction site to off-site areas will be swept or vacuumed each day before leaving the job site.
- Construction materials, waste, toxic and hazardous substances, stockpiles and other sources of pollution shall not be stored in buffer areas, near areas of concentrated flow, or areas abutting the Municipal Separate Storm Sewer System (MS4), receiving waters, or drainage improvements that discharge off-site. Primary and secondary containment controls and covers shall be implemented to the maximum extent practicable.
- Spill prevention and response plans to eliminate and minimize the discharge of pollutants to the MS4 and receiving waters from leaks and spills by reducing the chance far spills, absorbing, containing, and cleaning up spills and properly disposing of spill materials. At a minimum, all leaks and spills immediately shall be cleaned up immediately.
- Prevent fuel spills and leaks by using off-site facilities, fueling only in designated areas, enclosing or covering stored fuel, and implementing spill controls such as secondary containment and active measures using spill response kits.
- Stockpiles shall not be located in drainage ways, within 50 feet from areas of concentrated flows and are not allowed in the City Right-Of-Way. Sediment barriers or silt fences shall be used around the base of all stockpiles to prevent storm water carrying contaminants into drainage systems and State waters. Stockpiles greater than 15 feet in height shall require an 8-foot wide benching in accordance with ROH, Chapter 14, Article 15, *Grading, Grubbing and Stockpiling*. Stockpiles must

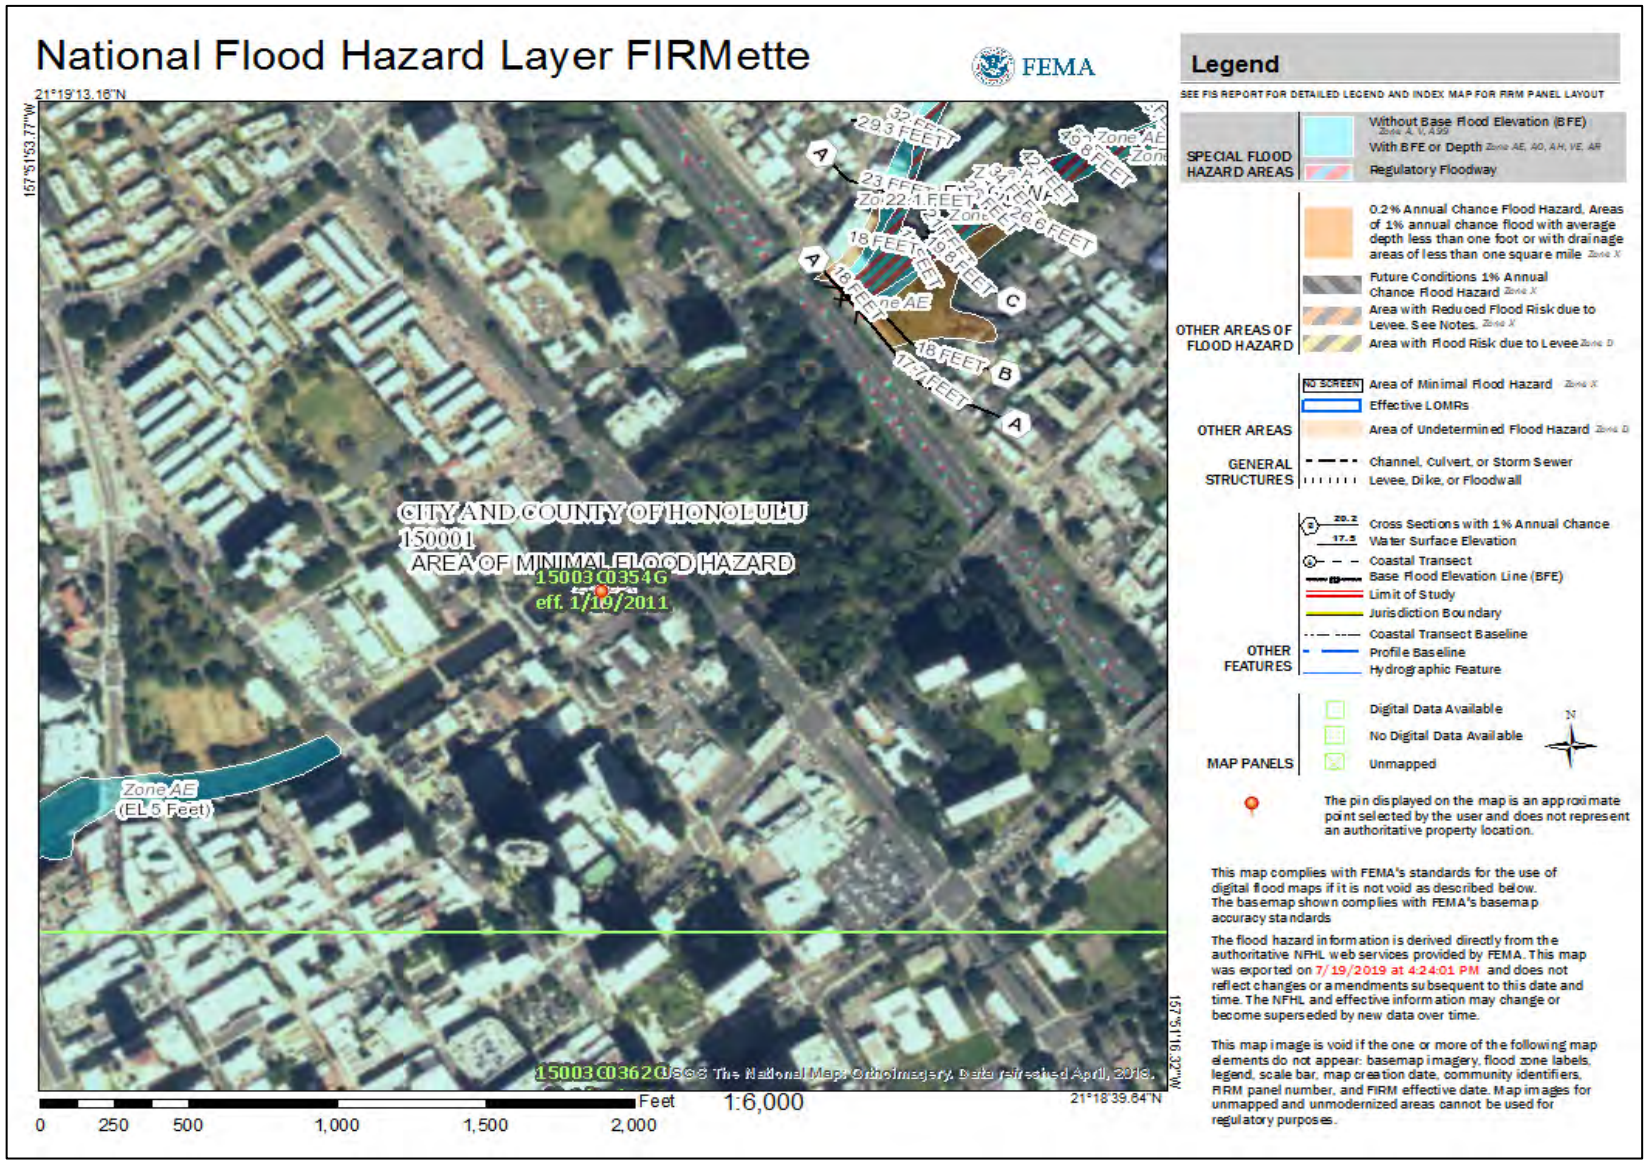
be covered with plastic sheeting or a comparable material if they will not be actively used within 7 days.
- Prevent or reduce discharge of pollutants to storm water from concrete waste by conducting washout offsite or performing onsite washout in a designated area constructed and maintained in sufficient quantity and size to contain all liquid and concrete waste generated by washout operations.
- Should heavy rains, tropical storm, or hurricane occur during construction, a Rain Response Plan has been developed.

Permanent BMPs may include the following. For additional details, see Sheets C005 and C006 in **Appendix A**.:

- Minimizing soil compaction and impervious surfaces;
- Directing runoff to engineered biofiltration cells;
- Limiting storm water runoff from landscape areas to impervious areas;
- Automatic irrigation systems to minimize runoff of excess irrigation water;
- Stenciled storm drain inlets;
- Prohibition of residential vehicle and equipment washing and cleaning;
- Locating the loading dock in the building; and
- Planting permanent ground cover as soon as possible.

The General Contractor may modify the proposed BMPs as necessary to account for unanticipated or site-specific conditions. Further mitigation measures are not anticipated to be required.

3.5 NATURAL HAZARDS



3.5.1 Existing Environment

Flood

Flooding in the Hawaiian Islands primarily occurs due to stream overflow and high surface runoff (non-channelized flow) as a result of torrential rains that fall on the steep slopes in the mountain ranges and drainage basins. The most frequent and severe flooding occur where steep sloping mountain ranges abruptly meet flat or low-lying coastal plains, as found in Waimanālo, Kailua, Kāneʻohe, and Lāʻie on the island of Oʻahu. Nearly every year flash floods cause damage to property, homes, highways, and crops in Hawaiʻi (Fletcher, et al., 2002).

According to the Federal Emergency Management Agency's (FEMA) Flood Insurance Rate Map (FIRM), map number 15003C0354G, effective on January 18, 2011, the Project Site is located in Zone "X." Zone "X" is an area of minimal flood hazard that has been determined to be outside the 0.2% annual chance floodplain and outside of the 500-year floodplain. The Project Site is not located within a FEMA Special Flood Hazard Area (SFHA). See **Figure 11: FEMA FIRMette No. 15003C0354G**. However, the Federal Emergency Management Agency (FEMA) completed a Base Level Engineering (BLE) study in 2019 for flood areas on Oahu that were not previously mapped. The BLE identified the flood areas adjacent to Nu'uanu Stream, makai of the Freeway. According to the BLE, the parcel is in the 100-year floodplain with a Base Flood Elevation (BFE) of 12.04. The Project will comply with applicable flood requirements for the Project.

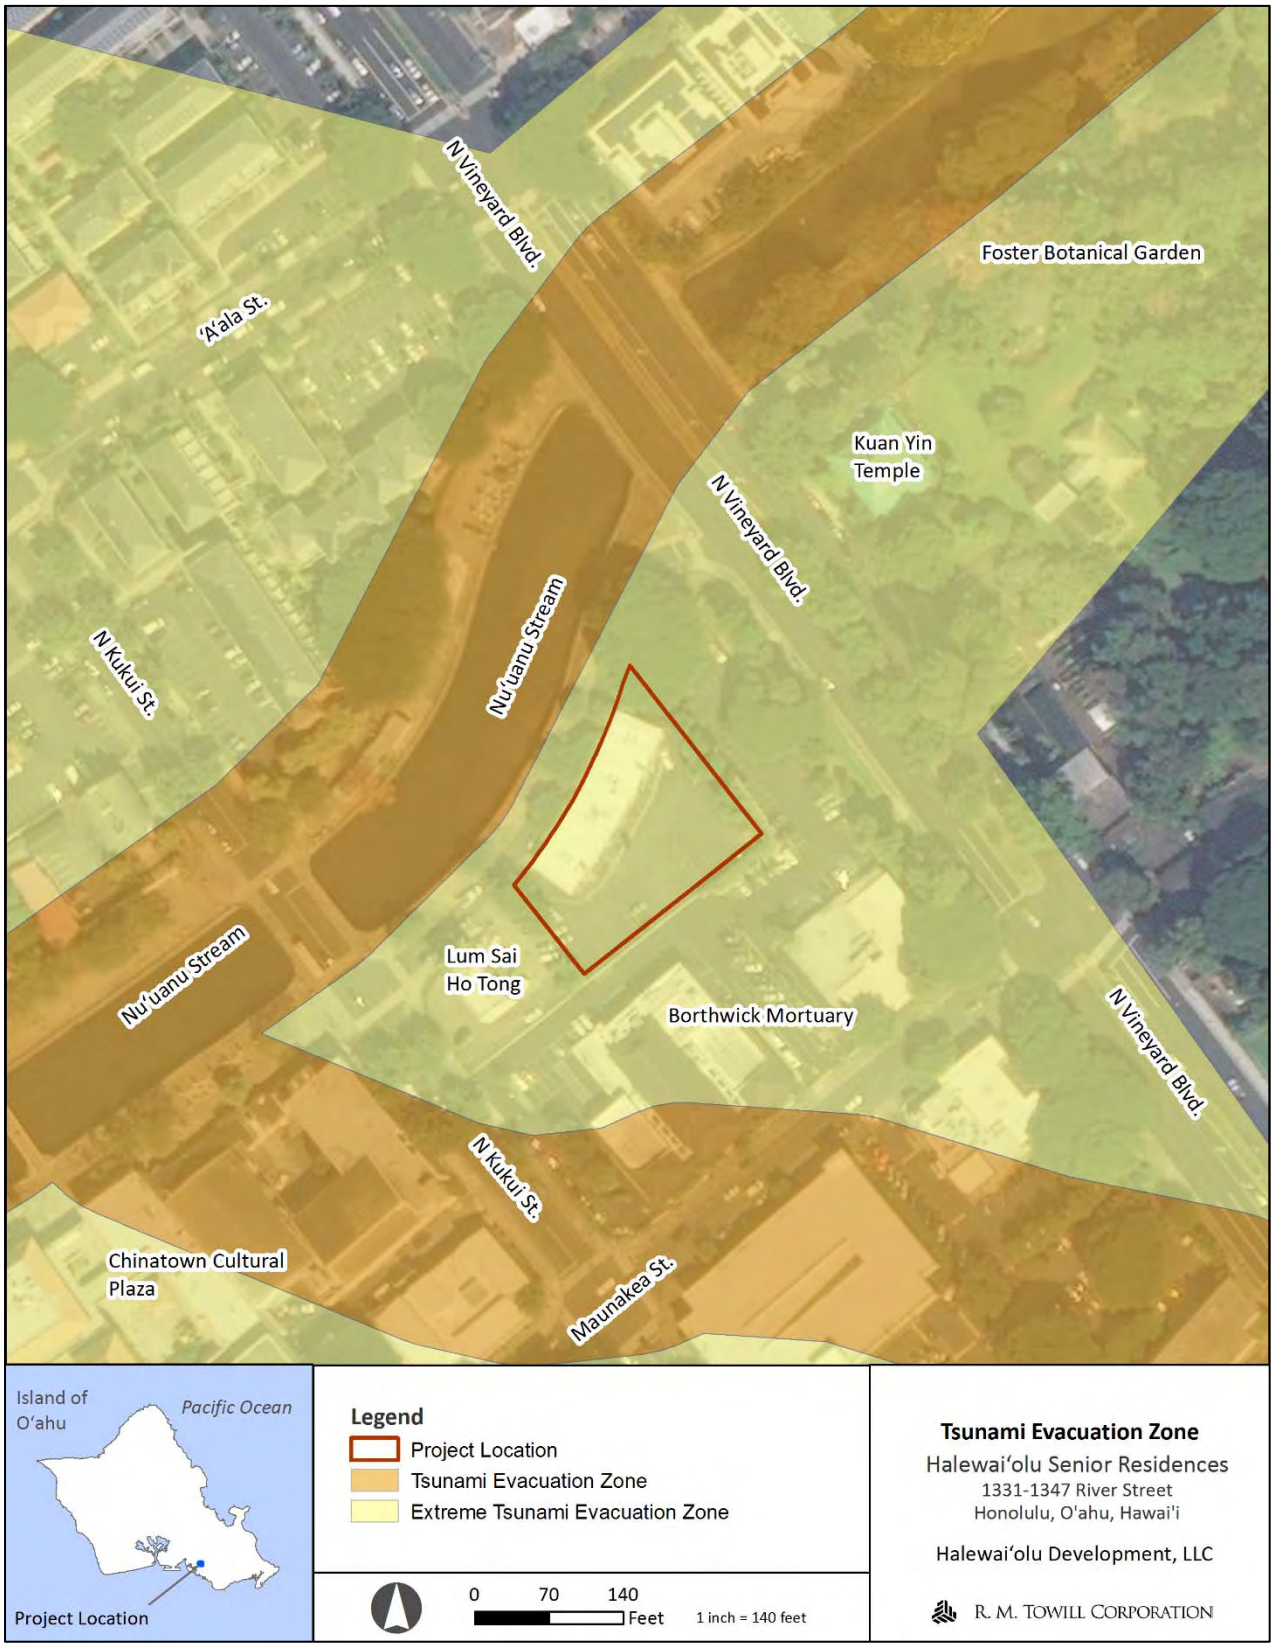
Figure 11: FEMA FIRMette No. 15003C0354G

Tsunami

Tsunamis involve the generation of a series of destructive ocean waves, due to a large displacement of water, created by sea floor movements caused by earthquakes, landslides, submarine faulting or volcanic eruptions. The characteristics of a tsunami are difficult to predict, as there are several factors to consider, including the depth, topography, and morphology of the offshore region, and the aspect, slope, geology, and morphology of the shoreline they inundate, which effects the distance over which they travel (Fletcher, et al., 2002).

Tsunamis differ from ordinary ocean waves and storm surges in that the entire water column from the sea floor to the ocean surface is displaced, not just the upper few feet of the ocean surface. As tsunamis enter shallower coastal waters, the speed of the wave slows down and the height increases. A wave that may be only 3 feet high or less in the ocean may climb to more than 60 feet when it hits the coastline. Therefore, a tsunami can cause great loss of life and property damage when they come ashore. The first wave is almost never the largest; successive waves may be spaced tens of minutes apart and continue to arrive for many hours.

Tsunamis that affect Hawai‘i typically originate from distant, seismically active areas bordering the Pacific Ocean (also known as the “Rim of Fire”), or from local, shallow undersea earthquakes, primarily near the island of Hawai‘i (“Big Island”). Twenty-six tsunamis with flood elevations greater than 3.3 feet have made landfall in the Hawaiian Islands in recorded history, and 10 of these had significant damaging effects on O‘ahu. Since 1946, there have been 4 significant tsunami “run-up” events in Hawai‘i, in 1946, 1957, 1960 and 1964, where heights varied from 1 to 14 feet. The most recent tsunami to impact O‘ahu, occurred on March 11, 2011, when the Tōhoku earthquake and tsunami originating from Japan caused damage at several locations around the island especially the north shore.



The Pacific Tsunami Warning Center (PTWC) issues warnings when a potential tsunami with significant widespread inundation is imminent or expected. Tsunami warnings alert the public that widespread, dangerous coastal flooding is possible and alert emergency management officials to take action for the entire tsunami hazard zone. The City, Department of Emergency Management prepares Tsunami Evacuation Zone Maps for the island of O‘ahu. According to Map 19, Inset 2 – Airport to Waikiki, the subject property is not within the Tsunami Evacuation Zone. It is however, within the “Extreme Tsunami Evacuation Zone” (XTEZ), or the areas that must be evacuated only during an extreme tsunami event generated from earthquakes of Magnitude 9+ on the Richter scale. **Figure 12: Tsunami Evacuation Zone**.

Seismic Hazard

Generally, earthquakes are caused by shifts in tectonic plates. In contrast, earthquake activity in Hawai‘i is linked primarily to volcanic activity and occurs on the Big Island. Approximately 95% of the earthquakes on the Big Island are directly related to the movement of magma within Kīlauea or Mauna Loa, beneath the earth's surface. Earthquakes that reach O‘ahu are generally not strong enough to be felt and cause little to no damage. O‘ahu does not have any active volcanoes; therefore, is not subject to *significant* earthquakes (Fletcher, et al., 2002).

Over the last 150 years of recorded history, earthquakes greater than Magnitude 6 were not reported on O‘ahu. Based on available information, it is assumed that an earthquake of about Magnitude 5.6 occurred on June 28, 1948 in the vicinity of O‘ahu, possibly along the hypothesized and controversial Diamond Head Fault feature. The Diamond Head Fault feature is believed to extend northeasterly away from the southeastern tip of the Island of O‘ahu (Geolabs, 2017). The most recent earthquake to cause minor

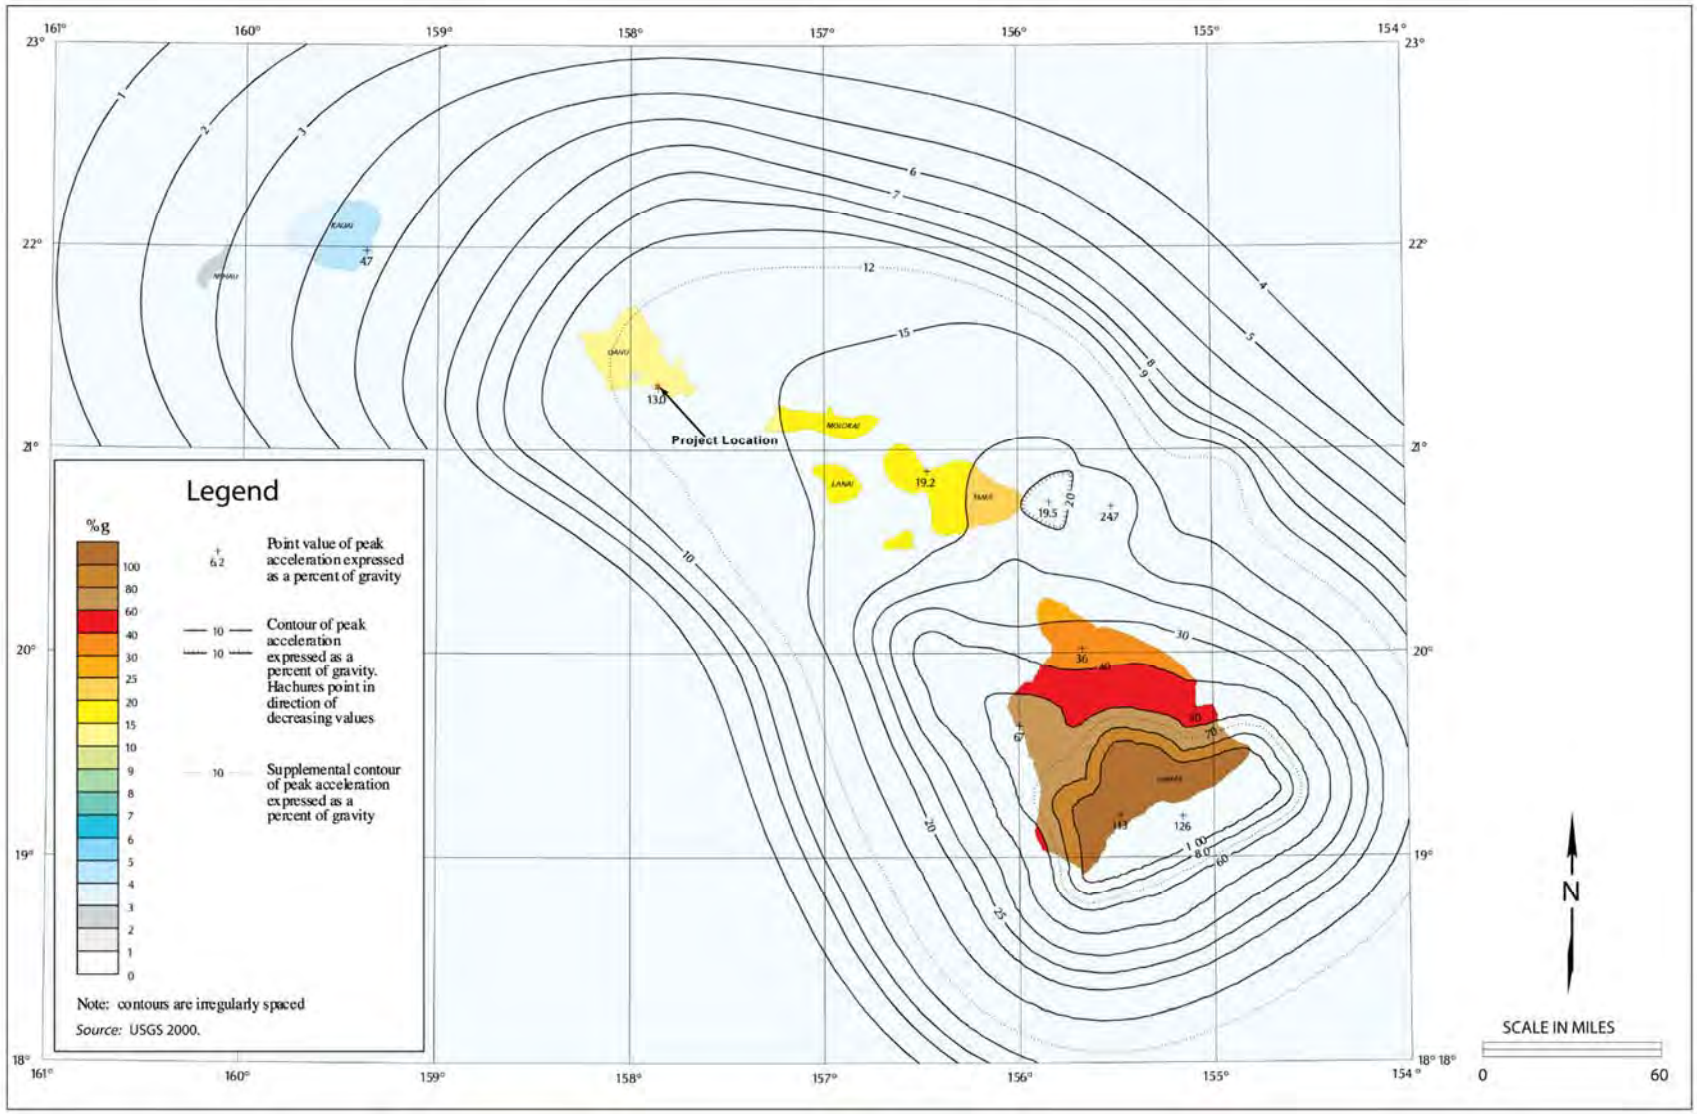
Figure 12: Tsunami Evacuation Zone

damage on the island of Oʻahu occurred on October 15, 2006, on the Big Island (southwest of Puakō), and measured a magnitude of 6.7 on the Richter scale.

Figure 13: State of Hawaiʻi Seismicity illustrates the estimated risk of earthquakes using the measure of ground motion hazard in terms of peak ground acceleration (PGA) measured as a percentage of Earth's gravitational acceleration (g). The map to the right depicts the maximum PGA expected over the next 50 years with at least a 2% chance of exceedance. The southeast part of the Island of Hawaiʻi has the highest expected ground acceleration at over 100% g. This amount of acceleration would make it difficult to stand and could topple structures. The color scale shows the island of Oʻahu to have an expected ground acceleration of 15%, a reduced risk in which a moderate amount of shaking may be experienced (USGS, 2017).

Hurricanes and High Winds

In Hawaiʻi, northeast trade winds predominate throughout most of the year and generally range in velocity between 10 and 20 miles per hour (mph) with trade winds of 40-60 mph periodically occurring. When wind speeds exceed 70 mph, the storms are characterized as hurricanes. Hurricanes are a type of tropical cyclone with wind speeds greater than 74 mph. Hurricanes occur seasonally in Hawaiʻi, typically during the summer to early winter months (June to November). During hurricanes and storm conditions high winds cause strong uplifting forces on structures, particularly roofs. Wind-driven materials and debris can attain high velocity, causing devastating property damage and harm to life and limb.



Hurricanes are classified according to categories, where "Category 1" hurricanes have wind speeds between 75-95 mph and "Category 5" hurricanes have wind speeds exceeding 155 mph. Hurricanes occasionally approach the Hawaiian Islands, but rarely reach the islands with hurricane force wind speeds. Hawaiʻi has been affected twice since 1982 by significant hurricanes. Hurricane ʻIwa was a category 1, which passed over Kauaʻi on November 23, 1982, while Hurricane Iniki was a Category 4, which passed over Kauaʻi on September 11, 1992. Hurricane Lane was the most recent hurricane to threaten Hawaiʻi, which started as a Category 5 on August 22, 2018 and was downgraded to below hurricane status, as it gradually weakened and dissipated on August 29, 2018.

3.5.2 Potential Impacts

Flood

During construction, the Project is not expected to be significantly impacted by flooding due to its location within the FEMA Flood Zone X. The National Flood Insurance Program (NFIP) does not regulate development within Zone X. The Project Site is not located within a SFHA or the Base Flood Plain. However, the Federal Emergency Management Agency (FEMA) completed a Base Level Engineering (BLE) study in 2019 for flood areas on Oahu that were not previously mapped. The BLE identified the flood areas adjacent to Nu'uanu Stream, makai of the Freeway. According to the BLE, the parcel is in the 100-year floodplain with a Base Flood Elevation (BFE) of 12.04. The Project will comply with applicable flood requirements for the Project.

Figure 13: State of Hawai'i Seismicity

Tsunami

During construction, the Project is not expected to be significantly impacted by tsunamis. The Project Site (located about 0.4 miles from the shoreline) is not located within the tsunami evacuation zone.

The Project will not result in permanent facilities or site conditions that will significantly exacerbate property damage or increase risk to the public's health and safety in the event of tsunami. Once construction is completed, the Project will continue to be at risk from the threat of an extreme tsunami. In the event of a tsunami, residents of the Project may be required to evacuate to safe areas.

Seismic Hazards

During construction, the Project is not expected to be adversely impacted by seismic activity.

The Project will comply with the IBC, 2006 Edition, which provides design criteria to safeguard against potential damage from seismic activity. The new residential facility will improve safety for nearby neighbors, as it will replace an outdated, nonconforming building with a residential facility that has enhanced structural resistance to potential earthquakes. The Project will not result in permanent facilities or site conditions that will significantly exacerbate property damage or increase risk to the public's health and safety in the event of an earthquake. The Project will be designed to safeguard against the potential damage from seismic activity. In the event of an earthquake, residents of the Project may be required to be evacuate to safe areas.

Hurricanes and High Winds

During construction, the Project is not expected to be significantly impacted by hurricanes and high winds.

The Project will not result in permanent facilities or site conditions that will significantly exacerbate property damage or increase risk to the public's health and safety in the event of a hurricane. Once construction is completed, the Project will continue to be at risk from the threat of a hurricane but will have been designed and constructed to meet building code requirements to mitigate hurricane impacts.

3.5.3 Avoidance, Minimizations, and/or Mitigation Measures

Flood

In the event of a flood event, construction activities will cease; equipment and materials will be secured; and all Federal, State and City requirements will be implemented to ensure the safety construction crews and community members near the Project area.

The residential facility tower and podium will adhere to design standards as set forth in the IBC, 2006 Edition and ROH, Chapter 21A, *Flood Hazards*. Any increase in runoff caused by an increase in impervious surfaces will be mitigated on site as required to meet City standards. Further mitigation measures are not anticipated to be required.

Tsunami

In the event of a potential tsunami, the PTWC will issue warnings. Depending on the type of tsunami warning and what phase of and where construction is occurring, work may have to come to a halt.

The residential facility tower and podium will be designed to meet applicable building code requirements. Further mitigation measures are not anticipated to be required.

Seismic Hazards

In the event of an earthquake, the U.S. Geological Survey (USGS), Central North Pacific office will provide updates on seismic activity. Construction activities may cease and equipment and materials will be secured. All Federal, State and City requirements will be implemented to ensure the safety of construction crews and community members near the project area.

The Project will be designed to meet applicable building code requirements to mitigate potential impacts from seismic activity. Further mitigation measures are not anticipated to be required.

Hurricane and High Winds

The National Hurricane Center issues a "Hurricane Watch" 48 hours in advance of a potential hurricane event and issues a "Hurricane Warning" when sustained winds of at least 74 mph are expected within 36 hours. Upon issuance of a Hurricane Warning, construction operations will cease, work crews will finalize securing the Project Site and evacuate until the hurricane threat has passed. Upon issuance of a Hurricane Watch, work crews will begin securing the construction site as follows:

- Remove or secure equipment, machinery, construction materials, and portable toilets;
- Stop scheduled deliveries of building materials;
- Remove jobsite signage, dust screens, silt screens, and other temporary installations; and
- Locate and turn off jobsite utilities, including electricity, water, and gas.

The Project will be designed to meet applicable building code requirements to mitigate potential impacts from hurricanes and high winds. Further mitigation measures are not anticipated to be required.

3.6 SCENIC AND VISUAL RESOURCES

3.6.1 Existing Environment

Scenic and visual resources include panoramic views and vistas; landmarks, including distinctive or cherished structures and physical features; and landscape features including significant trees and open space areas.

The PUC DP encourages the preservation of the following significant panoramic views and vantage points in Honolulu:

Section 3.1.1.2 Scenic Views

- *The Koʻolau and Waiʻanae Mountain Ranges and their foothills (notably, Red Hill and Puu Ualakaa, or Round Top);*

- *The Pacific Ocean, Pearl Harbor's East Loch, Ford Island, Honolulu Harbor, Ke'ehi Lagoon and Kewalo Basin, and their respective shorelines;*
- *The craters of Leahi (Diamond Head), Puowaina (Punchbowl) and Aliamanu; and*

Section 3.1.2 Policies

- *Preserve panoramic views of natural landmarks and the urban skyline. Preserve views of the Koolau and Waianae Mountain Ranges, Punchbowl, Diamond Head, Pearl Harbor and other natural landmarks. Maintain important view corridors within and across urban Honolulu and keep Downtown as the most prominent feature of the urban skyline. Views along the Pearl Harbor shoreline and the Pearl Harbor Historic Trail toward the mountains, shoreline, significant landmarks, and adjacent communities should be created and maximized wherever possible and appropriate.*

Section 3.1.3.3 Urban Skyline and Mauka-Makai Views

- *Maintain the visual prominence of important districts by allowing a greater height and massing of buildings, such as in the Downtown area;*
- *Apart from downtown and other central Honolulu locations, promote mid-rise or low-rise scale for new buildings;*
- *Preserve the following panoramic views indicated schematically in Figure 3.1 by establishing building height limits and setbacks that are based on viewplane analyses to determine the sight lines and desired view dimensions and characteristics*
    - *From Ala Wai Canal Promenade toward the Ko'olau Range;*
    - *From Ala Moana Beach Park toward the Ko'olau Range;*
    - *From Kewalo Basin toward the Ko'olau Range and Punchbowl;*
    - *From Kaka'ako Waterfront Park toward Punchbowl and the Ko'olau Range;*
    - *From Punchbowl Lookout toward Diamond Head;*
- *Preserve and enhance significant mauka or makai view corridors along major collector streets indicated in Figure 3.1 through a combination of zoning controls and streetscape improvements.*

Panoramic view planes identified in the PUC DP that are in viewing range near the Project site include public views of the Ko'olau Mountain range and Punchbowl.

3.6.2 Potential Impacts

During construction, construction activities will be visibly apparent due to the staging of heavy equipment and vehicles, nighttime lighting, and the presence of dust screens. However, dust screens also function to screen views into construction areas, thereby mitigating the visual distraction and contrast of an active construction area from the surrounding uses. Construction-related impacts to visual and scenic resources are temporary and will end upon completion of the Project.

The Project involves construction of a residential tower about 174 feet tall in an area zoned for 350-foot heights. Proposed elevations of the residential facility from various viewpoints are in **Appendix A, Drawings**. The tower will be built in a mauka-makai orientation, whereby, the short side of the tower is facing the north-south direction. See **Figure 14** for the mauka-makai view from North Kukui Street and **Figure 15** for the mauka-makai view from River Street. Therefore, the new residential facility will not significantly obstruct mauka-makai views of the Ko'olau Mountain range from the southern shore,

Downtown Honolulu or the Honolulu Harbor. The Project may partially obstruct views of Punchbowl from neighboring buildings immediately southwest of the Project Site. Although, existing buildings in the vicinity of the Project partially obstruct views of the Koʻolau range and Punchbowl; thus, the Project will integrate into the present urban fabric. Moreover, the Project will align with the PUC DP by maintaining the visual prominence of Downtown Honolulu, by encouraging a greater height and massing of buildings.

The Project is not anticipated to result in a significant adverse impact to any visual or scenic resources, as the proposed improvements will not result in a *substantial* and permanent alteration of a region's visual character, a recognized view plane, an obstruction of a landmark feature, or lighting characteristics. Conversely, the Project may result in a minor beneficial visual impact to River Street with the removal of the blighted property, new landscaping, and activation of the street frontage.

3.6.3 Avoidance, Minimizations, and/or Mitigation Measures

During construction General Contractors will employ the following measures to mitigate impacts on visual and scenic resources:

- Schedule and phase construction activities to minimize the project duration.
- Schedule material and equipment delivery and refuse removal during non-peak use periods on public roadways and within areas of high public use.
- Install dust fences with a minimum height of 12 feet to screen active construction areas and staging and stockpile areas from view.

The Project is oriented mauka-makai to preserve a view corridor of the Koʻolau Mountain Range. Final design treatments to minimize the impact of the residential facility on surrounding neighborhood may include height setbacks, screening for the parking podium, active ground floor uses and/or landscaping. Additional consideration may be given to the architectural elements for building materials, color, patterns and texture, to reduce the appearance of the scale and massing of the tower.

3.7 NOISE CONDITIONS

3.7.1 Existing Environment

Noise is defined as sound that is undesirable because it interferes with communication, is intense enough to damage hearing, or is otherwise annoying. Under certain conditions, noise can interfere with human activities at home or work and affect human health and well-being.

Figure 14: Mauka-Makai View from North Kukui Street

Figure 15: Mauka-Makai View from River Street

Sound levels are easily measured, but human response and perception of the wide variability in sound amplitudes is subjective. The accepted unit of measure for noise levels is the decibel (dB) because it reflects the way humans perceive changes in sound amplitude. A-weighted decibel (dBA) sound levels are typically used to account for the response of human ear. The term "A-weighted" refers to a filtering of the noise signal to emphasize frequencies in the middle of the audible spectrum and to de-emphasize low and high frequencies in a manner corresponding to the way the human ear perceives sound. The dBA has been found to correlate well with a person's judgment of the noisiness of different sounds and has been used for many years as a measure of community noise.

The noise descriptor currently used by federal agencies, including HUD, to assess environmental noise is the Day-Night Average Sound Level (DNL). In urbanized areas shielded from high volume streets, DNL levels generally range from 55 to 65 DNL, and are usually controlled by motor vehicle traffic noise. Residences which front major roadways are generally exposed to levels of 65 to 75 DNL when the roadway is a high-speed freeway. For purposes of determining noise acceptability for funding assistance from federal agencies, an exterior noise level of 65 DNL or less is considered acceptable for residences (Ebisu, 2019).

The State HDOH monitors noise in accordance with HRS, Chapter 342F. and HAR, Title 11, Chapter 46, *Community Noise Control*. HAR §11-46-3 defines maximum permissible sound levels for three classifications of land use (by zoning district). The Project Site is in "Class A," the class for all residential, conservation, preservation, public space, open space or similar types of zoning districts. The maximum permissible sound levels in Class A is 55 dBA during the daytime (7 a.m. to 10 p.m.) and 45 during the nighttime (10 p.m. to 7 a.m.). Although dBA is not directly comparable to DNL, State HDOH noise limits for multifamily residential, commercial, and resort lands are at approximately 60 DNL (HDOH, 1996b). The maximum permissible sound level can be exceeded for short periods, but not for more than 10% of the time within any 20-minute period. Construction activities are regulated through the issuance of noise permits which allow excessive construction noise during limited time periods.

An *Acoustic Study for the Halewai'olu Senior Residences Project* ("Acoustic Study") was prepared by Y. Ebisu and Associates in April 2019. See **Appendix G, Acoustic Study**. The Acoustic Study assessed existing and future traffic and ambient noise conditions in the vicinity of the proposed Project in March 2019. The major contributor to existing ambient noise levels within the Project area was traffic along North Vineyard Boulevard. The noise levels did not exceed 65 DNL at ground level on the Project Site or at existing buildings along River Street, North Kukui Street, and Maunakea Street (Ebisu, 2019). Ebisu and Associates amended the Acoustic Study on September 26, 2019 to adjust the Project completion date of 2022 instead of 2021. The amendment letter is provided in **Appendix G**.

3.7.2 Potential Impacts

During construction of the Project will involve excavating, grading, concrete casting, the placement of pre-cast structural components, and paving. Most of the noise will be generated during mobilization and operation of heavy construction equipment comprised of earth moving equipment, such as diesel engine powered bulldozers, trucks, backhoes, front-end loaders, graders, and similar equipment. Construction equipment noise is expected to be in the range of 55 and 90 dBA near the Project Site. Predicted maximum construction noise levels at these buildings during the site preparation and earthwork phases of

construction ranged from 88 to 86 dBA (plus or minus 5 dBA). The highest noise levels at existing residences during site preparation and building erection work are expected to occur at the existing Waena Apartments across Nu'uanu Stream, where minimum buffer distances are moderately large (in the order of 200 feet).

However, all noise exposure is not expected to be continuous during the total construction period and noise related to construction is expected to cease upon completion of the proposed Project. These impacts are unavoidable and will be temporary.

The Acoustic Study found that noise level predictions in 2022 should fall within a range of 64.4 to 65.0 DNL along the residential tower's mauka face. Additionally, the construction of the tower will have a noise mitigating effect from traffic along North Vineyard Boulevard, and River Street, North Kukui Street, and Maunakea Street. Therefore, future traffic noise levels are predicted to not exceed the federal standard of 65 DNL (Ebisu, 2019). The Project is not anticipated to result in a significant, long-term adverse impact to existing noise conditions. The Project will not involve construction-related or permanent increases in noise levels that fail to meet federal regulations; or involve noise that persistently disrupts normal routines or causes harm to human health.

A separate analysis was done on the noise level predictions from a mature rail system projected for year 2030 by R.M. Towill Corporation, based on the operational HART system along Nimitz Highway and noise impacts described in the Final Environmental Impact Statement for the Honolulu High Capacity Transit Corridor dated July 8, 2010. Based on the projected noise impact at the residential tower at 215 North King Street located 145 feet away from the centerline of the rail line with a projected 63 DNL and the projected noise impact at the residential tower at 700 Richards Street located 85 feet away from the centerline of the rail line with a projected 63 DNL, the impact at the Project Tower located 2,000 feet away from the centerline of the rail line at Nimitz Highway will be between 52 and 53 DNL. For purposes of determining noise acceptability for funding assistance from federal agencies, an exterior noise level of 65 DNL or less is considered acceptable for residences. Since the 52 and 53 DNL projected impact from the HART system is well below the acceptable 65 DNL no mitigation measures are required.

3.7.3 Avoidance, Minimization, and/or Mitigation Measures

Under HAR, Title 11, Chapter 46, noisy construction activities are restricted to hours between 7:00 AM and 6:00 PM, from Monday through Friday, and exclude certain holidays. Noisy construction activities are normally restricted to the hours of 9:00 AM to 6:00 PM on Saturdays, with construction not permitted on Sundays. To mitigate short-term Construction-related noise, project Contractors will be required to comply with the provisions of HAR, Chapter 11-46, Community Noise Control. Construction activities will be subject to the following limitations:

- A Community Noise Permit will be obtained for construction activities conducted between 7:00 a.m. to 6:00 p.m., Monday through Friday, and 9:00 a.m. to 6:00 p.m. on Saturdays.
- The use of certain construction equipment, including pile drivers, hydraulic hammers, and jackhammers, will be limited to 9:00 a.m. to 5:30 p.m., Monday through Friday.
- An approved Community Noise Variance will be required for any construction activities that exceed permissible sound levels before 7:00 a.m. and after 6:00 p.m., Monday through Friday, or before 9:00 a.m. and after 6:00 p.m. on Saturdays, or at any time on Sunday and holidays.

Construction equipment and vehicles will be appropriately muffled and maintained to reduce backfires. All generators will be housed in baffle boxes (a sound-resistant box placed over or around a generator), be equipped with an attached muffler, or use other noise-abatement methods in accordance with industry standards. In addition, the use of properly muffled equipment, quieted portable engine generators, and diesel equipment would be specified for use within 500 feet of noise sensitive properties. Heavy truck and equipment staging areas would be located at areas that are at least 500 feet from noise sensitive properties

whenever possible. Truck routes which avoid residential communities should be identified wherever possible. Construction barriers may also be used, as required. Additionally, construction activities and use of heavy equipment would be scheduled as much as possible during daylight hours to avoid disturbing area residents during the evening.

Traffic noise levels at all units are predicted to not exceed the FHA/HUD standard of 65 DNL when the Project is complete. Therefore, long-term traffic noise mitigation measures are not required.

3.8 TERRESTRIAL BOTANICAL RESOURCES

3.8.1 Existing Environment

A *Biological Resources Survey for the Halewai'olu Senior Residences* ("Biological Survey") was prepared for the Project by Robert W. Hobdy in March 2019. See **Appendix H, Biological Resources Survey**.

Terrestrial botanical species consisted of a few small to medium sized trees in planter areas around the perimeter of the parking area. A variety of grasses and urban weeds were growing beneath these plants. A total of 45 plant species were recorded on the Project Site; none were native species or special plant habitats. No plant species currently proposed for listing or listed under either the federal or State endangered species statutes or Critical Habitat were identified during the survey on the Project Site. Nine plant species were of uncommon occurrence: plains bluestem (*Bothriochloa bladhii*), common sandbur (*Cenchrus echinatus*), swollen fingergrass (*Chloris barbata*), Bermuda grass (*Cynodon dactylon*), oleander (*Neriu oleander*), straggler daisy (*Calyptocarpus vialis*), pink tecoma (*Tabebuia heterophylla*), Geiger tree (*Cordia sebestina*) and false mallow (*Malvastrum coromandelianum*). The remaining thirty-six plant species were of rare occurrence Project Site (Hobdy, 2019).

In accordance with Section 7 of the Endangered Species Act (ESA) of 1973, the U.S. Fish and Wildlife Service (USFWS) was consulted regarding federally-listed species in the Project area. On June 28, 2019, a species list provided by the USFWS did not identify critical habitats or federally-listed terrestrial flora in the Project area (USFWS, 2019a). See **Appendix I, U.S. Fish and Wildlife Service – Technical Assistance.**

3.8.2 Potential Impacts

During construction, the Project will involve clearing, grubbing, and site disturbances related to construction. Short-term adverse impacts to rare, threatened, endangered or protected plant species in the Project area are not anticipated. Construction work will be within an urban area that has been previously disturbed and is heavily trafficked.

The Project involves the development of a residential facility in urban Honolulu. Long-term adverse impacts to rare, threatened, or endangered flora are not anticipated from the Project. The Project will not

result in a substantial decline or take of a federally-listed plant species or a substantial damage of a designated critical habitat.

3.8.3 Avoidance, Minimizations, and/or Mitigation Measures

Landscape designs may include the use of lowland native plant species to the extent practicable. Further mitigation measures are not anticipated to be required.

3.9 TERRESTRIAL FAUNAL AND AVIFAUNAL RESOURCES

3.9.1 Existing Environment

The Biological Survey prepared for the Project included a survey of terrestrial faunal and avifaunal resources in the Project area. See **Appendix H.**

Insects

One non-native insect species was recorded during the survey, the dung fly (*Musca sorbens*).

Mammalian

No mammalian species were seen in the Project area during the survey. An evening survey was conducted with the use of bat detector, and no activity from the endangered ʻōpeʻapeʻa or Hawaiian hoary bat (*Lasiurus semotus*) was detected. While not seen, non-native mammals, including domestic dogs (*Canis familaris*), domestic cats (*Felis catus*), mongoose (*Herpestes auropunctatus*), rats (*Rattus spp.*) and mice (*Mus domesticus*) may occur in the Project area. No mammalian species currently proposed for listing or listed under either the federal or State endangered species statutes were recorded at the Project Site (Hobdy, 2019).

The USFWS indicated that the Hawaiian hoary bat may occur in the Project area (USFWS, 2019a).

Avian

During the survey, two non-native species and two native species were observed during two site visits. The two non-native species, the zebra dove (*Geopelia striata*) and the common pigeon (*Columba livia*), were both common in and around the Project area (Hobdy, 2019).

The native manu o kū or white tern (*Gygis alba rothschildi*) was seen regularly flying above the Project area in small numbers and were judged to be uncommon. The white tern is an indigenous seabird that is found on many Pacific islands and atolls. Prior to 1959 white terns were not known to breed in the main Hawaiian Islands. However, their numbers have been growing on Oʻahu and can now be seen regularly in Honolulu, flying amongst tall buildings and landing in trees. Several were seen flying above the Project area. White terns do not carry federally protected, endangered or threatened status. Two indigenous migratory kōlea or Pacific golden-plovers (Pluvialis fulva) were seen as individuals in the Project area and were judged to be rare. The Pacific golden-plover is a migratory bird that spends its summers breeding and raising its young on arctic tundra, then flies south to spend its winters on Pacific islands. Many thousands winter in Hawaiʻi where they can be found in almost all habitats from sea level to mountain

tops. Pacific golden-plovers are quite common here and do not carry federally protected, endangered or threatened protected status. Both the White tern and kōlea are listed as protected species under the 50 CFR 10.13, Migratory Bird Treaty Act (Hobdy, 2019).

Waterbirds, such as the aeʻo or Hawaiian stilt (*Himantopus mexicanus knudseni*), ʻalae keʻokeʻo or Hawaiian coot (*Fulica alai*), ʻalae ʻula or common moorhen (*Gallinula chloropus sandvicensis*) or the koloa or Hawaiian duck (*Anas wyvlliana*) were not seen during the survey and no suitable wetland habitat occurs within the Project area. Seabirds, such as Hawaiian petrels (Pterodroma phaeopygia sandwichensii) and Newell's shearwaters (Puffinus newelli), were not seen during the survey, but may transit over the Project area when

flying between the ocean and nesting sites in the mountains during their breeding season (March through November) (Hobdy, 2019).

The USFWS indicated that the white tern may occur in the Project area (USFWS, 2019a).

3.9.2 Potential Impacts

Pursuant to Section 7, ESA, informal consultation was conducted with USFWS to determine the impact of the Project on federally-endangered resources in the Project area. In a letter dated July 26, 2019, the USFWS concurred that the Project "may affect, but is not likely to adversely affect" Hawaiian seabirds, Hawaiian hoary bats, or Hawaiian waterbirds in the Project area (USFWS, 2019b). See **Appendix J, U.S. Fish and Wildlife Service – Informal Consultation**.

The following short-term impact analysis is based off informal consultation with the USFWS:

- Hawaiian seabirds – Nighttime work is not anticipated. If nighttime work becomes necessary there is the potential that nocturnally flying seabirds, especially fledglings on their way to sea in the summer and fall, can become disoriented by exterior lighting. When disoriented, seabirds may collide with man-made structures and, if not killed outright, dazed or injured birds become easy targets of opportunity for feral mammals. However, an increase in light pollution due to the Project will be indistinguishable in urban Honolulu, and therefore is not likely to increase seabird fallout (USFWS, 2019b).
- Hawaiian hoary bat – During the clearing and grubbing phase of construction, woody plants or trees greater than 15 feet will not be removed or disturbed during the Hawaiian hoary bat's pup rearing season. Additionally, as discussed in Section 3.8.1, vegetation in the Project area consists of a few small to medium-sized trees in planter areas around the perimeter of the existing parking area and a variety of grasses and weeds (Hobdy, 2019); therefore, the likelihood that the Hawaiian hoary bat will utilize foliage and/or trees for nesting on the Project Site is not likely.
- Hawaiian waterbirds – The Project Site does occur near the concrete chanelized Nu'uanu stream, but this area is not suitable habitat for Hawaiian waterbirds, and their occurrence in the project area has not been observed. It is not probable that Hawaiian waterbird nests or chicks would be crushed as a result of the proposed project, as they are not known to occur within the project area. Therefore, the impacts are discountable. Because impacts from the proposed project are discountable, we concur with your determination that the proposed project may affect, but is not likely to adversely affect the Hawaiian waterbirds (USFWS, 2019b).

The Project involves the development of a residential facility in urban Honolulu. Long-term adverse impacts to rare, threatened, or endangered fauna are not expected from the Project. The Project will not result in a substantial decline or take of federally-listed insect, mammalian or avian species; a substantial damage of a designated critical habitat; or a substantial interference with daily or seasonal movements of migratory seabirds.

3.9.3 Avoidance, Minimization, and/or Mitigation Measures

During construction, the following mitigation measures will be implemented to minimize the potential for impacts to avifaunal species, such as Hawaiian seabirds, Hawaiian waterbirds and the Hawaiian hoary bat:

- Trimming of trees greater than 15-feet tall will not occur between June 1 and September 15, and barbed wire will not be used for fencing;

- If nighttime work becomes necessary, construction will be avoided during seabird fledgling season (September 15 through December 15) and outdoor lighting will be sensor activated or turned off to avoid seabird disorientation and fallout;
- All outdoor lights shall be fully shielded so that the bulb can only be seen from below bulb height and used when needed, and automatic motion sensors shall be installed or turned off when human activity is not occurring in the lighted area;
  Erosion control for earth disturbing activities will be employed to ensure that sediments are not delivered to drainages or waterways as a result of the Project;
- Construction crews will be informed of potential endangered species that may occur within or transit through the Project area and that any intentional physical interactions with identified endangered species will be explicitly prohibited;
- If a previously undiscovered nest is found after work begins, work will cease within a minimum radius of 100 feet of the nest, and USFWS will be contacted (808-792-9400) within 24 hours; and
- Contact USFWS within 24 hours of finding a downed seabird. If alive, place the bird in the cat kennel and contact Save Our Shearwaters (808-246-4348) immediately for further instruction on where to bring the bird (USFWS, 2019b).

No significant adverse long-term or cumulative impacts to fauna are anticipated. Further mitigation measures are not anticipated to be required.

4.0 PUBLIC SERVICES

4.1 TRANSPORTATION FACILITIES

4.1.1 Existing Environment

The MAR analyzed existing traffic operations at two intersections near the Project Site (Kukui Street/Maunakea Street and Kukui Street/River Street), estimated trip generation, reviewed site access and considered the Project's potential impacts on pedestrian, bicycle and transit modes (Fehr and Peers, 2019). See **Appendix E**, **Focused Mobility Analysis Report**.

Roadway System

Vehicle access/ to the Project Site is provided by Kukui Street and River Street. Egress from the Project Site is provided by River Street and a stop-controlled right turn onto North Vineyard Boulevard.

The analysis in the MAR is based on engineering methodologies published in the Highway Capacity Manual (HCM), published by the Transportation Research Board. The operations of roadway facilities are described with the term Level of Service (LOS). The HCM defines LOS as "a quantitative stratification of a performance measure or measures representing quality of service." HCM defines the six levels of service from the traveler's perspective, ranging from the best – LOS "A" – to the worst – LOS "F." LOS's "A," "B," and "C" are considered satisfactory levels of service. LOS "D" is generally considered a "desirable minimum" operating LOS. LOS's "E" and "F" are undesirable conditions. Intersection LOS is primarily based upon average delay in seconds per vehicle (sc/veh) (Fehr & Peers, 2019).

A description of the existing roadway system near the Project area is below:

- **River Street** is a local street that traverses in a mauka-makai direction and provides direct access to the Project Site. River Street is a one-way, one-lane street under the jurisdiction of City from

North Kukui Street to North Vineyard Boulevard. The posted speed limit is 25 mph. Makai of North Kukui Street, River Street becomes a pedestrian promenade and continues as a vehicular roadway makai of North Beretania Street;

- **North Vineyard Boulevard** is a major arterial road within the vicinity of the Project Site. It is a six-lane arterial that extends between Pālama Street and Lunalilo and is under the jurisdiction of State, Department of Transportation (HDOT). The posted speed limit is 30 mph. The intersections of North Vineyard Boulevard at River Street and Maunakea Street are signalized;
- **Kukui Street** traverses an ʻEwa-Diamond Head direction between Aʻala Street and Pali Highway. Kukui Street is a two-way, two-lane local street under the jurisdiction of the City, DTS. The posted speed limit of Kukui Street is 25 mph; and,
- **Maunakea Street** is a two-lane local street that is aligned in a mauka-makai direction. It is located on the Diamond Head side of the Project Site and connects North Vineyard Boulevard and Kukui Street. The posted speed limit is 25 mph. Maunakea Street is under the jurisdiction of DTS (Fehr & Peers, 2019).

The intersections of Kukui Street/Maunakea Street and Kukui Street/River Street were evaluated during weekday AM and PM peak periods (6:00 AM – 9:00 AM and 3:00 PM – 6:00 PM). The weekday AM peak hour of traffic occurred between the hours of 7:15 AM and 8:15 AM. Weekday PM peak hour of traffic occurred between the hours of 5:00 PM and 6:00 PM at the N Kukui Street/River Street intersection, and between 4:45 PM and 5:45 PM at N Kukui Street and Maunakea Street. Both intersections were found to function at a LOS C or better during the AM and PM peak hours (Fehr & Peers, 2019). See **Table 12, Existing (2019) Intersection Levels of Service.**

Public Transit Service

Bus service in the Project area is provided by Oʻahu Transit Services, which operates TheBus. The closest bus stops are located 0.1 mile away (or roughly a four-minute walk) from the Project Site on North Beretania Street at River Street (Stop ID: 439) and Nuʻuanu Avenue at North Vineyard Boulevard (Stop ID: 389). These bus stops serve about 25 different routes, which provide transit users good access to most destinations in and around Downtown Honolulu (Fehr & Peers, 2019).

Table 12: Existing (2019) Intersection Levels of Service

Intersection	Traffic Control	Peak Hour	Delay (seconds/vehicle)	LOS
1. North Kukui Street/River Street	Unsignalized	AM	7.6	A
		PM	7.5	A
2. North Kukui Street/Maunakea Street	Signalized	AM	21.3	C
		PM	23.5	C

Source: Fehr & Peers, 2019

The City is currently in the construction stages of its fixed rail transit system, Honolulu Authority for Rapid Transportation (HART) Rail, which begins in Kapolei and ends at Ala Moana Center in the PUC. The proposed transit system is being constructed in phases. The Chinatown Station No. 17 is planned to serve Chinatown, Pali, Downtown, and outlying residential areas, and is located approximately 0.4 mile southwest of the Project area. The station features ADA pedestrian access, bicycle parking, elevator and stairs, restroom, connections to the TheBus, and TheHandiVan pick- up and drop-off. The entire system is estimated to be operational by 2025. HART estimates that the operation of the rail system will remove approximately 40,000 vehicles from the roads by 2030 (HART, 2019).

Pedestrian and Bicycle Access

A description of the existing bicycle and pedestrian network near the Project area is below:

River Street – Project Site Sidewalks are provided along both sides of River Street, with an attached sidewalk on the Diamond Head side fronting the Project Site and a pedestrian pathway (separated by a landscaped buffer) on the ʻEwa side of the street adjacent to Nuʻuanu Stream. Marked crosswalks are provided at the River Street's intersection with North Kukui Street providing access from the Project Site to the River Street promenade. At the intersection with North Vineyard Boulevard a pedestrian signal is present providing a controlled crossing of this six-lane roadway. Designated bicycle facilities are not currently provided on River Street. Bicyclists are required to share the roadway with vehicles, although some cyclists choose to ride on the pedestrian path on the ʻEwa side of the street.

North Vineyard Boulevard includes sidewalks provided on both sides of the road. Crosswalks and pedestrian countdown signals are provided on the Diamond Head and makai legs of the intersection at Maunakea Street. As mentioned above, a pedestrian signal is provided at the intersection with River Street to provide a protected crossing of North Vineyard Boulevard. Separate or designated

bicycle facilities are not provided on Vineyard Boulevard in the vicinity of the Project. Bicyclists are required to share the roadway with vehicles.

Kukui Street includes sidewalks on both sides of the street. Crosswalks are provided across all roadway legs of the River Street intersection. Crosswalks and pedestrian countdown signals are also provided on all four legs of the Maunakea Street intersection. Separate or designated bicycle facilities are not provided on Kukui Street. Bicyclists must share the roadway with vehicles.

Maunakea Street includes sidewalks on both sides of the road. Crosswalks and pedestrian countdown signals are provided at the intersections with Kukui Street and Vineyard Boulevard. Separate or designated bicycle facilities are not provided on Maunakea Street. Bicyclists must share the roadway with vehicles (Fehr & Peers, 2019).

Pedestrian counts collected during the peak periods at the two study intersections indicated that the highest volumes of pedestrians crossing at a study intersection occurred during the PM peak hour, with 203 people crossing at the North Kukui Street/Maunakea Street intersection. Most pedestrians crossed Maunakea Street on the Diamond Head side of the intersection. The pedestrian pathways between the Project Site and the two nearest bus stops were found to provide adequate access in terms of pavement quality and limited conflicts with vehicles (Fehr & Peers, 2019).

Bicycle activity in the vicinity of the Project area is low, based on counts collected during the peak periods. A total of 11 bicyclists were observed at the North Kukui Street/River Street intersection during AM and PM peak hours, and 22 bicycles were observed at the North Kukui Street/Maunakea Street intersection during the AM and PM peak hours (Fehr & Peers, 2019).

4.1.2 Potential Impacts

Roadway System

During construction, short-term impacts to traffic circulation may occur; however, traffic impacts will be temporary and will cease with the completion of the Project. Traffic increases will result from construction crews traveling to and from the Project Site, as well as construction vehicles making deliveries and removing demolition debris.

Once construction is completed, the project is forecasted to generate 310 net new daily vehicle trips, five net new AM peak hour trips (0 inbound/5 outbound), and 11 net new PM peak hour trips (3 inbound/8 outbound). It should be noted that this forecast is a conservative estimation, as an existing daily driveway count was not completed for the survey (Fehr & Peers, 2019). The Project trip generation estimates are based on data that was developed using MainStreet, a web application developed by Fehr & Peers, and are summarized in **Table 13: Project Trip Generation Estimates**:

Table 13: Project Trip Generation Estimates

Project Component	Size	Daily Trips	AM Peak Hour			PM Peak Hour		
			In	Out	Total	In	Out	Total
Senior Adult Housing - Attached	156 units	577	11	20	31	22	19	41
Transit/Walk/Bike Trip Reduction[4]		267	-7	-13	-20	-12	-11	-23
Existing Trip Reduction[5]		--	-4	-2	-6	-7	0	-7
Total		**310**	**0**	**5**	**5**	**3**	**8**	**11**

Source: Fehr & Peers, 2019

The Project will generate few vehicular trips and is expected to have a negligible impact on traffic operations. Therefore, no roadway improvements are proposed. Vehicular access for the Project will be provided by a single driveway on River Street at the makai end of the Project Site. This driveway provides access to the Project's parking area provided on the second and third stories of the building, which will provide approximately 51 parking spaces. In addition, the driveway provides access to a loading area on the first floor that can accommodate one van or single-unit truck for deliveries or passenger loading (Fehr & Peers, 2019).

The Project is not anticipated to have a significant long-term or a cumulative adverse impact on the existing traffic network in the Project area; and/or substantially decrease the LOS of the existing roadway network (e.g. change in LOS A to LOS F).

Public Transit Service

The Project is not anticipated to have a significant long-term or a cumulative adverse impact to existing bus services in the Project area and/or substantially increase the need for public transportation. Existing bus services appear to be sufficient to serve the Project. Multiple bus stops are located within a reasonable walking distance of the Project Site, with the two closest bus stops located within a four-minute walk. Pedestrian access to these stops appears to be accessible for a disabled person utilizing a wheelchair or a walking aid. The Project will be approximately 0.4 miles from the proposed HART rail Chinatown station. This rail will enhance transit access and further reduce the need for Halewai`olu residents to use or own a car (Fehr & Peers, 2019).

Pedestrian and Bicycle Access

[4] Internal capture and active/transit trip reductions calculated using MainStreet web app (see **Appendix E** for details).

[5] Existing trip reduction based on Project Site driveway counts conducted in March 2019.

Pedestrian circulation will be provided via the sidewalk fronting the Project Site along River Street, as well as a pedestrian alley located on the mauka side of the building providing access to a stairwell. All pedestrian access within the building is provided by stairs or elevators. The Project will provide bicycle parking stalls on levels 1-4 (Fehr & Peers, 2019).

The Project is not anticipated to have a significant long-term or a cumulative adverse impact to existing or proposed bicycle and pedestrian networks in the Project area. The Downtown TOD Plan identifies pedestrian intersection improvements that are to be made at the River Street's intersections with Kukui Street and North Vineyard Boulevard. A pedestrian signal was recently installed at River Street's intersection with North Vineyard Boulevard. The Project will not conflict with these improvements or significantly impact the existing sidewalk provided along its frontage. *The O'ahu Bike Plan* (2012) provides guidance on desired bike facilities across the island of O'ahu. This plan is currently being updated. The *O'ahu Bike Plan Update (*2018 Draft) identifies a proposed bicycle path on the 'ewa side of River Street, and proposed bicycle lanes on both sides of North Vineyard Boulevard and North Kukui Street. The Project will not conflict with the installation of these bicycle facilities (Fehr & Peers, 2019).

4.1.3 Avoidance, Minimizations, and/or Mitigation Measures

Roadway System

During construction, the following mitigation measures will be implemented to minimize disruptions to traffic:

- The General Contractor may schedule heavy truck activity as much as possible between the hours of 9:00 a.m. and 3:00 p.m. on weekdays. Work on weekends may also be avoided to minimize traffic disruptions. The Honolulu Police Department (HPD) will be notified prior to periods of heavy truck activity or during transport and operation of heavy equipment.
- The General Contractor will be required to keep all construction vehicles in proper operating condition and ensure that material loads are properly secured to prevent dust, debris, leakage, or other adverse conditions from impacting public roadways.
- Traffic control barricades, cones, signage, and lighting will be used as necessary to alert drivers and delineate construction boundaries. Staging areas will be located on site. Approach signs and a flag person will be positioned to direct traffic through temporary traffic control zones as necessary.
- Construction schedules will be coordinated with other nearby properties that have planned improvements to ensure minimal effects on local streets.

Public Transit Service

No mitigation measures are proposed.

Pedestrian and Bicycle Access

No mitigation measures are proposed.

Future Traffic Plans to be Submitted, As Required by DPP

1. A Construction Management Plan (CMP) will be submitted to DPP for review and approval prior to the issuance of demolition/building permits for major construction work. The CMP will identify the type, frequency, and routing of heavy trucks and

construction related vehicles. Every effort will be made to minimize impacts from these vehicles and related construction activities.

The CMP will identify and limit vehicular activity related to construction to periods outside of the peak periods of traffic where feasible, utilizing alternate routes for heavy trucks, provisions for either on-site or off-site staging areas for construction related workers and vehicles to limit the use of on-street parking around the Project site, and other mitigation measures related to traffic and potential neighborhood impacts. Preliminary or conceptual traffic control plans will be included in the CMP. The Applicant will document the condition of roadways prior to the start of construction activities and provide remedial measures, as necessary, such as restriping, road resurfacing, and/or reconstruction if the condition of the roadways has deteriorated as a result of the related construction activities.

2. A Traffic Management Plan (TMP) will be submitted and approved prior to the issuance of the (temporary) Certificate of Occupancy (CO). The TMP will demonstrate how the loading area will be managed with the mix of residential drop-off/pick-up as well as trash pick-up and commercial loading activities.

3. Updates to the Focused Mobility Analysis Report (MAR) will be provided approximately one year after the issuance of the CO, to validate the traffic projections, trip reduction rates, distribution, and assignment contained in the initial MAR dated August 6, 2019.

4.2 PARKS, OPEN SPACE AND RECREATION FACILITIES

4.2.1 Existing Environment

The Project Site is near several recreational facilities in the Downtown-Chinatown community. The Project Site is bounded by River Street to the northwest. The sidewalks along River Street serve as a promenade also known as Sun Yat Sen Mall along the Nu‘uanu Stream, located approximately 54 feet north of the Project Site. Further south, River Street becomes a pedestrian-only promenade adjacent to the Chinese Cultural Plaza, which is host to various cultural events throughout the year. The Foster Botanical Garden, which is managed by the City, Department of Parks and Recreation (DPR), is located approximately 246 feet northeast of the Project Site. Beretania Community Park, managed by DPR, is located approximately 0.16-mile northwest of the Project Site. Kauluwela Community Park, managed by DPR, is located approximately 0.18-mile north of the Project Site. See **Figure 16: Parks and Recreation Facilities**.

4.2.2 Potential Impacts

During construction, a short-term, increase in traffic congestion may have effects on the public accesses to the Sun Yat Sen Mall along the Nu‘uanu Stream. Minor impacts to the existing noise conditions and air quality may also occur as a result of construction activities. However, these construction-related impacts will be temporary, and will cease upon Project completion.

Residents of the Project will benefit from the existing surrounding community and social networks, and the convenient proximity to recreation activities and social opportunities. Access to parks and open space would give senior residents an opportunity to maintain their health by providing ample space to walk. Moreover, the Project will include recreational facilities for future senior residents, such as a garden,

recreation deck, computer room, and pet area. The multi-purpose and activity rooms on the ground floor will also be available for residents and may host neighborhood events, thus encouraging social networking with the surrounding community.

The Project is not anticipated to have a significant adverse long-term impact on the existing parks and recreational resources, as the proposed Project will not involve a long-term loss of access to, permanent change to or conflict with any parks or recreational resources.

4.2.3 Avoidance, Minimization, and/or Mitigation Measures

No mitigation measures are proposed.

4.3 FIRE, POLICE AND MEDICAL SERVICES

4.3.1 Existing Environment

Fire protection services on O‘ahu are provided by the City, HFD. HFD responds to emergencies including, but not limited to fires, emergency medical calls, hazardous materials incidents, motor vehicle accidents, natural disasters and technical rescues. The Central Fire Station 01 is located approximately 0.3-mile south of the of the Project Site at 104 South Beretania Street

Police protection services on O‘ahu are provided by the City, HPD. HPD divides the island into eight patrol districts; district stations are located in Kalihi, Pearl City, Kapolei, Wahiawa, and Kaneohe, and police substations are located in Waianae, Kailua, Kahuku, Waikiki, and Chinatown. The Project area is within District 1 – Central Honolulu, Sector 1, which is based at the Downtown Substation located approximately 0.3 miles southwest of the Project Site at 79 North Hotel Street.

Emergency medical service is provided by the City’s Emergency Services Department (DEM), Emergency Medical Services (EMS) Division. EMS operates 22 ambulance units under two districts. All ambulance units are designated as advanced life support units, meaning they are staffed by at least two people. The Project area is served by District 2, which includes the southeast region of O‘ahu. HFD also responds to medical emergencies, providing first aid in coordination with EMS.

Medical services in close proximity to the Project Site include the Kuakini Medical Center, located approximately 0.47-mile northeast, and the Queen’s Medical Center, located approximately 0.6-mile southeast of the Project Site. Kuakini Medical Center is a private hospital licensed for 212 acute care beds that includes 188 medical/surgical beds and 24 critical care beds. The Queen’s Medical Center hospital is licensed for 505 acute and 28 sub-acute care beds. Queen’s serves as the major referral center for cancer, heart disease, neuroscience, orthopedics, surgery, emergency medicine, and behavioral health, and has the only organ transplantation program in the state. Queen’s is also the state’s designated trauma center - the first and only Level I trauma center in the state.

Figure 16: Parks and Recreation Facilities

4.3.2 Potential Impacts

During construction, there may be an increase in phone calls to HPD regarding Project-related traffic and noise. There may also be minor adjustments to HPD's manpower if the Project requires traffic control during the construction. Additionally, construction activities could potentially increase the demand on police and medical services should worker safety emergency situations arise. Emergency vehicle access to the Project Site will be maintained for the duration of construction. Increased calls to HFD are not expected to result from construction activities.

The Project will increase the population within the immediate Project area; however, the residential facility will not substantially increase the population in the region, as it is assumed the future residents will be relocating from other communities in Honolulu. The Project is not anticipated to have a significant long-term or a cumulative adverse impact on existing fire, police and medical services, as the Project will not result in an appreciable increase on the demand for such services; or lead to an obstruction or reduction of such services, which would endanger the health and safety of individuals on the Project Site or surrounding community.

4.3.3 Avoidance, Minimization, and/or Mitigation Measures

In the interest of protecting seniors of the building, the residences will be private with controlled access and only residents (or their guests) will be allowed entry to the residences. A resident manager will also remain onsite.

The residential facility will be designed and built in compliance with applicable fire code requirements, as listed in ROH Chapter 20. The residential facility will be provided with approved water supply and flow required for fire protection. Construction drawings will be submitted to the Fire Prevention Bureau of HFD for review and approval. Coordination with HPD during construction will be necessary to mitigate traffic congestion and ensure public safety. Further mitigation measures are not anticipated to be required.

4.4 EDUCATION FACILITIES

4.4.1 Existing Environment

The Project Site is located within the State Department of Education's (DOE) McKinley Complex (Kaimuki-McKinley-Roosevelt Complex Area), which includes the following schools: Kaahumanu Elementary, Kaiulani Elementary, Kauluwela Elementary, Lanakila Elementary, Likelike Elementary, Royal Elementary, Central Middle School, and McKinley High School. These schools serve approximately 6,440 students (DOE, 2017). Public charter schools located within the McKinley Complex include the Myron Thompson Academy and Voyager School. The Complex also includes the McKinley Community School.

4.4.2 Potential Impacts

The Project involves a residential facility for seniors aged 62 and older. Therefore, the Project is not anticipated to have a significant long-term or cumulative adverse impact on the public-school system.

4.4.3 Mitigation Measures

No mitigation measures are proposed.

4.5 POTABLE WATER

4.5.1 Existing Environment

The City, BWS constructs, operates and maintains O'ahu's municipal potable water system, which comprises of an interconnected distribution network of reservoirs, wells, shafts, water tunnels, booster and pumping stations and water mains.

A *Halewai'olu Senior Residences Preliminary Engineering Report* ("Preliminary Engineering Report") was prepared for the Project by Gray, Hong, Nojima & Associates, Inc. in April 2019. See **Appendix K, Preliminary Engineering Report**. The Preliminary Engineering Report confirmed that the existing BWS potable water system serving the Project Site consists of an 8-inch diameter water line which runs within River Street. Four water laterals serve the Project Site from the 8-inch water line. There are nine abandoned water meter boxes located within the concrete sidewalk fronting the Project Site (Gray et al., 2019). See Attachment C-4 of **Appendix K** for locations of existing utilities.

According to a letter from the BWS, dated March 7, 2019, "the existing water system is adequate to accommodate the domestic demands and offsite fire protection for the proposed development." However, the final decision on the availability of water will be confirmed during the building permit application approval process (Gray et al., 2019).

4.5.2 Potential Impacts

During construction, the Project will involve the use of potable water for dust control, vehicle wash down, concrete mixing, general housekeeping activities, and for pipe pressure testing. However, quantities of water required for these uses are relatively minor, and these uses will be intermittent and will cease upon Project completion.

The Project involves the development of a residential facility with 156 multifamily units. The projected average daily demand per multifamily unit is 400 gallons per unit. Therefore, the Project is anticipated to require 62,400 gallons per day (GPD) for the 156 units (Gray et al., 2019). The Project is not anticipated to result in a significant long-term or cumulative adverse impact on the potable water system as the system is adequate to support the Project. The Project does not involve the creation of point-source pollution that leads to permanent damage to the watershed, surface waters or aquifers that replenish O'ahu's potable water supply; nor does the Project involve a substantial alteration to any portion of the existing potable water system; or a substantial consumption of potable water.

4.5.3 Avoidance, Minimization, and/or Mitigation Measures

No mitigation measures are proposed. The HSD will continue to consult with BWS as the Project moves forward to the building permit application stage.

4.6 ELECTRICAL AND COMMUNICATIONS FACILITIES

4.6.1 Existing Environment

The Project Site is served by an existing 167 KVA, 120/240V, single phase, pad- mounted Hawaiian Electric Company (HECO) transformer located at the southern driveway, which connects to underground HECO duct lines that are routed along River Street, Maunakea Street, North Kukui Street, and North Vineyard

Boulevard. A HECO handhole located on the sidewalk next to the southern driveway currently distributes primary utility power to the Project Site (Gray et al., 2019).

The Project Site is served by Spectrum's telecommunications services via Hawaiian Telcom (HT) underground conduit system. Spectrum uses the HT pull box located next to the southern driveway near the HECO handhole to deliver telephone, internet and cable television services. HT has confirmed that the existing infrastructure is adequate to provide telephone and high-speed internet services to the Project Site, in accordance with a will serve letter from HT, dated September 27, 2016. The HT pull box will be the point of connection for both HT and Spectrum services. See Attachment E-1 of **Appendix K** for the HT will serve letter. (Gray et al., 2019).

4.6.2 Potential Impacts

During construction, the Project is not anticipated to create a delay or disruption in the provision of electrical power for the surrounding community. Construction activities will not adversely impact the existing communications system.

The Project may include extending new HECO underground conduits, installing new handholes and manholes, and upsizing primary utility conductors, pending HECO's upgrade of underground duct lines and circuits. The Project may include the installation of fiber optic cables to deliver telephone, high-speed internet services and digital television services. Associated off-site improvements will include telecommunication system improvements, including extending new underground conduits, installing new pullboxes, handholes and manholes, and supplementing the existing underground support structure (Gray et al., 2019).

The Project is not anticipated to have a significant long-term or a cumulative adverse impact on the existing electrical or communications facilities, as the electrical power demands do not exceed the utility providers' service capacity and the Project is not anticipated to create a delay or disruption in provision of electrical power or communications for the surrounding community.

4.6.3 Avoidance, Minimization, and/or Mitigation Measures

In the event of a utility power outage, the General Contractor should be prepared with a backup power generator on-site. HSD will continue to coordinate with the HECO, HT, and Spectrum as the Project progresses. The Project will obtain necessary permits and regulatory approvals prior to construction.

4.7 WASTEWATER FACILITIES

4.7.1 Existing Environment

The Project Site is served by an existing 6-inch sewer lateral that connects to a 12-inch sewer main located in River Street, owned and maintained by the City, ENV. The 6-inch sewer lateral is located approximately at the midpoint of the northwestern boundary fronting River Street (Gray et al., 2019).

4.7.2 Potential Impacts

During construction, the Project will not have an adverse impact on the existing wastewater facilities. The General Contractor will provide portable toilets for use by the construction workers. Wastewater from the portable toilets will be collected and discharged into an acceptable sewer manhole designated for receiving septage.

The Project involves a residential facility with 156 units. The estimated design flow for 156 units (716.8 persons) is 152,388 GPD. A Sewer Connection Application (2019/SCA-0111) for the Project was issued by the City, DPP on January 29, 2019 (Gray et al., 2019). See Attachment C-6 of **Appendix K**.

The Project is not anticipated to result in a significant long-term or a cumulative adverse effect on the existing wastewater system, as the wastewater collection system is adequate to support the proposed development.

4.7.3 Avoidance, Minimization, and/or Mitigation Measures

No mitigation measures are proposed.

4.8 SOLID WASTE COLLECTION AND DISPOSAL

4.8.1 Existing Environment

The City, ENV, Refuse Division is the agency responsible for the collection, transport and disposal or O‘ahu’s solid waste. Liquid and solid waste is disposed of at the Campbell Industrial Park’s H-POWER Plant and the Waimānalo Gulch Sanitary Landfill (WGSL) in Kapolei. Construction and demolition (C & D) solid waste is handled of by the privately-owned PVT Land Company’s landfill, the only publicly-accessible, commercial landfill on O‘ahu. The PVT landfill accepts approved contaminated soil for disposal or use in solidification of liquid wastes and sludge material for processing or disposal.

4.8.2 Potential Impacts

During construction, liquid waste, solid waste and C & D debris will be generated. Liquid waste will be contained in a controlled area such as a holding pit, sediment basin, or portable tank; containment areas will be impermeable and leak free and will not be located where accidental release of the liquid will discharge into storm drains. The General Contractor will be responsible for the disposal of solid waste and C & D debris at the appropriate above-mentioned landfills in accordance with City, State and federal regulations. The General Contractor will also be responsible for ensuring that the loads are properly secured and covered to prevent the inadvertent loss of solid waste while in transit and to prevent the commingling of rainfall with solid waste.

The Project involves the development of a residential facility with a total of 156 units. A private company will pick up and transport solid waste generated by this Project. While the Project will lead to a generation of solid waste, the Project is not anticipated to lead to a substantial increase in the generation of liquid and solid waste, nor will the Project lead to a delay or disruption in the City’s collection of solid waste for the surrounding community. Therefore, no significant long-term or cumulative adverse impacts to the City’s solid waste collection and disposal facilities are anticipated.

4.8.3 Avoidance, Minimization, and/or Mitigation Measures

Disposal of solid waste and hazardous materials will be handled in accordance with City, State and federal rules and regulations. All construction-related materials and debris will be disposed of at an approved landfill site. The General Contractor will ensure that waste loads are properly secured and covered to prevent the inadvertent loss of waste along the roadway and the commingling of rainfall with waste materials while it is in transit.

4.9 STORM WATER AND DRAINAGE

4.9.1 Existing Environment

The City, DFM, Storm Water Quality Branch (SWQB), is responsible for maintaining the drainage system on O'ahu. The Project Site is almost entirely covered by impervious surfaces, consisting of an existing building and an asphalt paved parking lot. Storm water runoff flows from the Project Site toward a concrete swale near the southern most driveway and into a catch basin on River Street. The existing drainage system fronting the Project Site consists of concrete gutters along both sides of River Street and curb inlets/catch basins located at the northwest boundary and near the intersection of River Street and North Kukui Street. Underground 18-inch diameter, reinforced, concrete pipes run from the catch basins and discharge into the adjacent Nu'uanu Stream (Gray et al., 2019).

4.9.2 Potential Impacts

Construction will involve excavation, trenching and other ground disturbing activities. The total area of construction ground disturbance will not exceed the 1-acre size threshold which triggers the need for a NPDES permit, construction storm water discharges from DOH, CWB, in accordance with HAR, Chapter 11-54 and 11-55.

Once construction is completed, approximately 94% of the Project Site will be impervious surfaces of either paved or roof topped areas. In accordance with the City's R*ules Relating to Storm Drainage Standards*, the estimated storm water runoff is 3.06 cubic feet/second. On-site storm water will be collected by a drain inlets, biofiltration cells and underground drainage pipes which are anticipated to connect to the existing catch basin located in River Street (Gray et al., 2019).

Any increase in runoff caused by an increase in impervious surfaces will be retained on site as required to meet City standards, and onsite drainage will be designed to flow away from the building, towards landscaped areas.

The Project is not anticipated to have a significant, long-term or cumulative adverse impact to the City's existing storm drainage system. Moreover, storm water runoff will be pre-treated on site before entering the City's storm water drainage system. Further mitigation measures are not anticipated to be required.

4.9.3 Avoidance, Minimization, and/or Mitigation Measures

During construction, BMPs will include the installation of a stabilized construction entrance/exit, catch basin inlet protections, and temporary filter sock perimeter controls. See additional discussion in **Section 3.4.3**. See Sheets C005 and C006 in **Appendix A.**

The Project will comply with DPP's Administrative Rules, Title 20, Chapter 3, *Rules Relating to Water Quality*. Post-construction storm-water requirements include retaining as much water on-site as feasible with the use of LID retention BMPs, whilst using a biofilter to filter residual storm water that is not retained

on-site. The Project Site will be permanently stabilized using vegetative covering, pavement or equivalent, prior to the removal of erosion and sediment measures. For a full list of post-construction storm water BMPs, see Section 3.4 of **Appendix K**.

4.10 HAZARDOUS WASTES AND MATERIALS

4.10.1 Existing Environment

A *Hazardous Materials Assessment Survey* ("HMAS") was prepared by Ford & Associates, Inc. in April 2019; see **Appendix L, Hazardous Materials Assessment Survey**. The HMAS was performed of the interior and exterior portions of the existing building on the Project Site. The HMAS resulted in the identification, bulk sample collection, and laboratory analyses of suspect hazardous materials, such as asbestos-containing materials (ACM), lead-based paint (LBP). The HMAS confirmed that nine materials in the existing building contain ACM above the regulatory level of 1%, as defined by EPA and DOH. The HMAS did not find LBP above the EPA/HUD regulatory level of 0.5% lead by weight; however, seven paint samples reported lower concentrations of lead. Other potentially hazardous materials observed on the Project Site include the following: Polychlorinated Biphenyls- Containing (PCB) units such as fluorescent lighting fixtures; mercury-containing fluorescent bulbs and high intensity discharge lamps; chlorofluorocarbon (CFC)-containing air conditioning units; ionizing radiation smoke detectors containing a small radioactive source (typically Americium 241); and emergency exit light fixtures that contain a rechargeable lead-acid battery (Ford & Associates, 2019).

Phase I Environmental Site Assessment

"Michaels Development Company ("Client") retained Bureau Veritas North America, Inc. (Bureau Veritas) to conduct a Phase I Environmental Site Assessment ("ESA" or "assessment") of Halewaiolu Residences property located at 1331-1347 River Street (Tax Map Key Number [TMK]: [1] 1-7-006: Parcel 012) in Honolulu, Oahu, Hawaii (the "subject property"). The objective of the assessment was to provide an independent, professional opinion regarding the presence or absence of recognized environmental conditions, as defined by ASTM International (ASTM), associated with the subject property."
A complete copy of the Phase I Environmental Assessment is provided in **Appendix R**.

FINDINGS AND OPINIONS

"Bureau Veritas has performed a Phase I ESA in conformance with the scope and limitations of ASTM Practice E1527-13 for Halewaiolu Residences located at 1331-1347 River Street (Tax Map Key Number [TMK]: [1] 1-7-006: Parcel 012) in Honolulu, Oahu, Hawaii (the "subject property"). Any exceptions to, or deletions from, this practice are described in Sections 1.2 and 1.3 of this report.

This assessment has revealed no evidence of recognized environmental conditions, as defined by ASTM, in connection with the subject property, except for the following:

A. **Former Auto Repair Facility on the Northeast Adjoining Property-** The 1950 and 1955 fire insurance maps depicted an "Auto Repair" on the northeast adjoining property. The 1955 fire insurance map also depicted an "Oil and Grease Storage" on the northeast adjoining property.

   This is considered a recognized environmental condition because there is a potential for past releases of petroleum hydrocarbons and other chemicals from the northeast adjoining

property to migrate to the subject property. Bureau Veritas recommends conducting a subsurface investigation along the northeastern boundary of the subject property, including soil and groundwater sampling with laboratory analyses.

However, this assessment has revealed the following environmental conditions, which are not considered recognized environmental conditions, as defined by ASTM, in connection with the subject property:

B. **Suspect ACM** –The building on the subject property was constructed in 1959 and may contain ACM. Suspect ACM were observed in the subject building, including vinyl floor tiles with associated mastic, drop and hard wall plaster. The building may also include suspect ACM that were hidden from view, such as caulking or sealant between building components and roofing materials.

   This finding is not considered a recognized environmental condition because asbestos is not an ASTM issue. However, prior to any activities (i.e., repair, renovation, demolition) which may disturb suspect ACM, these and similar materials should be sampled and analyzed for possible asbestos content. If these materials are found to contain asbestos, the building owner or leased space tenant may be required to comply with applicable United States Environmental Protection Agency (EPA), Occupational Safety and Health Administration (OSHA), National Emission Standards for Hazardous Air Pollutants (NESHAPS), and state and local regulations.

C. **Suspect LBP-** The subject property is improved with a multi-tenant building constructed in 1959. Therefore, LBP could be an issue at the subject property. The way to determine if LBP is an issue is through sampling and laboratory analysis to determine the presence or absence of LBP.

   This finding is not considered a recognized environmental condition because LBP on buildings is not considered an ASTM issue. Sampling and analysis should be conducted prior to renovation or demolition activities that may disturb painted surfaces. If the paints are found to contain lead, the building owner or leased space tenant may be required to comply with applicable USEPA, and state and local regulations."

A Phase II Environmental Site Assessment was conducted to further investigate concerns presented in this Phase I Environmental Site Assessment.

Phase II Environmental Site Assessment

"Halewaiolu Senior Development, LLC retained Ford & Associates, Inc. (FAI) to perform a Phase II Environmental Site Assessment (ESA) for the Halewaiolu Residences Redevelopment Project, located at 1331-1347 River Street (Tax Map Key Number [TMK]: [1] 1-7-006: Parcel 012), in Honolulu, Oahu, Hawaii (herein referred to as the "site"). A Site Location Map showing the location of the site is included as Figure 1, located behind the *Figures* tab.

The site is the current location of a two-story, multi-tenant commercial building intended for redevelopment. In July 2015, Bureau Veritas North America, Inc. (BVNA) conducted a Phase I ESA of the

site to assess for the presence of recognized environmental conditions (RECs) related to historical use (BVNA, 2015). Based on this investigation, BVNA identified the former presence of automobile repair structures and an oil and grease storage area on the northeast adjacent property.

Therefore, the purpose of this investigation was to perform subsurface soil and groundwater sampling and analysis at the site to assess for the potential migration of chemicals of potential concern (COPC) from these historical features on the neighboring property."

SUMMARY AND CONCLUSIONS

"Based on review of the fire insurance maps from 1950 and 1955, the northeast adjoining property was occupied by a structure labeled "Auto Repair." Furthermore, on the 1955 fire insurance map, there was an additional structure on the northeast adjoining property labeled "Oil and Grease Storage." Therefore, the purpose of this investigation was to perform subsurface soil and groundwater sampling and analysis at the site to assess for the potential migration of COPC from these historical features on the neighboring property.

FAI mobilized to the site on April 1, 2019 to perform soil and groundwater sampling activities. During this time, FAI supervised Geotek, a drilling subcontractor, during the drilling of three borings at the site (identified as B-1 through B-3). Drilling and subsurface soil sampling were performed using the direct push drilling method. Soil samples were collected using the multi-increment sampling approach recommended by the HDOH (HDOH, 2017b). In each boring, one soil sample was collected from the capillary fringe. Following completion of each boring, Geotek installed a temporary groundwater well consisting of 1-inch diameter Schedule 40 PVC well casing, with 0.010 inch screen size. Groundwater purging and sampling was performed following installation, using a low-flow sampling technique (HDOH, 2017b).

In total, three soil samples (identified as *B-1*, *B-2*, and *B-3*) and three groundwater samples (identified as *MW-1* through *MW-3*) were collected from the site and analyzed for the following:

- TPH-GRO, DRO, and RRO using EPA Methods 8015M.
- Total Lead and Cadmium using EPA Methods 6020B/3050B/3005A.
- PCBs using EPA Methods 8082A/3550C/3510C.
- VOCs using EPA Methods 8260C/5030B.
- PAHs using EPA Method 8270D/3550C/3010C.

Based upon the laboratory analytical results, no COPC were detected above the laboratory reporting limits, or the Unrestricted and C/I EALs in either the soil samples or groundwater samples. Therefore, it does not appear that the site has been impacted by historical features on the neighboring property, and no further investigation appears necessary at this time."

A complete copy of the Phase II Environmental Assessment is provided in **Appendix S**.

4.10.2 Potential Impacts

During construction, the Project will involve demolition of the existing building, containing hazardous materials. As a result, the following hazardous materials will require removal and proper disposal prior to demolition:

- ACM must be properly removed and disposed.
- Fluorescent light ballasts and high intensity discharge light fixtures be inspected for PCB units as well as mercury-containing waste.
- Two pad-mounted, split-system air-conditioning units containing CFC should be removed and recycled.
- No special handling or disposal will be required when disturbing LBP.
- Ceiling-mounted smoke detectors that have radioactive sources.
- Emergency exit-light fixtures that rechargeable lead-acid battery (Ford & Associates, 2019).

The Project, as a multi-family dwelling for seniors, is not anticipated to have a significant long-term or cumulative adverse impact on the use of hazardous wastes and materials. The Project involves the removal of existing hazardous materials from the Project Site; and therefore, a minor beneficial impact on surrounding environment.

4.10.3 Avoidance, Minimization, and/or Mitigation Measures

HSD will coordinate with the HDOH, Asbestos Abatement Office prior to demolition and work with a General Contractor who is trained in LBP and ACM abatement to safely remove hazardous materials and limit any potential exposure to anyone who may be onsite. ACM materials will be properly removed and disposed of at an approved waste depository facility prior to general demolition/construction activities. A licensed asbestos abatement contractor shall conduct the removal and disposal work under the supervision of a qualified industrial hygiene professional. Additionally, all demolition and construction activities would adhere to the provisions of the HDOH's *Guidance for Construction and Demolition Waste Disposal* (HDOH, 2013) to ensure proper handling of potentially contaminated materials. All abatement work will be performed per all applicable State and federal requirements and guidelines. Upon completion of the work, all required clearances will be provided for the abated areas of work and LBP chips will be HEPA-vacuumed from the surrounding ground and placed in DOT-approved disposal containers. If there are any potential hazardous wastes or materials found during construction that were not identified during the survey, the General Contractor should make a hazardous waste determination in accordance with the HAR, Chapter 11-262-11, *Hazardous Waste Management*, and then properly dispose the hazardous material to an approved waste facility.

Fluorescent light ballasts not displaying the "No PCBs" indication should be removed from the light fixture, placed in a State-approved waste container/drum, properly labeled, and disposed as PCB waste. PCB waste generated in the State must be shipped to an approved waste depository facility located in the Continental U.S. for final disposal. All lighting fixtures and high intensity discharge lamps that may contain mercury shall be managed in accordance with the 40 CFR Part 273. Bulbs/lamps may be recycled, if possible. CFC-containing units, ionizing radiation smoke detectors, and emergency exit light fixtures shall be removed and recycled in accordance with current regulatory requirements prior to demolition.

During construction, the Contractor shall also prevent or reduce the discharge of hazardous materials to storm water through proper material use and waste disposal. Construction materials and hazardous substances, stockpiles and other sources of pollution shall not be stored in buffer areas, near areas of concentrated flow, or areas abutting the MS4, receiving waters, or drainage improvements that discharge off-site. In the unlikely event that hazardous materials are discharged to the MS4, the DFM, HFD, and HPD shall be immediately notified, and a written report shall detailing the pollutants discharged, reasons for the discharge, and the measures that will be taken to prevent a reoccurrence of the discharge will be submitted to DFM.

5.0 SOCIOECONOMIC, HISTORIC AND CULTURAL ENVIRONMENT

5.1 SOCIO-ECONOMIC ENVIRONMENT AND DEMOGRAPHICS

This section details the Project's potential impacts on the following socio-economic indicators: population and housing, economic and public fiscal impacts, employment and earnings, and social networks. To support the analysis, *Halewai'olu Senior Residences 2019 Market Study* ("Market Study") was prepared by Ricky Cassiday in 2019; see **Appendix B**. Additionally, the *Halewai'olu Senior Residences Economic and Fiscal Impact Assessment* ("EFIA") was prepared by PBR Hawai'i and Associates (PBR) in 2019; see **Appendix M, Economic and Fiscal Impact Assessment**.

5.1.1 Existing Environment

Population and Housing

Table 14: Estimated Demographics Data for 2018 shows various summary data on current overall population demographics of the State, City, and the Urban Honolulu Census Designated Place (CDP), is generally comparable to the PUC.[6] An estimated 19.2% of the population in the Urban Honolulu CDP is over the age of 65, compared to 18.4% in Hawai'i (U.S. Census Bureau, 2018).

According to DBEDT's *Population and Economic Projections for the State of Hawai'i to 2045 (2018),* population aging is one of the most prominent features of the State's population trend, increasing by 3.3% annually across the State on average. Honolulu's senior population is projected to significantly increase over other segments of the population from 2020-2040. The projected population for those aged 65 to 84 is 154,087 in 2020, 175,938 in 2025 and 190,661 in 2040 (Cassiday, 2019). Figure 4: Population Growth Rates in **Section 2.5** illustrates the demographic changes projected over the next 20 years in the City.

Table 14: Estimated Demographics Data for 2018

	Urban Honolulu CDP	City	Hawai'i
Population	347,397	980,080	1,420,491
Race			
White	17.7%	21.7%	25.6%
African American	1.7%	2.8%	2.2%
Asian	54.1%	43%	37.6%

Native Hawaiian/Pacific Islander	8.1%	9.6%	10.2%
Two or More Races	17.4%	22.6%	24%
Hispanic/Latino	7.0%	10%	10.7%
Age			
65 and Over	19.2%	17.7%	18.4%
Median Income by Household	$65,707	$80,078	$74,923
Persons Below Poverty Level	11.6%	8.3%	8.8%

[6] DBEDT notes that the former Honolulu CDP was separated in 2010 into 3 areas – Urban Honolulu CDP, East Honolulu CDP and a portion placed in the already existing Hickam CDP. Comparably, the PUC is defined as extending "from the core of historic downtown Honolulu to Pearl City in the west and Waialae-Kahala" (DPP, 2004).

	Urban Honolulu CDP	City	Hawai'i
Median Home Value	$628,300	$626,400	$563,900
Median Gross Rent	$1,411	$1,653	$1,507
Median Household Size	2.62	3.06	3.02

Source: U.S. Census Bureau, July 1, 2018 estimates

Population trends will continue to impact the housing demand on the islands. According to the 2010 Census, the total number of housing units in the City was 329,724, with 92% of the units occupied. Approximately 26,000 units were vacant, with about one-third of them or 9,477 accessible to those seeking a housing unit. Most of the units were in Waikiki and Makiki and remain unaffordable to households with low- to moderate incomes. Thus, large numbers of low- to moderate-income households have very few options for housing. Honolulu has been named as the least affordable housing market in the nation in a number of studies and is rated one of the lowest in the nation, in terms of the rental unit vacancy rate (Cassiday, 2019).

Economic and Public Fiscal Impacts

The State's main source of revenue, in terms of Gross Domestic Product (GDP), is from industries such as "Government," "Real Estate, Rental, & Leasing," and "Accommodation & Food Services." Combined, these industries account for approximately 50% of the of the State's GDP. Hawai'i's GDP reached approximately $92 billion in 2018 (DBEDT, 2018).

The City's main source of revenue is real property taxes and a 0.5% surcharge in Gross Excise Tax (GET) collections (PBR, 2019).

Employment and Earnings

According to the Bureau of Labor Statistics (BLS), Urban Honolulu has a civilian labor force of 450,000 in August 2019. A majority of persons are employed in the following sectors: Government; Trade, Transportation and Utilities, Leisure and Hospitality; and, Professional and Business Services (BLS, 2019). The most recent unemployment rate for the City published by the DLIR was 2.8% (DLIR, 2019).

Persons below the poverty level are reflected in **Table 14**. According to DBEDT's *2018 State of Hawai'i Data Book,* the poverty level in the City is 8.7% among persons aged 18 to 64 years old and 7.7% among persons aged 65 years and over. By contrast, the Project Site is located in the HUD-defined 2019 QCT 51.00 with a poverty rate of 22.5%[7], substantially higher than the poverty rates across the City.

Social Networks

While not within the Chinatown SD as defined by the City, the Project's neighborhood is generally considered Chinatown (PBR, 2019). Historic Chinatown is vibrant and home to numerous stores, restaurants, and small business establishments. Various popular recreational and cultural facilities are

[7] A QCT is any census tract (or equivalent geographic area defined by the Census Bureau) in which at least 50% of households have an income less than 60% of the Area Median Gross Income (AMGI). HUD has defined 60% of AMGI as 120% of HUD's Very Low Income Limits (VLILs), which are based on 50% of area median family income, adjusted for high cost and low income areas.

located adjacent or near the Project Site (see **Section 4.2** for further discussion). Chinatown is also home to an engaged and active social community. HSD began conducting community outreach in August 2014 with various Downtown-Chinatown community stakeholders. Further discussion is provided in **Section 7.7**.

5.1.2 Potential Impacts

Population and Housing

The Project will not have adverse impacts to the existing population, demographics or a decrease in housing stock during and after construction.

Once construction is complete, the vast majority of the tenants living at the Halewai'olu Senior Residences are expected to be existing residents of O'ahu. However, about 5% or 6 to 10 persons, are projected to move from a neighbor island or from out-of-State because of the Project. The Project is not anticipated to increase population due to employment opportunities, as the majority of 96% of the labor force is expected to be filled by persons who are already established residents of O'ahu. The Project is also not anticipated to increase population due to visitation, as the Project will not have facilities that cater to visitors or tourists (PBR, 2019). On a neighborhood level, full occupancy of the Project's 156 units, is anticipated to result in approximately 210 persons. The Project is not anticipated to have a significant long-term or cumulative adverse impact on the existing population or a change in the demographics.

The Project involves the development of a new affordable, rental housing residential facility for seniors aged 62 and over at 80% and below of the HUD AMI. Currently there are no other affordable senior housing projects planned in the immediate area. Honolulu's real estate market is anticipated to see several years of increased prices for all condominium units, and the market for rental housing will experience a similar trend. The market for the proposed Project is promising, with the majority of comparable residential facilities exhibiting stable occupancies and low vacancy rates. Thus, there is adequate demand for the Project and it can be expected that the Project will attain and maintain a 97%-100% occupancy in the first 6 to 9 months (Cassiday, 2019). The Project is not anticipated to have a significant long-term or cumulative adverse impact on the existing rental housing stock.

Economic and Public Fiscal

The Project will not have adverse impacts or lead to a decrease in tax revenue during and after construction.

The total estimated development cost (direct, indirect and induced) of the Project is $85.6 million, subject to the review of the final construction budget of which $78.6 million is estimated to result in direct benefits for Hawai'i. This excludes certain non-construction related costs such as operating and lease-up reserves, developer fees, and entitlement expenses. Construction costs include labor and materials, as well as design, engineering, legal fees, permitting, insurance, administrative and other office costs. As of October 2019, HSD had already expended some $2.9 million, demonstrating their commitment to the Project (PBR, 2019). See **Table 15: Summary of Economic and Fiscal Impacts (2019 dollars)** for a summary of the economic and fiscal impacts of the Project in Hawai'i.

Table 15: Summary of Economic and Fiscal Impacts (2019 dollars)

	2020-2022 (Development period)	2023 (Operations)	Total/Stabilized Operations
Hawai'i development costs	$78.6 million	$0	**$78.6 million**
	-		
Full-time Equivalent (FTE) Employment (av. annual)[8]			
Development-related	260	0	**0**
Operations-related

For the County	0.4	0.3	**0.4**
For the State	27.8	1.4	**1.5**

Source: PBR, 2019

As an affordable housing development, the Project is not conceived as a means of generating income for County or State. The Project will seek exemptions under the City's HRS, Chapter 201H process, considered key to the feasibility of such affordable housing developments. The Project is not anticipated to generate any real property taxes or other County revenues at this time except for the small commercial space on the ground floor, as the Project's affordable senior rental development is eligible for real property tax exemption throughout the regulated affordability period agreed to with the County and is also expected

[8] Average annual direct, indirect and induces impacts; FTE = defined as 40 hours per week or 2,080 hours per year.

[9] On-site estimates reflect direct employment only; other categories reflect total (direct, indirect and induced) impacts on a statewide basis.

[10] Earnings are defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance, and reflect total (direct, indirect and induced) impacts on a statewide basis.

to be exempt from GET. The Project is anticipated to generate approximately $0.9 million in State taxes as a result of the income taxes from employees, spending by residents (PBR, 2019).

At a neighborhood level, the Project will have a minor beneficial impact by bringing new investment and activity to a property where the existing improvements have been abandoned. The Project will attract new residents who are expected to enhance spending at area retail, dining, entertainment, and other commercial establishments. The Project is located within the Downtown TOD Plan area, which is expected to spur economic investment in the neighborhood. Since most residents are not expected to drive, they may have a positive impact on commerce, especially within the immediate vicinity of the project.

Employment and Earnings

The Project is not anticipated to have an adverse impact or lead to a decrease in employment and earnings during and after construction.

During construction, the Project is expected to generate approximately 780 FTE jobs, when considering direct, and indirect development expenditures; approximately 122 direct FTE jobs are expected during the years 2020-2022. Development-related positions attributable to the Project are to support total earnings of some $53.6 million over the three-year period evaluated, representing an average of about $17.9 million per year. These earnings are estimated to average $81,000 per direct FTE job, and $58,000 per indirect and induced job, for an overall average of $69,000 (PBR, 2019).

Once the Project is constructed and full-operational, it is expected to create 5 FTE direct jobs on-site. The Project is also expected to create 12 FTE jobs statewide, in terms of employment supported by direct purchases from vendors or other impacts of additional spending the Project generates. The latter could include jobs that are directly created by the Project off-site, such as for elevator maintenance, utility services, and the like, as well as those supported through indirect and induced effects. On average, these net new FTE direct, indirect and induced positions, are expected to earn about $75,000 per FTE job (PBR, 2019).

Social Networks

The Project will have a minor beneficial impact and will enhance social networks in the surrounding neighborhood. The Project will include a Multi-Purpose Room, Recreation Deck, Garden Area, Retail/Commercial Area, and two Activity Rooms. See Sheets A-111 and A-113 in **Appendix A**. These areas will be available to residents and the neighboring community. The Project will attract new residents who are expected to enhance spending at area retail, dining, entertainment, and other commercial establishments.

5.1.3 Avoidance, Minimizations, and/or Mitigation Measures

The Project will provide much need affordable senior housing that is intended to support the island's aging population. The Project will result in the generation of nominal City and State tax revenues. The Project will result in FTE jobs during and after construction. The Project is further anticipated to enhance the social networks of resident seniors and seniors in the Project area.

No mitigation measures are required.

5.2 HISTORIC AND ARCHAEOLOGICAL RESOURCES

5.2.1 Existing Environment

A Draft *Archaeological Inventory Survey Report* was prepared for the Project by Cultural Surveys Hawai'i (CSH) in December 2019. See **Appendix N, Archaeological Inventory Study Report**. The Draft AIS was prepared in accordance with HRS §6E-8 and HAR §13-275, and as 24 CFR, Part 58, to comply with NHPA Section 106.

The Project's Area of Potential Effect (APE) is approximately 45 acres; however, the AIS study area is the entire 0.6181-acre Project Site. The Draft AIS consisted of subsurface testing excavations throughout the study area. The excavations identified one archaeological historic property, SIHP # 50-80-14-8840 with components 1-3. Component 1 consists of multiple, buried agricultural deposits associated with use of the Nu'uanu Stream floodplain. Component 2 consists of possibly pre- to post- Contact habitation layers, including associated pit features and a human burial site. Component 3 consists of historical infrastructure remnants associated with the residential and commercial development of Honolulu. SIHP # 50-80-14-8840 is assessed as significant under Criteria D and E and is eligible for inclusion in the Hawai'i Register of Historic Places (HRHP) and the National Register of Historic Places (NHRP) under Criterion D.

Consultation conducted for the Draft AIS has been extensive and is on-going. CSH met with SHPD on April 12, 2017 to initiate consultation under HRS §6E-8. On 8 May 2019, CSH presented the sub-surface testing strategy and discussed the need to undertake NHPA Section 106 consultation with the O'ahu Island Burial Council. On June 10, 2019, CSH sent invitations the SHPD and various consulting parties to attend a public meeting at the Blaisdell Center, which was held on June 25, 2019. Follow-up meetings were held with SHPD on July 9, 2019 and July 22, 2019. On September 19, 2019, a second public informational meeting was held at the Blaisdell Center. For a full discussion on consultation efforts, see Section 7 of the Draft AIS.

As part of the Draft AIS, a *Reconnaissance Level Survey* (RLS) was conducted by Fung and Associates in 2016 and is included in Appendix A of the Draft AIS. The RLS identified the existing building as eligible for listing on the NHRP under Criterion C. The SHPD concurred with this assessment in a letter dated, February 27, 2017 (Log No.: 2017.02503; Doc. No.: 1702JLP04). The building was constructed in 1958 and was designed by engineer Kenneth Sato. The building retains much of its historic character in terms of design, materials, workmanship, and construction methods and was determined as a very good example of a small retail/office building constructed in Hawai'i in a modern style in the 1950s. Consultation, as required, is being fulfilled with the State Historic Preservation Officer (SHPO).

5.2.2 Potential Impacts

The Project involves the construction of a new residential facility and the demolition of the existing commercial building. Additional ground disturbance will include borings related to foundation pile installation; excavations for structural footings, utility installation, roadway and parking area installation; and landscaping.

The Draft AIS determined that the Project will impact the archaeological historic property (SIHP # -8840) and thus the Project's effect determination per HAR §13-275-7 is "effect, with agreed upon mitigation commitments." In addition, under Section 106 of the NHPA, the Project will have an "adverse effect" on SIHP # -8840.

5.2.3 Avoidance, Minimizations, and/or Mitigation Measures

The agreed upon mitigation commitments included in the Draft AIS, include preparing a burial treatment plan (BTP) for the human burial site, identified as Component 3 of SIHP # -8840 and archaeological monitoring for Components 1–3 of SIHP # -8840. With the implementation of these mitigation commitments, the Project's potential adverse effect on SIHP # -8840, subsurface cultural deposits will be reduced. These mitigation measures will be detailed in a Memorandum of Agreement (MOA), which is currently being prepared pursuant to 36 CFR Part 800.6 and in consultation with SHPD. The Draft MOA is in **Appendix P, Memorandum of Agreement.**

The MOA must be signed by the City and County of Honolulu ("CCH") in its capacity as the Responsible Entity, the Hawai'i State Historic Preservation Officer ("SHPO") through the office of the Hawai'i State Historic Preservation Division, a division of the Department of Land and Natural Resources of the State of Hawai'i ("SHPD") and Halewai'olu Senior Development, LLC, ("Developer" or "HSD") (collectively "Signatory Parties"). Other consulted parties may also sign the MOA.

Under Section 106 of the National Historic Preservation Act and its implementing regulations (36 CFR Part 800), the Department of Land Management (DLM) initiated consultation with the State Historic Preservation Officer (SHPO) with a June 10, 2019 consultation letter. Subsequently, with its consultants present, the DLM furthered consultation through an in person meeting on July 9, 2019 with the SHPO, represented by Tanya Gumpac-McGuire of the State Historic Preservation Division (SHPD) Architecture Branch.

A series of Public Informational Meetings (June 25, 2019 and September 19,2019), presentations to the Oahu Island Burial Council (May 8, 2019, August 14, 2019), and consultation has taken place in an ongoing effort to keep our preservation partners informed about the project. These partners include: the Advisory Council on Historic Preservation (ACHP), SHPO, as well as area Native Hawaiian cultural descendants, NHOs, and individuals, the Historic Hawaii Foundation, and businesses and organizations who have expressed an interest in the Halewaiolu Senior Residences Project to date.

Through the Public Information Meetings, concurring parties were identified for further participation in developing the Memorandum of Agreement (MOA). An MOA integrating consultation feedback from identified concurring parties, the developer, the SHPO, and DLM is currently being prepared. This included a November 19, 2019 Section 106 Consultation meeting regarding the project's MOA that was attended by Dr. Susan Lebo (SHPD Archaeology Branch Chief) and Tanya Gumpac-McGuire (SHPD Architecture Branch [via phone]); Randy Chiu of the City and County DLM; Howard and Kehaulani Lum of Lum Sai Ho Tong; Liana Benn of the Chinatown Community Center Association; Native Hawaiian cultural descendants Mana and Kalehua Caceres; Daron Makaiwi of the Marin 'Ohana; Jay Morford of Hawaiian Memorial Life Plan; Mel Kalahiki of Borthwick Mortuary; Kiersten Faulkner of the Historic Hawai'i Foundation; and Sylvia Young of Hawaii USA Federal Credit Union. Based on consultation feedback we received, the MOA will specify parameters for how adverse effects will be minimized and/or mitigated. The Advisory Council on Historic Preservation elected not to participate.

The Halewaiolu Senior Residences Project has completed the required archaeological inventory survey (AIS) investigation, carried out pursuant to Hawai'i Administrative Rules 13-276. The AIS draft report is currently under SHPD review.

5.3 CULTURAL IMPACT ASSESSMENT

5.3.1 Existing Environment

A Draft *Cultural Impact Assessment for the Halewai'olu Senior Residence Project* was prepared for the Project by CSH in October 2019. See **Appendix Q, Cultural Impact Assessment**. It should be noted, that the preparation of a CIA is not required under NEPA and NHPA Section 106; rather the CIA was conducted by HSD on behalf of the City. The purpose of the Draft CIA is to assess the Project's potential effect on cultural beliefs, practices, and resources, through document research and cultural consultation efforts. CSH made an effort to contact kūpuna (elders), kama'āina (native born), cultural practitioners, lineal and cultural descendants, Native Hawaiian Organizations (NHOs, including Hawaiian Civic Clubs and those listed on the Department of Interior's NHO list), community groups, SHPD, OHA, and the O'ahu Island Burial Council to identify cultural expertise and/or knowledge of the CIA study area and Honolulu Ahupua'a. CSH initiated its outreach effort in July 2019 via letters, emails, telephone calls, and in person contact. For a full list of the outreach contact list, see Table 2 in the Draft CIA in Section 6.3. As a result of the outreach process, CSH consulted with the following individuals:

- Gerald Lam;
- Howard Lum of Lum Sai Ho Tong;
- Kehaulani Lum of Lum Sai Ho Tong; and Ali'i Pauahi Hawaiian Civic Club
- Wesley Fong, Chinatown Community Association; and
- Bruce Keaulani, Hawaiian practitioner (CSH, 2019).

5.3.2 Potential Impacts

Based on information gathered from the cultural and historical background and the community consultation, the Project may have a potential impact on undetected *iwi kūpuna* (ancestral remains of Native Hawaiians) at the Project Site. Consultation with the aforementioned stakeholders is ongoing.

5.3.3 Avoidance, Minimizations, and/or Mitigation Measures

The following preliminary recommendations were listed in the Draft CIA:

- "Project construction workers and all other personnel involved in the construction and related activities of the project should be informed of the possibility of inadvertent cultural finds, including human remains. In the event that any potential historic properties are identified during construction activities, all activities will cease and the SHPD will be notified pursuant to HAR §13-280-3. In the event that iwi kūpuna are identified, all earth moving activities in the area will stop, the area will be cordoned off, and the SHPD and Police Department will be notified pursuant to HAR §13-300- 40. In addition, in the event of an inadvertent discovery of human remains, the completion of a BTP, in compliance with HAR §13-300 and HRS §6E-43, is recommended.
- In the event that *iwi kūpuna* and/or cultural finds are encountered during construction, Project proponents should consult with cultural and lineal descendants of the area to develop a reinternment plan and cultural preservation plan for proper cultural protocol, curation, and long-term maintenance" (CSH, 2019).

6.0 RELATIONSHIP TO LAND USE PLANS, POLICIES AND CONTROLS

6.1 FEDERAL REGULATIONS

6.1.1 Airport Hazards (24 CFR Part 51, Subpart D)

The purpose of 24 CRF Part 51, Subpart D, "Siting of HUD Assisted Projects in Runway Clear Zones at Civil Airports and Clear Zones and Accident Potential Zones at Military Airfields" is to promote compatible land uses around civil airports and military airfields by identifying suitable land uses for Runway Clear Zones at civil airports and Clear Zones and Accident Potential Zones at military airfields and by establishing them as standards for providing HUD assistance, subsidy or insurance. Compatible developments pursuant to 24 CFR Part 51, Subpart D are at least 15,000 feet away from a military airport or 2,500 feet away from a civilian airport.

Discussion: The Project Site is located approximately 4-miles southeast of the Daniel K. Inouye Airport, and thus meets the requirements of 24 CFR Part 51, Subpart D. No military airfields are in proximity of the Project Site. No mitigation measures are required.

6.1.2 Coastal Barrier Resources

The Coastal Barrier Resources Act (CBRA) of 1982 designated relatively undeveloped coastal barriers along the Atlantic and Gulf coasts as part of the John H. Chafee Coastal Barrier Resources System (CBRS) and made these areas ineligible for most new Federal expenditures and financial assistance.

The Coastal Barrier Improvement Act of 1990 reauthorized the CBRA; expanded the CBRS to include undeveloped coastal barriers along the Florida Keys, Great Lakes, Puerto Rico, and U.S. Virgin Islands; and added a new category of coastal barriers to the CBRS called "otherwise protected areas." These areas are predominantly comprised of conservation and/or recreation areas such as national wildlife refuges, state and national parks, local conservation areas, and private conservation areas, though they may also contain private areas that are not held for conservation and/or recreation.

The law encourages the conservation of hurricane prone, biologically rich coastal barriers by restricting Federal expenditures that encourage development, such as Federal flood insurance. HUD financial assistance may not be used for most activities in CBRS units.

Discussion: According the FEMA FIRMette No. 15003C0354G, the Project Site (located about 0.4 miles from the shoreline) is not located within a designated CBRS unit. See **Figure** . No mitigation measures are proposed.

6.1.3 Flood Insurance (Flood Disaster Protection Act of 1973 and National Flood Insurance Reform Act of 1994)

The Flood Disaster Protection Act of 1973 (42 U.S.C. 4012a) requires that projects receiving federal assistance and located in an area identified by FEMA as being within a SFHA be covered by flood insurance under the NFIP. In order to be able to purchase flood insurance, the community must be participating in the NFIP. If the community is not participating in the NFIP, federal assistance cannot be used in those areas.

Discussion: The proposed Project is located in the Zone "X" floodplain and is not located within a FEMA Special Flood Hazard zone. See **Figure 11**.

DPP has noted in a memorandum to DLM that, "Although Section 6.1.3 of the DEA discloses that the project is not in a Flood Hazard District, the Federal Emergency Management Agency (FEMA) completed a Base Level Engineering (BLE) study in 2019 for flood areas on Oahu that were not

previously mapped. The BLE identified the flood areas adjacent to Nu'uanu Stream, makai of the Freeway. According to the BLE, the parcel is in the 100-year floodplain with a Base Flood Elevation (BFE) of 12.04. The BFE will be further refined when FEMA completes a detailed flood study in the near future. However, if development permit applications are submitted before that happens, the BFE from the BLE should be used for flood protection purposes. This should be disclosed in the DEA. Further, DEA Sections 3.5.1, 3.5.2, 6.1.3, and 6.1.11 should be revised to indicate that there will be compliance with flood requirements for the Project." These EA Sections have been revised to indicate there will be compliance with applicable flood requirements for the Project.

6.1.4 Clean Air Act of 1970 (as amended)

The CAA and amendments (42 U.S.C. §7401 et seq.) is the comprehensive Federal law that regulates air emissions from area, stationary, and mobile sources. This law authorizes the U.S. EPA to establish NAAQS to protect public health and the environment. These are limits on certain "criteria" air pollutants, including limits on how much of these pollutants can be in the air anywhere in the United States. Criteria pollutants include the following: CO, NO_2, O_3, PM, $PM_{2.5}$, and SO_2. Geographic areas that are in compliance with standards are called "attainment areas," while areas that do not meet standards are called "nonattainment" areas. Pursuant to the CAA and amendments, State-operated permit programs serve to control emissions. In Hawai'i, the operating permit program is implemented by HDOH, and emissions of regulated air pollutants within the State may be subject to permitting as required under HAR, §11-60.1.

Discussion: O'ahu is in attainment of both Federal and State air quality standards, as discussed in **Section 3.2**.

6.1.5 Coastal Zone Management (Coastal Zone Management Act, Sections 307(c) and (d))

The Federal Coastal Zone Management Act (CZMA), enacted 1972, provides states with financial incentives for the development and implementation of Coastal Zone Management (CZM) practices, and limited review power over Federal actions affecting the State's Coastal Zone. The law is administered at the federal level by the Coastal Programs Division within the National Oceanic and Atmospheric Administration's (NOAA) Office of Ocean and Coastal Resource Management.

As a response, HRS, Chapter 205(A), *Hawai'i Coastal Zone Law*, as amended, was enacted in 1977. The State has designated the Coastal Zone Management Program (CZMP) to manage the intent, purpose and provisions of HRS, Chapter 205(A)-2 for the areas from the shoreline to the seaward limit of the State's jurisdiction, and any other area which a lead agency may designate for the purpose of administering the CZMP. All land and water use activities in the State must comply with HRS, Chapter 205(A). The CZMP is administered by the DBEDT, OP.

The Office of Planning (OP) administers Hawai'i Revised Statutes (HRS) Chapter 205A, the Coastal Zone Management (CZM) law. The purpose of HRS Chapter 205A is to "provide for the effective management, beneficial use, protection, and development of the Coastal Zone." L. 1977, c188 §1. Special Management Area (SMA) permitting system is part of the CZM Program approved by Federal and State agencies.

Projects that can affect the coastal zone must be carried out in a manner consistent with the State CZMP under Section 307(c) and (d) of the CZMA, as amended. For HUD policy, see 24 CFR 58.5(c) or 24 CFR 50.4(c) (2).

A discussion regarding the proposed project's compliance with the CZMA is as follows (emphasis added).

A) Recreational Resources

Objective:

Provide coastal recreational opportunities accessible to the public.

Policies:

A) Improve coordination and funding of coastal recreational planning and management; and

B) Provide adequate, accessible and diverse recreational opportunities in the coastal zone management area by:

i) Protecting coastal resources uniquely suited for recreational activities that cannot be provided in other areas;

ii) Requiring replacement of coastal resources having significant recreational value, including but not limited to surfing sites, fishponds and sand beaches, when such resources will be unavoidably damaged by development; or requiring reasonable monetary compensation to the state for recreation when replacement is not feasible or desirable;

iii) Providing and managing adequate public access, consistent with conservation of natural resources, to and along shorelines with recreational value;

iv) Providing an adequate supply of shoreline parks and other recreational facilities suitable for public recreation;

v) Ensuring public recreational use of county, state and federally owned or controlled shoreline lands and waters having recreational value consistent with public safety standards and conservation of natural resources;

vi) Adopting water quality standards and regulating point and non-point sources of pollution to protect and where feasible, restore the recreational value of coastal waters;

vii) Developing new shoreline recreational opportunities, where appropriate, such as artificial lagoons, artificial beaches and artificial reefs for surfing and fishing; and

viii) Encouraging reasonable dedication of shoreline areas with recreational value for public use as part of discretionary approvals or permits by the land use commission, board of land and natural resources, county planning commissions; and crediting such dedication against the requirements of Section 46-6, HRS.

Discussion: The Project Site (located about 0.4 miles from the shoreline) is not within the Special Management Area (coastal zone management area), but will comply with applicable rules and regulations designed to control or reduce pollution, including point and non-point source water pollution, to conserve both the natural resources and recreational value of Nu‘uanu Stream.

B) Historic Resources

Objective:

Protect, preserve, and where desirable, restore those natural and manmade historic and prehistoric resources in the coastal zone management area that are significant in Hawaiian and American history and culture.

Policies:

A) Identify and analyze significant archaeological resources;

B) Maximize information retention through preservation of remains and artifacts or salvage operations; and

C) Support state goals for protection, restoration, interpretation, and display of historic resources.

Discussion: The Project Site is not within the coastal zone management area. However, the existing building has been deemed eligible for listing in the NRHP. See **Sections 5.2 and 5.3** for further discussion. HSD will continue to consult with SHPD and consulting parties regarding appropriate mitigation.

D) Scenic and Open Space Resources

Objective:

Protect, preserve, and, where desirable, restore or improve the quality of coastal scenic and open space resources.

Policies:

A) Identify valued scenic resources in the coastal zone management area;

B) Ensure that new developments are compatible with their visual environment by designing and locating such developments to minimize the alteration of natural landforms and existing public views to and along the shoreline;

C) Preserve, maintain, and, where desirable, improve and restore shoreline open space and scenic resources; and

D) Encourage those developments that are not coastal dependent to locate in inland areas.

Discussion: The Project Site (located about 0.4 miles from the shoreline) is not anticipated to have a significant negative impact on coastal scenic view planes or scenic resources in the Downtown Honolulu area. The proposed residential facility is planned for a height of approximately 174 feet, in an area zoned for a 350-foot height limit and will therefore be more visible than the existing building on the Project Site. However, surrounding buildings are of equal or higher elevation. The Project tower will be oriented in the mauka-makai direction to minimize impacts to mountain and ocean views from surrounding properties. The Project will not interfere with scenic views specified in the PUC DP. See **Section 3.6** for further discussion.

E) Coastal Ecosystems

Objective:

Protect valuable coastal ecosystems, including reefs, from disruption and minimize adverse impacts on all coastal ecosystems.

Policies:

A) Exercise an overall conservation ethic, and practice stewardship in the protection, use, and development of marine and coastal resources

B) Improve the technical basis for natural resource management

C) Preserve valuable coastal ecosystems, including reefs, of significant biological or economic importance

D) Minimize disruption or degradation of coastal water ecosystems by effective regulation of stream diversions, channelization, and similar land and water uses, recognizing competing water needs; and

E) Promote water quantity and quality planning and management practices that reflect the tolerance of fresh water and marine water ecosystems and maintain and enhance water quality through the development and implementation of point and nonpoint source water pollution control measures.

Discussion: The Project, although located about 0.4 miles from the shoreline, will be consistent with these policies as they relate to Nu'uanu Stream which is located northwest of the subject property and feeds into the shoreline and could affect the coastal system. The Nu'uanu Stream is classified by HDOH as a "Class 2" inland water body, as discussed in **Section 3.4**. Appropriate mitigative measures and controls will be applied consistent with sound engineering and operating practices for the protection of groundwater and surface water resources. Such measures will be developed during the design of this Project and will comply with the City's erosion and sedimentation control regulations. Storm water runoff from construction areas will be regulated through adherence to permit conditions. Any increase in runoff caused by an increase in impervious surfaces will be retained or treated on site as required to meet City standards, and onsite drainage will be designed to flow away from buildings towards landscaped areas. Drainage will be designed to maintain acceptable drainage patterns, as discussed in **Section 4.9**.

F) Economic Uses

Objective:

Provide public or private facilities and improvements important to the State's economy in suitable locations.

Policies:

A) Concentrate in appropriate areas the location of coastal dependent development necessary to the State's economy;

B) Insure that coastal dependent development such as harbors and ports, visitor industry facilities, and energy generating facilities are located, designed, and constructed to minimize adverse social, visual, and environmental impacts in the coastal zone management area; and

C) Direct the location and expansion of coastal dependent developments to areas presently designated and used for such development and permit reasonable long-term growth at such areas, and permit coastal dependent development outside of presently designated areas when:

i) Utilization of presently designated locations is not feasible;

ii) Adverse environmental effects are minimized; and

iii) Important to the State's economy.

Discussion: The proposed Project will be consistent with these policies. The proposed affordable housing Project for seniors is located in a suitable location. Because of the property location in Downtown-Chinatown, future residents and employees will have convenient access to shopping and dining needs, and senior residents will have the option to reach their destination without the use of a car. There are ample socialization and recreation opportunities for seniors in the Downtown-Chinatown area, as discussed in **Section 4.2**.

G) Coastal Hazards

Objective:

Reduce hazard to life and property from tsunami, storm waves, stream flooding, erosion, and subsidence.

Policies:

A) Develop and communicate adequate information on storm wave, tsunami, flood erosion, and subsidence hazard;

B) Control development in areas subject to storm wave, tsunami, flood, erosion, and subsidence hazard;

C) Ensure that developments comply with requirements of the Federal Flood Insurance Program; and

D) Prevent coastal flooding from inland projects.

Discussion: The proposed Project Site is not located in the tsunami evacuation zone, as designated by the City. The Project will be designed to meet applicable building code requirements.

H) Managing Development

Objective:

Improve the development review process, communication, and public participation in the management of coastal resources and hazards.

Policies:

A) Effectively utilize and implement existing law to the maximum extent possible in managing present and future coastal zone development;

B) Facilitate timely processing of application for development permits and resolve overlapping or conflicting permit requirements; and

C) Communicate the potential short- and long-term impacts of proposed significant coastal developments early in their life cycle and in terms understandable to the general public to facilitate public participation in the planning and review process

Discussion: The Project will be consistent with these policies. The Project is entirely located within the PUC DP's "Urban Community Boundary." The proposed Project will upgrade a site that is currently blighted and underutilized. The Project will seek affordable housing exemptions through the HRS, Chapter 201H process, and will work with all required agencies, administration officials, and the community to ensure that the process is followed. Both the EA and HRS, Chapter 201H process requires public notification and allowance for public comment.

I) Public Participation

Objective:

Stimulate public awareness, education, and participation in coastal management.

Policies:

J) Maintain a public advisory body to identify coastal management problems and to provide policy advice and assistance to the coastal zone management program;

K) Disseminate information on coastal management issues by means of educational materials, published reports, staff contact, and public workshops for persons and organizations concerned with coastal-related issues, developments, and government activities; and

L) Organize workshops, policy dialogues, and site-specific mediations to respond to coastal issues and conflicts.

Discussion: HSD began conducting community outreach in August 2014 with various Downtown-Chinatown community stakeholders. Since then, the Project has been revised to accommodate as much as possible the concerns and incorporate stakeholder suggestions. In-depth discussion regarding outreach is provided in **Section 7.7**.

M) Beach Protection

Objective:

Protect beaches for public use and recreation.

Policies:

A) Locate new structures inland from the shoreline setback to conserve open space and to minimize loss of improvements due to erosion;

B) Prohibit construction of private erosion-protection structures seaward of the shoreline, except when they result in improved aesthetic and engineering solutions to erosion at the sites and do not interfere with existing recreational and waterline activities; and

C) Minimize the construction of public erosion-protection structures seaward of the shoreline.

Discussion: The Project is located about 0.4 miles from the shoreline and beaches will not be impacted by this Project.

N) Marine Resources

Objective:

Implement the State's ocean resources management plan.

Policies:

A) Exercise an overall conservation ethic, and practice stewardship in the protection, use, and development of marine and coastal resources;

B) Assure that the use and development of marine and coastal resources are ecologically and environmentally sound and economically beneficial;

C) Coordinate the management of marine and coastal resources and activities management to improve effectiveness and efficiency;

D) Assert and articulate the interests of the State as a partner with federal agencies in the sound management of ocean resources within the United States exclusive economic zone;

E) Promote research, study, and understanding of ocean processes, marine life, and other ocean resources in order to acquire and inventory information necessary to understand how ocean development activities relate to and impact upon ocean and coastal resources; and

F) Encourage research and development of new, innovative technologies for exploring, using, or protecting marine and coastal resources.

Discussion: The Project will be consistent with these policies. The Project will avoid any negative effects to marine and coastal resources, and will incorporate appropriate LID measures to minimize impacts to streams and near-shore waters.

6.1.6 Contamination and Toxic Substances (24 CFR Part 50.3(i) & 58.5(i)(2)

It is HUD policy, as described in 24 CFR Part 50.3(i) and 24 CFR 58.5(i)(2), that:

1. All property proposed for use in HUD programs be free of hazardous materials, contamination, toxic chemicals and gasses, and radioactive substances, where a hazard could impact the health and safety of occupants or conflict with the intended utilization of the property.
2. Environmental review of multifamily and non-residential properties shall include evaluation of previous uses on the Project Site and other evidence of contamination on or near the Project Site, to assure that occupants of proposed sites are not adversely impacted by the hazards.
3. Particular attention should be given to any proposed site on or in the general proximity of such areas as dumps, landfills, industrial sites, or other locations that contain, or may have contained, hazardous wastes.
4. The responsible entity shall use current techniques by qualified professionals to undertake investigations determined necessary

Discussion: A Hazardous Materials Assessment Survey (HMAS) was performed on the Project Site. The HMAS identified ACM, LCP, PCB units, and CFC units within and around the existing property; see **Appendix L**. The existing building is planned to be demolished to make way for the new affordable housing facility. As discussed in **Section 4.10**, proper mitigation measures prior general to demolition/construction work will be employed including, but not limited to, employment of a qualified Contractor specifically trained in LBP and ACM abatement to ensure safe removal of hazardous materials and disposal of all materials potentially containing hazardous materials to an approved waste facility. Upon demolition of the existing building, the Project Site shall no longer contain any hazardous materials. All materials used for construction of the new tower will be comprised of contaminate-free material.

6.1.7 Endangered Species Act of 1973

The ESA of 1973 (16 U.S.C. 1531-1544) establishes a process for identifying and listing threatened and endangered species. The law requires Federal agencies to carry out programs for the conservation of federally-listed endangered and threatened plants and wildlife and designated critical habitats for such species, and prohibits actions by Federal agencies that would likely jeopardize the continued existence of those species or result in the destruction or adverse modification of designated critical habitat. The ESA is administered by the DOI through the USFWS, the U.S. Department of Commerce through the NOAA, National Marine Fisheries Service (NMFS). Section 7 of the ESA requires consultations with Federal wildlife management agencies, such as the USFWS and NMFS.

Discussion: As discussed in **Sections 3.8 and 3.9**, no federally-listed threatened or endangered species occur on the Project Site. Pursuant to Section 7, ESA, HSD conducted informal consultation with USFWS to determine the effect of the Project on biological resources in the Project area. USFWS concurred that the Project may affect, but is unlikely to adversely affect threatened or endangered plant or animal species, or critical habitats within the Project limits (File No.

01EP1F00-2019-I-0399, July 26, 2019). See **Appendix H**. Mitigation measures to minimize the potential for impacts to species are provided in **Sections 3.8 and 3.9**.

6.1.8 Migratory Bird Treaty Act of 1918

The Migratory Bird Treaty Act (MBTA) of 1918, as amended (16 U.S.C. 760), protects migratory wild birds found in the U.S. The MBTA makes it unlawful to pursue, hunt, take, capture, possess, sell, purchase, barter, import, export, or transport any migratory bird or any part, next, or egg of any such bird, unless authorized under a permit issued by the DOI Secretary.

Discussion: During a Biological Survey conducted for the Project Site, two MBTA-protected species were observed to traverse over the Project Site: the white tern and kōlea (Hobdy, 2019). With the implementation of mitigation described in **Section 3.9.3**, impacts to MBTA-protected species would be avoided.

6.1.9 Explosive and Flammable Hazards (24 CFR Part 51 Subpart C)

There are inherent potential dangers associated with locating HUD projects near hazardous facilities which store, handle, or process hazardous substances of a flammable or explosive nature. Project Sites located too close to facilities handling, storing, or processing conventional fuels, hazardous gases or chemicals of an explosive or flammable nature may expose occupants or end-users of a Project to the risk of injury in the event of an explosion.

Blast overpressure and thermal radiation standards are used as a basis for calculating acceptable separation distances (ASDs) for HUD projects from specific, stationary hazardous operations which store, handle, or process substances of fire or explosive prone nature. HUD projects must meet ASDs or else mitigation measures must be undertaken.

Discussion: There is an aboveground stationary storage tank (propane) at Zippy's Vineyard located within one mile of the Project, about 412 feet from the south property line. The Environmental Planning Division (EPD) of HUD has developed an electronic-based assessment tool that calculates the Acceptable Separation Distance (ASD) from stationary hazards. Based on the size (250 gallon) and type of fuel (Propane), the ASD for Thermal Radiation for People (ASDPPU) is 155.23 and the ASD for Thermal Radiation for Buildings (ASDBPU) is 26.49 feet.

The Project will include a 660 gallon diesel fuel tank will be designed "in compliance with NFPA 58 (2017)" that meets the following HUD Guideline for Explosive and Flammable Facilities and is not subject to review even if within one mile of this or any other Project Site:

"Evidence that within one mile of the project site there are no current or planned stationary aboveground storage containers except:

- Containers less than 100-gallons capacity containing common liquid industrial fuels
- Containers that are 1,000 gallons or less water volume capacity and in compliance with NFPA 58 (2017)"

6.1.10 Farmlands Protection (Farmland Protection Policy Act of 1981, sections 1504(b) and 1541; 7 CFR Part 658)

The purpose of the Farmland Protection Policy Act (FPPA) (7 U.S.C. 4201 et seq, implementing regulations 7 CFR Part 658, of the Agriculture and Food Act of 1981, as amended) is to minimize the effect of Federal programs on the unnecessary and irreversible conversion of farmland to nonagricultural uses.

The FPPA does not apply to projects already in or committed to urban development or those that could otherwise not convert farmland to non-agricultural uses. However, land that meets the definition of prime or unique farmlands or is determined to be of statewide or local significance (with concurrence by the U.S. Secretary of Agriculture) is subject to the FPPA. In some states agricultural lands are protected from development by agricultural districting, zoning provisions, or special tax districts.

> **Discussion:** The Project Site is located on land classified by the State as Urban and zoned by the City as a BMX-4 district. The PUC DP further identifies this parcel as prime for "Medium and Higher-Density Residential Mixed Use" development. The Project Site is not identified by any State or City plans as suitable for agricultural activities. Furthermore, the Project does not include any activities that would convert its present commercial use to an agricultural use.

6.1.11 Floodplain Management, Executive Orders 11988 and 12148

Executive Order (E.O.) 11988, Floodplain Management, dated May 24, 1977 requires Federal agencies to take action to reduce the risk of flood loss, restore the natural and beneficial values of floodplains, and minimize the impacts of floods on human safety, health, and welfare. E.O. 12148, July 20, 1979, amended E.O. 11988. The main feature of the amendment added that agencies with responsibilities for Federal real estate properties and facilities will, at a minimum, require the construction of Federal structures and facilities to be in accordance with the criteria of the NFIP.

HUD's regulations in 24 CFR Part 55 outline HUD's procedures for complying with E.O. 11988. Part 55 applies to all HUD actions that could be harmed or cause harm if located in a floodplain, including but not limited to proposed acquisition, construction, demolition, improvement, disposition, and financing actions under any HUD program. The purpose of Part 55 is not in most cases to prohibit actions in a floodplain, but to provide the method for HUD projects to comply with E.O. 11988 and avoid unnecessary impacts.

> **Discussion:** As discussed in **Section 3.5**, the Project Site is not located within the Base Floodplain. The Project would not result in any impacts to the base floodplain or indirectly support floodplain development. However, the Federal Emergency Management Agency (FEMA) completed a Base Level Engineering (BLE) study in 2019 for flood areas on Oahu that were not previously mapped. The BLE identified the flood areas adjacent to Nu'uanu Stream, makai of the Freeway. According to the BLE, the parcel is in the 100-year floodplain with a Base Flood Elevation (BFE) of 12.04. Construction of the Project would adhere to applicable design standards as set forth in ROH, Chapter 21A, *Flood Hazard Areas*. This includes compliance with applicable flood requirements for the Project. Any increase in runoff caused by an increase in impervious surfaces will be retained or treated on site as required to meet City standards, and onsite drainage will be designed to flow away from buildings towards landscaped areas. The Project would also meet applicable NFIP requirements.

6.1.12 Historic Preservation (Section 106 of the National Historic Preservation Act of 1966)

The NHPA of 1966, as amended (PL 89-665, codified as 16 United States Code [U.S.C.] 470), recognizes the nation's historic heritage and establishes a national policy for the preservation of historic properties as well as the NRHP. Section 106 of the NHPA (16 U.S.C. 470f) requires that Federal agencies consider the effects of their projects on historic properties. Use of Federal funds sets forth the need for Section 106 consultation. The purpose of the Section 106 consultation process is to evaluate the potential for effects on existing historic sites, if any, resulting from the Project. The NHPA Section 106 review process encompasses a "good faith effort" in ascertaining the existence and location of historic properties near and within the Project Site, establishing an APE of the Project, identifying whether a potential for "adverse effects" on historic properties by the Project exists, and developing a reasonable and acceptable resolution in the monitoring and treatment of any historic sites that is agreed upon by the agency, the SHPO, consulting government agencies, NHOs, and community associations. NHPA is administered by the U.S. DOI NPS and the Advisory Council on Historic Preservation. At the State level, NHPA is implemented by the SHPO. The use of Federal funds and the requirement of Federal permits for the Project trigger the need for NHPA, Section 106 compliance.

> **Discussion:** The Draft AIS found that the Project will have an impact the archaeological historic property (SIHP # -8840) and thus the Project's effect determination under Section 106 of the NHPA is "adverse effect." The agreed upon mitigation commitments included in the Draft AIS, include preparing a BTP for the human burial site, identified as Component 3 of SIHP # -8840 and archaeological monitoring for Components 1–3 of SIHP # -8840. With the implementation of these mitigation commitments, the Project's potential adverse effect on SIHP # -8840, subsurface cultural deposits will be reduced. For further discussion, see **Section 5.2.** See also **Appendix N, Archaeological Inventory Study Report** and **Appendix P, Memorandum of Agreement.**

6.1.13 Noise Abatement and Control (Noise Control Act of 1972, as amended by the Quiet Communities Act of 1978; 24 CFR Part 51 Subpart B)

The HUD noise standards may be found in 24 CFR Part 51, Subpart B. For proposed new construction in high noise areas, the Project must incorporate noise mitigation features. All sites where environmental or community noise exposure exceeds the DNL of 65 dB are considered noise-impacted areas. For new construction that is proposed in high noise areas, grantees shall incorporate noise attenuation features to the extent required by HUD environmental criteria and standards contained in Subpart B (Noise Abatement and Control) of 24 CFR Part 51. The interior standard is 45 dB.

The "Normally Unacceptable" noise zone includes community noise levels from above 65 dB to 75 dB. Approvals in this noise zone require a minimum of 5 dB additional sound attenuation for buildings having noise-sensitive uses if the DNL is greater than 65 dB but does not exceed 70 dB, or a minimum of 10 Db of additional sound attenuation if the DNL is greater than 70 dB but does not exceed 75 dB.

Locations with day-night average noise levels above 75 dB have "Unacceptable" noise exposure. For new construction, noise attenuation measures in these locations require the approval of the Assistant Secretary for Community Planning and Development (for projects reviewed under Part 50) or the Responsible Entity's Certifying Officer (for projects reviewed under Part 58). The acceptance of such locations normally requires an environmental impact statement.

In Unacceptable noise zones, HUD strongly encourages conversion of noise-exposed sites to land uses compatible with the high noise levels.

Discussion: An acoustic study performed for the Project found that increases in future noise levels resulting from Project-related traffic are predicted to be 0.2 DNL (negligible). The study further found that future traffic noise levels at all of the residential units of the proposed Project would not exceed 65 DNL.

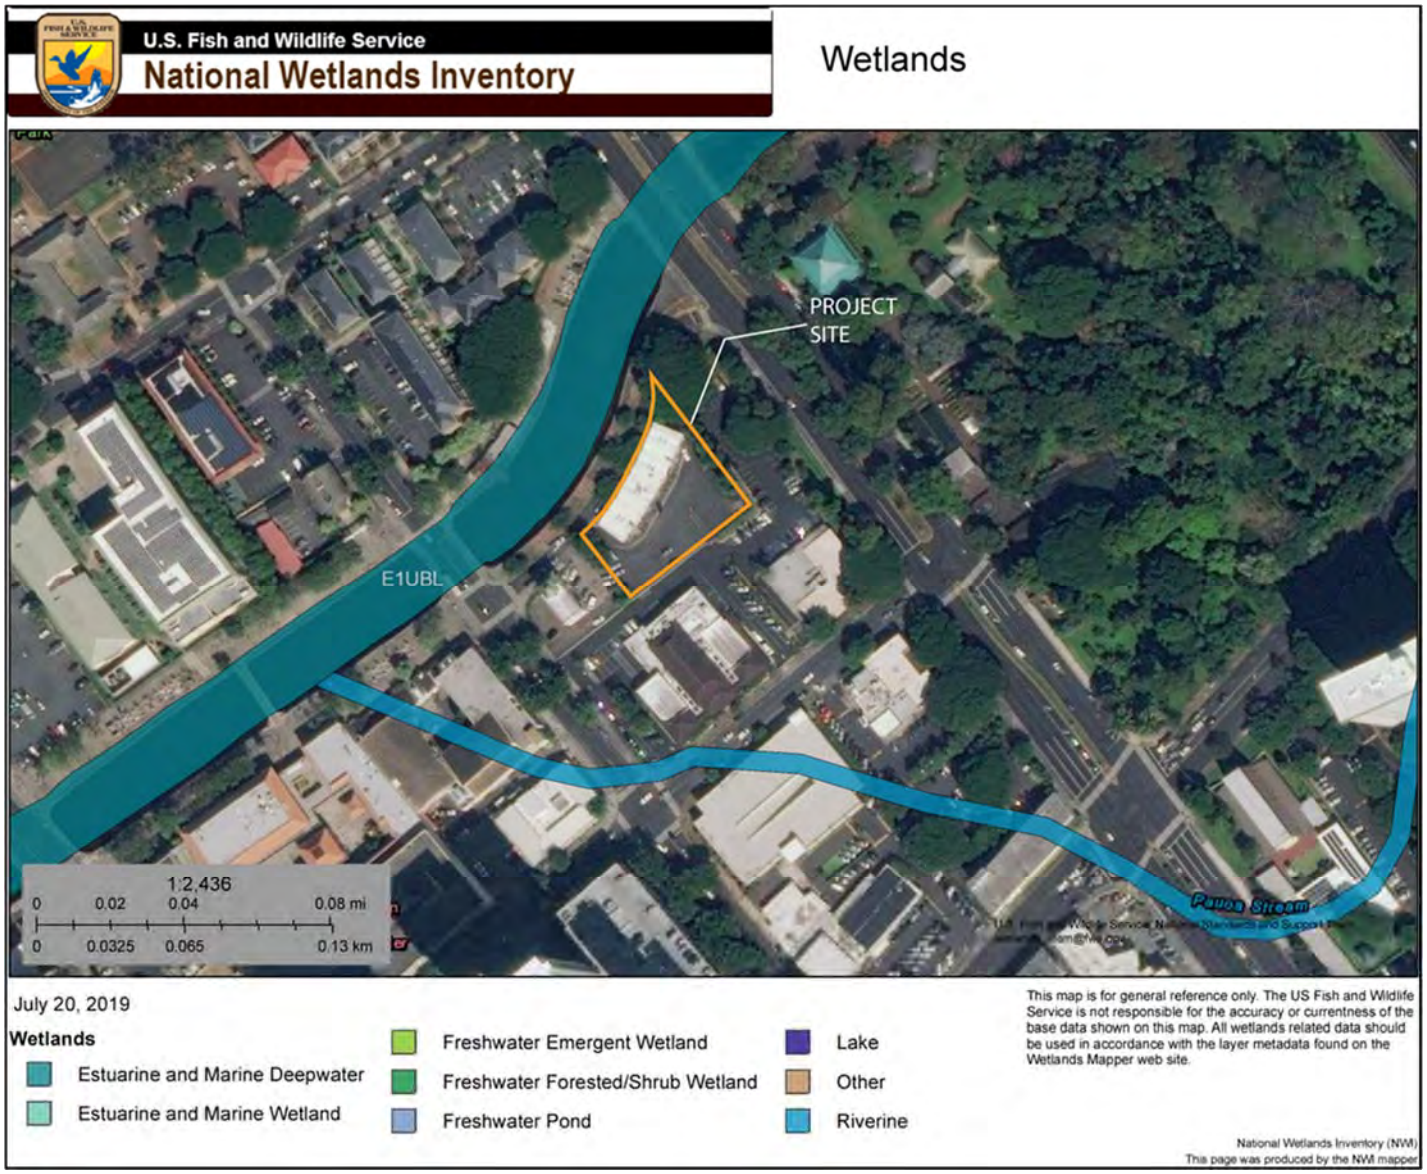
A separate analysis was done on the noise level predictions from a mature rail system projected for year 2030 by R.M. Towill Corporation, based on the operational HART system along Nimitz Highway and noise impacts described in the Final Environmental Impact Statement for the Honolulu High Capacity Transit Corridor dated July 8, 2010. Based on the projected noise impact at the residential tower at 215 North King Street located 145 feet away from the centerline of the rail line with a projected 63 DNL and the projected noise impact at the residential tower at 700 Richards Street located 85 feet away from the centerline of the rail line with a projected 63 DNL, the impact at the Project Tower located 2,000 feet away from the centerline of the rail line at Nimitz Highway will be between 52 and 53 DNL. For purposes of determining noise acceptability for funding assistance from federal agencies, an exterior noise level of 65 DNL or less is considered acceptable for residences. Since the 52 and 53 DNL projected impact from the HART system is well below the acceptable 65 DNL no mitigation measures are required. See **Section 3.7** for further discussion.

6.1.14 Sole Source Aquifers (Safe Drinking Water Act of 1974, as amended)

The SDWA of 1974 requires protection of drinking water systems that are the sole or principal drinking water source for an area and which, if contaminated, would create a significant hazard to public health. SSA designations are one tool to protect drinking water supplies in areas where alternatives to the groundwater resource are few, cost-prohibitive, or nonexistent. A SSA is defined as an aquifer that supplies at least 50% of the drinking water for a community. The designation protects an area's groundwater resource by requiring EPA review of any proposed projects within the designated area that are receiving federal financial assistance. The Project Site is located on the SOBA, an EPA-designated SSA; therefore, coordination with EPA is required. See **Figure 17: National Wetland Inventory Map.**

Discussion: According to the HDOH, Safe Drinking Water Branch, Groundwater Protection Program's Groundwater Contamination Maps, there are no public drinking or non-drinking water wells, such as irrigation and industrial wells, on or near the Project Site, nor are there any sites that were flagged for potential groundwater contamination. The Project will be coordinated with the EPA, Region 9 (Pacific Southwest).

6.1.15 Wetlands Protection (Executive Order 11990)



E.O. 11990, *Protection of Wetlands*, of May 24, 1977 requires Federal activities to avoid adverse impacts to wetlands where practicable. As primary screening, HUD or grantees must verify whether the Project is located within wetlands identified on the National Wetlands Inventory (NWI).

Discussion: The Project Site is not located within a wetland identified on the NWI; therefore, not adverse impact to wetlands is expected. See **Figure 17: National Wetland Inventory Map.** The Nu'uanu Stream is located approximately 54 feet northwest of the Project Site, and is considered an Estuarine and Marine Deep Water by USFWS. Mitigation measures to protect the Nu'uanu Stream during construction activities in the short-term and from storm water runoff in the long-term are discussed in **Sections 3.4.3 and 4.9.3**.

6.1.16 Wild and Scenic Rivers Act of 1968

The Wild and Scenic Rivers Act (WSRA) (16 U.S.C. 1271-1287) provides federal protection for certain free-flowing, wild, scenic, and recreational rivers designated as components or potential components of the National Wild and Scenic Rivers System. The system was created by Congress in 1968 (Public Law 90-542; 16 U.S.C. 1271 et seq., as amended) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA is notable for safeguarding the special character of these rivers, while also recognizing the potential for their appropriate use and development. The WSRA encourages river management that crosses political boundaries and promotes public participation in developing goals for river protection.

Figure 17: National Wetland Inventory Map

Each river or river segment in the system is administered with the goal of protecting and enhancing the values that caused it to be eligible for inclusion in the system. Designated rivers need not include the entire river and may include tributaries. Wild and Scenic Rivers are classified into the following three types: Wild and Scenic Rivers, Study Rivers, and the Nationwide Rivers Inventory (maintained by the National Park Service).

> **Discussion:** There are no designated Wild and Scenic Rivers in the State; therefore, no impacts due to the Project are anticipated.

6.1.17 Environmental Justice, Executive Order 12898

The E.O. 12898 further directed efforts to prevent environmental injustice under Title VI of the 1964 Civil Rights Act. Title VI prohibits discrimination on the basis of race, color, or national origin. It also prohibits

recipients of federal funds, including federal and state agencies, from discriminatory actions. The U.S. Council on Environmental Quality (CEQ) and DOT define minority as persons self-identifying as any one of the following U.S. Census categories for race and ethnicity: Black/African American, Asian, Native Hawaiian or Other Pacific Islander, American Indian or Alaska Native, or Hispanic (USDOT 2011).

To satisfy Title VI and environmental justice (EJ) requirements, a Project must illustrate that concern for EJ is integrated into every transportation decision, from the first thought about a transportation plan to the post-construction operations and maintenance. Every effort was made to ensure that a full and fair opportunity was made available to all members of all communities to participate in the development of the plan. In particular, the public outreach program was designed to ensure that this was accomplished. For example, the members of the Citizen Advisory Committees were invited from a broad spectrum of each community on each island in the state to ensure that all potential groups, interests, and points of view would be represented on each committee. This included the low-income and minority population, the elderly, the disabled or otherwise challenged individuals, and special interest groups.

All projects involving a federal action (funding, permit, or land) must comply with E.O. 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, signed by President William J. Clinton on February 11, 1994. This E.O. directs federal agencies to take the appropriate and necessary steps to identify and address disproportionately high and adverse effects of federal projects on the health or environment of minority and low-income populations to the greatest extent practicable and permitted by law. Low income is defined based on the U.S. Department of Health and Human Services (HHS) poverty guidelines. The intent of E.O. 12898 is to avoid disproportionately high adverse human health or environmental effects of projects on minority and low-income populations. E.O. 12898 also requires Federal agencies ensure that minority and low-income communities have adequate access to public information related to health and the environment.

There are three fundamental EJ principles:

- To avoid, minimize, or mitigate disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority populations and low - income populations;
- To ensure the full and fair participation by all potentially affected communities in the transportation decision-making process; and
- To prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations.

To satisfy Title VI and EJ requirements, a project must illustrate that concern for EJ is integrated into every transportation decision, from the first thought about a transportation plan to the post-construction operations and maintenance. Every effort was made to ensure that a full and fair opportunity was made available to all members of all communities to participate in the development of the plan. In particular, the public outreach program was designed to ensure that this was accomplished. For example, the members of the Citizen Advisory Committees were invited from a broad spectrum of each community on each island in the state to ensure that all potential groups, interests, and points of view would be represented on each committee. This included the low-income and minority population, the elderly, the disabled or otherwise challenged individuals, and special interest groups.

CEQ and DOT define minority as persons self-identifying as any one of the following U.S. Census categories for race and ethnicity: Black/African American, Asian, Native Hawaiian or Other Pacific Islander, American Indian or Alaska Native, or Hispanic (USDOT 2011). See further definitions below:

- *Black* – a person having origins in any of the black racial groups of Africa;
- *Hispanic* – a person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race;
- *Asian* – a person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent;
- *American Indian and Alaskan Native* – a person having origins in any of the original people of North America and who maintains cultural identification through tribal affiliation or community recognition;
- *Native Hawaiian or Other Pacific Islander* – a person having origins in any of the original peoples of Hawai'i, Guam, Samoa, or other Pacific Islands; and
- *Low-Income* – a person whose household income (or in the case of a community or group, whose median household income) is at or below the HHS's poverty guidelines.

Additionally, for the purposes of this analysis, minority also includes all other non-white racial categories that were added in the most recent Census, such as "some other race" and "two or more races." The Project Site does meet the definition of a minority population as defined by the CEQ.

> **Discussion:** Using the U.S. EPA EJ Screening and Mapping Tool (EJSCREEN) (Version 2018), data shows that 89% of the residents within one mile of the Project Site are considered a minority population. See **Table 16: EJSCREEN Report** on the subsequent page. Furthermore, according to the EJSCREEN report, 37% of the population within one mile of the property is considered low-income.

6.1.18 Potential Impacts

HSD began outreach with the surrounding community in 2014, and has made design modifications based on feedback received. HSD will continue to keep neighborhood groups and organizations apprised of Project developments. As part of the Section 106 consultation, NHOs in the Project area have been consulted regarding affected historic properties, as discussed later in **Sections 6.2 and 6.3.** Potential for adverse effects relating to EJ or Title VI populations are not anticipated or expected. A minor beneficial impact is expected through the provision of 155 affordable senior rental housing that will support the growing senior demographic. Additionally, the existing building on the Project Site contains hazardous materials. Removal of hazardous materials prior to commencement of construction will result in an improvement in the overall environmental quality.

* The National-Scale Air Toxics Assessment (NATA) is EPA's ongoing, comprehensive evaluation of air toxics in the United States. EPA developed the NATA to prioritize air toxics, emission sources, and locations of interest for further study. It is important to remember that NATA provides broad estimates of health risks over geographic areas of the country, not definitive risks to specific individuals or locations. More information on the NATA analysis can be found at: https://www.epa.gov/national-air-toxics-assessment.

6.1.19. Avoidance, Minimization, and/or Mitigation Measures

No minimization or mitigation measures, other than those related to historic properties, are proposed.

6.2 STATE OF HAWAIʻI LAND USE PLANS AND REGULATIONS

6.2.1 Hawaiʻi State Plan

The Hawaiʻi State Plan, HRS, Chapter 226, adopted in 1978 and revised in 1986, serves as a guide for the future long range development of the State by identifying goals, objectives, policies, and priorities. The Hawaiʻi State Plan consists of three major part:

Part I, describes the overall theme including Hawaiʻi's desired future and quality of life as expressed in goals, objectives, and policies;

Part II, Planning Coordination and Implementation, describing a statewide planning system designed to coordinate and guide all major state and county activities and to implement the goals, objectives, policies, and priority guidelines of the Hawai‘i State Plan; and

Part III, Priority Guidelines, which express the pursuit of desirable courses of action in major areas of statewide concern.

The proposed Project is consistent with the objectives and policies of the Hawai‘i State Plan. An analysis of the project’s ability to meet the objectives, policies, and priority guidelines of the Hawai'i State Plan are provided in **Table 17: Hawai‘i State Plan Objectives, Policies, and Priority Guidelines** below.

Table 17: Hawai‘i State Plan Objectives, Policies, and Priority Guidelines

Hawai‘i State Plan Objectives, Policies, and Priority Guidelines	Applicability to the Proposed Project
Objectives and Policies	
§226-5 Objective and policies for population	**Applicable**
§226-6 Objectives and policies for the economy--in general	**Applicable**
§226-7 Objectives and policies for the economy-- agriculture	Not Applicable
§226-8 Objective and policies for the economy--visitor industry	Not Applicable
§226-9 Objective and policies for the economy--federal expenditures.	Not Applicable
§226-10 Objective and policies for the economy--potential growth activities	Not Applicable
§226-10.5 Objectives and policies for the economy--information industry	Not Applicable
§226-11 Objectives and policies for the physical environment--land-based, shoreline, and marine resources.	**Applicable**
§226-12 Objective and policies for the physical environment--scenic, natural beauty, and historic resources.	**Applicable**
§226-13 Objectives and policies for the physical environment--land, air, and water quality	**Applicable**
§226-14 Objective and policies for facility systems--in general	Not Applicable
§226-15 Objectives and policies for facility systems--solid and liquid wastes	Not Applicable
§226-16 Objective and policies for facility systems--water	Not Applicable
§226-17 Objectives and policies for facility systems--transportation	**Applicable**
§226-18 Objectives and policies for facility systems—energy/telecommunications	Not Applicable
§226-19 Objectives and policies for socio-cultural advancement--housing	**Applicable**
§226-20 Objectives and policies for socio-cultural advancement--health	Not Applicable
§226-21 Objective and policies for socio-cultural advancement--education	Not Applicable
§226-22 Objective and policies for socio-cultural advancement--social services	Not Applicable
§226-23 Objective and policies for socio-cultural advancement--leisure	Not Applicable
§226-24 Objective and policies for socio-cultural advancement--individual rights and personal well-being	Not Applicable
§226-25 Objective and policies for socio-cultural advancement--culture	Not Applicable
§226-26 Objectives and policies for socio-cultural advancement--public safety	Not Applicable
§226-27 Objectives and policies for socio-cultural advancement--government	Not Applicable
Priority Guidelines	
§226-103 Economic priority guidelines	Not Applicable

§226-104 Population growth and land resources priority guidelines	**Applicable**
§226-105 Crime and criminal justice	Not Applicable
§226-106 Affordable housing	**Applicable**
§226-107 Quality education	Not Applicable
§226-108 Sustainability	**Applicable**
§226-109 Climate change adaptation priority guideline	**Applicable**

The objectives, policies, and priority guidelines of the Hawai‘i State Plan directly applicable to the proposed Project are discussed in further detail below.

Section 226-5 Objectives and policies for population

(b)(1) Manage population growth statewide in a manner that provides increased opportunities for Hawai‘i's people to pursue their physical, social, and economic aspirations while recognizing the unique needs of each county.

(b)(3) Promote increased opportunities for Hawai‘i's people to pursue their socio-economic aspirations throughout the islands.

Discussion: The proposed Project is planned to be affordable rental housing for seniors with the following proposed housing mix: 8 units for seniors earning 30% of the AMI or below; 131 units for seniors earning 60% of the AMI or below; and 16 units for seniors earning 80% of the AMI or below. Demographic trends on the island show that in the next 20 years, the segments of the population that will grow the most are those aged 45 to 64, 65 to 81, and 82, as discussed in **Section 5.1**. The island as a whole is aging. The Project will create the opportunity for much-needed affordable housing for the growing senior population, and maintain socio-economic diversity in the urban core of Honolulu. Creation of additional affordable housing will allow local people to pursue other aspirations while easing the burden of rising housing costs.

Section 226-6 Objectives and policies for the economy- in general.

(b)(6) Strive to achieve a level of construction activity responsive to, and consistent with, state growth objectives.

(b)(8) Encourage labor-intensive activities that are economically satisfying and which offer opportunities for upward mobility.

(9) Foster greater cooperation and coordination between the public and private sectors in developing Hawai‘i's employment and economic growth opportunities.

Discussion: The Project is estimated to result in the creation of approximately 260 development--related jobs and five operations-related jobs. Employees would primarily be comprised of local people, thus contributing to greater job security within the construction and building sector.

Section 226-11 Objectives and policies for the physical environment--land-based, shoreline, and marine resources.

(b)(3) Take into account the physical attributes of areas when planning and designing activities and facilities.

(b)(4) Manage natural resources and environs to encourage their beneficial and multiple use without generating costly or irreparable environmental damage.

(b)(7) Provide public incentives that encourage private actions to protect significant natural resources from degradation or unnecessary depletion.

(b)(8) Pursue compatible relationships among activities, facilities, and natural resources.

(b)(9) Promote increased accessibility and prudent use of inland and shoreline areas for public recreational, educational, and scientific purposes.

Discussion: The physical attributes of this area along with the surrounding uses were taken into account in planning the proposed facility. The Project Site has already been developed, and does not contain environmentally-sensitive habitats. Northwest of the Project Site is the Nu'uanu Stream. A pedestrian mall, Sun Yat Sen Mall, runs adjacent to the Nu'uanu Stream. The Nu'uanu Stream is also considered by HDOH as impaired for various pollutants. During construction, various mitigation measures as discussed throughout will be employed to minimize impacts to the Nu'uanu Stream. In the long-term, the Project will include storm water drainage improvements. The proposed Project will not adversely impact this stream. Rather, the proposed Project will enhance the existing streetscape environment that will allow residents to interact with the natural surrounding environment.

Section 226-12 Objective and policies for the physical environment-scenic, natural beauty, and historic resources.

(b)(1) Promote the preservation and restoration of significant natural and historic resources.

(b)(3) Promote the preservation of views and vistas to enhance the visual and aesthetic enjoyment of mountains, ocean, scenic landscapes, and other natural features.

(b)(4) Protect those special areas, structures, and elements that are an integral and functional part of Hawai'i's ethnic and cultural heritage.

Discussion: The Project includes the demolition of the existing building. The Draft AIS determined that the Project has the potential to impact the archaeological historic property (SIHP # -8840) and thus the Project's effect determination per HAR §13-275-7 is "effect, with agreed upon mitigation commitments." In addition, under Section 106 of the NHPA, the Project will have an "adverse effect" on SIHP # -8840. For further discussion, see **Section 5.2**. See **also Appendix N, Archaeological Inventory Study Report** and Appendix P, Memorandum of Agreement. The Project will not have an adverse impact on any views or vistas identified in the PUC DP, as discussed in **Section 3.6**.

Section 226-13 Objectives and policies for the physical environment--land, air, and water quality.

(b)(2) Promote the proper management of Hawai'i's land and water resources.

(b)(3) Promote effective measures to achieve desired quality in Hawai'i's surface, ground, and coastal waters.

(b)(4) Encourage actions to maintain or improve aural and air quality levels to enhance the health and well-being of Hawai'i's people.

(b)(7) Encourage urban developments in close proximity to existing services and facilities.

> **Discussion:** The Project is located within the PUC, in an area well-served by public transit, shopping, and social and recreational resources. Furthermore, it is located within the Downtown TOD Plan area. Because of its convenient location, the Project Site is ideal for the use of residential development for seniors because it offers an opportunity to access needs and recreation without the use of a car. Construction BMPs will be implemented to protect land and water resources. The Project will incorporate LID design techniques, and effects to Nu'uanu Stream will be minimized.

Section 226-17 Objectives and policies for facility systems--transportation.

(a)(1) An integrated multi-modal transportation system that services statewide needs and promotes the efficient, economical, safe, and convenient movement of people and goods.

(a)(2) A statewide transportation system consistent with planned growth objectives throughout the State.

(b)(1) Design, program, and develop a multi-modal system in conformance with desired growth and physical development as stated in this chapter.

(b)(5) Promote a reasonable level and variety of mass transportation services that adequately meet statewide and community needs.

(b)(6) Encourage transportation systems that serve to accommodate present and future development needs of communities.

(b)(10) Encourage the design and development of transportation systems sensitive to the needs of affected communities and the quality of Hawai'i's natural environment.

> **Discussion:** The proposed Project is located within a walkable community within the proposed Downtown TOD SD. The Project Site is also in proximity to bus service, as discussed in **Section 4.1**. Close proximity to public transit alternatives will offer seniors the ability to access shopping and recreational resources without the need of a car. Additionally, secured, long-term bicycle storage within the parking structure will be available to residents. The location of the residential facility will allow residents to utilize alternative modes of transportation, thus contributing to a reduction in GHG emissions.

Section 226-19 Objectives and policies for socio-cultural advancement – housing

(b)(1) Effectively accommodate the housing needs of Hawai'i's people.

(b)(2) Stimulate and promote feasible approaches that increase housing choices for low-income, moderate-income, and gap-group households.

(b)(3) Increase homeownership and rental opportunities and choices in terms of quality, location, cost, densities, style, and size of housing.

(b)(4) Promote appropriate improvement, rehabilitation, and maintenance of existing housing units and residential areas.

(b)(5) Promote design and location of housing developments taking into account the physical setting, accessibility to public facilities and services, and other concerns of existing communities and surrounding areas.

Discussion: The Project will provide 155 rental housing units for seniors earning 80% or below AMI within the PUC. The proposed housing mix is presented in **Table 1**. The provision of affordable rental housing will achieve the State Plan objective of increasing rental opportunities and choice for various income groups. The Project will meet the needs of the island's progressively aging population. The Project Site is located in an area of Downtown-Chinatown that will allow residents to take advantage of the surrounding social and recreational opportunities, which will greatly contribute to seniors' quality of life. The demolition of the existing, dilapidated, vacant building and improvements to the Project Site will enhance the surrounding community.

Section 226-104 Population growth and land resources priority guidelines.

(a)(1) Ensure that adequate support services and facilities are provided to accommodate the desired distribution of future growth throughout the State.

Discussion: The Project site is located within the PUC, which is home to almost half of the island's population. While growth is expected to be directed towards the 'Ewa region, City projections still forecast an increase of the population within the PUC as discussed in **Section 5.1**. The Project would provide 155 rental housing units for seniors, which will be essential in accommodating the expected population growth. *Section 226-109 Climate change adaptation priority guidelines. Priority guidelines to prepare the State to address the impacts of climate change, including impacts to the areas of agriculture; conservation lands; coastal and nearshore marine areas; natural and cultural resources; education; energy; higher education; health; historic preservation; water resources; the built environment, such as housing, recreation, transportation; and the economy shall:*

(5) Encourage the preservation and restoration of natural landscape features, such as coral reefs, beaches and dunes, forests, streams, floodplains, and wetlands, that have the inherent capacity to avoid, minimize, or mitigate the impacts of climate change;

(6) Explore adaptation strategies that moderate harm or exploit beneficial opportunities in response to actual or expected climate change impacts to the natural and built environments;

(7) Promote sector resilience in areas such as water, roads, airports, and public health, by encouraging the identification of climate change threats, assessment of potential consequences, and evaluation of adaptation options;

(8) Foster cross-jurisdictional collaboration between county, state, and federal agencies and partnerships between government and private entities and other nongovernmental entities, including nonprofit entities.

(9) Use management and implementation approaches that encourage the continual collection, evaluation, and integration of new information and strategies into new and existing practices, policies, and plans; and

(10) Encourage planning and management of the natural and built environments that effectively integrate climate change policy.

Discussion: The Project will consider sea level rise and climate change adaptation policies as recommended in the *Hawai'i Sea Level Rise Vulnerability and Adaptation Report*. (2017) and updated by the Guidance from the Honolulu Climate Change Commission, the City and County of Honolulu has found that a planning benchmark of six feet of sea level rise (SLR) is appropriate for projects with a life-span beyond mid- century, and for critical infrastructure. High tide flooding and nuisance flooding may be present and precede global mean SLR by decades. The National Oceanic and Atmospheric Administrators (NOAA) have come up with a viewer to view impacted areas at different levels of sea level rise. At six feet the Project Site will not be affected by sea level rise. The Project is pursuing LEED certification and will be designed to meet LEED silver, which is understood to contribute to overall resilience of the Project site and wider community. Design features may include, but are not limited to, the use of landscape buffers and other LID measures. Additionally, smart growth policies advocate compact development and neighborhood design that reduces the use of cars, which emit GHGs. The Project Site is well-served by public transit, and is in close proximity to the future Chinatown Rail station. The Project will also improve the streetscape along the frontage of the new building, which will improve the pedestrian environment. The convenient location of the Project near services and the existing transportation network will allow seniors the freedom to move about without the need of a car.

6.2.2 Hawai'i State Land Use Law

The Hawai'i State Land Use Law (HRS, Chapter 205), adopted in 1961, is intended to preserve and protect Hawai'i's lands and encourage the uses to which the lands are best suited. All land in Hawai'i is classified in one of the following four SLUDs: Urban, Rural, Agricultural or Conservation.

The subject Project site is located in the "Urban" district. See **Figure 18: State Land Use Map.** HRS, Chapter 205-2, "Districting and classification of lands" states the following:

(a) There shall be four major land use districts in which all lands in the State shall be placed: urban, rural, agricultural, and conservation. The land use commission shall group contiguous land areas suitable for inclusion in one of these four major districts. The commission shall set standards for determining the boundaries of each district, provided that:

(1) In the establishment of boundaries of urban districts those lads that are now in urban use and a sufficient reserve area for foreseeable urban growth shall be included.

In establishing the boundaries of the districts in each county, the commission shall give consideration to the master plan or general plan of the county.

(b) Urban districts shall include activities or uses as provided by ordinances or regulations of the county within which the urban district is situated.

Discussion: The Project is located in the Urban district. A SLUD Boundary Amendment is not needed to redevelop the property as proposed. The proposed use of the subject property for residential development would be consistent with the Urban designation.

6.2.3 Affordable Rental Housing Report and Ten-Year Plan (July 2018)

In July 2018, the DBEDT-OP published the *Affordable Rental Housing Report and Ten-Year Plan* ("Ten-Year Plan"), in accordance with Act 127 signed by Governor David Y. Ige on June 29, 2016, which established a goal of developing 22,500 affordable rental units statewide by December 31, 2026. However, the Ten-Year Plan cites DBEDT statistics that project statewide demand to be 64,693 units statewide by 2025, with nearly 70% needed for households earning 80% or less of the AMI. The DBEDT-OP's Ten-Year Plan further specified the housing production goals for each HUD income group. The goal stipulated for Honolulu under Act 127 is to develop 9,002 new affordable rental units (while the need is projected to be and 25,847 units by 2025) with the greatest need being as follows:

- Less than 30% AMI: 2,160 units
- 30% to 50% AMI: 1,740 units
- 50% to 60% AMI: 884 units

Figure 18: State Land Use Map

6.2.4 Coastal Zone Management Act (CZMA), HRS, 205(A)

The Federal CZMA enacted in 1972, provides states with financial incentives for the development and implementation of CZM practices, and limited review power over Federal actions affecting the State's Coastal Zone. As a response, HRS, Chapter 250(A), Hawai'i Coastal Zone Law, as amended, was enacted in 1977. The State has designated CZMP to manage the intent, purpose and provisions of HRS, Chapter 250(A)-2 for the areas from the shoreline to the seaward limit of the State's jurisdiction, and any other area which a lead agency may designate for the purpose of administering the CZMP. All land and water use activities in the State must comply with HRS, Chapter 205(A). The CZMP is administered by the DBEDT, OP.

Discussion: The Project Site is not within a Coastal Zone Management Area. See **Section 6.1.5** for a full discussion.

6.3 CITY AND COUNTY OF HONOLULU LAND USE PLANS AND REGULATIONS

6.3.1 General Plan for the City and County of Honolulu (Proposed Revised Plan, 2017)

The City's General Plan (GP) is a comprehensive statement of objectives and policies which sets forth the long-range aspirations of O'ahu residents, as well as strategies of action needed to achieve such goals. It is the focal point of a comprehensive planning process that addresses physical, social, economic, and environmental concerns affecting the City. This planning process serves as the coordinative means by which the City provides for the future growth of the metropolitan area of Honolulu.

The GP was adopted in 1992, and amended in 2002. DPP completed its Proposed Revised GP in December 2017. The Proposed Revised GP has been reviewed by the Planning Commission, and is currently being reviewed by the Honolulu City Council for adoption. An update to the GP is underway. Its working title is *O'ahu 2035: General Plan Focused Update*. The update considers critical issues of growth, development, and quality of life that island residents are most concerned about, including regional population, economic health, affordable housing, and sustainability.

The following sections highlight excerpts of the Proposed Revised GP that are particularly relevant to this Project (emphasis added).

PART I: POPULATION.

- *Objective A: To plan for anticipated population growth in a manner that acknowledges the limits of O'ahu's natural resources, that protects the environment, and that minimizes social, cultural, and economic disruptions.*
  - *Policy 1: Allocate efficiently the money and resources of the City and County in order to meet the needs of O'ahu's anticipated future population.*
  - *Policy 3: Seek a balanced pace of physical development in harmony with the County's environmental, social, cultural, and economic goals by effecting and enforcing City and County regulations.*
- *Objective B: To establish a pattern of population distribution that will allow the people of O'ahu to live and work in harmony.*
  - *Policy 1: Facilitate the full development of the primary urban center.*

Discussion: The Project will be developed on a City property that is currently underutilized and considered urban blight. City support for the Project represents an efficient use of their resource. The Project will also be developed under the HRS, Chapter 201H Affordable Housing exemption

program. The Project exceeds the minimum requirements of HRS, Chapter 201H because it provides 100% of the units to seniors earning 80% or below of the AMI.

As discussed throughout this EA, the Project Site is located within the PUC, which is home to almost half of the island's population. City projections still indicate an increase of the population within the PUC of 67,000 people from 2000 to 2025, for a total of 486,000 persons (DPP, 2004). As discussed in **Section 5.1**, population aging is one of the most prominent features of the State's population trend, increasing by 3.3% annually on average. The proposed Project would provide 155 affordable senior rental housing units, which will be essential in accommodating the expected population growth amongst the senior demographic.

PART IV: HOUSING.

- *Objective A: To provide decent housing for all the people of O'ahu at prices they can afford.*
  - *Policy 5: Make full use of State and Federal programs that provide financial assistance for low- and moderate-income homebuyers.*
  - *Policy 12: Promote higher-density, mixed use development, including transit-oriented development, to increase the supply of affordable and market homes convenient to jobs, shops, and public transit.*
  - *Policy 13: Encourage the provision of affordable housing designed for the elderly and the handicapped.*

- *Objective C: To provide the people of O'ahu with a choice of living environments which are reasonably close to employment, recreation, and commercial centers and which are adequately served by public utilities.*

  - *Policy 1: Encourage residential developments that offer a variety of homes to people of different income levels and to families of various sizes.*
  - *Policy 3: Encourage residential development near employment centers.*
  - *Policy 4: Encourage residential development in areas where existing roads, utilities, and other community facilities are not being used to capacity.*
  - *Policy 5: Support mixed-use, higher-density redevelopment in areas surrounding future transit stations.*

Discussion: The Project will be a direct fulfillment of the GP policy to provide affordable housing for the elderly. LIHTC has been approved by the HHFDC, and units will be affordable for seniors earning 80% or below of the AMI, with a majority of units available for seniors earning 60% of the AMI or below (refer to Table 1) for the proposed housing mix. The Project would include units that range from one to two-bedrooms, further contributing to a mix of housing.

As discussed throughout this EA, the Project Site is located within 0.4-mile of the future Chinatown Rail Station. The proposed Project would be consistent with the Downtown TOD Plan goals in providing affordable housing near Rail and other public transit. The Project Site is currently underutilized, but near various shopping, cultural, and social/recreational opportunities for seniors. Therefore, the Project will result in an optimization of use of the property.

PART V. TRANSPORTATION & UTILITIES.

- *Objective A: To create a transportation system which will enable people and goods to move safely, efficiently, and at a reasonable cost; serve all people, including the poor, the elderly, and the physically handicapped; and offer a variety of attractive and convenient modes of travel.*

    - *Policy 7: Promote the use of public transportation as a means of moving people quickly and efficiently, of conserving energy, and of guiding urban development.*

Discussion: The Project Site is located within 0.4-mile of the future Chinatown Rail Station and within the proposed Downtown TOD SD. The Project will be consistent with the Downtown TOD SD goals in providing affordable housing near Rail and other public transit. The Project location is near services, recreation, and cultural resources for seniors that will allow seniors the opportunity to forgo the costs of supporting a vehicle.

PART VII: PHYSICAL DEVELOPMENT AND URBAN DESIGN.

- *Objective A: To coordinate changes in the physical environment of O'ahu to ensure that all new developments are timely, well-designed, and appropriate for the areas in which they will be located.*
    - *Policy 1: Provide infrastructure improvements to serve new growth areas, redevelopment areas, and areas with badly deteriorating infrastructure.*
    - *Policy 5: Provide for more compact development and intensive use of urban lands where compatible with the physical and social character of existing communities.*
    - *Policy 6: Facilitate transit-oriented development in rail transit station areas to create live/work/play multi-modal communities that reduce travel and traffic congestion.*
    - *Policy 13: Promote opportunities for the community to participate meaningfully in planning and development processes, including new forms of communication and social media.*
- *Objective F: To create and maintain attractive, meaningful, and stimulating environments throughout O'ahu.*

    - *Policy 1: Encourage distinctive community identities for both new and existing communities and neighborhoods.*

- *Objective G: To promote and enhance the social and physical character of O'ahu's older towns and neighborhoods.*

    - *Policy 1: Encourage new construction in established areas to be compatible with the character and cultural values of the surrounding community.*

    - *Policy 2: Encourage, wherever desirable, the rehabilitation of existing substandard structures.*

    - *Policy 6: Support and encourage cohesive neighborhoods which foster interactions among neighborhoods, promote vibrant community life, and enhance livability.*

Discussion: The Project will revitalize a currently underutilized property considered to be urban blight. The existing building will be demolished to make way for the new facility. The building is currently vacant, dilapidated, and contains hazardous materials. The proposed Project has been designed in consultation with the community and Feng Shui advisors as discussed in detail in **Section 7.7**. As discussed throughout this EA, the Project Site is located within 0.4-mile of the future Chinatown Rail Station. The proposed Project will be consistent with the Downtown TOD SD goals in encouraging compact development and providing affordable housing near Rail and other public transit. Residents of the Project would also be provided various amenities on the ground floor, including an outdoor courtyard, multi-purpose room and activity rooms, along with a computer room. The proposed Project will also place senior residents near cultural, social, and recreational opportunities that contribute to the vibrancy of the Chinatown neighborhood.

Part IX: Health and Education: To protect the health and well-being of residents and visitors.

- *Objective A: To protect the health and well-being of residents and visitors.*
  - *Policy 9: Support becoming an age-friendly city that provides people of all ages with user-friendly parks and other public gathering places, that offers safe streets and multi-modal transportation options, that provides an adequate supply of affordable housing, that encourages growth in needed and desirable jobs, that provides quality health-care and support services, and that encourages civic participation, social inclusion, and respect between interest groups.*
  - *Policy 10: Plan for our aging population's growing health-care, personal service, and diverse daily activity needs, and encourage these services to be provided in a timely manner, including age-specific social activities.*

Discussion: The Project is a direct fulfillment of the City's Age-Friendly policies. As discussed, the Project will provide units affordable to seniors earning 80% of the AMI or below, with a majority of units for seniors earning 60% of the AMI or below (see **Table 1**). The Project is intended to meet the demand of the island's growing senior population. Furthermore, the Project Site's location will put senior residents near cultural, social, and recreational opportunities/amenities and reduce their need to drive.

X. Culture and Recreation

- *Objective A: To foster the multiethnic culture of Hawai'i and respect the host culture of the Native Hawaiian people.*
  - *Policy 2: Promote the preservation and enhancement of local cultures, values, and traditions.*
  - *Policy 4: Encourage opportunities for better interaction among people with different ethnic, social, and cultural backgrounds.*
  - *Policy 5: Preserve the identities of the historical communities of O'ahu.*
- *Objective B: To protect, preserve and enhance O'ahu's cultural, historic, architectural, and archaeological resources.*

- *Policy 2: Identify and, to the extent possible, preserve and restore buildings, sites, and areas of social, cultural, historic, architectural, and archaeological significance.*
- *Cooperate with the State and Federal governments in developing and implementing a comprehensive preservation program for social, cultural, historic, architectural, and archaeological resources.*

Discussion: The Project is located within the Downtown-Chinatown neighborhood of Honolulu (though not within the Chinatown SD or Punchbowl SD). Various cultural establishments that contribute to the unique character of the neighborhood are located in close proximity to the Project Site. The Project will revitalize a currently underutilized property considered to be urban blight. The existing building will be demolished to construct the new residential facility. The existing building is currently vacant, dilapidated, and contains hazardous materials. Additionally, the new residential facility has been designed in consultation with the community and Feng Shui advisors as discussed in **Section 7.7**. NHPA Section 106 consultation was conducted, as discussed in **Section 5.2**.

XI. Government Operations and Fiscal Management

- *Objective A: To promote increased efficiency, effectiveness, and responsiveness in the provision of government services by the City.*
  - *Policy 3: Ensure that government attitudes, actions, and services are sensitive to community needs and concerns.*

Discussion: As discussed in **Section 2.6.2**, the community preferred the construction of a senior residence facility as opposed to a "Housing First" alternative. The City therefore entered into a Development Agreement with HSD to develop the Project on its property as such. Since 2014, HSD has consulted extensively with the community and made design modifications in response to stakeholder needs and concerns.

6.3.2 Primary Urban Center Development Plan

Supporting the GP are the sustainable communities plans and development plans (DPs) for various regions of O'ahu. Each plan explains the role of the particular region in O'ahu's overall development pattern; the vision statement for the area; land use policies, principles and guidelines; public facilities and infrastructure policies and principles; implementation strategies; and maps of Open Space, Land Use and Public Utilities. The PUC DP was adopted by the City Council via Ordinance 04-14 in June 2004, and is currently being updated by DPP. The plan was prepared as a community-developed guidance document for orderly and coordinated public and private sector development in the PUC DP area in a manner that is consistent with applicable GP provisions, including the designation of the PUC as the principal region for future growth in residential population and jobs.

The Project site is located within the PUC DP area, specifically within the "Urban Community Boundary" and has been designated as "Medium and Higher-Density Residential Mixed Use." See **Figure 4**.

The following sections highlight excerpts of the PUC DP that are particularly relevant to this Project (emphasis added).

Chapter 2: The Vision for the PUC's Future

- *Livable neighborhoods have business districts, parks and plazas, and walkable streets.*
- *The PUC offers in-town housing choices for people of all ages and incomes.*
- *A balanced transportation system provides excellent mobility for residents and visitors.*

Discussion: The proposed Project would help fulfill the development vision set forth in the PUC DP. The proposed Project Site is near shopping, restaurants, cultural, social, and recreational opportunities and reduces the need to drive. The use of bus and rail transit, bicycling and walking will be encouraged by the Project proximity to the future Chinatown Rail Station. The courtyard and improvements to the River Street streetscape will help integrate the Project with neighboring uses. HSD will contribute to the supply of affordable rental units by supporting housing for seniors in the 30% AMI, 60% AMI, and 80% AMI or below income brackets. All units will be ADA compliant or adaptable and equipped with energy saving kitchen appliances, along with air conditioning.

Chapter 3: Land Use and Transportation

Protecting and Enhancing Natural, Cultural and Scenic Resources

- *Preserve historic and cultural sites*
- *Preserve panoramic views of natural landmarks and the urban skyline*
- *Provide parks and active recreation areas*

Discussion: Section 106, NHPA consultation was conducted for the Project. The Draft AIS determined that the Project has the potential to impact the archaeological historic property (SIHP # -8840) and thus the Project's effect determination per HAR §13-275-7 is "effect, with agreed upon mitigation commitments." In addition, under Section 106 of the NHPA, the Project will have an "adverse effect" on SIHP # -8840. The agreed upon mitigation commitments included in the Draft AIS, include preparing a BTP for the human burial site, identified as Component 3 of SIHP # -8840 and archaeological monitoring for Components 1–3 of SIHP # -8840. With the implementation of these mitigation commitments, the Project's potential adverse effect on SIHP # -8840, subsurface cultural deposits will be reduced. For further discussion, see **Section 5.2.**

As discussed in **Section 3.6**, the proposed building will not interfere with any panoramic views. The Project Site is well-served by parks and recreational resources, as discussed in **Section 4.2**. Additionally, the new building will include a multi-purpose room with warming kitchen, restrooms, storage, a computer room, social services activity rooms, social services office, a courtyard, and retail space. The fourth floor will include a covered recreation deck and dog area for additional recreation opportunities.

Cultivating Livable Neighborhoods

- *Develop a system for collaborative neighborhood planning:*
- *Cultivate existing and new "neighborhood centers"*
- *Make streets "pedestrian-friendly"*

Discussion: The existing Project Site is underutilized and considered urban blight. The proposed Project would renew the Project Site and enhance the design and safety of the surrounding neighborhood through streetscape enhancements. The Project will include a multi-purpose room for resident and neighborhood use. HSD started consultation with the surrounding community and

other stakeholders on the Project in 2014 and has incorporated various design recommendations. The Project has also been conceived with input from Feng Shui professionals.

In-Town Housing Choices

- *Reduce costs for apartment homes.*
- *Preserve and expand the current inventory of affordable rental housing units.*
- *Provide incentives and cost savings for affordable housing.*
- *Provide for high-density housing optiotemp to deletens in mixed-use developments around transit stations.*

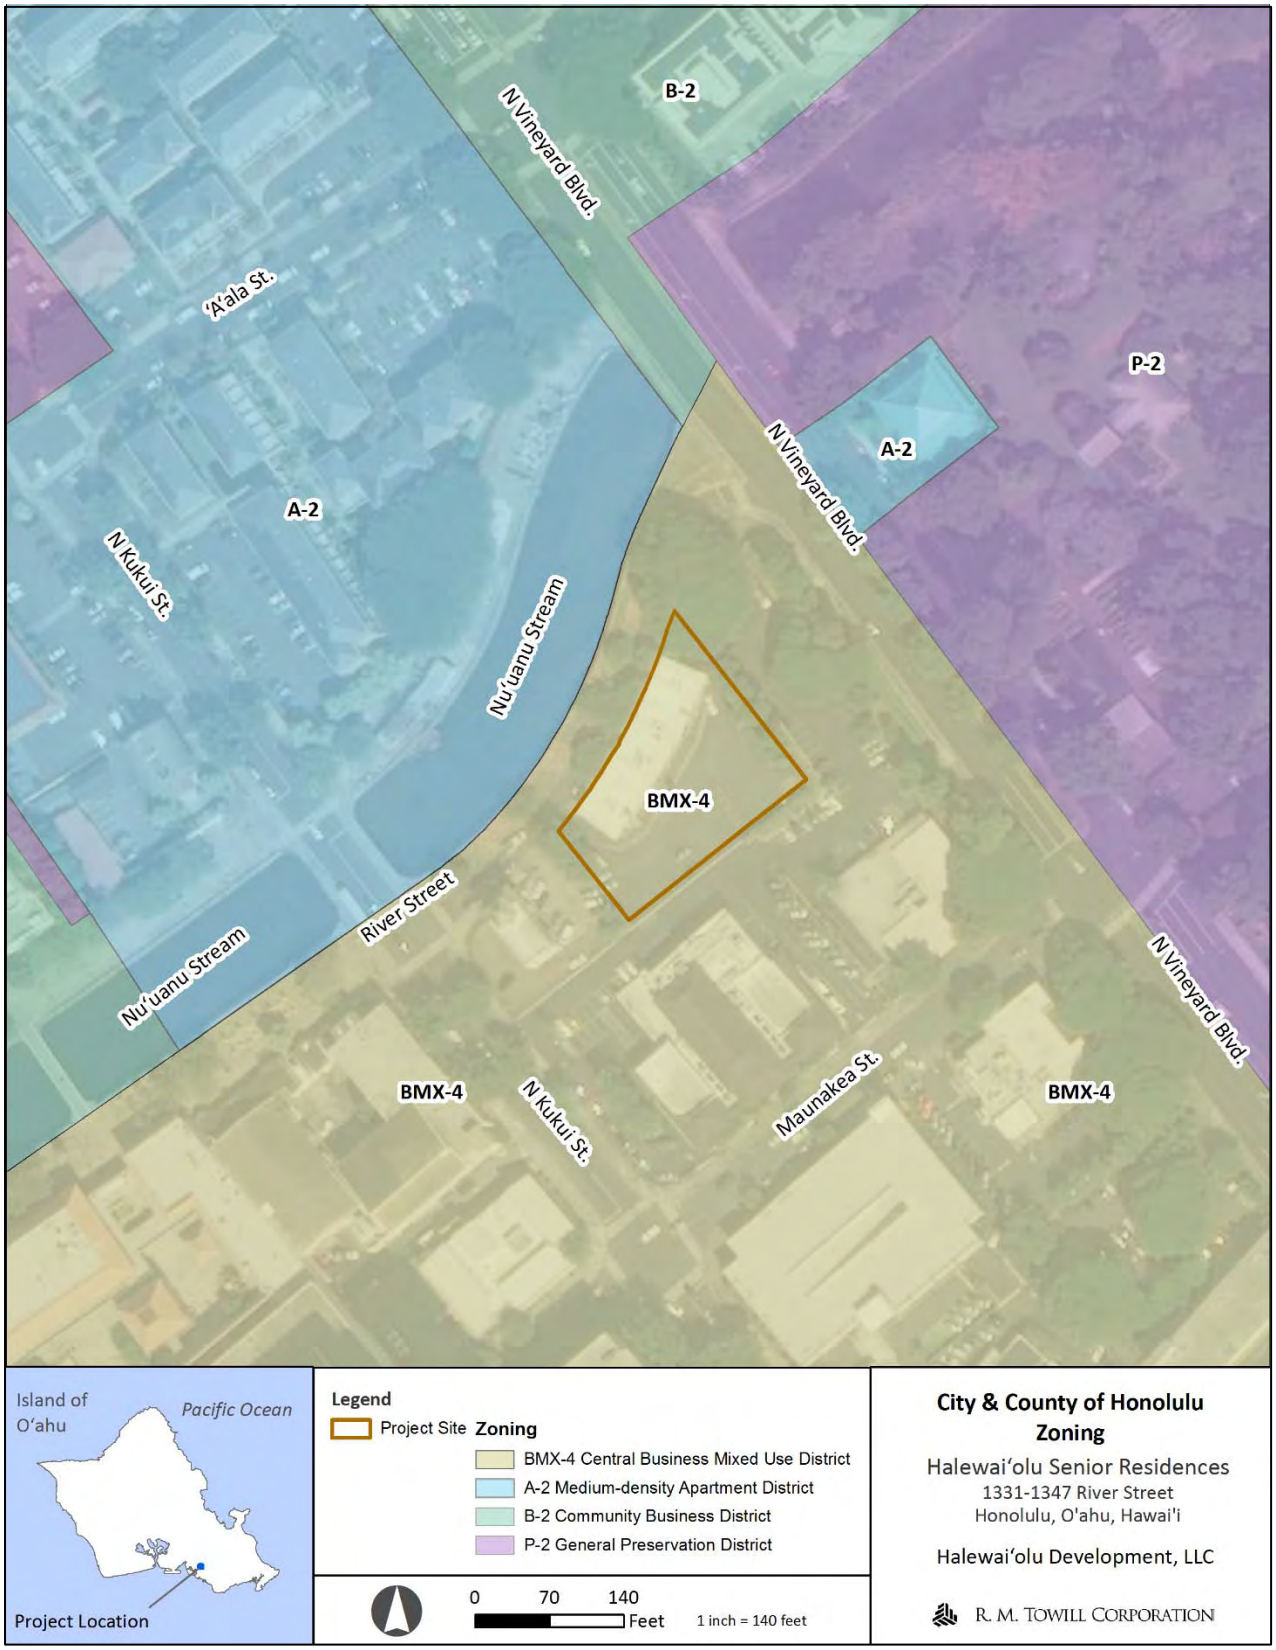
Discussion: The Project will consist of one- and two-bedroom affordable rental units for seniors earning 30% of the AMI, 60% of the AMI, and 80% of the AMI or below. In order to construct the Project, HSD will seek Chapter HRS, 201H exemptions to ameliorate the cost of the Project.

The proposed Project is a recipient of various affordable housing financing tools, including LIHTC, as discussed in **Section 2.7**. HSD will also seek affordable housing exemptions under HRS, Chapter 201H as discussed in **Section 6.3.4**.

Develop a Balanced Transportation System

- *Implement land use strategies to achieve a balanced transportation system.*
- *Implement Transportation Demand Management strategies.*
- *Implement the Honolulu Bicycle Master Plan.*
- *Enhance and improve pedestrian mobility.*
- *Encourage the full use of existing private and public parking garages.*

Discussion: Because the Project is targeted to seniors and is located in close proximity to shopping, cultural, social, and recreational resources/amenities, HSD will seek exemptions to off-street parking and loading requirements through the HRS, Chapter 201H process. The Project will be constructed with 51 parking stalls. Sidewalks along River Street will be improved with landscaping and trees that enhance the pedestrian environment. The proposed Project is consistent with these policies and guidelines.



6.3.3 City and County of Honolulu Zoning

The subject property is in the BMX-4 district. See **Figure 19: City and County of Honolulu Zoning**. Land uses within the City jurisdiction are regulated under the ROH, Chapter 21, LUO. The LUO regulates land use in a manner that encourages the orderly development in accordance with the GP and DPs. The intent of the Business Mixed Use (BMX) district is to:

> *"Set apart that portion of Honolulu which forms the city's center for financial, office and governmental activities and housing. It is intended for the downtown area and not intended for general application. It provides the highest land use intensity for commerce, business, and housing."*

The residential housing proposed by this Project is a permitted use within the BMX-4 district, per ROH, Sec. 21-3, Table 21-3, *Master Use Table*. See Table 18: Land Use Development Standards below for the development standards for BMX-4 district as compared to the proposed Project.

Figure 19: City and County of Honolulu Zoning

Discussion: The Project use will be conforming with respect to land use and most zoning development standards. For those standards it does not meet, the Project will seek HRS Chapter 201H exemptions for affordable housing.

Table 18: Land Use Ordinance Development Standards

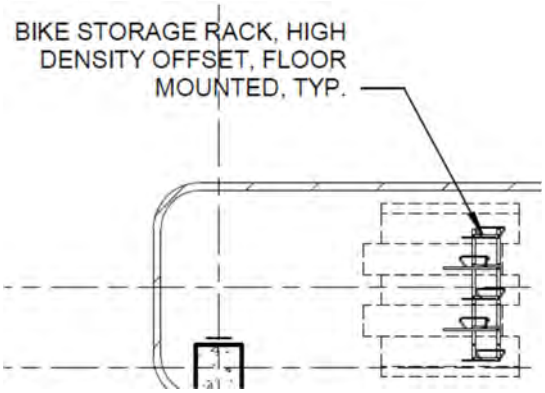
Development Standard	BMX-4	Proposed
Minimum Lot Area	5,000 square feet	26,925 square feet Compliant
Minimum Lot Width and Depth	50 feet	200 feet/143 feet Compliant
Front Yard	10 feet for dwellings 5 feet for other uses	0 feet Noncompliant
Side and Rear Setbacks	0 feet	3 feet Compliant
Maximum Building Area (square feet)	Not regulated	20,976 square feet
Maximum Height (feet)	350 feet	about 174 feet Compliant
Height Setbacks	"…for a minimum of 50% of any contiguous street frontage, no portion of a structure located on a lot adjacent to a street may exceed a height that is intersected by a plane over the buildable area that makes an angle of 65 degrees with the horizontal at ground elevation at the centerline of	54% provided Compliant
Maximum Allowable Floor Area	FAR 4.0 4.0 x 26,925 = 107,700 square feet	FAR 5.9 or 157,946 square feet Noncompliant
Minimum Off-street Parking Requirements	1. Dwelling units: 1 stall per unit = 156 stalls 2. Multi-purpose Room: 1 stall per 300 square feet = 35 stalls 3. Retail: 1 stall per 600 square feet (if > 4,000 square feet) = 0 stalls 4. Office: (1 stall per 600 square feet over 4,000 square feet) = 0 stalls Accessible Stalls: 4 Total Required: 191 stalls	51 stalls provided, includes 4 accessible stalls Noncompliant

Development Standard	BMX-4	Proposed
Off-street Loading Requirements	2 Loading Stalls: • One 12 feet x 35 feet x 14 feet • One 8.5 feet x 19 feet x 10 feet	1 Loading Stall (8 feet x 24 feet x 10 feet) Noncompliant
Bicycle Parking	Residential • Short-term: 1 space for every 10 units = 16 spaces • Long-term: 1 space for every 2 dwellings = 78 spaces	• 6 short-term stalls (Noncompliant) • 76 long-term stalls (Noncompliant)
	Non-Residential • Short-term: 1 per 2,000 square feet = 3 stalls • Long-term: 12,000 square feet = 1 stall	• 3 short-term stalls • 1 long-term stall

The Project will provide 51 off-street parking stalls that will include stalls to meet ADA requirements (the Development Agreement which projected 75 parking stalls and 10 ADA stalls for the Project will need to be modified, after the parameters of the 201H Approval by City Council, which may involve other changes to the Project described in the Development Agreement). One off-street loading area will be provided. DPP has recommended 25 parking stalls, since the Project Site is in walking distance to the future transit station and bus stops. The proposed 51 parking stalls represents a middle ground between the Development and DPP's recommendation. As necessary, the number of accessible parking stalls provided will be based on the requirements of the HDOH, DCAB Interpretive Opinion 2014-05.

Bicycle parking stalls located on the ground floor will be used for short-term bicycle parking.

Table 19: Land Use Ordinance Development Standards – Special District – Transit Oriented Development (TOD)



Development Standard	TOD	Proposed
Front Yard Setback ROH,21-9.100-8(a)(3)(D)(iii)	On a lot with a street frontage greater than 100 feet per frontage, the ground floor building facade must be placed within the maximum front setback for at least 65 percent of the linear street frontage.	Activities Center to be setback 0 feet and makes up 40% of street frontage. Noncompliant
Front Yard Setback ROH, 21-9.100-8(a)(3)(E)(ii)	For ground-floor residential uses, covered porches, stoops, or lanais may encroach into the required front yard. Other portions of the front yard must be landscaped, except for necessary access drives and walkways.	An open paved courtyard will encroach into the required front yard and as proposed landscaping will include potted trees. Noncompliant

Development Standard	TOD	Proposed
Building Orientation and Entrances ROH, 21-9.100-8(a)(4)(C)	At least one entrance must be placed every 50 feet of the building facade facing a street or pedestrian plaza.	One entrance facing the street along the 217-foot street frontage and two entrances facing the courtyard. Noncompliant
Building Transparency ROH, 21-9.100-8(a)(5)(A)	Building facades within 20 feet of a front or street-facing property line must contain windows, doors, or other openings for at least 60 percent of the building facade area located between 2.5 and 7 feet above the level of the sidewalk. Blank walls cannot extend for more than 25 feet in a continuous horizontal plane without an opening on the ground floor of a building.	Compliant
Minimum Off-street Parking Requirements ROH,21-9.100-8(c)(1)	1. Dwelling units 301-600 sq.ft. – 0.50 stalls – 130 = 65 601-800 sq.ft. – 0.75 stalls – 26 = 26 2. No minimum parking requirements for non-residential uses Multi-purpose Room: 0 stalls Retail: 0 stalls Office: 0 stalls Total Required: 91 stalls	51 stalls provided, includes 4 accessible stalls Noncompliant

Requested Exemptions and Deferrals

Although the Downtown TOD Plan was adopted by the City by Resolution 16-247, CD1, FD1, the boundaries of the Downtown TOD SD have not yet been designated, as defined in the ROH, Chapter 21, LUO. Therefore, there is some uncertainty as to whether or not the Project is also within the Downtown TOD SD. Therefore, **Table 20: Summary of Requested Exemptions and Deferrals** includes a summary of requested exemptions and deferrals related to both the BMX-4 district and the anticipated Downtown TOD SD, pursuant to HRS, Chapter 201H.

Table 20: Summary of Requested Exemptions and Deferrals

Development Standard / Requirement	Relevant Section	Requested Exemption	Applicable Agency
Front Yard Setback	ROH, Table 21-3.4	Exemption from 5-foot minimum front yard setback to 0 feet.	DPP/LUPD
FAR	ROH, Table 21-3.4	Maximum allowable density is 4.0; proposed FAR is 5.9.	DPP/LUPD
Off-street Parking Requirements	ROH, Table 21-6.2	Reduction in off-street parking requirement of 191 stalls per Sec. 21-6.20 to 51 stalls.	DPP/LUPD
Loading Space Requirements	ROH, 21-6.100	Reduction in required loading from 2 spaces to 1 space (large).	DPP/LUPD
Loading Space Requirements Size	ROH, 21-6.120	Exemption from loading stall sizes to allow a loading stall sized at 8 x 24 x 10.	DPP/LUPD
Bicycle Parking	ROH, 21-6.150(a)	Reduction in number of bicycle parking stalls for residential uses from 16 short-term spaces to 6 spaces, and 78 long-term spaces to 76 spaces for a total of 82 spaces for residential stalls. Reduce bicycle stall dimensions from 2'-0" x 6'-0" to 1'-4" x 6'-0" (to allow high-density, offset bike parking). See image 	DPP/LUPD
Location	ROH, 21-6.150(b)	Short-term bicycle parking should be located as close as possible to the entrances of the principal uses on a lot so that it is highly visible and easily identifiable.	
Front Yard Setback	ROH,21-9.100-8(a)(3)(D)(iii)	Exemption from standard to allow for the Activities Center to be setback 0 feet and make up 40% of street frontage.	DPP/LUPD
Front Yard Setback	ROH, 21-9.100-8(a)(3)(E)(ii)	Exemption from standard to allow an open paved courtyard to encroach into the required front yard and to approve proposed landscaping (potted trees).	DPP/LUPD

Development Standard / Requirement	Relevant Section	Requested Exemption	Applicable Agency
Structured Parking and Podiums	TOD Design Guidelines	Exemption from standard requiring parking podium be lined with habitable spaces or screened with a green wall or architecturally integrated false façade or screen.	DPP/LUPD
Structured Parking and Podiums	TOD Design Guidelines	Exemption from standard requiring structured parking to be located underground.	DPP/LUPD
Structured Parking and Podiums	TOD Design Guidelines	Exemption from standard requiring that parking podiums must be built with standard ceiling heights and level floors.	DPP/LUPD
Vehicle Parking, Loading, and Bicycle Parking	ROH,21-9.100-8(c)(3)	Exemption from standard to locate service areas and loading stalls at the side or rear of the site.	DPP/LUPD
Vehicle Parking, Loading, and Bicycle Parking	ROH,21-9.100-8(c)(5)	Exemption from standard that ground floor of parking structures on all streets must be designed and used for active ground floor activities within 40 feet of the front property line.	DPP/LUPD
Building Orientation and Entrances	ROH, 21-9.100-8(a)(4)(C)	Exemption from standard to allow for one entrance facing the courtyard along the 217-foot street frontage instead of one entrance placed every 50 feet of the building façade.	DPP/LUPD
Building Permit Fees	ROH, 18-6.2	Exemption from building permit fees (including demolition, building, foundation, plumbing, electrical, fire sprinkler, etc.).	DPP
Plan Review Fees	ROH, 18-6.1	Exemption from plan review fees.	DPP
Grading, Grubbing, and Stockpiling permit	ROH, 14-14.4	Exemption grading stockpiling, trenching, grubbing and de-watering fees.	DPP
Storm Drain Connection	ROH, 14-12.12	Exemption from storm drain connection license fee to facilitate the achievement of Project economic feasibility.	DPP and ENV
Trenching	ROH, 14-17.1	Exemption from trenching, repair and service permit fees.	DPP

Development Standard / Requirement	Relevant Section	Requested Exemption	Applicable Agency
Water System Connection	1-102, 2-202(2), and 2-202(3) of the Board of Water Supply Rules and Regulations	Exemption from water system connection and facility charges attributed to affordable dwelling units. If required, deferral of fees until certificate of occupancy.	BWS
Sewer Lateral Connection and Facility	ROH, 14-3.2	Exemption of payment of sewer lateral connection and installation charges.	DPP/ Wastewater Branch
Wastewater System Facility Charge	ROH, 14-10.3	Exemption from payment of wastewater connection fees. If required, deferral of fees until certificate of occupancy.	DPP/ Wastewater Branch
Park Dedication	ROH, 22-7	Exemption from park dedication requirements as proposed and exemption from the park dedication process.	DPP and DPR
Fire Department Plan Review Fees	ROH, 20-1.1(3)10.a	Exemption from HFD plan review fees.	HFD
Downtown TOD Special District Permit Process	ROH, 21-2.40-2 Major Permits	Exemption from Major Permit process for the Downtown TOD Special District.	DPP

6.3.4 Downtown Neighborhood TOD Plan (2017)

The City has prepared neighborhood TOD plans that integrate land use and transportation planning around the rail stations in anticipation of the rail. These plans are intended to address opportunities for new development, including rehabilitation and adaptive reuse of existing buildings and assets, increased density and height limits in appropriate areas around the stations to leverage locational advantages, and a holistic plan for orderly growth and improved accessibility around the stations. The Downtown TOD Plan addresses land use, local transportation, public facilities and services, economics, infrastructure planning, and options for implementation around the three Downtown stations: Downtown, Chinatown, and Iwilei. The Honolulu City Council adopted the August 2017 version of the Downtown TOD Plan on September 6, 2017 as City, Council Resolution No. 16-247, CD1, FD1. The Downtown TOD Plan defines TOD as follows:

> *"Transit-oriented development (TOD) typically refers to development within easy walking distance of a major transit stop that both capitalizes on and supports transit ridership. TOD may be redevelopment of existing facilities or new development. Transit stops may be rail stations, major bust stops, or other well-used transit hubs. The area where TOD typically occurs is the 1/4 -or 1/2-mile radius around the station/stop (a five or ten-minute walk). TOD should be designed at the pedestrian scale since all transit trips begin and end as walking trips. TOD is typically moderate to higher density development, with a mix of residences, employment, and shopping. Higher densities are an important part of the TOD definition in order to encourage use of transit, reduce the area developed to parking, and support shopping, open space and pedestrian facilities."*

The Project is located within the proposed Downtown TOD SD and 0.4-mile from the future Chinatown Rail Station. The Project Site has been designated as "Mixed Use – High Intensity" per the plan's vision and guiding principles. See **Figure 20: Downtown Neighborhood TOD Plan - Plan Concept**. The plan's vision for the Chinatown Station and neighborhood are as follows:

> *"The scale and character of historic buildings and historic Chinatown are maintained following rail's arrival, but transit access is improved, and key opportunities for development are pursued on parking lots along Nimitz Highway. An enhanced promenade along Nu'uanu Stream creates a stronger open space link between the waterfront and Foster Botanic Garden and expanded places for gathering. New uses and public services accommodate the needs of seniors, children and families, and a multi-cultural community."*

The following sections discuss the Halewai'olu Senior Residence Project consistency with applicable recommendations for the Chinatown Station and the Downtown TOD Plan (emphasis added).

Section 1.3: Corridor Vision and Planning Principle

Community Vision: Downtown Honolulu will continue to be the region's premier employment center with a substantial residential population and easy access to stores and everyday amenities. An accessible and activated waterfront with promenades and community uses, a vibrant, historic Chinatown, and a new high-intensity mixed-use Iwilei district as an extension of Downtown will create a new image for Downtown Honolulu.

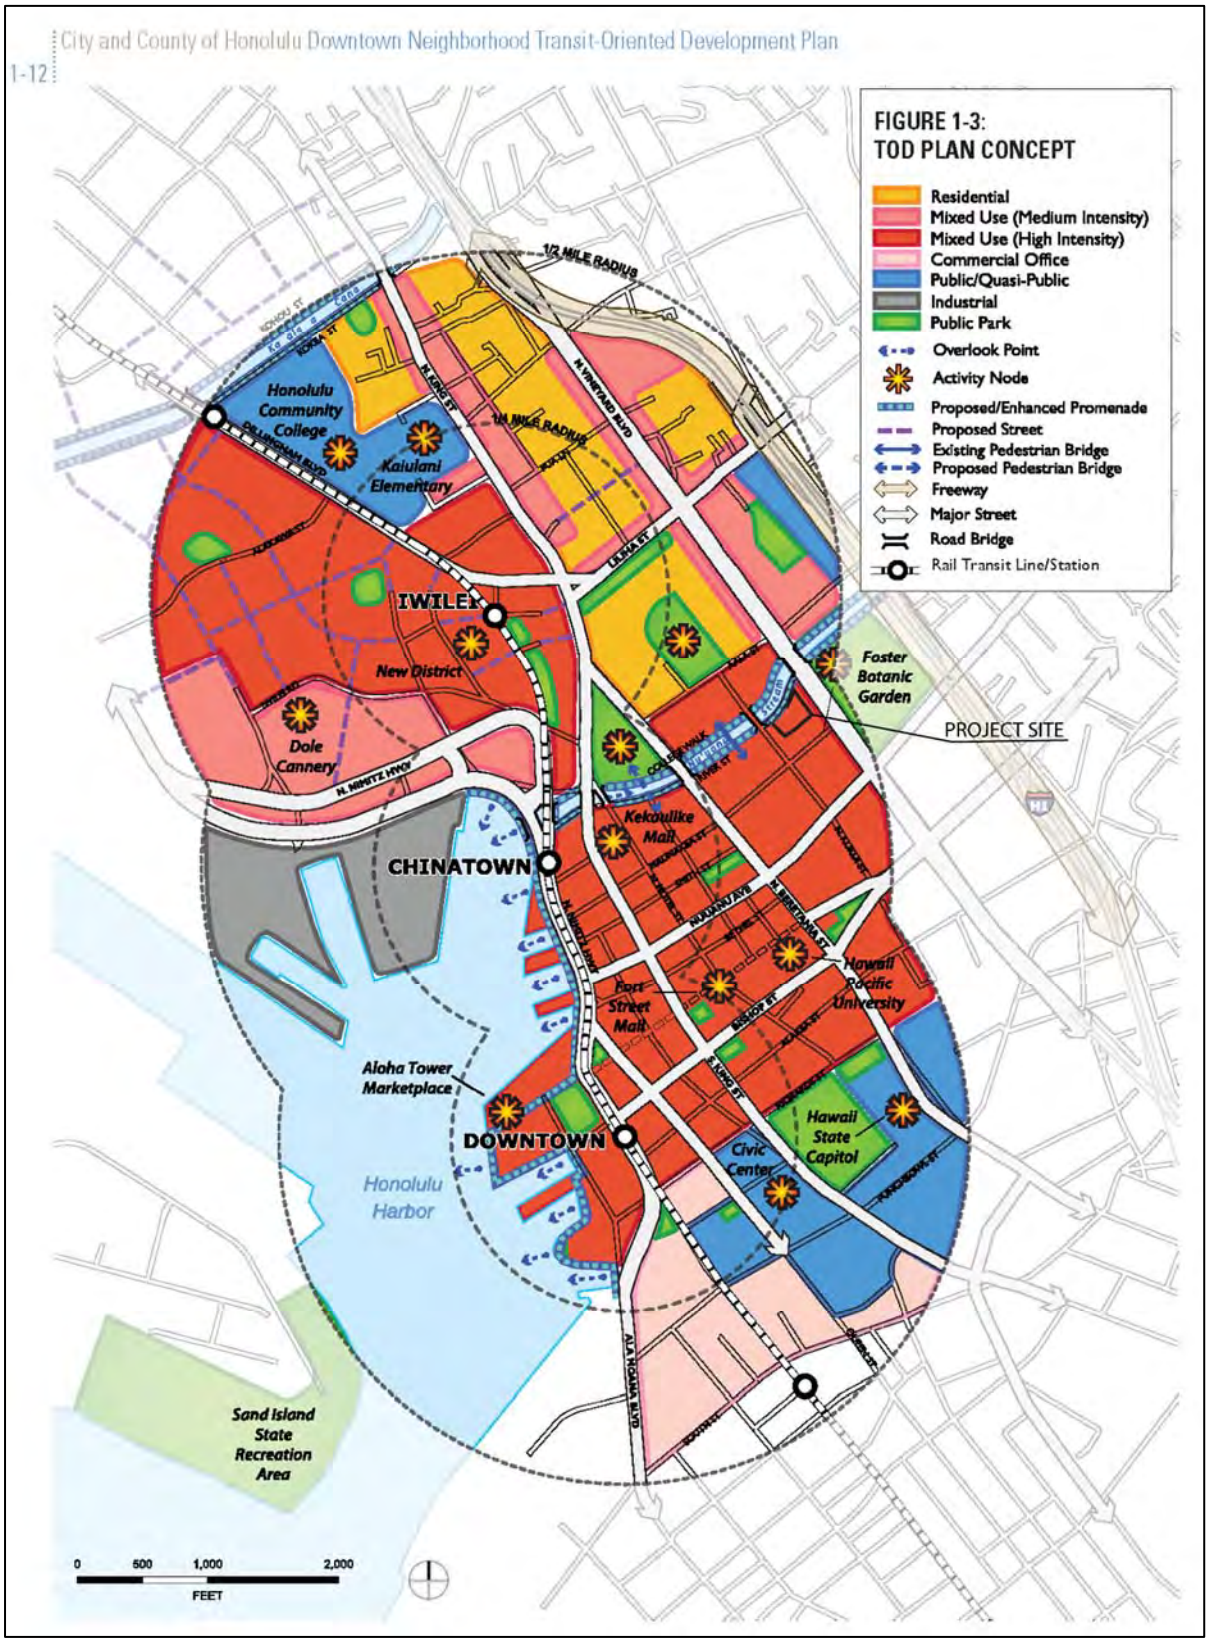
Guiding Principles:

1. Develop a Vibrant Mixed-Use Downtown

2. Expand Housing Opportunities and Provide a Range of Housing Types.

3. Balance Density with Green Space

Discussion: The Project will expand housing opportunities in the Downtown TOD Plan area by providing one- and two-bedroom affordable rental units for seniors earning 30% of the AMI, 60% of the AMI, and 80% of the AMI or below. The Project's Multi-Purpose Room at the ground floor will contribute to the lively environment envisioned in the Downtown TOD Plan. The courtyard/plaza will provide a balance between density and green space with an opportunity for plants as envisioned in the guiding principles.



Chapter 2. Land Use

2.2. Development Framework

Land Use Classification: Specific allowed uses will be regulated through a TOD Special District in the Land Use Ordinance, which will also reflect the building intensity and heights established in this plan.

Active Ground-Floor Frontage and Pedestrian-Oriented Design: The Plan seeks to create concentrated areas of vitality by identifying streets where "active" ground-floor frontages are required.

Figure 20: Downtown Neighborhood TOD Plan – Plan Concept

Building Intensity: Allowable intensities decline with distance from the station. In the Downtown Mixed Use designation, in exchange for additional publicly accessible open space, streets/connections, and/or affordable housing (beyond what is required), sites within the TOD Zone are eligible for building intensity bonuses

Building Heights - The tallest building heights will continue to be located in the Downtown core. Low building heights are shown in the Chinatown core and in the Capital District area, consistent with the existing requirements of those special districts.

Discussion: The Project Site has been designated as "Downtown Mixed Use." See **Figure 21: Downtown Neighborhood TOD Plan – Land Use Plan**. The Downtown TOD Plan defines this designation as follows:

"Intended to support Downtown and Chinatown's role as a center of regional importance, allowing a variety of uses in the central business district including: office, government, retail, and multi-family residential uses, as well as public/quasi-public facilities.

Discussion: As a residential Project, Halewai'olu Senior Residence would comply with the uses appropriate for this designation. The multi-purpose room will be available to residents and the neighborhood. Active frontages are not required for the Project Site; however, pedestrian-oriented design is required. The Project will include an entry courtyard and improvements will be implemented to the River Street frontage that will make the property more inviting than its existing condition. The maximum building intensity for the Project Site is 7.5 FAR. See **Figure 22: Downtown Neighborhood TOD Plan – Maximum Building Intensity.** The Project will be developed at 5.9 FAR, which is consistent with the vision articulated in the Downtown TOD Plan.

As an affordable housing development, HSD will be requesting exemptions, including fee waivers/deferrals and exemptions from certain LUO requirements in order to achieve a greater density than what is currently allowed.

Although the Downtown TOD Plan (and current BMX-4 district) allows a maximum building height of 350 feet tall, the Project will be constructed at about 174 feet tall. This will limit the visual impact of the Project on existing panoramic public views.

Chapter 2. Land Use

2.3 Potential Development

TOD could result in approximately 6,500 additional housing units, which translates to 13,400 new residents based on the City's projections for future household size

Discussion: The Downtown TOD Plan estimates that the development potential for the Chinatown Station Area is 1,466 net new residential dwelling units. As discussed in **Section 6.3.4,** HSD will add 156 new rental dwelling units to Honolulu's housing inventory, which aligns with goals articulated in the Downtown TOD Plan.

2.4 Land Use Goals and Policies

Goals:

- *LU-G1: Develop vibrant mixed-use districts with a range of residential, shopping, employment, and cultural uses that provide activities during the day and evening and support rail transit ridership.*
- *LU-G3: Establish a contiguous pedestrian-oriented area within the corridor to enhance walkability and pedestrian comfort.*
- *LU-G7: Expand housing opportunities with a range of housing types—townhomes, mid-rise, and high-rise—to create a new mixed-income neighborhood in Iwilei with a full range of amenities and services, including parks and open space, a walkable street grid, and enhanced connectivity to the waterfront.*
- *LU-G11: Preserve the height and scale of development in the core of Chinatown's historic district.*

Policies:

- *LU-P6: Chinatown - Buildings and open spaces should be designed to highlight the identity of the district and its rich multi-cultural character.*
- *LU-P19: Residential, office, or hotel uses should include accessible and inviting lobbies, architectural features such as stoops or porticoes, or public plazas at the sidewalk.*

Discussion: The Project is consistent with the Land Use Goals and Policies specifically related to expanding affordable housing opportunities and creating a pedestrian-friendly environment, articulated in the Downtown TOD Plan. The Project will include a courtyard entryway (pubic plaza at the sidewalk) and Feng Shui elements have been incorporated into the design. The courtyard and Multi-Purpose Room will enhance the pedestrian experience along River Street.

Chapter 3. Mobility Goals and Policies

3.4 Goals and Policies

Goals:

- *MB-G1: Create an integrated multi-modal transportation system that fosters livable, walkable communities around the stations, and supports increased rail ridership.*
- *MB-G2: Prioritize pedestrian, bicycle and bus transit access to the rail stations through strategic improvements.*
- *MB-G3: Design transportation infrastructure as an integrated component of the neighborhoods and greater public realm of streets, landscaping, plazas, and parks.*
- *MB-G4: Prioritize pedestrian and bicycle safety, including for students going to and from local schools.*
- *MB-G5: Accommodate existing and future on- and off-street parking demand through a coherent parking management strategy that includes support for alternative travel modes.*

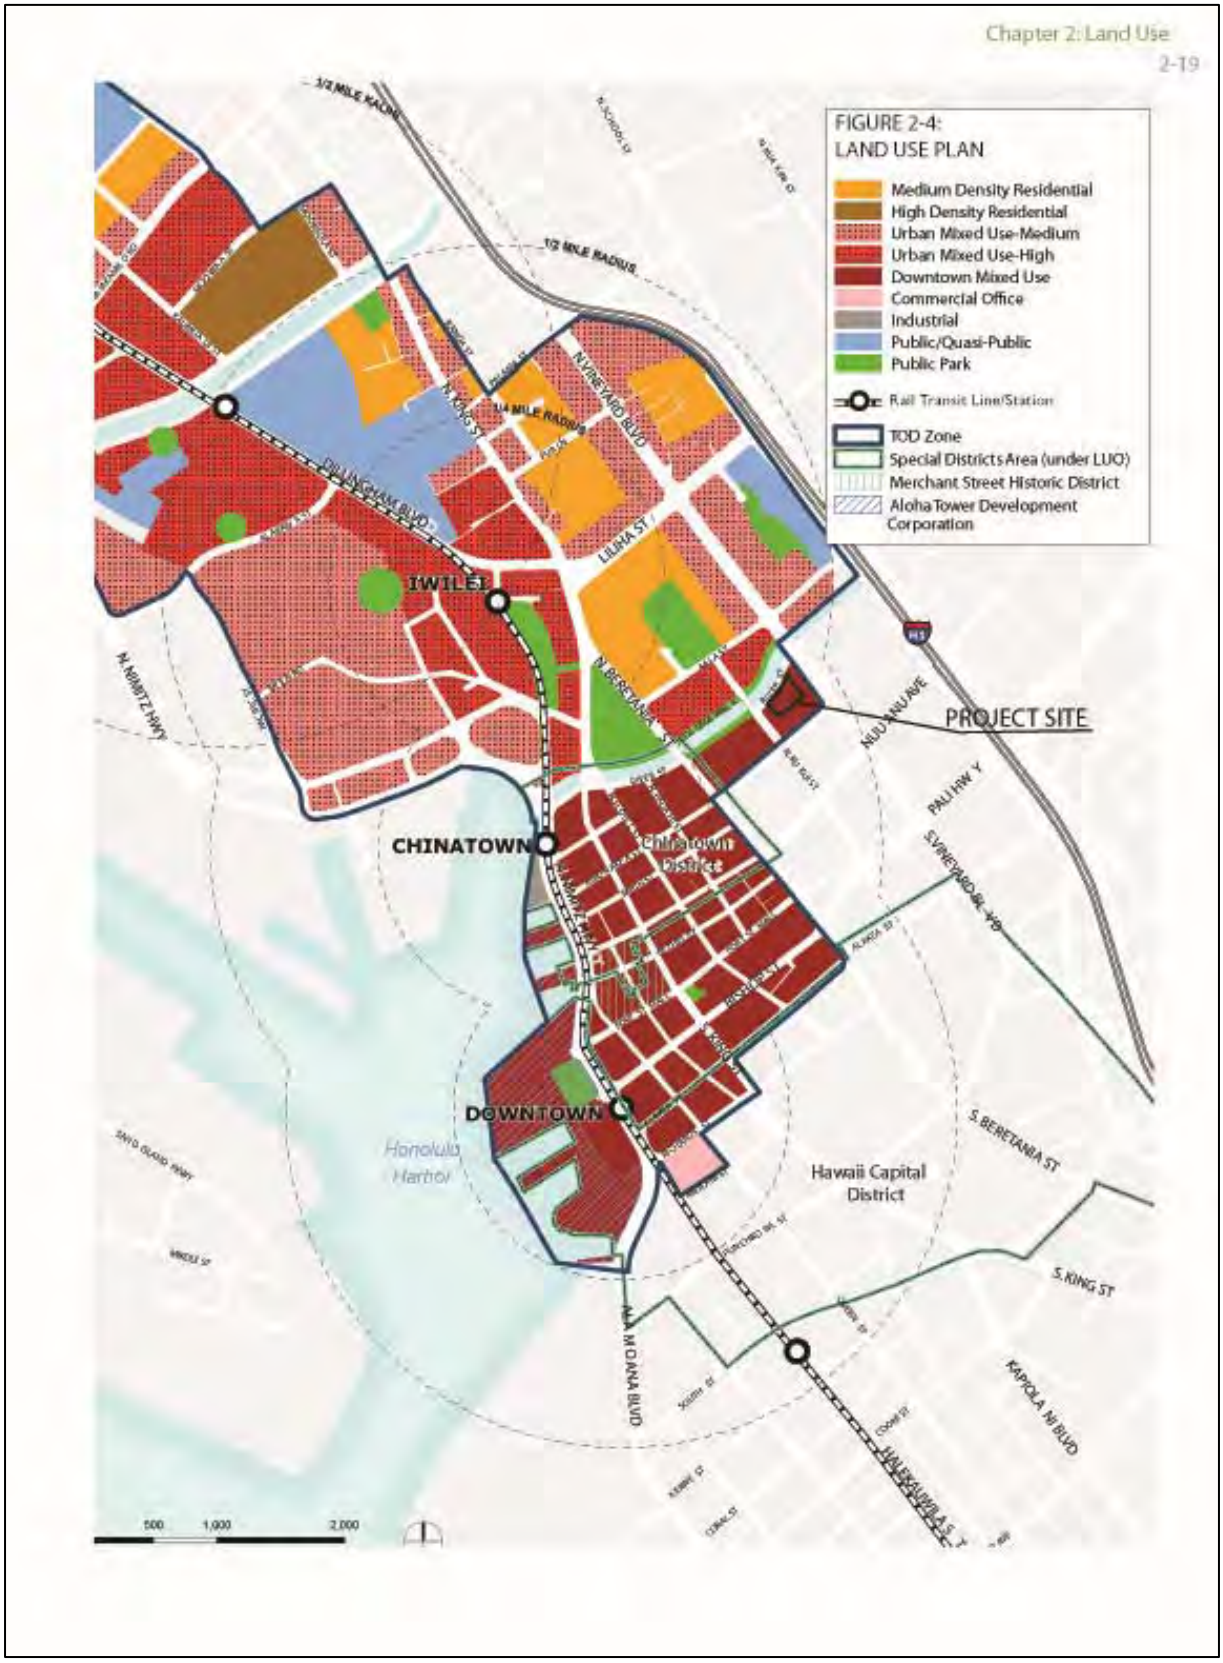
Policies:

- *MB-P3: Create a well-connected network of streets and pedestrian routes to improve access for all modes to the stations and to new and existing destinations within the station areas.*
- *MB-P15: Design safe, well-lit promenades along the harbor front and both sides of Nu'uanu Stream to enable continuous pedestrian and bicycle travel.*

- *MB-P30: Allow exemptions from parking minimums in the area (No exemptions for Project Site)*

- **Discussion:** The Project will include improvements to the River Street frontage, which will enhance the Sun Yat Sen Mall pedestrian corridor and contribute to the walkability of the community. It is anticipated that senior development will not require much parking due to the proximity to necessary services and the existing transit network. Bicycle parking will also be provided on site.

Figure 21: Downtown Neighborhood TOD Plan – Land Use Plan



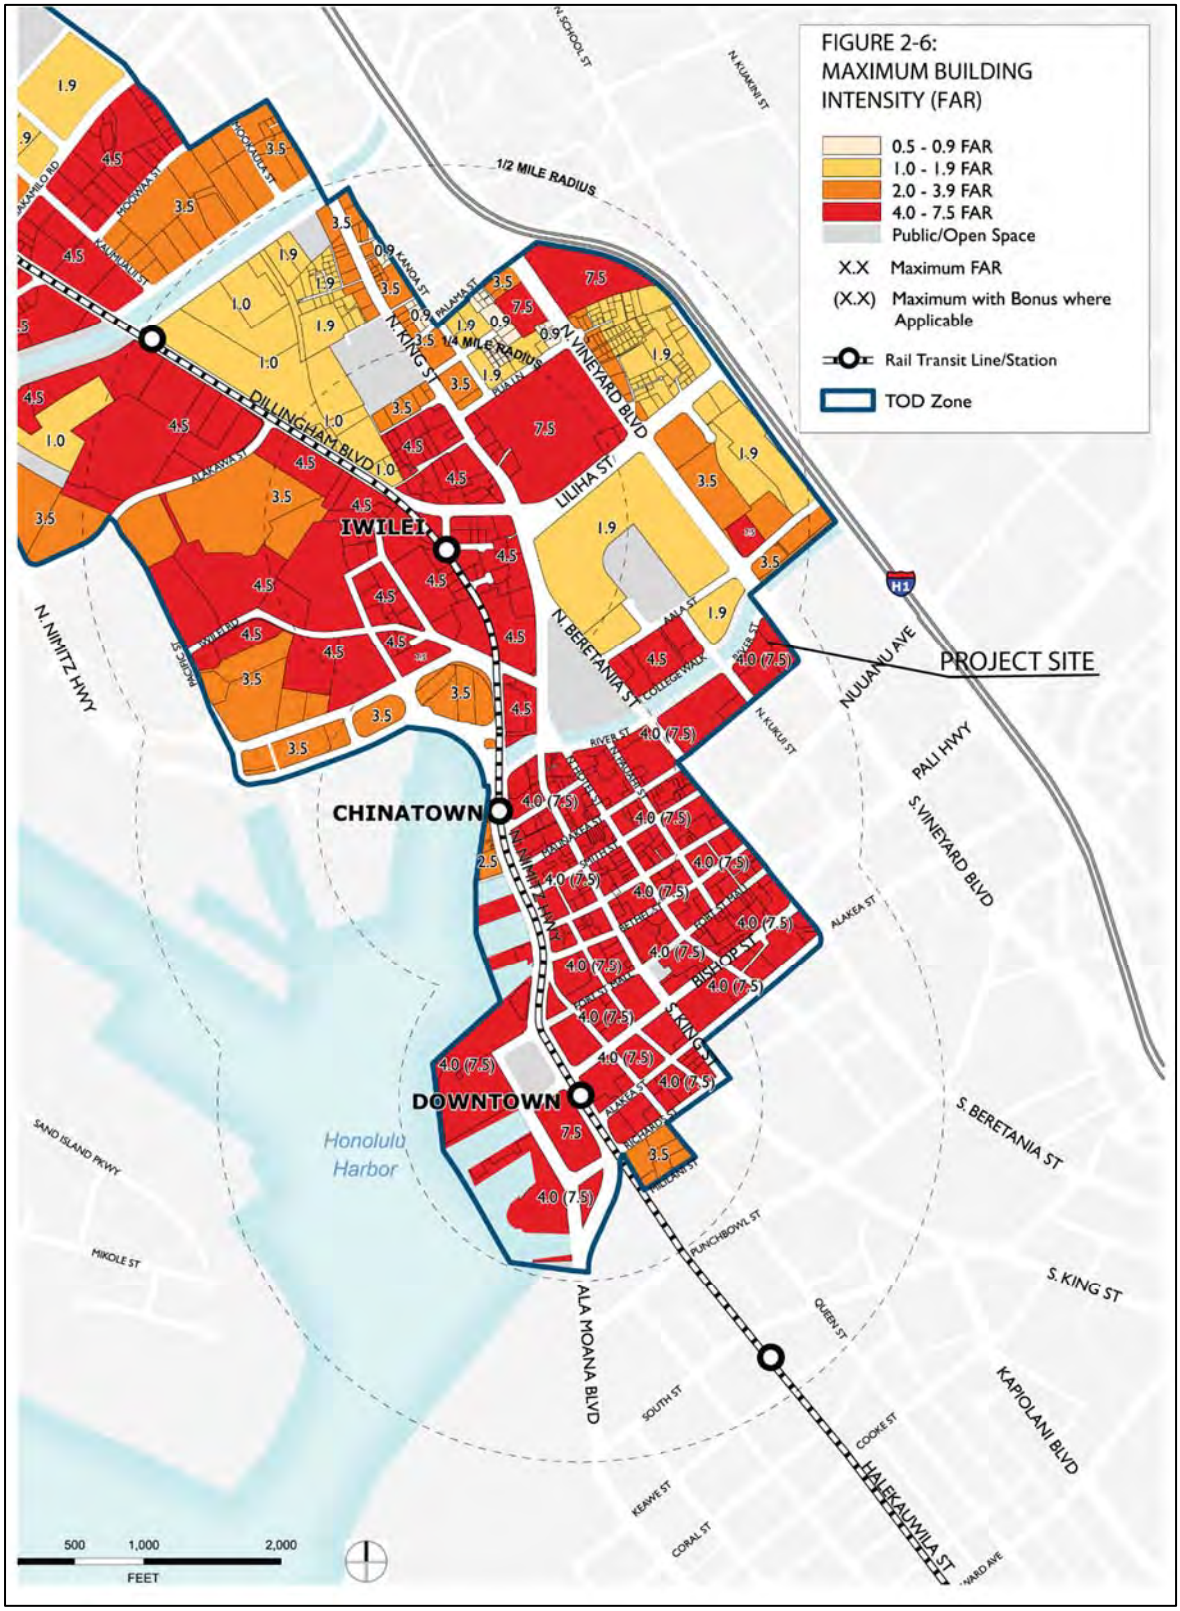


Figure 22: Downtown Neighborhood TOD Plan – Maximum Building Intensity

Chapter 4. Urban Design Goals and Policies

4.4 Goals and Policies

Goals:

- *UD-G3: Create memorable and livable streets and streetscapes that promote identity and enhance pedestrian comfort and safety.*
- *UC-G4: Enable high-quality architecture and site plans that are well-integrated with public streets and enhance the livability of the districts.*
- *UD-G7: Integrate parks and plazas throughout new development along pedestrian and bike paths to create a cohesive and connected open space network.*
- *UD-G9: Design high quality open spaces and a public realm that is safe, accessible, and integrated into the existing community, balancing new high-density development.*
- *UD-G10: Improve access to a variety of transportation modes and opportunities for physical activity that enhances health and supports community members of all ages, lifestyles, income, and abilities.*

Policies

- *UD-P5: Design sidewalks to include an unobstructed path for travel, separate from street landscaping and street furniture areas.*
- *UD-P7: Scale development along pedestrian-oriented retail streets and pedestrian connections with fine-grained, highly articulated facades, changes in materials, ample fenestration, and visible entryways.*
- *Equip pedestrian paths with shade trees, seating, kiosks, lighting, and other amenities.*
- *UD-P12: Maintain a continuous street wall along public streets. Articulate building facades with three dimensional elements that create a visual play of light and shadow, including balconies, recesses, reveals, and brackets:*
    - *Maximize transparency of ground floor non-residential uses through large windows and architectural features.*
    - *On blocks where active frontage is required, limit the length of blank walls to 20 feet. Where active frontages are allowed, limit the length of blank walls to 60 feet. Use murals, public art, living walls, and landscaping where windows and articulation are not feasible.*
    - *Provide awnings, overhangs over the sidewalk, and arcades to enhance pedestrian comfort.*
    - *Orient public entrances to face a public street or open space and ensure that they are visible and accessible from the street.*
- *UD-P13: Locate buildings close to the sidewalk in order to define the public realm and provide active uses next to the sidewalk. Buildings may be set back to allow for outdoor dining, plazas, or other active public spaces.*
- *UD-P32: Where possible, orient private open spaces, such as courtyards, balconies, and building entrances, toward open spaces to provide a transition between private and public activities and to increase safety*

Discussion: The Project will enhance this portion of River Street, which is currently considered urban blight. A courtyard/plaza will line the River Street frontage and will result in setting back the building in accordance with UD-P13. The courtyard will be a gathering area and outdoor extension of the Project and will provide a transition between the public sidewalk and the private structure.

The proposed multi-purpose room will also be located along River Street, which will create a more vibrant street environment. The makai setback will include landscaping to enhance the streetscape. In order to protect the senior residents, the building will have a secure entry and an on-site resident manager.

Chapter 5. Public Facilities, Services, and Infrastructure

5.4 Goals and Policies

Goals:

- *PF-G1: Provide public facilities—including police and fire services—commensurate with the needs of existing and future community members.*
- *PF-G3: Foster adequate provision of social and health services, such as housing and reintegration services for homeless; youth activities; and senior programs.*
- *PF-G4: Support maintenance of existing and development of new affordable housing units and associated services for low- and very low-income households.*
- *PF-G5: Encourage mixed-income housing and distribute affordable housing throughout the planning area. Mitigate potential for gentrification and avoid displacing low- and moderate-income residents.*
- *PF-G6: Facilitate development of infrastructure—including wastewater, water, drainage, and high-speed broadband internet systems—that is designed and timed to be consistent with project capacity requirements and development occupancy.*

Policies

- *PF-P6: Encourage housing and social service providers to serve seniors with recreation and programs that encourage their health, safety, and welfare. Work in partnership with community organizations and institutions to maintain the availability of appropriate senior and medical services.*

Discussion: The Project Site is well-served by public services as discussed throughout **Section 4.0**. Development will also include upgrades to existing infrastructure, as discussed in **Sections 4.5, 4.6, 4.7, and 4.9**. A Social Services Coordinator will be available to assess and coordinate the activities and services for the residents.

6.3.5 Making Honolulu an Age-Friendly City: An Action Plan (2015)

In 2013, the City applied for and was accepted into the World Health Organization's (WHO) Global Network of Age-Friendly Cities and Communities and AARP's National Network of Age- Friendly Communities. This initiative was driven by the fact that Hawai'i is the most diverse state, and is growing older at a faster pace than the rest of the nation. The UH's Center on Aging coordinated Honolulu's Age-Friendly City effort, facilitated CAC workgroups and conducted focus groups and key informant interviews, which resulted in the *Making Honolulu an Age-Friendly City Action Plan* ("Action Plan"), published in June 2015. The Action Plan includes a vision for an Age-Friendly Honolulu. The vision in the Action Plan is as follows:

> *"In an age-friendly Honolulu, inter-connected communities embrace older adults who want to remain socially involved and physically active; the city infrastructure remains responsive to capabilities and safety of its people; equitable services enable communitywide health promotion; robust opportunities for intergenerational exchanges exist; and, quality of life thrives among all residents. Honolulu's leadership understands active aging is a lifelong process and this initiative embodies the city's commitment to Honolulu being livable for all ages, not just for older adults. Safe*

and affordable transportation benefits for all people, young and old. Families experience less stress when they have access to community support and health services for older adults under their care. A barrier-free city infrastructure enhances the mobility and independence of people of all ages with disabilities."

With this vision of an age-friendly Honolulu, the City embarked on a two year- long community input and planning process to develop this Age-Friendly City Action Plan which was completed in 2015. The Action Plan includes a set of visions, goals, and recommendations for Honolulu's age-friendly "domains," which encompasses all facets of community life. The first three domains, Outdoor Space and Buildings, Transportation, and Housing are key features of the built environment and have a strong impact on mobility, safety, and security. The next three domains, include health and social welfare and ensure that we live vibrant and healthy lives over of life course. These domains are Communications and Social Involvement, Civic Participation and Employment, and Community Support and Health Services.

Discussion: As discussed in **Section 5.1**, demographic trends in the City point to an increasingly aging population. The Project's consistency with the relevant visions, goals, and recommendations of the Action Plan are discussed below, emphasis added.

Outdoor Spaces and Buildings

Vision

We envision an outdoor environment that is clean, well designed and well maintained. There are many trees to offer shade, paths for walking and spaces to rest that can be used by people of all ages. Sidewalks are wide and include street trees and lighting. Public restrooms are available, clean, and safe. Buildings are accessible, even to people with limited mobility. People of all ages and abilities are able to move about with ease, enjoy Honolulu's sunshine and natural beauty, and share the Aloha spirit with one another.

Goals and Recommendations for Outdoor Spaces and Buildings

- *Goal A: Outdoor spaces free of criminal activity and vandalism*
- *Goal B: Accessible spaces that accommodate persons with a range of disabilities*
- *Goal C: Outdoor spaces with services and amenities nearby*
- *Goal D: Clean and attractive outdoor spaces*
- *Goal E: Multigenerational/multiuse spaces*

Discussion: The existing building on the Project Site is currently dilapidated and considered urban blight. The Project proposed demolishing the existing building in order to construct a 155-unit senior affordable rental housing facility with one additional resident manager's unit. All units will be ADA compliant or adaptable. The redevelopment will include enhancements to the River Street streetscape, thereby enhancing Sun Yat Sen Mall overall and activating a part of Downtown-Chinatown that is not heavily trafficked by pedestrians. The new facility will include a multi-purpose room, warming kitchen, restrooms, storage rooms, utility rooms, computer room, social services activity rooms, social services office, property management offices, mail and package boxes, and elevator lobby on the ground level. On the ground level will also be a courtyard (plaza), retail space, and parking access, along with bicycle parking, the trash compactor room and loading area. The fourth floor will include a covered recreation deck and dog area for additional resident recreation opportunities. These spaces would provide senior residents with recreation and social spaces and

complement the neighborhood resources, such as parks, community centers, and cultural centers that are located nearby.

Transportation

Vision

We envision a city where everyone has access to safe, clean, and timely transportation island wide. People are able to choose their preferred mode of transportation, whether it's walking, and biking, driving, or specialized transport such as TheHandi-Van. It is easy to get where you want to go, even without a car. Public transportation is clean and safe, and streets are designed for all types of users.

Goals and Recommendations for Transportation

- *Goal A: Timely and responsive public transport*
- *Goal B: Increased pedestrian safety*
- *Goal C: Safe and maintained roadway design/infrastructure*
- *Goal D: Increased bicycle safety*

Discussion: The Project Site is well-served by existing public transit and is located within the proposed Downtown TOD SD approximately 0.4-mile from the future Chinatown Rail Station. Furthermore, the Project Site is near health centers, shopping, restaurants, and cultural and recreational resources. This Project location allows senior residents the option to access multiple neighborhood resources without the use of a car. Bicycle parking will also be provided on site.

Housing

Vision

We envision a city where people have the ability to choose where they want to live as their needs change. Housing is clean, safe, and accessible for all. People are able to connect with their neighbors, and the communities they live in are safe. Public transportation is nearby for those who desire it, along with services like grocery stores, pharmacies, and doctor's offices. People are able to stay in their homes for as long as they desire, and those who chose to relocate to be closer to family or have more help with daily living have affordable options.

Goals and Recommendations for Housing

- *Goal A: Affordable housing options are widely available*
- *Goal B: Home modifications are affordable and widely available to older adults and persons with disabilities*
- *Goal C: Age-friendly design is incorporated in new housing communities and units*

Discussion: The purpose of the Project is to provide senior affordable rental housing for seniors earning 80% of the AMI or below, with a majority of units designated as affordable for 60% of the AMI or below (see **Table 1**). There are 155 units plus one resident manager's unit planned, and units will range from one- to two-bedrooms. All units will be ADA compliant or adaptable. Each unit will include a kitchen with energy efficient appliances and air conditioning.

Communication and Social Involvement

Vision

We envision a Honolulu where people have information about events, activities, services, and resources that help them stay connected. This information is available in many languages and formats (radio, TV, newspaper, at local community centers). For people who want to use computers, they have access to them in multiple places, and classes are available for those who want them. For people who don't want to use computers, they still have access to the same information through their families, schools, churches, social clubs, or neighborhood associations. We also envision a Honolulu where people can participate in a wide range of events and activities (cultural, leisure, recreational) that bring generations together. There are opportunities for older adults to share knowledge with younger generations, and build friendships. The places where these events are held are easy to get to, for example, near public transportation routes. For those who cannot leave their homes, neighbors reach out to them through friendly visits or phone calls.

Goals and Recommendations for Communication and Social Involvement

- *Goal A: Intergenerational opportunities to share knowledge, encourage mentorship, cultural exchange, and volunteer opportunities are available*
- *Goal B: Programs, events, volunteer opportunities, and opportunities for lifelong learning are available*
- *Goal C: Information and data are easily accessible and user-friendly*
- *Goal D: People have the support to understand and use new technology*
- *Goal E: All segments of the population have access to information via a variety of modalities*

Discussion: The Project will include a computer room, multi-purpose room with warming kitchen, social services activity rooms, social services office, and a courtyard. These spaces would serve as spaces for seniors to socialize with one another, participate in activities, utilize the provided computers, and attain various services.

6.3.6 City and County of Honolulu Special Management Area

HRS, Chapter 205A outlines control, policies, and guidelines for development within an area along the shoreline referred to as the SMA. CZM policies are administered by each County. The management of lands located within the SMA is regulated through ROH, Chapter 25, *Special Management Area*. Chapter 205A, HRS also establishes the Shoreline Setback Area (SSA) to further manage uses along the shoreline. The City is the delegated authority to regulate uses located within the established SSA for the island of O'ahu.

Discussion: The Project is not located within the SMA or SSA. The Project's conformance to CZM policies are described in Section 6.1.5.

6.3.7 Chinatown Action Plan, March 2016

"Honolulu's Chinatown is one of the oldest neighborhoods in Hawaii, and one of the oldest Chinatowns in the United States. Today, it remains a vibrant place with a dynamic mix of newcomers, multigenerational residents and multicultural businesses in continuous evolution. Despite ongoing challenges, the Chinatown community continues to be actively engaged in neighborhood improvement.

Several community plans have been developed for Chinatown over the last decade, so the purpose of the Action Plan is to identify and prioritize near-term implementation actions, while refining longer-term strategies that are consistent with the previous visioning efforts. Longer-term

redevelopment strategies are outlined in the Downtown Neighborhood TOD Plan, which covers Chinatown."

6.3.7.1. Streets as Places

6.3.7.2 Revitalize the Nu'uanu Stream Corridor

"Funding for planning is being requested for FY2017-18, with additional appropriations in future years for design and construction

The Chinatown community expressed strong interest in revitalizing the Nu'uanu Stream corridor, which includes Nu'uanu Stream, River Street, 'A'ala Park, Sun Yat-sen Mall, College Walk, and Foster Botanical Garden. The City is requesting capital funds to address pedestrian safety, crumbling street pavement, aggressive tree roots, seating and other amenities, landscaping and shade, opportunities to interact with the water, and improved bicycle access. Some of these improvements may be included in upcoming street rehabilitation projects. Events and activities to increase usage of the corridor are addressed in other proposed actions."

The Applicant is in strong support of this action to provide activities and events along an improved mall to engage the public and the residents of the Project.

6.3.7.3 Provide Pedestrian Crossing of Vineyard Blvd at River Street

"In 2016, there was no pedestrian crossing of Vineyard Boulevard (a state roadway) at River Street or College Walk. Increased pedestrian and bicycle activity was expected in the area due to new development and the future Chinatown rail station. The State of Hawai'i Department of Transportation has installed a pedestrian crossing across Vineyard Boulevard to facilitate mauka-makai connectivity. This improvement also enhances the connection between the Nu'uanu Stream Corridor and Foster Botanical Garden."

This signalized pedestrian crossing has since been installed and is operating.

6.3.7.4. A Cleaner and Safer Chinatown

"Improving safety and sanitation remains a priority for the Chinatown community. These objectives are essential to improving the district's image and depend on continued cooperation between the community and the City. Potential strategies relate to waste management and recycling, street cleaning, graffiti prevention, lighting, and close collaboration on security issues. Creation of a business improvement district would expand the solutions available to address many of these issues."

- Establish a Business Improvement District (Bid) for Chinatown
- Develop Improved Food Waste Management Practices
- Increase the Frequency of Sidewalk Power Washing on Particular Streets

- Revise the Street Sweeping Schedule Based on Alternate Side Parking Restrictions
- Pilot a Mobile Public Restroom

The Applicant supports these initiatives to be led by City Agencies and is willing to participate to the extent required in the Business Improvement District for Chinatown.

6.3.7.5. Chinatown's Vibrant Economy

- Host Activities on River Street
- Repurpose and Market Vacant and Underutilized Properties
- Provide High-Speed Public Wi-Fi
- Preserve the Neighborhood's Cultural and Historic Resources

The Applicant supports these initiatives and recognizes that under item 3.2, the Project Site is one of the underutilized properties planned for repurposing.

The Project is also participating in the preservation and protection of the Neighborhood's Cultural and Historic Resources, through Section 106 of the National Historic Preservation Act of 1966. The Applicant will be signing a Memorandum of Agreement with other parties, agreeing to mitigate impacts to culturally, historically and archaeologically significant properties and finds.

7.0 AGENCIES, ORGANIZATIONS, AND INDIVIDUALS CONSULTED

The agencies, organizations, and individuals listed below have been contacted during the NEPA environmental review process to review and comment on the environmental conditions of the Project Site, the proposed undertaking, and/or the potential impacts and mitigation measures that will be applied to ensure against adverse impacts.

Although not a requirement of NEPA as set forth in 40 CFR Parts 1500-1508, HUD environmental review compliance pursuant to 24 CFR 58, and, other environmental compliance requirements and implementing regulations, the Applicant will extend the NEPA EA process to include a public and agency 30-day review period.

The Applicant will request that the OEQC (Office of Environmental Quality Control) publish in their Environmental Notice the availability of the NEPA EA for review and comment and the deadline for comments. We will have a 30-day comment period. All the agencies, organizations, and individuals listed in Section 7.1 through 7.8 will be contacted at the start of the 30-day comment period.

After receipt of comments, relevant comments will be addressed in the NEPA EA prior to finalizing.

If the Department of Land Management determines that the Project will not have a significant environmental impact, it will issue a FONSI that will allow the Project to proceed. The public will have 15 calendar days after publication of the FONSI in a local newspaper to comment.

7.1 FEDERAL AGENCIES

- HUD

- U.S. Fish and Wildlife Service, Pacific Islands Office, Honolulu, Hawai'i **(Appendix I and J)**

7.2 STATE AGENCIES

- Department of Business and Economic Development
- Department of Land and Natural Resources
    - O'ahu Island Burial Council
    - State Historic Preservation Division

7.3 CITY AND COUNTY OF HONOLULU

- Board of Water Supply **(Appendix K, Civil Attachment C-3)**
- Department of Planning and Permitting **(Appendix K, Civil Attachment C-6)**
- Honolulu Police Department
- Downtown-Chinatown Neighborhood Board (No. 13) **(Appendix O)**

7.4 ELECTED OFFICIALS

- State Senator Karl Rhoads, District 13
- State Representative Calvin Say, District 20
- State Representative Daniel Holt, District 29
- Councilwoman Carol Fukunaga, District 6

7.5 UTILITIES

- Hawaiian Electric Company **(Appendix K, Electrical Attachment E-1)**
- Hawaiian Telcom **(Appendix K, Electrical Attachment E-1)**

7.9 PUBLIC INVOLVEMENT

7.9.1 Public Information Meetings

HSD began conducting community outreach in August 2014 with various Downtown-Chinatown community stakeholders. Community input was also included in developing the Community Provisions section of the Development Agreement between HSD and the City, and in consideration of the Project design. In addition to government agencies and public officials, consultation has been ongoing with the members of the Downtown-Chinatown NB No. 13 and the numerous Downtown-Chinatown community members listed in **Section 7.6**. Between August 2014 and October 2019, HSD conducted 22 community meetings and modified the Project in consideration of the feedback received at the meetings. A table of all meetings to

date is provided in **Table 21: Community Outreach Timeline** below (note that the below table does not include numerous individual stakeholder meetings conducted since 2014 until publication of This EA):

Table 21: Community Outreach Timeline

No.	Date (Year-Month-Date)	Stakeholders
1	2015-05-26	Chinatown Business Leaders Presentation
2	2015-05-26	Participated in Mayor's Press Conference
3	2015-06-30	Design Workshop
4	2015-07-14	Development Agreement Community Provisions Discussion
5	2015-08-06	Presentation to NB No. 13
6	2015-09-11	Chinatown Community Tours of the Towers of Kūhiō Park
7	2015-11-05	Presentation at NB No. 13 (Concept Unanimous Approval)
8	2015-12-01	Presentation to Chinese Media (World Journal, Sing Tao Newspaper)
9	2015-12-08	Presentation at Community Planning for Kalihi to Kaka'ako Meeting
10	2016-02-04	HSD /City Update to Downtown Chinatown NB No. 13
11	2016-02-24	Neighbor Meeting
12	2016-03-01	Neighbor Meeting
13	2016-03-03	HSD / City Update to NB No. 13
14	2016-03-08	Community Meeting
15	2016-03-14	Community Meeting

17	2017-06-01	HSD / City Update to NB No. 13
18	2019-04-04	HSD / City Update to NB No. 13
19	2019-05-01	Community Meeting
20	2019-05-08	Presentation to O'ahu Burial Council
21	2019-05-25	Public information meeting for NEPA, HRS, Chapter 6E-8 & Section 106

No.	Date (Year-Month-Date)	Stakeholders
22	2019-06-25	Interested Parties Meeting
23	2019-07-09	Community Meeting
24	2019-08-14	Presentation to O'ahu Burial Council
25	2019-09-19	Public information meeting for NEPA, HRS, Chapter 6E-8 & Section 106
26	2019-10-03	NB No. 13 (HRS, Chapter 201H)
27	2019-10-29	O'ahu Island Burial Council recognizes "Ohana Caceres as cultural descendants to burials encountered during AIS fieldwork
28	2019-11-19	Memorandum of Agreement Meeting
29	2020-01-23	On-site meeting with recognized cultural descendants and potential cultural descendants to discuss burial treatment

Based on the comments from the Downtown-Chinatown business and community members that have attended various presentations, workshops and meetings, along with input from different Feng Shui Masters, HSD worked with architect firm WRNS to refine the conceptual plan, while retaining the essential components expected by the City from the Request for Proposals and Development Agreement.

The revisions from the original concept related to height, mass, adjacency, cultural reference, design, building code and budget include the following:

- **Massing** – The various revisions involved a massing change from two towers at different heights to a single tower that was shifted Mauka from the Makai boundary, along with a reduction in unit square footages, which helped to reduce the residential tower footprint and lessen its visual impact. The footprint of the parking podium and the community room have remained essentially the same, but were shifted slightly to increase building setbacks from zero to about three 3 feet from the Mauka and Diamond Head property lines and about 13 feet from the Makai property line.
- **Height –** Revisions also included a height reduction from 25 levels to 17 levels and design efficiencies allowed for an increase from 151 units to 156 units. Parking was reduced from three (3) to two (2) levels, decreasing the number of parking stalls from the conceptual 67 to 51.
- **Adjacency and Makai Façade** – When the Makai setback was increased to about 13 feet, a green landscape buffer was added between the Project and its Makai neighbor. The recreation deck was modified to improve openness and airflow, which reduced the solid portion of the Makai parking podium wall to about 30-foot high, which is closer to the existing building height on the Makai property. The parking podium wall was also pulled back away from the River Street property line to improve visibility at the corner, reduce the bulkiness of the building and improve airflow. Additional openings were added in the Makai and Diamond Head side of the parking podium walls to reduce bulk and improve airflow. The Makai setback to the residential tower was also increased by about 10 feet. The result is an open distance from building to building of approximately 60 feet (from the residential tower to the existing building on the Makai neighboring lot).
- **Sustainability** – Each unit will have openable windows and will also have air conditioning.

- **Color and Cultural References** – All building materials are now denoted with natural materials and colors, including stone, wood and metal with earth tones. Cultural references may include the Longevity symbol at the entrance to the building. There will also be opportunity to include culturally inspired plantings in the courtyard with judicious inclusion of colors, such as red and yellow, reflective of Chinese culture.
- **Green Space** – Open space will be provided by the courtyard at the ground floor entrance and green space will be provided at the Makai landscape area. The garden area and the recreation deck on the 4th level will create additional open / green space for the residents. Chinese heritage plantings will be used as much as practical in the Makai property green landscape and in pots and planters in the Courtyard.
- **Feng Shui** – HSD worked with different Feng Shui professional consultants to address community concerns related to Feng Shui principles. Dr. Simona Mainini generated a Feng Shui Evaluation report indicating that in general, the concept design, entrance, location, position, and orientation will be good for health, relationships, and prosperity.
- **Multi-purpose and Activity Rooms** – These ground-floor facilities will be used to support the senior residents and will be available for neighborhood events. Better Tomorrows will be coordinating with the Downtown-Chinatown NB No. 13; United Chinese Society, Chinese Chamber of Commerce, and Chinatown Community Center Association, along with a cross section of other interested organizations to form an Advisory Committee. Better Tomorrows will coordinate activities and consider requests with input from the Advisory Committee.
- **Retail Shop** – Careful consideration will be given to the type of business to assure that the needs of the facility are serviced.

Section 106 consultation for the Project, as required, is being fulfilled. See **Sections 5.2** and **5.3** for further discussion.

7.9.2 Downtown-Chinatown Neighborhood Board No. 13

The Project was presented at seven NB meetings from August 2015 to October 2019. See **Table 21** for the dates. A motion to support the Project's conceptual design passed unanimously at the Board's November 5, 2015 meeting. The City and HSD continue to give updates to the Board, presenting design revisions based on community comments. A full record of consultation with and presentations made to the Board is included in **Appendix O, Downtown Neighborhood Board No. 13 Meeting Record**. HSD will continue to present updates and consult with the community as the Project design moves forward.

8.0 CUMULATIVE IMPACT ANALYSIS AND CONCLUSION

In accordance with the content requirements of NEPA, the CEQ's *Regulations for Implementing the Procedural Provisions of NEPA* (40 CFR 1500-1508), and 23 CFR Part 771, *Environmental Impact and Related Procedures*, no significant adverse environmental impact will be anticipated resulting from the proposed Project. Temporary short-term potential impacts will occur during the Project construction phase. Long-term impacts to noise, traffic, and historic properties are anticipated, but will be addressed with mitigation measures as prescribed throughout this EA. Long-term, beneficial impacts are expected based on the evaluation of the surrounding resources. See **Table 1: Halewai'olu Senior Residence Project Impacts Summary** at the end of this section for a summary of impacts and proposed mitigation.

8.1 RELATIONSHIP BETWEEN THE SHORT-TERM USES OF THE ENVIRONMENT AND MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

The relationship between the short-term uses of the environment and the long-term productivity of the proposed Halewai'olu Senior Residence Project primarily involve the short-term impacts during construction and the long-term land use change of the property f rom a commercial use to a mixed-use property consisting primarily of residential use.

Short-term impacts during construction include temporary noise, air, and vibration impacts from the demolition of the existing buildings, site work as needed, and construction of the new facility. Construction efforts are required to adhere to all federal, state, and City regulations and to ensure the use of proper equipment and regular vehicle maintenance. Additional mitigation measures are required during demolition of the existing building due to hazardous materials on site. See **Section 4.9** for further discussion.

Traffic, including pedestrian, bicycle, bus, and vehicle circulation, may also be impacted temporarily during construction when materials and equipment are transported to the Project Site and if any lane or road closures are required (**Section 4.1**). Groundwork will disturb soils and construction must stop if any inadvertent archaeological finds are unearthed. Construction BMPs to minimize soil erosion, sediment runoff, and dust such as installation of dust screens and silt fences and careful dewatering practices will be implemented. Construction will be limited to daylight hours to minimize impacts to neighboring residents during construction.

Short-term impacts during construction will also include social impacts. The Lum Sai Ho Tong temple is located adjacent to the Project Site. Construction noise may impact the Project Site in the short-term. Construction BMPs, as described throughout this EA, will be employed, and HSD will continue to consult with adjacent neighbors as the Project progresses. In the long-term, no adverse impacts to surrounding cultural resources are expected.

8.2 CUMULATIVE IMPACTS

Cumulative impacts are defined by the CEQ as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-federal) or person undertakes such other actions" (40 CFR, Section 1508.7, "Cumulative impact").. The following section briefly describes the potential cumulative impacts the proposed Project may have in conjunction with other area improvements and projects. Known major projects or long-range development plans within the vicinity of the Halewai'olu Senior Residence include the HART Rail Transit project spanning from East Kapolei to Honolulu. The Project Site is located approximately 0.4-mile northeast of the Chinatown Rail Station, which will allow resident seniors to take advantage of a new mode of transportation, thus reducing their need for a car.

As discussed in **Sections 6.3.1, 6.3.2, and 6.3.5**, which highlights the GP, PUC DP, and Downtown TOD Plan, the overall intensification of land uses and creation of senior affordable housing are major goals of the City's long-range vision for O'ahu and general development pattern goals. All of these plans emphasize the need for the existing Honolulu urban core to remain the PUC of the island with a secondary center in 'Ewa in order to keep the remaining rural areas rural. Although there will be cumulative impacts to the Downtown-Chinatown area's infrastructure, roadways and traffic, transit ridership, density, medical services, and public services such as police, fire, and emergency, they are all consistent with the City's intention to construct additional affordable housing units in the urban core.

The cumulative intensification of development on the Project Site will also change the cityscape and view planes; however, no panoramic view planes noted in the PUC DP would be impacted. The proposed building height of about 174 feet would not exceed what is already allowed within the BMX-4 district, and is comparable to surrounding buildings. The Project will generate few additional vehicular trips compared to the previous commercial development on the Project Site and is expected to have a negligible impact on traffic operations in the vicinity of the Project. The existing building is dilapidated and considered urban blight. The proposed building will be designed to enhance the streetscape, and incorporate cultural elements in keeping with the surrounding Downtown-Chinatown neighborhood. Community open space will be provided at the entry courtyard, and may include streetscape enhancements, such as planters, which will also add to the vibrancy of this portion of the Sun Yat Sen Mall along River Street. Chinese heritage plantings will be used as much as practicable. Furthermore, the multi-purpose and activity rooms will be available for use by the neighborhood community, which will activate this portion of River Street.

Two known housing redevelopments are planned within the vicinity of the Project, including the Emma Building Affordable Housing project located approximately 0.35-mile southeast of the Project (Dudek, 2019) and the proposed Mayor Wright Homes Redevelopment, located approximately 0.33-mile northwest of the Project, which is planned to include a mix of uses, including retail, office space, and community services (HPHA, 2019). Cumulative impacts may also occur to the economy as the mix of uses in the area diversifies and is able to support an additional business or service in the proposed retail space. Cumulative impacts may also include a change the demographics of the area, impacting social networks and increasing the interactions between different income and ethnic groups. See **Section 5.1** for further discussion on the potential impacts to the socio-economic aspects of the Project. However, the overall cumulative impact of increased affordable housing options for seniors is anticipated to improve the overall social-economic conditions of the area, as well as improve safety as natural surveillance will increase with additional residents and increased activity. Individual health and well-being are also anticipated to improve as resident seniors of all abilities will be located in close proximity to services, shopping, restaurants, and social, cultural and recreational resources/amenities, as discussed in **Section 4.2**. The convenient location of the Project will reduce the need for residents to own a car. It is anticipated that many of the senior residents will take advantage of transit, bicycling, and walking, rather than driving, thus no cumulative impacts to vehicle traffic are expected.

Temporary cumulative impacts related to construction may also occur. Potential temporary impacts to air quality, surface waters from storm water runoff, and noise are expected. Temporary traffic and pedestrian and bicycle circulation impacts if other construction occurs at the same time as construction of the Project.

All short-term impacts from the proposed Project are not anticipated to result in secondary or cumulative impacts. Negative short-term impacts will be prevented and minimized with the use of mitigative measures as provided in this document.

8.3 SECONDARY IMPACTS

Secondary impacts include those that are indirectly caused by the action and are later in time or are farther removed in distance, but are still reasonably foreseeable.

The Project Site is already well-served by first-responders, such as the HFD and HPD. However, the Project would increase the population in the Downtown-Chinatown neighborhood. The Project may result in a need to shift or reallocate existing resources and staff to serve the increased population at the Project Site, as stated in **Section 4.3**.

The increase in resident population to the area may have a secondary impact on public transit facilities as more people may gather at transit stops and need additional space to safely accommodate those waiting at the stops. The Project Site is currently well-served by transit; however, if ridership increases beyond the capacity of the current service, an increase in service may be required. The Project Site would also see an increase in the use of pedestrian corridors along Sun Yat Sen Mall due to the neighborhood visitors of the multi-purpose and activity rooms and residents walking or bicycling to Downtown-Chinatown to patronize shops, restaurants and other services, such as banks. This will have the secondary impact of activating a portion of River Street that is not as commonly traversed.

The multi-purpose and activity rooms will stimulate new social networks and relationships between the senior residents and the surrounding community, fulfilling the vision set forth in the City's Age-Friendly Action Plan (**Section 6.3.6**). Future residents may also be able to walk, bicycle, or take transit to their places of work or for errands. This presents an opportunity to experience improved health benefits from increased physical activity, along with decreasing living costs by not supporting a vehicle, which then allows for increased savings or reinvestment in the community through increased spending on other items. Those reducing the use of a vehicle would contribute to the positive secondary impact of reducing the impacts on regional traffic, vehicle emissions, and fuel consumption. They would also have more time to spend on other social, cultural, or recreational activities.

8.4 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

Construction of the Project will require the irreversible and irretrievable commitments of construction materials and the various resources used to demolish existing improvements. Demolition of the existing building will remove hazardous materials, such as LBP and ACM and create a healthier and more sustainable living environment.

Benefits of the Project include the increase in the amount of much-needed senior affordable rental housing within the Honolulu urban core, the increase in economic and social activity generated by the commercial and social services, as well as the safe place to recreate and gather in the multi-purpose and activity rooms onsite, overall improved public health and community well-being, and the transformation of a single use, blighted property that is relatively isolated from the surrounding neighborhood, to a mixed-use development that is well-connected to neighborhood community where residents will be able to walk, bike, and take public transit to nearby jobs and businesses, reducing potential traffic impacts and increasing health and wellness and economic benefits. The Project is pursuing LEED certification and will be designed to meet LEED silver, which is understood to contribute to overall resilience of the Project, Project Site, and wider community.

8.5 PROBABLE ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

During construction, there may be short term interruptions to existing infrastructure and utility services and temporary impacts to air quality and the acoustic environment. However, as discussed throughout This EA, temporary impacts associated with construction will be mitigated to the fullest extent possible and all federal, State, and City regulations, and control measures will be implemented. Construction BMPs will be employed and energy efficient design measures will be incorporated in the Project to reduce long term impacts to the extent feasible.

Once constructed, there may be visual impacts with the increase in building height compared to current conditions. However, the Project will be oriented in a mauka-makai direction and no impacts are expected to panoramic views as articulated in the PUC DP. Surrounding buildings are also of comparable height to

the Project. The visual character of the streetscape will be enhanced by the multi-purpose room, courtyard and landscaping. Cultural references, such as a Longevity symbol at the entrance of the building, may be incorporated into the design of the building in honor of the Downtown-Chinatown neighborhood history and culture. The parking podium height was reduced to in order to be close to the same height as the adjacent neighboring buildings.

The Project involves the demolition of the existing building. The Draft AIS determined that the Project has the potential to impact the archaeological historic property (SIHP # -8840) and thus the Project's effect determination per HAR §13-275-7 is "effect, with agreed upon mitigation commitments." In addition, under Section 106 of the NHPA, the Project will have an "adverse effect" on SIHP # -8840. The agreed upon mitigation commitments included in the Draft AIS, include preparing a BTP for the human burial site, identified as Component 3 of SIHP # -8840 and archaeological monitoring for Components 1–3 of SIHP # -8840. With the implementation of these mitigation commitments, the Project's potential adverse effect on SIHP # -8840, subsurface cultural deposits will be reduced. For further discussion, see **Sections 5.2** and **5.3**.

8.6 RATIONALE FOR PROCEEDING WITH THE PROJECT NOTWITHSTANDING UNAVOIDABLE EFFECTS

As discussed throughout this EA, O'ahu residents are experiencing a housing inventory crisis, with increasingly unattainable housing sales prices and apartment rents. Furthermore, demand for housing is strong and will continue to grow as the population of O'ahu continues to age and there is already a shortage of rental housing options in the urban core. The proposed Project will provide 155 units for seniors earning 30% of the AMI or below, 60% of the AMI or below, and 80% of the AMI or below.

The Project will be near shopping, restaurants, services, and social, cultural, and recreational resources/amenities, offering seniors the opportunity to age in place. The Project Site is currently well-served by bus transit (with future rail transit) that will allow seniors the option of not owning a car to access everyday needs.

The Project will also improve an area of Downtown-Chinatown that is considered urban blight and is currently underutilized. The neighborhood community will benefit from the construction of the multi-purpose and activity rooms with the availability of programs and activities to enhance their lives and activate the neighborhood. The redevelopment is an efficient use of resources by leveraging both public and private funding to redevelop the existing site. There is a balance of the potential impacts onsite with the social and environmental considerations of creating a high-quality, comfortable, and inviting community for seniors in the vibrant, social neighborhood of Downtown-Chinatown.

8.7 SUMMARY OF FINDINGS AND CONCLUSIONS

Based on the information in this EA and coordination with local, state, and federal regulatory agencies and public, it is anticipated that, with the incorporation of mitigation measures, this Project will have no significant impact on the natural or human environment. See **Table 22** for a full list of anticipated impacts and mitigation measures. Therefore, in accordance with the provisions set forth in NEPA of 1969, as amended, CEQ Regulations for Implementing the Procedural Provisions of NEPA, 23 CFR Part 771, a FONSI is determined.

Table 22: Halewai'olu Senior Residence Project Impacts Summary

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
Climate and Air Quality	Construction-related fugitive dust and equipment emissions.	• Increased resident vehicular traffic. • No Adverse Impact.	• Construction equipment and vehicles shall be maintained in proper working order to reduce air emissions. • During construction, work activities will be in compliance with HAR, Chapter 11-59 and 11-60. • Incorporation of LID greening measures. • Encouragement of active and public transportation. • Reduction in parking requirements through HRS, Chapter 201H process.	3.1, 3.2
Geology, Topography, and Soils	No Adverse Impact.	No Adverse Impact.	• Erosion control measures and BMPs will be employed during construction. • Disposal will be at an approved facility or location in accordance with Federal, State, and City regulations. • Project design will incorporate mitigation measures included in the Geotechnical Report; see **Appendix F**. No mitigation for long-term impacts required.	3.3
Water Resources & Hydrology	Potential storm water runoff during construction.	No Adverse Impact.	• Construction will be regulated in accordance with Clean Water Act of 1972 (CWA) regulations. • During construction, work activities will be in compliance with HAR, §11-54 and HAR, §11-55. • Discharge pollution prevention measures will be employed in all phases of the Project. • Following construction all areas of ground disturbance will be stabilized with appropriate materials including the use of vegetative ground cover. • BMPs will be installed as described in **Section 3.4** and as shown on Sheets C002, C005, and C006 in **Appendix A**. No mitigation for long-term impacts required.	3.4

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
Natural Hazards	No impacts from tsunamis, flood zones, seismic hazards and hurricanes and high winds.	• Increase in impervious surfaces on the Project Site. • Development within the XTEZ. • No Adverse Impact.	• Incorporation of LID greening measures. • Proper design criteria will be applied to structures associated with this Project to ensure structures are protected against hurricane and high winds. No mitigation for long-term impacts required.	3.5
Visual Resources	Temporary visual impacts from the presence construction equipment	• Visual alteration of the Project area. • No Adverse Impact.	• Equipment will be confined to work areas. • All construction related equipment will be removed following the completion of work. No mitigation for long-term impacts required.	3.6
Noise Conditions	Temporary source of noise above ambient levels from construction noise.	Minimal long-term increase of noise along Vineyard Boulevard. No Adverse Impact.	• All residences will include air conditioning. • Mufflers will be used on all combustion powered construction vehicles and machinery, and all noise attenuation equipment maintained in good operating condition • Heavy truck and equipment staging areas would be located at areas which are at least 500 feet from noise sensitive properties whenever possible. • Truck routes which avoid residential communities should be identified wherever possible. • Construction activities and use of heavy equipment would be scheduled as much as possible during daylight hours to avoid disturbing area residents during the evening. • Noise reduction measures such as rough, non- painted driving surfaces and acoustical absorption on the ceiling may be implemented if necessary. • Design of the exterior elements of the building may incorporate features that reduce noise levels to the interior spaces of the apartment unit. • No additional mitigation required.	3.7
Flora and Fauna	• Increased lighting during construction	• Permanent exterior street	• Protection or potential relocation of the single endangered *Brighamia sp.* should relocation occur, the USFWS will be notified and concurrence	3.8, 3.9

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
	of the proposed Project could pose potential impact to protected seabirds. • Potential impact to the Hawaiian hoary bat during the clearing and grubbing phase of construction.	lighting. • No Adverse Impact	with a plan to protect the specimen(s) obtained. • Light fixtures utilized for this Project will be designed and installed to reduce glare and shield light from migrating and/or nocturnally flying seabirds. • Design features for lighting will be based on guidance in the *The Newell's Shearwater Light Attraction Problem, A Guide for Architects, Planners, and Resort Managers*. • In the few areas that have trees or shrubs greater than 15 feet (5.6 meters), trees will be removed or trimmed during the breeding season of June 1 to September 15. • The use of barbed wire fencing will be prohibited.	
Transportation Facilities	Temporary increase in construction-related traffic, particularly during mobilization and demobilization of the construction area.	No Adverse Impact.	• To minimize traffic disruption, traffic control barricades, cones, signage, and lighting will be used as necessary to alert drivers and delineate construction boundaries. • Approach signs and a flag person will be positioned to direct traffic through temporary traffic control zones as necessary. • To minimize traffic impacts to nearby residents, the Contractor will schedule heavy truck activity as much as possible between the hours of 9:00 a.m. and 3:00 p.m. on weekdays. • Work on weekends will also be avoided to minimize traffic disruptions. • The HPD will be notified prior to periods of heavy truck activity or during transport and operation of heavy equipment.	4.1
Parks, Open Space, and Recreation Facilities	No Adverse Impact.	No Adverse Impact.	No mitigation required.	4.2
Fire, Police, and Medical Facilities	No Adverse Impact.	Additional residents may result in a need to	No mitigation required.	4.3

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
		shift public safety resources to the region.		
Education Facilities	No Adverse Impact.	No Adverse Impact.	No mitigation required.	4.4
Potable Water	No Adverse Impact.	• Increase in need for potable water; however, BWS confirmed there is capacity. • No Adverse Impact.	HSD will continue to consult with BWS.	4.5
Electrical and Communications Facilities	No Adverse Impact.	• Increase in need for electricity; however, HECO confirmed there is capacity. • No Adverse Impact	• Final placement of utility lines would be determined as Project design progresses. • Continued consultation with HECO. • No additional mitigation required.	4.6
Wastewater Facilities	No Adverse Impact.	• Increase in need for potable water; however, DPP confirmed there is capacity. • No Adverse Impact.	Continued consultation with the City. No mitigation required.	4.7
Solid Waste Collection and Disposal	No Adverse Impact.	No Adverse Impact.	No mitigation required.	4.8
Storm water and Drainage	No Adverse Impact.	No Adverse Impact.	• Construction will be regulated in accordance with CWA regulations.	4.9

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
System			• Erosion control measures and BMPs, including storm drain inlet protection and biofiltration cells will be installed as shown on Sheets C002, C005, and C006 in **Appendix A**. LID measures will be incorporated.	
Hazardous Wastes and Materials	Disturbance of hazardous materials during site demolition.	No Adverse Impact.	• HSD will coordinate with HDOH's Asbestos Abatement Office of the Noise, Radiation and Indoor Air Quality Branch prior to demolition and work with Contractors who are specifically trained in LBP and ACM abatement to safely remove these hazardous materials and limit any potential exposure to anyone who may be onsite during demolition. • All hazardous materials will be properly removed and disposed of at an approved waste facility prior to general demolition/construction activities.	4.10
Socio-Economic Environment	No Adverse Impact.	No Adverse Impact.	No mitigation required.	5.1
Historic, Archaeological, and Cultural Resources	No Adverse Impact.	Demolition of existing two-story building. Adverse Impact.	• The agreed upon mitigation commitments included in the Draft AIS, include preparing a BTP for the human burial site, identified as Component 3 of SIHP # -8840 and archaeological monitoring for Components 1–3 of SIHP # -8840. With the implementation of these mitigation commitments, the Project's potential adverse effect on SIHP # -8840, subsurface cultural deposits will be reduced. • HSD will implement the MOA. • "Project construction workers and all other personnel involved in the construction and related activities of the project should be informed of the possibility of inadvertent cultural finds, including human remains. In the event that any potential historic properties are identified during construction activities, all activities will cease and the SHPD will be notified pursuant to HAR §13-280-3. In the event that iwi kūpuna are identified, all earth moving activities in the area will stop, the area will be cordoned off, and the SHPD and Police Department will be notified pursuant to HAR §13-300- 40. In addition, in the event of an inadvertent discovery of human remains, the completion of	5.2, 5.3

Resources Impacted	Potential Short-term Impacts	Long-term Impacts	Mitigation and BMPs	EA Section
			a BTP, in compliance with HAR §13-300 and HRS §6E-43, is recommended" (CSH, 2019). • "In the event that iwi kūpuna and/or cultural finds are encountered during construction, Project proponents should consult with cultural and lineal descendants of the area to develop a reinternment plan and cultural preservation plan for proper cultural protocol, curation, and long-term maintenance" (CSH, 2019).

APPLICABLE CODES & AGENCIES

THE INTENT OF THE DRAWINGS AND SPECIFICATIONS IS TO CONSTRUCT REFERENCED PROJECT IN ACCORDANCE WITH CHAPTER 180 OF TITLE 3 HAWAII ADMINISTRATIVE RULES ("STATE BUILDING CODE") WITH LOCAL AMENDMENTS AND CITY AND COUNTY OF HONOLULU. REVISED ORDINANCES OF HONOLULU CHAPTER 21 LAND USE ORDINANCE (LIO):

CHAPTER 16: BUILDING
(ADOPTED & AMENDED 2006 INTERNATIONAL BUILDING CODE)
(ADOPTED & AMENDED 2006 INTERNATIONAL EXISTING BUILDING CODE)

CHAPTER 17: ELECTRICITY
(ADOPTED & AMENDED 2008 NATIONAL ELECTRICAL CODE)

CHAPTER 19: PLUMBING
(ADOPTED & AMENDED HAWAII STATE PLUMBING CODE INCORPORATING 2006 UNIFORM PLUMBING CODE)

CHAPTER 20: FIRE
(ADOPTED & AMENDED HAWAII STATE FIRE CODE - INCORPORATING 2012 NFPA1 UNIFORM FIRE CODE)

CHAPTER 32: BUILDING ENERGY CONSERVATION CODE
(ADOPTED & AMENDED 2015 INTERNATIONAL ENERGY CONSERVATION CODE)

CHAPTER 21: LAND USE ORDINANCE, ROH, FEBRUARY 20'8

DEPARTMENT OF HEALTH, TITLE 11, CHAPTER 39

THIS PROJECT HAS BEEN DESIGNED FOR ACCESSIBLE ACCESS IN ACCORDANCE WITH HAWAII STATE BUILDING CODE SECTION 3-180-28, WHICH INCLUDES: 2010 ADA GUIDELINES FOR ACCESSIBLE DESIGN ADMINISTERED BY THE US DEPARTMENT OF JUSTICE; THE FAIR HOUSING ACT DESIGN MANUAL ADMINISTERED BY THE US DEPARTMENT OF HOUSING AND URBAN DEVELOPMENT; AND OTHER PERTINENT LAWS. THE CONTRACTOR SHALL ENSURE THAT ALL WORK ACCOMPLISHED WITHIN THIS PROJECT MAINTAINS CONFORMANCE WITH THESE STANDARDS AND LAWS AS INDICATED OR REASONABLY INFERRED.

DEFERRED SUBMITTALS

1. EMERGENCY GENERATOR
2. FIRE PROTECTION STANDPIPE AND SPRINKLER SYSTEM
3. FIRE ALARM SYSTEM
4. TWO-WAY COMMUNICATION SYSTEM
5. HANDRAILING AT RAMPS
6. MECHANICAL ENCLOSURE
7. GARDEN DECK DECKING AND FENCING
8. COLD-FORMED STEEL DESIGN (SEE 05 4000)

NOTE:
THE DEFFERED SUBMITTAL(S) SHALL FIRST BE SUBMITTED TO THE ARCHITECT AND/OR ENGINEER FOR REVIEW AND COORDINATION. FOLLOWING THE COMPLETION OF ARCHITECT/ENGINEER REVIEW AND COORDINATION, A SUBMITTAL TO THE CITY SHALL BE MADE (FOR CITY REVIEW AND APPROVAL), WHICH SHALL INCLUDE A LETTER STATING THIS REVIEW AND COORDINATION HAS BEEN PERFORMED AND COMPLETED AND PLANS AND CALCULATIONS FOR THE DEFERRED ITEMS ARE FOUND TO BE ACCEPTABLE (I.E., WITH REGARD TO GEOMETRY, LOAD CONDITIONS, ETC.) WITH NO EXCEPTIONS.

DESIGN ALTERNATES

1. ADDITIVE: APR DOUBLE DOORS IN LIEU OF SLIDING DOORS
2. ADDITIVE: 1 MINI-BLIND WINDOW TREATMENTS AT ALL UNIT WINDOWS
3. ADDITIVE: CEILING FANS IN ALL UNIT BEDROOMS
4. DEDUCTIVE: RESIDENT ELEVATOR ACCESS CONTROLS
5. DEDUCTIVE: CALL BOX AT PARKING GATE ARMS
6. DEDUCTIVE: STAIR TOWER DOOR LOCKS AND ASSOCIATED FIRE COMMAND UNLOCK PANEL
7. ADDITIVE: OFF-SITE TRANSIT FIRE MODIFICATIONS
- 8A. DEDUCTIVE: SINGLE AWNING WINDOWS IN LIEU OF DOUBLE AWNING WINDOWS AT ALL UNIT WINDOWS
- 8B. DEDUCTIVE: DOUBLE AWNING WINDOWS IN LIEU OF SINGLE AWNING WINDOWS AT ALL UNIT WINDOWS
9. ADDITIVE: TOTAL DOOR SYSTEM IN LIEU OF DOUBLE DOOR AT L4-17 ELEVATOR LOBBY
10. ADDITIVE: PROVIDE LVT FLOORING IN UNIT BEDROOMS IN LIEU OF CARPET
11. DEDUCTIVE: REMOVE CABLE VINE SYSTEM AT COURTYARD

PROJECT INFO

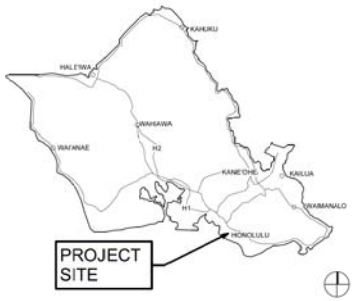
PROJECT LOCATION

1333 RIVER STREET
HONOLULU, HI 96817
TMK: 1-7-006-012

PROJECT SUMMARY

HALEWAI'OLU SENIOR RESIDENCES PROJECT IS A NEW AFFORDABLE RENTAL SENIOR HOUSING PROJECT PROPOSED AT 1333 RIVER STREET ALONG RIVER STREET IN HONOLULU. THE PROPOSED DEVELOPMENT REPLACES AN EXISTING TWO-STORY BUILDING AND PARKING LOT BEHIND THE EXISTING BUILDING.

THE 17 STORY APPROXIMATELY 190,000 SF BUILDING WILL HOUSE A MIX OF ONE AND TWO BEDROOM APARTMENTS AS WELL AS A GROUND LEVEL COMMUNITY MEETING FACILITY. TWO STORIES OF PARKING WILL PROVIDE PARKING FOR RESIDENTS AND VISITING COMMUNITY MEMBERS UTILIZING THE MEETING FACILITY.



THE PROJECT IS BEING PARTIALLY FUNDED WITH TAX CREDITS AND STATE RENTAL HOUSING FUNDS AND QUALIFIES THE PROJECT AS "STATE BUILDING CONSTRUCTION PER HRS PART II, SECTION 107-21.

TYPE OF CONSTRUCTION: 1A

OCCUPANCY GROUPS: R-2 (RESIDENTIAL), A-3 (ASSEMBLY), B (BUSINESS), F-1 (EQUIPMENT/MAINTENANCE), M (MERCANTILE), S-1 (STORAGE) AND S-2 (PARKING GARAGE)

THIS BUILDING IS PROVIDED WITH A FULLY AUTOMATIC FIRE SPRINKLER SYSTEM THROUGHOUT.

Mr. Adam Woltag, AIA, LEED AP, Partner
WRNS Studio
677 Ala Moana Boulevard, Suite 307
Honolulu, Hawaii 96813

Dear Mr. Woltag:

SUBJECT: Request for Confirmation of Alternative Building Code Use for Areas of Refuge
1333 River Street
Permit Application No. A2019-08-1296
Tax Map Key: 1-7-006: 012

This is in response to your letter dated October 7, 2019, regarding the above subject matter.

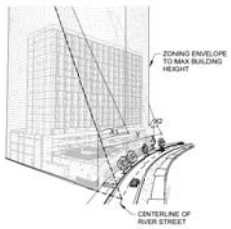
We have no objections to your request to use the 2012 International Building Code, Section 1007.3, which exempts the requirements of an area of refuge if equipped throughout by an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

Should you have any questions, please contact Mr. Willard Nishigata of our Plan Review Section, at 768-8232.

Very truly yours,

Wendel Ko, Acting Chief
Building Division

ZONING SUMMARY



REVISED ORDINANCE OF HONOLULU 2018, CHAPTER 21 - LAND USE ORDINANCE, ULO

TRANSIT-ORIENTED DEVELOPMENT DESIGN STANDARDS, ORDINANCE 17-54, WHICH AMENDS CHAPTER 21 AS RELATED TO TOD SPECIAL DISTRICTS.

SOUND TRANSMISSION — 1207.2, 1207.3

WALLS, PARTITIONS AND FLOOR / CEILING ASSEMBLIES SEPARATING DWELLING UNITS FROM EACH OTHER OR PUBLIC / SERVICE AREAS ARE DESIGNED TO MEET STC 50 FOR AIR-BORNE NOISE PER ASTM E 90.

FLOOR / CEILING ASSEMBLIES BETWEEN DWELLING UNITS OR BETWEEN A DWELLING UNIT AND PUBLIC / SERVICE AREA ARE DESIGNED TO MEET IIC 50 PER ASTM E 492.

HOUSING CODE ROH CHAPTER 27 — SEC 27-4.3(a), SEC 27-4.3(b), SEC 27-4.4(a)

ROOM DIMENSIONS
CEILING HEIGHTS:
(1) HABITABLE SPACES ARE PROVIDED WITH A CEILING/HEIGHT OF NOT LESS THAN 7'-6". KITCHENS AND BATHROOMS ARE PROVIDED WITH A CEILING HEIGHT OF NOT LESS THAN 7'-0".
(3) WHERE FURRED CEILINGS ARE PROVIDED THE CEILING HEIGHT IS NOT LESS THAN 7'-0".

FLOOR AREA
RESIDENTIAL UNITS COMPLY WITH AREA REQUIREMENTS FOR EACH SPACE.
(2) UNITS ARE PROVIDED WITH SEPARATE CLOSETS.
(3) UNITS ARE PROVIDED WITH KITCHENS CONTAINING A SINK, COOKING APPLIANCE AND REFRIGERATOR, CLEAR WORK SPACE IS PROVIDED. LIGHT AND VENTILATION CONFORMING TO THIS CODE IS PROVIDED.
(4) UNITS ARE PROVIDED WITH A BATHROOM CONTAINING A WATER CLOSET, LAVATORY, AND BATHTUB.

LIGHT AND VENTILATION
NATURAL LIGHT AND VENTILATION
(1) ALL HABITABLE ROOMS ARE PROVIDED WITH NATUIAL LIGHT BY MEANS OF WINDOWS WITH AN AREA OF NOT LESS THAN ONE-TENTH OF THE FLOOR AREA OF SUCH ROOMS WITH A MINIMUM OF 10 SQUARE FEET, NOT LESS THAN ONE-HALF OF THE REQUIRED WINDOW OR SKYLIGHT AREA SHALL BE OPENABLE TO PROVIDE NATURAL VENTILATION.

MECHANICAL VENTILATION
(1) IN LIEU OF REQUIRED OPENABLE WINDOWS FOR NATURAL VENTILATION, A MECHANICAL VENTILATION
SYSTEM MAY BE PROVIDED FOR ALL SPACES EXCEPT BEDROOMS.

S OCCUPANCY:	29	100'-0"

EXIT ACCESS TRAVEL DISTANCE (WITH FIRE SPRINKLERS) — TABLE 1016.1

A, F-1, M, R, S-1 OCCUPANCIES	250'-0"
B OCCUPANCY:	300'-0"
S-2 OCCUPANCY:	400'-0"

CORRIDOR DEAD ENDS — 1013.3, 1013.3, EXCEPTION 2

A-3 OCCUPANCY:	20'-0"
B OCCUPANCY:	50'-0"
F OCCUPANCY:	50'-0"
M OCCUPANCY:	20'-0"
R OCCUPANCY:	20'-0"
S OCCUPANCY:	20'-0"

*FOR CORRIDORS SERVING BOTH A, B, M & R OCCUPANCIES, THE SHORTEST DEAD END DISTANCE GOVERNS.

AUTOMATIC SPRINKLER SYSTEM — 903.1.1.1, 905

AUTOMATIC SPRINKLER SYSTEM (NFPA 13) PROVIDED THROUGHOUT IN ACCORDANCE WITH BC 903.3.1.1 AND A SECONDARY WATER SUPPLY WHERE REQUIRED BY SECTION 903.3.5.2.

STANDPIPE SYSTEMS SHALL COMPLY WITH SECTION 905.

FIRE ALARM SYSTEM — 907.1

FIRE ALARM SYSTEM SHALL BE PROVIDED IN ACCORDANCE WITH SECTION 907.2.

TYPE OF CONSTRUCTION RISK CLASSIFICATION — 602.2, TABLE 1604.5

TYPE IA, FULLY SPRINKLERED
II

OCCUPANCY CLASSIFICATION — 310.1

PRIMARY: R-2 - RESIDENTIAL APARTMENTS

ADDITIONAL (NON-SEPARATED OCCUPANCIES):
A-3 - ASSEMBLY — 303.1
B - BUSINESS — 304.1
F-1 - EQUIPMENT/MAINTENANCE — 306.2
M - MERCANTILE — 309.1
S-1 - STORAGE — 311.2
S-2 - PARKING GARAGE — 311.3

REQUIRED FIRE RESISTIVE RATINGS — 403.3.1.1, CHAPTER 6 TABLE 601

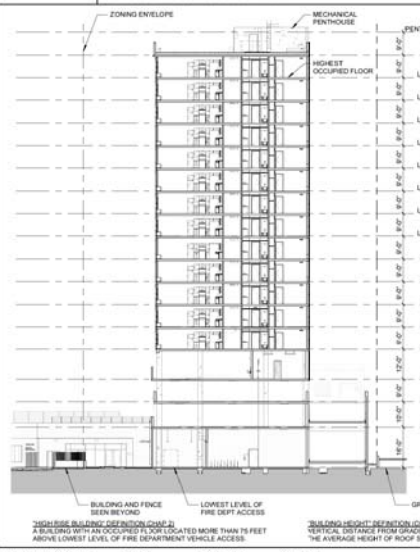
STEEL NOT REQ'D TO BE RATED:
-MECH EQUIP SUPPORT
-CANOPY FRAMING
-STAIRS
-ELEVATOR RAIL SUPPORTS & DIVIDER BEAMS

PRIMARY STRUCTURAL FRAME	2 HOUR* *COLUMNS SUPPORTING FLOORS SHALL NOT BE ALLOWED TO BE REDUCED PER 403.3.1.
BEARING WALLS - EXTERIOR	2 HOUR
BEARING WALLS - INTERIOR	2 HOUR
NON-BEARING WALLS - EXTERIOR	SEE "FIRE SEPARATION DISTANCE" BELOW
NON-BEARING WALLS - INTERIOR	NO RATING REQUIRED
FLOOR CONSTRUCTION	2 HOUR — TABLE 1505.1
ROOF CONSTRUCTION	1 HOUR, CLASS B CONSTRUCTION — TABLE 1505.1
ROOF SUPPORTS	1 HOUR — 1026.1
STAIRWAY ENCLOSURES	2 HOUR — 707.4
SHAFT ENCLOSURES	2 HOUR
EXIT PASSAGEWAY	2 HOUR - NOT LESS THAN THAT REQUIRED FOR ANY CONNECTNG EXIT ENCLOSURE — 1026.1, 1021.3
DWELLING UNIT SEPARATION WALLS	1 HOUR — 419.2, 708.3
FLOOR/CEILING ASSEMBLIES	1 HOUR — 419.3, 711.3

PARAPET — 705.11

SAME FIRE RATING AS SUPPORTING WALL. NON-COMBUSTIBLE FACES FOR UPPERMOST 18 INCHES. 30 INCH HEIGHT MINIMUM. NO PARAPET IS FEQUIRED IF ROOF AND SUPPORTING CONSTRUCTION IS NON-COMBUSTIBLE.

HIGH-RISE BUILDINGS



AUTOMATIC SPRINKLER SYSTEM PROVIDED THROUGHOUT IN ACCORDANCE WITH BC 903.3.1.1 AND A SECONDARY WATER SUPPLY WHERE REQUIRED BY BC 903.3.5.2.	403.2
EMERGENCY ESCAPE AND RESCUE OPENINGS PER BC 1026 ARE NOT REQUIRED.	403.4
AUTOMATIC FIRE/SMOKE DETECTION PROVIDED IN ACCORDANCE WITH BC 907.2.12.1.	403.5
EMERGENCY VOICE/ALARM COMMUNICATION SYSTEMS PROVIDED IN ACCORDANCE WITH BC 907.2.12.2.	403.6
TWO-WAY FIRE DEPARTMENT COMMUNICATION SYSTEM PROVIDED IN ACCORDANCE WITH BC 907.2.12.3.	403.7
FIRE COMMAND COMPLYING WITH BC 911 AND THE FIRE CODE PROVIDED. FIRE COMMAND STATIONS SHALL BE APPROVED BY THE FIRE CHIEF.	403.8 HAR 3-180-22 HAR 3-180-26
ELEVATORS PROVIDED IN ACCORDANCE WITH CHAPTER 30.	403.9
STANDBY POWER SYSTEM IN ACCORDANCE WITH BC 2702 AND BC 403.10.2 PROVIDED	403.10
EMERGENCY POWER SYSTEMS COMPLYING WITH BC 2702 AND BC 403.11.1 PROVIDED	403.11
SMOKEPROOF EXIT ENCLOSURES COMPLYING WITH BC 909.20 AND BC 1020.1.7 PROVIDED. EXIT STAIRWAY ENCLOSURES ARE PRESSURIZED PER BC 909.20.5	403.12

ALLOWABLE BUILDING HEIGHT & AREA (ALL OCCUPANCIES)

ALLOWABLE HEIGHT	UNLIMITED	TABLE 503
ALLOWABLE NO. OF STORIES	UNLIMITED	TABLE 503
ALLOWABLE AREA	UNLIMITED	TABLE 503

ACTUAL BUILDING HEIGHT & AREA
(SEE BUILDING HEIGHT DIAGRAM THIS SHEET)

ACTUAL HEIGHT	184'-0" TO AVERAGE HEIGHT OF MAIN ROOF SURFACE, WITHOUT PENTHOUSE	
ACTUAL NO. OF STORIES	17 STORIES	
ACTUAL AREA (PER FLOOR)	LEVEL 1:	19,659 FT²
	LEVEL 2:	15,905 FT²
	LEVEL 3:	14,889 FT²
	LEVEL 4:	9,312 FT²
	LEVELS 5 - 17:	9,209 FT²
ACTUAL AREA (GROSS BUILDING AREA)	TOTAL BLDG:	180,588 FT²

*HIGH RISE BUILDING" DEFINITION (CHAP 2)
A BUILDING WITH AN OCCUPIED FLOOR LOCATED MORE THAN 75 FEET ABOVE LOWEST LEVEL OF FIRE DEPARTMENT VEHICLE ACCESS.

*BUILDING HEIGHT" DEFINITION (CHAP 2)
VERTICAL DISTANCE FROM GRADE PLANE TO THE AVERAGE HEIGHT OF ROOF SURFACE

FIRE SEPARATION RATING REQUIREMENTS FOR EXTERIOR WALLS BASED ON FIRE SEPARATION DISTANCE AND TYPE OF CONSTRUCTION (IA) — CHP. 6 TABLE 602

DISTANCE	OCCUPANCY F-1, M, S-1	OCCUPANCY A, B, R, S-2
0 FT < X < 5 FT =	2 HR	1 HR
5 FT ≤ X < 10 FT =	2 HR	1 HR
10 FT ≤ X < 30 FT =	1 HR	1 HR*
30 FT ≤ X =	NR	NR

*OPEN PARKING GARAGES COMPLYING WITH BC 406 SHALL NOT REQUIRE A FIRE RESISTANCE RATING.

EXTERIOR WALLS OF MORE THAN 5 FEET FIRE SEPARATION DISTANCE SHALL BE RATED FOR EXPOSURE FROM THE INSIDE. EXTERIOR WALLS OF 5 FEET OR LESS FIRE SEPARATION DISTANCE SHALL BE RATED FOR EXPOSURE FROM BOTH SIDES. — 704.5

PLANT MATERIAL LIST

- ACCENT FLOWERING CANOPY TREE — MICHELIA CHAMPACA / PAK LAN
- TALL ACCENT SCREEN TREE — TABEBUIA HETEROPHYLLA / PINKTECOMA
- TALL VERTICAL SCREENING — BAMBUSA TEXTILIS / WEAVER'S BAMBOO
- TALL CLUMPING ACCENT/SCREEN PALM — PTYCHOSPERMA MACARTHURII / MACARTHUR PALM
- GRAVEL (MAINTENANCE STRIP)
- PSEUDERANTHEMUM CARRUTHERSII VAR. VARIEGATUM / GOLDEN ELDORADO
- THUNBERGIA MYSORENSIS / MYSORE TRUMPETVINE
- DIANELLA TASMANICA 'VARIEGATA' / VARIEGATED FLAX LILY
- PHILODENDRON 'XANADU' / XANADU PHILODENDRON
- MICROSORUM DIVERSIFOLIA / KANGAROO PAW FERN

For Courtyard Pots, use 3 Gal. Kwai Fah (Osmanthus fragrans) and Mei Sui Lan/Chinese Perfume Plant (Aglaia odorata). Pots and plants/soil for pots to be provided and installed by Owner.

Pots, planting media and vines for Bid Alternate cable system to be provided and installed by Owner. Vines should be Siephanotis floribunda vine, 3 gal and Thunbergia mysorensis, 3 gal.

IRRIGATION CONSTRUCTION NOTES:

(1D) POINT OF CONNECTION. THE CONTRACTOR SHALL LOCATE 'THE NEW BUILDING SERVICE LINE PIPE AND MAKE A TIE-IN DOWNSTREAM FROM THE EXISTING DOMESTIC WATER METER AND BEFORE THE PIPE ENTERS THE BUILDING (REFER TO DETAIL 'N'). THE CONTRACTOR SHALL RUN A 1 1/4" PVC SCHEDULE 40 MAIN LINE PIPETO THE 1" BACKFLOW PREVENTION DEVICE. THEN RUN A 1" PVC SCHEDULE 40 SUPPLY LINE TO THE SYSTEM AS NOTED ON THE DRAWINGS. FINAL LOCATION OF THE BACKFLOW PREVENTION DEVICE SHALL BE APPROVED BY THE OWNER'S AUTHORIZED REPRESENTATIVE. THE SYSTEM HAS BEEN DESIGNED FOR A MAXIMUM FLOW OF 8.5 GPM AT A MINIMUM OPERATING PRESSURE OF 48.0 PSI. VERIFY THAT THE STATIC PRESSURE IS AT LEAST 60.0 PSI PRIOR TO ANY CONSTRUCTION. IMMEDIATELY NOTIFY THE LANDSCAPE ARCHITECT SHOULD THE PRESSURE BE LESS THAN OPERATING PRESSURE.

(2) PROVIDE AND INSTALL A RAIN BIRD MODEL NUMBER ESP-LX-36 WALL MOUNT CONTROLLERS 'A'. THE MECHANICAL EQUIPMENT AREA. F INAL LOCATION OF THE CONTROLLER SHALL BE APPROVED BY THE OWNER'S AUTHORIZED REPRESENTATIVE. 120VAC POWER SHALL BE SUPPLIED BY OTHERS. THE LANDSCAPE CONTRACTOR SHALL COORDINATE THE 120VAC POWER FROM THE SOURCE TO THE CONTROLLER AND MAKE THE FINAL HOOK-UP. ALL 120VAC POWER WIRING SHALL BE COMPLETED BY A LICENSED ELECTRICAL CONTRACTOR. THE LANDSCAPE CONTRACTOR SHALL CONNECT THE LOW VOLTAGE CONTROL WIRES TO THE CONTROLLER TERMINAL STRIP IN THE SEQUENCE NOTED ON THE DRAWINGS. ANY DEVIATIONS SHALL BE NOTED ON THE AS-BUILT RECORD DRAWINGS.

(3) THE CONTRACTOR SHALL COORDINATE FOR THE INSTALLATION OF A 2" DIAMETER CONDUIT FROM THE IRRIGATION CONTROLLER TO THE NEAREST PLANTER AREA. PROVIDE SWEEP ELLS AND 2' BOXES AT ALL CHANGES OF DIRECTION. ANY EXPOSED CONDUIT SHALL BE PAINTED TO MATCH THE BUILDING COLOR.

SOILS REPORT RECOMMENDATION NOTES

1. Placement of new fills will likely induce some consolidation of the soft and/or loose lagoonal deposits underlying the site. Therefore, it is important to place the new fills as soon as practical to allow the ground settlements to occur first prior to construction of improvements, such as the slab-on-grade construction, to reduce the potential for adverse effects resulting from ground settlements.
2. A Geolabs representative shall monitor the grading operations to observe whether undesirable materials are encountered during the excavation and scarification process, and to confirm whether the exposed soil conditions are similar to those encountered in their field exploration.
3. At the on-set of earthwork, the site shall be cleared and grubbed thoroughly. Vegetation, debris, deleterious materials, existing structures to be demolished, and other unsuitable materials, shall be removed and disposed of properly off-site to reduce the potential for contaminating the excavated materials.
4. Soft and yielding areas encountered during clearing and grubbing below areas designated to receive fill and/or future improvements shall be over-excavated to expose firm natural material, and the resulting excavation shall be backfilled with well-compacted fill. The excavated soft soils shall not be re-used as fill materials and shall be properly disposed of off-site.
5. In general, the over-excavated subgrades and areas designated to receive fills shall be scarified to a depth of about 8 inches, moisture-conditioned to above the optimum moisture content, and recompacted to a minimum of 90 percent relative compaction. The compaction requirement of the finished subgrades for areas subjected to vehicular traffic shall be increased to a minimum of 95 percent relative compaction. Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density as determined by ASTM D1557. Optimum moisture is the water content (percentage by dry weight) corresponding to the maximum dry density.
6. In general, the near-surface clayey silt soils encountered during our field exploration may be suitable for use as general fill materials, provided that the maximum particle size is less than 3 inches in largest dimension. The on-site materials generated from the excavations may be used as a source of general fill or backfill materials provided that they are free of vegetation and deleterious materials and screened of the over-sized materials and/or processed to meet the above gradation requirements (less than 3 inches in largest dimension).
7. Imported materials to be used as select granular fill shall be non-expansive granular material, such as crushed coral or basalt. The select granular fill shall be well graded from coarse to fine with particles no larger than 3 inches in largest dimension. The material shall have a California Bearing Ratio (CBR) value of 20 or higher, and a swell potential of 1 percent or less when tested in accordance with ASTM D1883. The material also shall contain between 10 and 30 percent particles passing the No. 200 sieve. Imported fill materials shall be tested for conformance with these recommendations prior to delivery to the project site for the intended use.
8. Where groundwater is encountered (within the excavations), backfill materials shall consist of free-draining granular materials, such as No. 3B Fine gravel (ASTM C33, No. 67 gradation), wrapped on all sides with non-woven filter fabric. The free-draining granular materials shall be used up to a level of about 12 inches above the groundwater level to facilitate compaction of the fill materials.
9. Aggregate base and subbase courses required for the project shall consist of crushed basaltic aggregates and shall meet the requirements of Sections 30 and 31 of the City and County Standard Specifications (September 1986). Imported fill materials shall be tested for conformance with these recommendations prior to delivery to the project site for the intended use.
10. In general, fills and backfills shall be moisture-conditioned to above the optimum moisture content, placed in level lifts not exceeding 8 inches in loose thickness and compacted to at least 90 percent relative compaction. The compaction requirement for the last lift of fill (finished subgrade) below areas subjected to vehicular traffic shall be increased to at least 95 percent relative compaction.
11. Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density as determined by ASTM D1557. Optimum moisture is the water content (percentage by dry weight) corresponding to the maximum dry density. Compaction shall be accomplished by sheepsfoot rollers, vibratory rollers, or other types of acceptable compaction equipment. Water tamping, jetting, or ponding shall not be allowed to compact the fills.
12. Exterior concrete slabs, such as walkways and patios, also may be required for the project. In general, we recommend providing a minimum 6-inch thick cushion fill layer consisting of select borrow subbase below exterior concrete slabs that will not be subjected to vehicular traffic. The select borrow subbase shall be moisture-conditioned to above the optimum moisture, and compacted to at least 90 percent relative compaction. The select borrow subbase shall be increased to a minimum of 12 inches if expansive clayey soils are encountered at the slab subgrade level. To reduce the potential for significant slab cracking due to concrete shrinkage, crack control joints shall be provided at intervals equal to the width of the walkways with expansion joints at right-angle intersections.
13. We anticipate excavations on the order of up to about 13 feet below the ground surface may be required for construction of the building foundations and elevator pits. Based on the subsurface conditions encountered and the limited working space, we envision temporary shoring of some of the deeper excavations may be required.
14. The field exploration encountered a surface fill layer underlain by soft and/or loose lagoonal deposits near the existing ground surface. Therefore, we envision that conventional excavation techniques using a backhoe excavator may be used for the planned excavations. In general, we believe interlocking steel sheet piling may be used for temporary shoring purposes, especially where dewatering of the excavations will be necessary. However, it should be noted that use of a vibratory hammer to install the interlocking steel sheet piles shall be avoided to reduce the potential for inducing a liquefaction condition in the underlying very soft and/or loose lagoonal deposits, which would cause some settlements of the ground adjacent to the sheet pile shoring.
15. We also recommend the contractor develop and implement a monitoring program to detect ground movement and/or subsidence adjacent to the excavations, which may result in damage to nearby structures and pavements. It should be noted that minor settlements of the adjacent ground may occur during and after installation of the interlocking steel sheet piles. Therefore, we recommend the contractor retain a qualified geotechnical engineer to design and evaluate the shoring system planned.
16. In general, the contractor shall determine the method and equipment to be used for excavations, subject to practical limits and safety considerations. Based on the field exploration, the surface fill materials and underlying soft and/or loose lagoonal deposits encountered in the borings may be excavated with conventional earthmoving equipment. However, some localized areas of hard materials and/or obstructions may be encountered at the site. Therefore, the contractor may encounter difficult excavation conditions at localized areas, which should be expected considering the urban nature of the project site.
17. Dewatering of excavations will be necessary where the existing groundwater level is above the bottom of the proposed excavation. We encountered groundwater in our drilled borings at depths of about 7.2 to 8.0 feet below the ground surface at the time of our field exploration. The groundwater levels encountered generally correspond to about Elevations +1.1 to +2.5 feet MSL.
18. Based on the groundwater levels anticipated and the generally permeable nature of some of the silty sand soils below the surface fills to be encountered within the excavations, dewatering will be required at the planned excavations of the project construction. Because the excavation may involve discharge of groundwater, a National Pollutant Discharge Elimination System (NPDES) permit may be required for this discharge. The contractor shall consult their independent consultant for the latest regulations and information pertaining to the permit application.
19. Because of the granular nature of some of the subsurface soils, we anticipate the granular soils encountered below the surface fills are relatively permeable. Therefore, dewatering of the excavation may involve moderate volumes of water. Because of the presence of loose and/or soft soils, we do not recommend dewatering by means of a well point system along the outside of the excavations. The resultant areal depression of the natural groundwater table could induce consolidation of the compressible subsurface soils resulting in potential ground settlements, which could affect the adjacent existing structures. The potential impact of the dewatering system selected on depressing the natural groundwater table must be carefully evaluated by the contractor prior to dewatering.

SOILS REPORT RECOMMENDATION NOTES (CONTINUED)

20. It is our opinion that a cut-off wall system, such as interlocking steel sheet piles, shall be considered to aid in dewatering the excavation. However, sumps will be needed to collect water that percolates up into the base of the excavation or infiltrates through the sheet piles. The sheet piles shall be driven to a sufficient depth to reduce the potential for areal ground subsidence and to reduce the amount of dewatering needed within the excavations in areas underlain by granular subsurface soils with moderate permeability. Use of an interlocking steel pile shoring support system with jet-grouted soils (or tremie concrete plug) is relatively watertight, which should allow the groundwater levels outside the excavations to be maintained close to the original pre-construction levels.
21. Installation of the sheet pile shoring to the desired depths at the site may require predrilling of the sheet pile locations. The presence of these predrilled holes directly adjacent to the sheet pile shoring may serve as conduits for groundwater to infiltrate the sheet pile shored excavation. This condition could result in large volumes of seepage water to infiltrate the shored excavation requiring additional dewatering efforts and disposal of the dewatered effluent. Therefore, the contractor shall take precautionary measures to avoid these conditions, which could contribute significantly to the dewatering requirements for the project.
22. The contractor is responsible for dewatering for construction and disposal of the dewatered effluent. The selection of equipment and methods of dewatering shall be left up to the contractor, and he/she shall be aware that modifications to the dewatering system may be required during construction depending on the conditions encountered. The dewatering method selected shall have minimal impact on the groundwater level surrounding the proposed excavation. The dewatering operations shall be coordinated with the shoring support such that the stability of the excavations is not jeopardized. The operations shall be carried-out without softening the bottom of the excavations.
23. Based on our borings, the near-surface clayey silt fill soils were underlain by lagoonal deposits consisting of relatively thin layer of loose silty sands overlying a thick deposit of soft organic silts. The permeability of the subsoils at the site may be considered moderately permeable based on the materials encountered. Therefore, the contractor shall pay attention to the site-specific dewatering plan for the proposed excavations.
24. We suggest considering the following three basic criteria in selection of a suitable method of dewatering:
    a. The dewatering method shall result in the least disturbance or damage to existing buildings, roads, and environment.
    b. The dewatering method shall maintain stability of, and also provide safe and dry working conditions in, the excavation.
    c. The dewatering method shall be sufficiently flexible to allow modifications to accommodate various ground conditions.
25. The contractor must carefully evaluate the potential impact of the dewatering system selected on depressing the natural groundwater table prior to dewatering. The contractor shall retain a qualified geotechnical engineer to design and evaluate the dewatering system used.
26. The contractor shall be solely responsible for the impact and safety of the dewatering operations. His/her qualified representative, who shall be continuously present on-site during dewatering activities, will have the best opportunity to promptly observe the effects of dewatering during construction and to implement, as soon as possible, necessary precautionary or remedial measures including, but not limited to, slowing down or stopping the dewatering operations.
27. Where encountered at the bottom of excavations, permeable granular soils may be susceptible to piping and "quick" conditions. The dewatering operations shall be carried-out without creating a "quick" condition or softening of the excavation bottoms. Therefore, the project dewatering operations shall be performed without pumping out soil fines (pumping clear water only) and shall be coordinated with the shoring installation such that the excavation stability is not adversely affected. Excessive pumping, which removes soil fines, may result in "blowing" or heaving of the excavation bottom or sides.
28. Groundwater drawdown outside the excavation will cause additional settlement resulting from consolidation of the soft and/or loose compressible soils. Therefore, the use of a deep well system outside the excavations to draw down the groundwater level shall not be allowed.
29. Special caution also shall be taken to avoid dewatering utility trenches connected to the excavations. If this occurs, the granular bedding and/or backfill in the utility trenches could act as subdrains and cause significant areal groundwater drawdown. Significant areal groundwater drawdown would result in appreciable ground settlements and potential damage to utility lines and/or other adjacent existing structures.
30. The subgrade soils under the pavement areas shall be scarified to a minimum depth of 8 inches, moisture-conditioned to above the optimum moisture, and compacted to at least 95 percent relative compaction. If the pavement subgrade soils are pumping during the compaction operation, a layer of woven geotextile fabric, such as Mirafi 500X or equivalent, shall be provided between the aggregate subbase and the underlying subgrade soils. CBR tests and/or field observations shall be performed on the actual subgrade soils during construction to confirm that the above design sections are adequate. The aggregate base and subbase courses shall consist of crushed basaltic aggregates compacted to a minimum of 95 percent relative compaction.
31. In addition, paved areas shall be sloped, and drainage gradients shall be maintained to carry the surface water off the site. Surface water ponding shall not be allowed on-site during or after construction.
32. In general, for utility trenches, we recommend using granular bedding consisting of 6 inches of free-draining granular materials (ASTM C33, No. 67 gradation) below the pipes for uniform support. Free-draining granular materials, such as No. 3B Fine gravel (ASTM C33, No. 67 gradation), also shall be used for the initial trench backfill up to about 12 inches above the pipes.
33. Where groundwater is encountered, the bedding shall be wrapped on all sides by non-woven filter fabric (Mirafi 180N or equivalent).
34. We envision soft and/or loose lagoonal deposits will be encountered at or near the invert elevations along the utility lines and underground structure. Therefore, we recommend providing a subgrade stabilization layer consisting of 24 inches of No. 2 Rock (ASTM C33, No. 4 gradation) wrapped in a non-woven filter fabric (Mirafi 180N or equivalent) below the bedding layer for uniform support. The stabilization layer shall extend beyond the sides of the pipe a minimum width of one-fourth the outside diameter of the pipe or 12 inches, whichever is greater.
35. The upper portion of the trench backfill from a level of 12 inches above the pipes to the top of the subgrade or finished grade shall consist of the excavated granular materials with a maximum particle size of 6 inches or select granular fill materials. The backfill material shall be moisture-conditioned to above the optimum moisture content, placed in maximum 8-inch level loose lifts, and mechanically compacted to at least 90 percent relative compaction. In areas where trenches will be in paved areas, the upper 3 feet of the trench backfill below the pavement finished grade shall be compacted to no less than 95 percent relative compaction.
36. Where competent ground conditions are exposed at about the utility line invert elevations, the 24-inch thick stabilization layer may be omitted.
37. The requirement for the 24-inch stabilization layer shall be determined in the field based on the exposed ground conditions at the pipe invert elevations. Therefore, a Geolabs representative shall observe the exposed trench subgrade conditions before placement of the pipe bedding to evaluate if the 24-inch thick stabilization layer below the on-site underground utility lines is necessary.
38. A Geolabs representative shall monitor the other aspects of the earthwork construction. This is to observe compliance with the intent of the design concepts, specifications, or recommendations and to expedite suggestions for design changes that may be required in the event that subsurface conditions differ from those anticipated at the time this report was prepared.
39. If the actual subsurface conditions encountered during construction are different from those assumed or considered in this report, then appropriate modifications to the design shall be made.

GRADING NOTES

1. All grading work shall be done in accordance with Chapter 14, Articles 13, 14, 15 & 16 as related to Grading, Soil Erosion and Sediment Control, of the Revised Ordinances of Honolulu, 1990, as amended, and Soils Report by Geolabs, Inc. entitled "Geotechnical Engineering Exploration, Halewai'olu Senior Residences" dated June 14, 2019.
2. No Contractor shall perform any grading operation so as to cause falling rocks, soil or debris in any form to fall, slide or flow onto adjoining properties, streets or natural watercourses. Should such violations occur, the contractor may be cited and the contractor shall immediately make all remedial actions necessary.
3. The Contractor, at his own expense, shall keep the project area and surrounding area free from dust nuisance. The work shall be in conformance with the air pollution control standards contained in the Hawaii Administrative Rules, Title II, Chapter 60.1, "Air Pollution Control".
4. The underground pipes, cables or ductlines known to exist by the engineer from his search of records are indicated on the plans. The Contractor shall verify the locations and depths of the facilities and exercise proper care in excavating in the area. Wherever connections of new utilities are shown on the plans, the Contractor shall expose the existing lines at the proposed connections to verify their locations and depths prior to excavation for the new lines.
5. Adequate provisions shall be made to prevent surface waters from damaging the cut face of an excavation or the sloped surfaces of a fill. Furthermore, adequate provisions shall be made to prevent sediment-laden runoff from leaving the site.
6. All slopes and exposed areas shall be grassed, paved, or approved equal as soon as final grades have been established. Grassing shall not be delayed until all grading work has been completed. Grading to final grade shall be continuous, and any area within which work has been interrupted or delayed shall be grassed.
7. Fills in slopes steeper than 5:1 shall be keyed.
8. The City shall be informed of the location of the borrow/disposal site for the project when the application for a grading permit is made. The borrow/disposal site must also fulfill the requirements of the grading ordinance.
9. No grading work shall be done on Saturdays, Sundays and holidays at any time without prior notice to the Director D.P.P., provided such grading work is also in conformance with Hawaii Administrative Rules, Title II, Chapter 46, "Community Noise Control".
10. The limits of the area to be graded shall be flagged before the commencement of the grading work.
11. The general contractor/developer/owner of the project shall be responsible for all grading operations to be performed in conformance with applicable provisions of the Hawaii Administrative Rules, Title 11, Chapter 54, "Water Quality Standards", and Title 11, Chapter 55, "Water Pollution Control", as well as Chapter 14 of the Revised Ordinances of Honolulu, as amended. Best Management Practices shall be employed at all times during construction.

    The general contractor/developer/owner of the project shall obtain National Pollutant Discharge Elimination System (NPDES) Permit coverage(s) for the following:

    1. Storm water discharges associated with construction activities that disturb one (1) acre or more, and
    2. Discharges of hydrotesting effluent, dewatering effluent, and well drilling effluent to State waters.

    In accordance with State law, all discharges related to project construction or operations are required to comply with State Water Quality Standards (Hawaii Administrative Rules, Chapter 11-54). Best Management Practices shall be used to minimize or prevent the discharge of sediment, debris, and other pollutants to State waters. Permit coverage is available from the Department of Health, Clean Water Branch at http://health.hawaii.gov/cwb. The owner/developer/contractor is responsible for obtaining other Federal, State, or local authorizations as required by law.
12. Where applicable and feasible the measures to control erosion and other pollutants shall be in place before any earth moving phase of the grading is initiated.
13. Temporary erosion controls shall not be removed before permanent erosion controls are in-place and established.
14. Temporary Erosion Control Procedures shall be submitted for approval prior to application for grading permit.
15. If the grading work involves contaminated soil, then all grading work shall be done in conformance with applicable State and Federal requirements.
16. For non-City projects, the Contractor shall notify the Civil Engineering Branch, Department of Planning and Permitting at 768-8084 to arrange for inspectional services and submit two (2) sets of approved Construction Plans seven (7) days prior to commencement of construction work. For City projects, the Contractor shall coordinate inspectional services with the responsible agency.
17. Pursuant to Chapter 6E, HRS, in the event any artifacts or human remains are uncovered during construction operations, the Contractor shall immediately suspend work and notify the Honolulu Police Department, the State Department of Land and Natural Resources-Historic Preservation Division (692-8015). In addition, for non-City projects, the Contractor shall inform the Civil Engineering Branch, D.P.P. (768-8084); and for City projects, notify the responsible City Agency.
18. For all projects, which will disturb one (1) acre or more of land, the contractor shall not start construction until a Notice of General Permit Coverage (NGPC) is received from the Department of Health, State of Hawaii, and has satisfied any other applicable requirements of the NPDES permit program. Also, for non-City and other non-governmental agency projects, the Contractor shall provide a written copy of the NGPC to the Permitting and Inspection Section, Civil Engineering Branch, D.P.P., at least seven (7) calendar days before the start of the construction. For City or other governmental projects, the Contractor should provide a written copy of the NGCP to the appropriate City department or governmental agency per their requirements.
19. All grading and construction work shall implement measures to ensure that the discharge of pollutants from the construction site will be reduced to the maximum extent practicable and will not cause or contribute to an exceedance of water quality standards.
20. Non-compliance to any of the above requirements shall mean immediate suspension of all work, and remedial work shall commence immediately. All costs incurred shall be billed to the violator. Furthermore, violators shall be subjected to administrative, civil and/or criminal penalties.
21. For Bench Mark, see sheet 1.

GAS FACILITIES CONSTRUCTION NOTES:

1. The Hawaii Gas pipelines in the project area are plastic coated and cathodically protected. The Contractor shall be extremely careful when working near these gas pipelines.
2. Written clearances must be obtained from the Hawaii Gas, Maps and Records Department, 515 Kamokee Street, at least five (5) working days prior to starting excavation near these gas pipelines.
3. Since gas line locations on field maps are approximate, the Contractor, after obtaining written clearance, shall call Hawaii One Call Center a minimum of five (5) working days before starting excavation to arrange for field location of the existing gas pipelines. The telephone number is 1-866-423-7287.
4. The Contractor shall excavate and backfill around gas pipelines in the presence of a representative of Hawaii Gas. All backfill within six inches of any gas pipeline shall be select cushion material approved by Hawaii Gas.
5. For relocation of any gas pipeline, the Contractor shall notify Hawaii Gas five (5) working days before starting work. The telephone number is 594-5574. The Contractor shall provide the necessary excavation and backfill, obtain traffic permits, and restore pavement, sidewalks, and other facilities. Any relocation of gas facilities shall be done by Hawaii Gas and paid for by the Contractor.
6. The Contractor shall notify Hawaii Gas immediately after any damage has been caused to existing gas pipelines, coatings, or its cathodic protection devices. The telephone number is 535-5933, 24 hours a day. The Contractor shall be liable for any damage to Hawaii Gas facilities. Repair work on such damage shall be done by Hawaii Gas with payment for this work to be borne by the Contractor.
7. Minimum vertical and horizontal clearance between the gas pipelines and other pipelines, conduits, ductlines, or other facilities shall be 12 inches. Adequate support and protection of gas pipelines exposed in the trench shall be provided by the Contractor and approved by Hawaii Gas.
8. The Contractor shall work in an expeditious manner in order to keep the uncovered gas pipelines exposed for as short a period of time as possible.

CONSTRUCTION NOTES

1. All applicable construction work shall be done in accordance with the Standard Specifications for Public Works Construction, September 1986 and Standard Details for Public Works Construction, September 1984, as amended, of the Department of Public Works, City and County of Honolulu and the Counties of Kauai, Maui and Hawaii. Also, all construction work relating to High Density Polyethylene Drain Pipes shall be done in accordance with the Standard Specifications for Public Works Construction, High Density Polyethylene Smooth Interior Corrugated Drain Pipes, March 2013, of the Department of Planning and Permitting, City and County of Honolulu.
2. The underground pipes, cables or ductlines known to exist by the engineer from his search of records are indicated on the plans. The Contractor shall verify the locations and depths of the facilities and exercise proper care in excavating in the area. Wherever connections of new utilities to existing utilities are shown on the plans, the Contractor shall expose the existing lines at the proposed connections to verify their locations and depths prior to excavation for the new lines.
3. No Contractor shall perform any construction operation so as to cause falling rocks, soil or debris in any form to fall, slide or flow into existing City drainage systems, or adjoining properties, streets or natural watercourses. Should such violations occur, the Contractor may be cited and the Contractor shall immediately make all remedial actions necessary.
4. The general contractor/developer/owner of the project shall be responsible for conformance with applicable provisions of the Hawaii Administrative Rules, Title 11, Chapter 54, "Water Quality Standards" and Title 11, Chapter 55, "Water Pollution Control", as well as Chapter 14 of the Revised Ordinances of Honolulu, as amended. Best Management Practices shall be employed at all times during construction.

    The general contractor/developer/owner of the project shall obtain National Pollutant Discharge Elimination System (NPDES) Permit coverage(s) for the following:

    a. Storm water discharges associated with construction activities that disturb one (1) acre or more, and
    b. Discharges of hydrotesting effluent, dewatering effluent, and well drilling effluent to State waters.

    In accordance with State law, all discharges related to project construction or operations are required to comply with State Water Quality Standards (Hawaii Administrative Rules, Chapter 11-54). Best Management Practices shall be used to minimize or prevent the discharge of sediment, debris, and other pollutants to State waters. Permit coverage is available from the Department of Health, Clean Water Branch at http://health.hawaii.gov/cwb. The owner/developer/contractor is responsible for obtaining other Federal, State, or local authorizations as required by law.
5. For non-City projects, the Contractor shall notify the Civil Engineering Branch, DPP at 768-8084 to arrange for inspectional services and submit two (2) sets of approved Construction Plans seven (7) days prior to commencement of construction work. For City projects, the Contractor shall coordinate inspectional services with the responsible City agency.
6. For non-City Projects, the Contractor may submit a substitution request to precast any City owned and/or maintained drainage structure (ex., catch basins, drain manholes, drain inlets, culverts, etc). However, prior to construction and installation of any precast structures, the Cotractor shall a)submit six (6) sets of shop drawings to the Civil Engineering Branch, DPP and obtain written approval and b) notify the Civil Engineering Branch, DPP at 768-8084 to arrange for inspectional services. Non-compliance with any of these requirements shall mean immediate suspension of all precast construction work and rejection of all precast structures already constructed.
7. Confined Space:
    For entry by City Personnel, including Inspectors, into a permit required confined space as defined in 29 CFR Part 1910.146(b), the Contractor shall be responsible for providing:

    A. All safety equipment required by the confined space regulations applicable to all parties other than the construction industry, to include, but not limited to, the following:
        1.) Full body harnesses for up to two personnel.
        2.) Lifeline and associated clips.
        3.) Ingress/egress and fall protection equipment.
        4.) Two-way radios (walkie-talkies) if out of line-of-sight.
        5.) Emergency (escape) respirator (10 minute duration).
        6.) Cellular telephone to call for emergency assistance.
        7.) Continuous gas detector (calibrated) to measure oxygen, hydrogen sulfide, carbon monoxide and flammables (capable of monitoring at a distance at least 20 feet away).
        8.) Personal multi-gas detector to be carried by inspector.

    B. Continuous forced air ventilation adequate to provide safe entry conditions.

    C. One attendant/rescue personnel topside (two, if conditions warrant it).
8. Pursuant to Chapter 6E, HRS, in the event any artifacts or human remains are uncovered during construction operations, the Contractor shall immediately suspend work and notify the Honolulu Police Department, the State Department of Land and Natural Resources-Historic Preservation Division (692-8015). In addition, for non-City projects, the Contractor shall inform the Civil Engineering Branch, Department of Planning and Permitting (768-8084); and for City projects, notify the responsible City agency.
9. For Bench Mark, see sheet 1.

SIGNS AND MARKINGS NOTES:

1. All traffic sign and pavement marking installations shall be done in accordance with the "Manual on Uniform Traffic Control Devices for Streets and Highways," 2009 edition, as amended, the latest specifications from the Traffic Review Branch, Department of Planning and Permitting, and as shown on the plans.
2. Contractor shall notify and coordinate work with the Civil Engineering Branch, Department of Planning and Permitting, one (1) week in advance of commencing work at 768-8084.
3. Contractor shall submit material brochures for all signs and paint materials to the Civil Engineering Branch, Department of Planning and Permitting.
4. The signing and/or striping contractor shall keep one (1) set of approved plans at the project site at all times during construction work.
5. Contractor shall paint temporary guidelines and outline of arrows, legends, and crosswalks with a two inch (2") wide brushed line on the day the roadway is opened to traffic. These markings must be approved by the inspector from the Civil Engineering Branch, Department of Planning and Permitting.
6. Contractor shall notify the Civil Engineering Branch, Department of Planning and Permitting at 768-8084, three (3) days in advance of final inspection.
7. Contractor shall meet with the inspector from the Civil Engineering Branch, Department of Planning and Permitting during the final inspection.
8. Within ten (10) days following notification of award of contract, the contractor shall submit to the Department of Planning and Permitting (phone: 768-8084) for approval, a list of any signing and pavement marking material which he proposes to install. The list shall be complete as to the name of manufacturer, catalog number, and shall be supplemented with material brochures.
9. Upon final inspection of the project, the contractor shall submit a letter of certification for all traffic signing and pavement marking materials installed.
10. Signs shall be attached to brackets with 5/16" zinc plated steel bolts, nuts and washers. Signs 48" wide or larger than 10 sq ft in area shall be mounted on two 2" galv. pipe post. The sign shall be installed with at least (1) one foot clearance from the sign edge to the curb face.
11. All traffic signs shall be reflectorized.
12. Raised pavement markers shall be installed in accordance with the Department of Planning and Permitting standards.
13. Location of "STOP" sign:
    A. Install "STOP" sign at curb tangent point.
    B. Install "STOP" sign on metal street light standard if a standard is located within 10 feet of curb return.
    C. Install "STOP" sign in front of utility pole if a pole is located within 10 feet of curb return.
14. Pavement word and symbol markings shall be in accordance with the Department of Planning and Permitting Standards.
15. The contractor shall use thermoplastic material, approved by the Civil Engineering Branch, Department of Planning and Permitting, for all crosswalks, stop bars, pavement arrows, center lines, lane lines, arc lines, channelized traffic islands, and legends.

WATER NOTES

1. Unless otherwise specified, all materials and construction of water system facilities and appurtenances shall be in accordance with the City and County of Honolulu Board of Water Supply's "WATER SYSTEM STANDARDS", DATED 2002, THE "WATER SYSTEM EXTERNAL CORROSION CONTROL STANDARDS", VOLUME 3, DATED 1991, and all subsequent amendments and additions.
2. The contractor shall chlorinate the entire inside surface of each pipe and fitting with disinfection solution of 5 ounces of sodium hypochlorite mixed with 10 gallons of water. (For connection only)
3. The project shall pay the applicable water system facilities and/or one-time service charge and for the meter which will be furnished by BWS and installed by the Contractor when the lateral is installed.
4. The Contractor shall notify BWS Capital Projects Division, Construction Section in writing and submit six (6) sets of approved construction plans one week prior to commencing construction activities.
5. Contractor shall cut and plug all existing unused laterals at the main whether or not shown on the plans. Meter and valve boxes to be or already abandoned shall be demolished or removed and properly disposed of. The damaged area shall be repaired to an equal or better condition than the immediate area. All work shall be done at the expense of the Contractor.
6. All plans approved by the Board of Water Supply are based solely on the adequacy of the water supply.
7. For meters 3 inches and larger (Compound, F.M. and Detector Check), contractor shall notify Customer Care Division – Service Engineering Section in writing after the plan is approved, no later than 120 days, prior to withdrawing meter from BWS storeyard. Such notice shall indicate number, size, and type of meter (Compound, F.M. or Detector Check) and approximate month and year meter is anticipated to be drawn out. If the approved plan is allowed to lapse, the 120-day notice will be voided.
8. Board of Water Supply approval of these plans does not constitute a water commitment. Availability of water will be determined when building permit is presented to the Department. Water commitment will depend upon the status of the water system at that time. Should water service be made available, the water commitment will be effective when the project receives an approved building permit from the Building Department. All water commitments will be canceled in the event the building permit is canceled.
9. The project shall be subject to the Board of Water Supply's Cross-Connection Control requirements prior to issuance of the Building Permit.
10. The installation, chlorination and testing of the water main and facilities after the meter shall not be the responsibility of the Board of Water Supply.
11. The existence and location of underground utilities and structures as shown on the plans are from the latest available data but is not guaranteed as to the accuracy or the encountering of other obstacles during the course of the work. The Contractor shall be responsible and pay for all damages to existing utilities. The Contractor shall not assume that where no utilities are shown, that none exist.
12. Prior to installation, the Contractor shall submit for approval by Board of Water Supply, the manufacturer's certification that all cast iron (gray or ductile) fittings for the project conform in all respects to the Water System Standards, dated 2002.
13. Polygon shape for mechanical joint glands as described in AWWA Standard C111 shall be "straight-sided" or an approved equal on a lot-to-lot basis.
14. Re-approval shall be required if this project is not under construction within a period of two (2) years.
15. The backflow preventer device must be installed before meter is issued.
16. The Contractor/Developer shall obtain a NPDES permit prior to chlorination and/or dewatering. A copy of the permit shall be submitted to the Board of Water Supply, Capital Projects Division, Construction Section.
17. Pipe cushion shall be of high resistivity material. The contractor shall submit a soil certification that high resistant cushion material has a resistivity greater than 5,000 OHM-CM. Remainder of the backfill material shall be as specified in the Water System Standards. Pipe cushion and backfill material shall contain no hazardous substances above regulatory action levels including but not limited to lead, asbestos, mercury, chromium, cadmium, zinc, strontium, and polychlorinated biphenyls (PCB).
18. Install 4 mil thick, non-metallic, blue colored, 6 inches wide warning tape over centerline of the pipe and below the base course along the entire length of trench. Tape should be marked with "CAUTION WATER LINE BURIED BELOW".
19. The contractor shall install electronic markers to ALL mains and test the electronic markers prior to installations to verify proper operation. BWS personnel shall verify the number and locations of placed electronic markers before final paving of the project.
20. After installation of tapping sleeve and valve prior to actual tapping operations, the assembly shall be tested at 150 psi on both sides of the valve.
21. At the electrical/cable/signal ductline water crossings, adjust all electrical/cable/signal ductline elevations to maintain 12" vertical clear separation from all waterlines at no cost to the Board of Water Supply.
22. Maintain 3'-0" minimum horizontal clear separation between all waterline and nearest electrical/cable/signal ductlines paralleling the water system at no cost to the Board of Water Supply.
23. Maintain 3'-0" minimum horizontal clear separation between electrical/cable/signal appurtenances, (including any modular units), and the nearest waterline or water appurtenance. Contractor shall field verify for any conflicts at each electrical/cable/signal appurtenance location. Where conflicts occur, the Contractor shall coordinate with the project engineer to revise the electrical/cable/signal appurtenance to provide the required clearances at no cost to the BWS.
24. Cleaning shall be by the use of "pigs" introduced into the pipeline and run completely through all installed pipelines and all branch lines for fire hydrants. "Pigging" of service laterals is not required. Bore foam "pigs" shall be used to swab piping clean at each length of the pipeline is installed. Each "pig" shall consist of a cylindrical piece of polyurethane foam with a density of 3-7 pounds per cubic foot and a vinyl-coated nose. Outside diameter of the "pig" shall be equal to 1-1/4 to 1-1/2 times the inside diameter of the pipe being installed. The length of the "pig" shall be 1-1/2 to 2 times its diameter. Prior to use, the "pig shall be submerged in a chlorine solution of 1 oz. of 5% chlorine bleach in 5 gallons of water. "Pigging" of the pipeline shall be considered incidental to the installation of the new pipeline.
25. The contractor shall be responsible for the protection of all waterlines during construction. The contractor shall be especially careful when excavating behind waterlines, tees, and bends wherever there is a possibility of waterline movement due to the removal of the supporting earth beyond the existing reaction blocks. The Contractor shall take whatever measures necessary to protect the waterlines, such as constructing special reaction blocks (with BWS approval) and/or modifying his construction method.
26. Prior to any excavating, the Contractor shall verify in the field, the location of existing waterlines and appurtenances.
27. Any adjustments to the existing water system required during construction, to meet the requirements of the BWS Standards, whether shown on the plans or not, shall be done by the Contractor at no cost to the Board.
28. Nuts and bolts for flange connections within meter boxes shall be bronze or stainless steel except coupling adapters where "COR-TEN" (U.S. Steel) or "MAYARI" (Bethlehem Steel) may be used. Flange connections outside of meter box may use "COR-TEN" or "MAYARI" type nuts and bolts.
29. Test pressure shall be one of the following: (a) prevailing line pressure, joints left exposed for 24 hours to check for leaks prior to backfill or (b) 150 psi. During the 30-minute pressure test, the pressure shall not drop more than 10 psi.
30. All ductile iron pipe, fittings and valves shall be wrapped with two layers of 8 mil. polyethylene wrap. The inside surface of the polyethylene wrap to be in contact with the pipe exterior shall be infused with a blend of an antimicrobial to mitigate microbiologically influenced corrosion and a volatile corrosion inhibitor to control galvanic corrosion.
31. All waterline construction requiring shutdown connection shall be scheduled for after working hours at six (6) hours maximum downtime.
32. All ductile iron pipe and fittings, including sections requiring reinforced concrete jacketing shall be ductile iron class 53, and coated as per the BWS Water System Standards.

PRIVATE DRAIN NOTE

1. Private drainlines 36" and smaller shall be ADS N-12 Polyethylene Pipe (Type S), or PVC (SDR 35) as indicated on the plans. When installing HDPE for storm drain pipe material, the Contractor shall comply with DPP Engineering and Policy Memorandum No. CEB-2-13 (dated March 6, 2013), "City and County of Honolulu Department of Planning and Permitting Standard Specifications for Public Works Construction High Density Polyethylene Smooth Interior Corrugated Drain Pipes", dated March 1, 2013.

PVC WATER NOTES

1. Polyvinyl chloride (PVC) pipes shall be DR 14 (for 4"-16"). All ductile iron valves and metallic fittings shall be wrapped with two layers of 8 mil polyethylene wrap. No bending of polyvinyl chloride pipes shall be permitted. The installation of PVC pipe, according to the plans and specifications as bid on by the contractor, may require additional design work and additional fittings, and shall be considered incidental to the unit price bid in the proposal for PVC pipe. Any additional design work shall be the responsibility of the Contractor.
2. PVC fittings, including deflection couplings, are not approved.
3. The Contractor shall furnish and install polyethylene wrap, 3 feet minimum at all taps (for DI pipe and copper lateral combination only).
4. All sections of the water main requiring reinforced concrete jacketing shall be ductile iron pipe Class 53 with ductile iron fittings.
5. Bossed tees required for all lateral and ARV connections to PVC mains 12" and smaller (Ductile Iron Connector Piece larger than 12").
6. Ductile iron fittings shall be used for all types of fittings.

SEWER NOTES

1. All sewer construction shall be performed in accordance with the City's Standard Specifications, Sept. 1986, the Department of Environmental Services Wastewater System Design Standards, July 2017, and Wastewater System Standard Details, July 2017, current city practices and Revised Ordinances of Honolulu, 1990, as amended.
2. In the event that any change in alignment or grade for the proposed sewers are required due to unforeseen conflict with other utilities, the Contractor shall be responsible for the required changes which are to be presented to the engineer for approval.
3. Crushed rock cradle is permitted where soil is stable. In areas of unstable soil, the maker of the plans and the construction engineer will determine the pipe support required.
4. The underground pipes, cables or ductlines known to exist by the engineer from his search of records are indicated on the plans. The Contractor shall verify the location and depth of the facilities, including and affecting sewerlines in the presence of the Wastewater Inspector and exercise proper care in excavating the area. The Contractor shall be responsible and shall pay for all damaged utilities.
5. Sewer lateral shall be clear of and not conflicting with any other utility. Minimum horizontal and vertical clearances shall be strictly observed and followed.
6. Slope for sewer laterals shall be 2.00% and laterals shall be 6" diameter pipes unless otherwise noted.
7. Building plumbing facilities shall be controlled by sewer lateral inverts.
8. The Contractor shall be responsible for maintaining continuous sewer service to all affected areas during construction.
9. The Contractor shall submit to the engineer "as-built" drawings of the construction plans as actually constructed, showing all changes from the original plans.
10. The Contractor shall be responsible for any sewage spills caused during construction. The Contractor shall notify the State Department of Health and utilize appropriate sampling and analyzing procedures. The Contractor shall be responsible for all public notifications and press releases.
11. The Contractor shall Install "Rainstopper" manhole inserts in all sewer manholes with Type "SA" frame and cover.
12. The Contractor shall obtain approval for advance sewer riser agreement at Department of Planning & Permitting and obtain building permit for plumbing work before any advance riser is made.
13. For entry by City Personnel, including inspectors, into a permit required confined space as defined in 29 CFR Part 1910.146(b), the Contractor shall be responsible for providing:
    A. All safety equipment required by the confined space regulations applicable to all parties other than the construction industry, to include, but not limited to, the following:
       1.) Full body harnesses for up to two personnel.
       2.) Lifeline and associated clips.
       3.) Ingress/egress and fall protection equipment.
       4.) Two-way radios (walkie-talkies) lit out of line-of-sight.
       5.) Emergency (escape) respirator (10 minute duration).
       6.) Cellular telephone to call for emergency assistance.
       7.) Continuous gas detector (calibrated) to measure O , H S, CO and flammables (capable of monitoring at a distance at least 20 feet away).
       8.) Personal multi-gas detector to be carried by inspector.
    B. Continuous forced air ventilation adequate to provide safe entry conditions.
    C. One attendant/rescue personnel topside (two, if conditions warrant it).
14. The contractor shall notify the Construction Management Branch, Wastewater Engineering and Construction Division, ENV, at 768-8785, 768-8769, or 768-8753 to arrange for inspection services and submit four (4) sets of approved construction plans to Wastewater Branch, DPP seven (7) days prior to commencement of sewer work. The contractor shall pay for all inspection costs.
15. 54C pipe cradle seals shall be installed 10 feet from all sewer manholes to prevent soil migration.
16. Contractor to maintain minimum 3' horizontal clearance between sewerline, electrical boxes & manholes and minimum 3' horizontal clearance between sewerline & electrical ductlines.
17. When connecting to a live sewer line, the contractor shall abide by all conditions that the State Department of Health sets forth to mitigate any wastewater spill that may occur. The contractor shall inform the City Inspector five (5) working days prior to the actual connection. The contractor shall be responsible for any fines and penalties due to any spills resulting from the connection.
18. No rungs shall be installed inside new manholes.
19. For sewer manhole adjustments upward less than 3", see C&C Std Detail S-28. For SMH adjustments upward greater than 3" or for any adjustments downward, reconstruct SMH top from below the cone section.
20. If contractor encounters flow monitoring devices such as special sewer manhole cover embedded with solar panels; notify C & C Honolulu, ENV-CSM at 768-7272 to coordinate temporary removal.
21. Contractor shall maintain visibility and maintenance access to live sewer manhole locations at all times, including during non-work hours and paving operations.
22. Contractor shall use manhole debris catching device when performing manhole height adjustment work and remove any construction debris that has fallen into the manhole. Disposal of construction debris in the sewer system is strictly prohibited.
23. Maintain 3'-0" min. horizontal clear separation between all sewer systems and nearest electrical ductlines, pullboxes, and handholes paralleling the sewer system. Maintain 6' min. horizontal clear separation between all sewer system and electrical transformer pads. Maintain 5' min. horizontal clear separation between all sewer system and street light poles and traffic signal poles. Do not place electrical appurtenances in between sewer laterals.
24. At the electrical ductline sewer crossings, adjust all electrical ductline elevations to maintain 24" vertical clear separation above all sewer lines. If less than 24" clear above the sewer line, RC jacket the sewer line per City Standard Detail S-03.

SPECIAL PROVISIONS FOR PVC PLASTIC SEWER PIPE (FOR PIPES 6" TO 12" IN DIAMETER ONLY)

1. Polyvinyl chloride (PVC) plastic sewer pipe and appurtenances used on this project shall conform to the requirements of Section 21 of the Standard Specifications for Public Works Construction dated September 1986, except as modified herein.
   A. General. PVC gravity sewer pipe shall conform to the requirements of C-900/C-905 (DR 18 minimum wall thickness).
   B. Acceptance. The basis for acceptance shall be the inspection of pipe, fittings and couplings, the tests specified herein and in Section 21, and compliance with the specifications. At the time of manufacture, each lot of pipe and fittings shall be inspected for defects and tested for impact, stiffness and flattening in accordance with ASTM D3034. The Engineer may require certification by the manufacturer that the test results comply with specification requirements. When the pipe is delivered to the job site, the Engineer may require the Contractor to provide additional testing to insure the quality of the pipe at no expense to the City. Pipe which is not installed within 120 days of the latest factory test shall not be used without prior approval of the Engineer.
   C. Selection of Test Pipe. When testing is required by the Engineer, one test pipe shall be selected at random by the Engineer from each 1200 linear feet or fraction thereof of each size of pipe delivered to the job site but no less than one test pipe per lot. A lot shall be defined as pipe having the same identification marking. The length of specimen of each selected pipe shall be a minimum of 8 feet.
   D. Cell Classification. Pipe shall be made of PVC plastic having a cell classification of 12454-B, 13364-A, or 13364-B as defined in ASTM D1784. The fittings shall be made of PVC plastic having a cell classification of 12454-B, 12454-C, or 13343-C. PVC compounds of other cell classifications shall be pre-qualified by the manufacturer.
   E. Joints. Pipe joints shall be bell and spigot type with an elastomeric gasket. The gasketed joints shall be manufactured with a socket configuration which will preclude improper installation of the gasket and will insure the gasket remains in place during the joining operation. All pipe shall have a home mark on the spigot end to indicate proper penetration when the joint is made.
   F. Identification Marks. All pipe fittings and couplings shall be clearly marked at an interval not to exceed 5 feet as follows:
      (1) Nominal pipe diameter.
      (2) PVC cell classification.
      (3) Company, plant, shift, ASTM, SDR, and date designations.
      (4) Service designation and legend.
   G. Dimensions and Tolerances:

Table – Pipe Dimension (inches)

Nominal Size	Average O.D.	Tolerance on Average	Minimum Wall Thickness	Wt./20' Length (lbs.) Approx.
6	6.90	±0.011	0.383	104
8	9.05	±0.012	0.503	178
10	11.10	±0.015	0.617	268
12	13.20	±0.018	0.733	382

   H. Chemical Resistance. The PVC compound for cell classifications not specifically identified in Item D above shall be prequalified by the pipe manufacturer by meeting the chemical resistance tests which follow. Compound samples and molded test specimens shall be prepared in accordance with ASTM D543.

Tensile and Izod impact exposure specimens shall be immersed in the solutions specified in Table 2 for a period of 112 days. Test specimens shall be conditioned to constant weight at 110°F (43.3°C) before and after submersion. The solutions shall be kept at a temperature of 77°F ±5°F (24°C ±3°C). At 28-day intervals, selected specimens shall be removed, washed, surface dried and tested.

TABLE 2 – Test Solutions

Chemical Solution	Concentration (%)
Sulfuric Acid	20*
Sodium hydroxide	5
Ammonium hydroxide	5*
Nitric acid	1*
Ferric chloride	1
Soap	
Detergent (Linear alkyl benzyl sulfonate or LAS)	0.1
Bacteriological	BOD not less than 700 ppm.

* Volumetric percentages of concentrated reagents of C.P. grade

Weight change specimens shall be 2 inches in diameter and may be molded discs or discs cut from the pipe wall. Specimens shall be conditioned for seven days at 43° ±2°C, cooled in a desiccator for the three hours at 23° ±2°C, weighed, and then immersed in the solutions. At 4 week intervals, selected specimens shall be removed, washed, surface dried and weighed. These same specimens shall then be reconditioned for seven days at 43° ±2°C, cooled in a desiccator for three hours at 23° ±2°C and again weighed.

Initial and post exposure specimens shall meet the following requirements when tested at 23° ±2°C:

Property	ASTM Test Method	Cell Class Minimum Values 12454	13343	13364
Tensile Strength (Yield), psi	D 638	7000	6000	6000
Impact Strength, ft-lbs/in.	D 256 Method A	0.65	1.5	1.5
Weight Change, %	D 543	1.5	1.5	1.5

If any specimen fails to meet the requirements at any time during the 112 day exposure period, the material will be subject to rejection.

SPECIAL PROVISIONS FOR PVC PLASTIC SEWER PIPE (CONT'D)

   I. Trench Excavation. Trenches for PVC sewer pipe shall be excavated and prepared in accordance with the requirements of Section 11 of the Standard Specifications for Public Works Construction except as modified herein.
      (1) Overexcavation. The maximum allowable trench width shall be equal to the outside diameter of the PIPE plus 18-inches for pipe up to 12" (I.D.). If the trench excavation exceeds the computed maximum allowable trench width whether by excavation, cave-in, or by ground movement, the Contractor shall provide at his own expense additional bedding, another type of bedding, and/or a higher strength of pipe designated by the Engineer. Where shoring is required, the allowable width of the trench shall be increased only by the thickness of the sheathing.
   J. Pipe Bedding. Where unsuitable material is encountered at the subgrade and additional excavation is required, the void created by the additional excavation shall be filled and compacted with bedding material specified on the plans or special provisions. Where concrete is specified to bed the pipe, the top of the concrete shall be considered as the top of the bedding.

      Bedding material shall consist of one of the following:

      (1) Beach sand.
      (2) No. 8 or No. 67 aggregate conforming to the gradation requirements of ASTM C33.
      (3) 3/8" filter aggregate.
      (4) Native free-draining granular material having a minimum sand equivalent of 30 or having a coefficient of permeability greater than 0.001 centimeter per second.
      (5) Other material approved by the Engineer.

      Bedding material shall first be placed so that the pipe is supported for the full length of the barrel with full bearing on the bottom segment of the pipe equal to a minimum of 0.4 times the outside diameter of the barrel. If the pipe is to be laid in a rock excavation, the rock shall be removed such that no ribs, rocks, or solid projections shall be within 6 inches of the sewer pipe horizontally and there shall be at least 4 inches of bedding below the pipe.

      Compaction of the bedding from the bottom of the pipe to 12 inches above the pipe barrel by jetting will be permitted provided that the foundation material will not soften or be otherwise damaged by the applied water. Flooding or ponding methods of achieving the required relative density will not be permitted. The size and length of jet pipe, quantities and pressure of water, and jetting locations shall be sufficient to compact the bedding to 87% minimum relative density. Compaction of the backfill from 12 inches above the pipe barrel to the finish surface shall conform to the requirements of Section 11.4 of the Standard Specifications for Public Works Construction.
   K. Mandrel Test of PVC Pipe. A mandrel test shall be performed no sooner than 30 days after the trench backfill is completed. In roadway areas the 30-day period shall begin after installation and compaction of bedding, backfill and subbase to within 2 feet of the finished pavement grade. A rigid mandrel shall be pulled through the pipe by hand between adjacent manholes to measure for obstructions (deflections, joint offsets and lateral pipe intrusions). The mandrel shall have a cross section equivalent to a circle having a diameter at least 95 percent of the specified average inside diameter of the pipe. The minimum length of the circular portion of the mandrel shall be equal to the nominal diameter of the pipe. This test shall be performed by the Contractor in the presence of the Engineer. All material, equipment and labor required to perform the test shall be provided by the Contractor at no cost to the City. Any section of pipe that fails to permit passage of the mandrel will not be accepted until properly repaired or replaced and retested.
2. Bedding for PVC Pipe sewer shall be Class "B" as shown on S-47 of the Standard Details for Public Works Construction unless otherwise noted.
3. The maximum design deflection (flattening) for plastic pipe shall be 5 percent. The maximum SDR (Standard Dimension Ratio of pipe outside diameter to pipe wall thickness) shall be 35.
4. Special watertight manhole couplings per standard detail S-48 will be required for all manhole connections. Couplings may be cast directly into cast-in-place manholes or grouted into precast concrete manholes with non-shrink or expansion type grout.
5. For connections of PVC lateral sewers to mains of different materials, an approved saddle wye fitting constructed of the same material as the main line shall be installed. Connection to the saddle fitting shall be made by means of an approved flexible rubber coupling in accordance with the coupling manufacturer's installation recommendations or by other means acceptable to the Engineer.
6. PVC Pipe shall be limited to use in agricultural, residential and apartment zoned areas and in sizes from 6 inches to 12 inches in diameter.

HONOLULU FIRE DEPARTMENT NOTES

1. Fire department access roads shall be provided such that any portion of the facility or any portion of an exterior wall of the first story of the building is located not more than 150 feet (46 m) from fire department access roads as measured by an approved route around the exterior of the building or facility. (NFPA 1, 2012 Fire Code, Section 18.2.3.2.2).
2. A fire department access road shall extend to within 50 ft (15m) of at least one exterior door that can be opened from the outside and that provides access to the interior of the building (NFPA 1, 2012 Fire Code, Section 18.2.3.2.1).
3. An approved water supply capable of supplying the required fire flow for fire protection shall be provided to all premises upon which facilities, buildings, or portions of buildings are hereafter constructed or moved into the jurisdiction. The approved water supply shall be in accordance with Section 18.4 – Fire Flow Requirements for Buildings (NFPA 1, 2012 Fire Code, Section 18.3.1).
4. Where underground water mains and hydrants are to be provided, they should be installed, completed, and in service prior to commencing construction work on any structure (NFPA 1, 2012 Fire Code, Section 16.4.3.1.3).
5. Fire department access roads provided in accordance with Section 18.2.3 shall be provided at the start of a project and shall be maintained throughout construction (NFPA 1, 2012 Fire Code, Section 16.1.4).
6. The authority having jurisdiction (AHJ) shall have the authority to require that construction documents for all fire protection systems be submitted for review and approval and a permit be issued prior to the installation, rehabilitation, or modification. Further, the AHJ shall have the authority to require that full acceptance tests of the fire protection system be performed in the AHJ's presence prior to final system certification (NFPA 1, 2012 Fire Code, Section 13.1.1).
7. When buildings are protected throughout with an approved automatic sprinkler system that is installed in accordance with NFPA 13, NFPA 13D, or NFPA 13R, an increase in distance in Section 18.2.3.2.2 shall be permitted as set forth by the AHJ.
8. A water supply approved by the county, capable of supplying the required fire flow for fire protection shall be provided to all premises upon which facilities or buildings, or portions thereof, are hereafter constructed, or moved into or within the county. When any portion of the facility or building is in excess of 150ft from a water supply on a fire apparatus access road, as measured by an approved route around the exterior of the facility or building, on-site fire hydrants and mains capable of supplying the required fire flow shall be provided when required by the AHJ. For on-site fire hydrant requirements see section 18.5.1.
   Exceptions
   1. When facilities or buildings, or portions thereof, are completely protected with an approved automatic fire sprinkler system, the provisions of section 18.3.1 may be modified by the AHJ.
   2. When water supply requirements cannot be installed due to topography or other conditions, the AHJ may require additional fire protection as specified in section 18.3.1.1, as amended in this code.
   3. When there are not more than two dwellings, or two private garages, carports, sheds and agricultural Occupancies, the requirements of section 18.3.1 may be modified by the AHJ.
9. One set of approved plans, specifications, and computations shall be retained by the building official for a period of not less than 90 days from date of completion of the work covered therein, and one set of approved plans shall be returned to the applicant, and said set shall be kept on the site of the building or work at all times during which the work authorized thereby is in progress. (sec. 18-5.2 R.O. 1978 (1983 Ed.); Am. Ord. 93-59)

PROJECT CATEGORY: CATEGORY 4

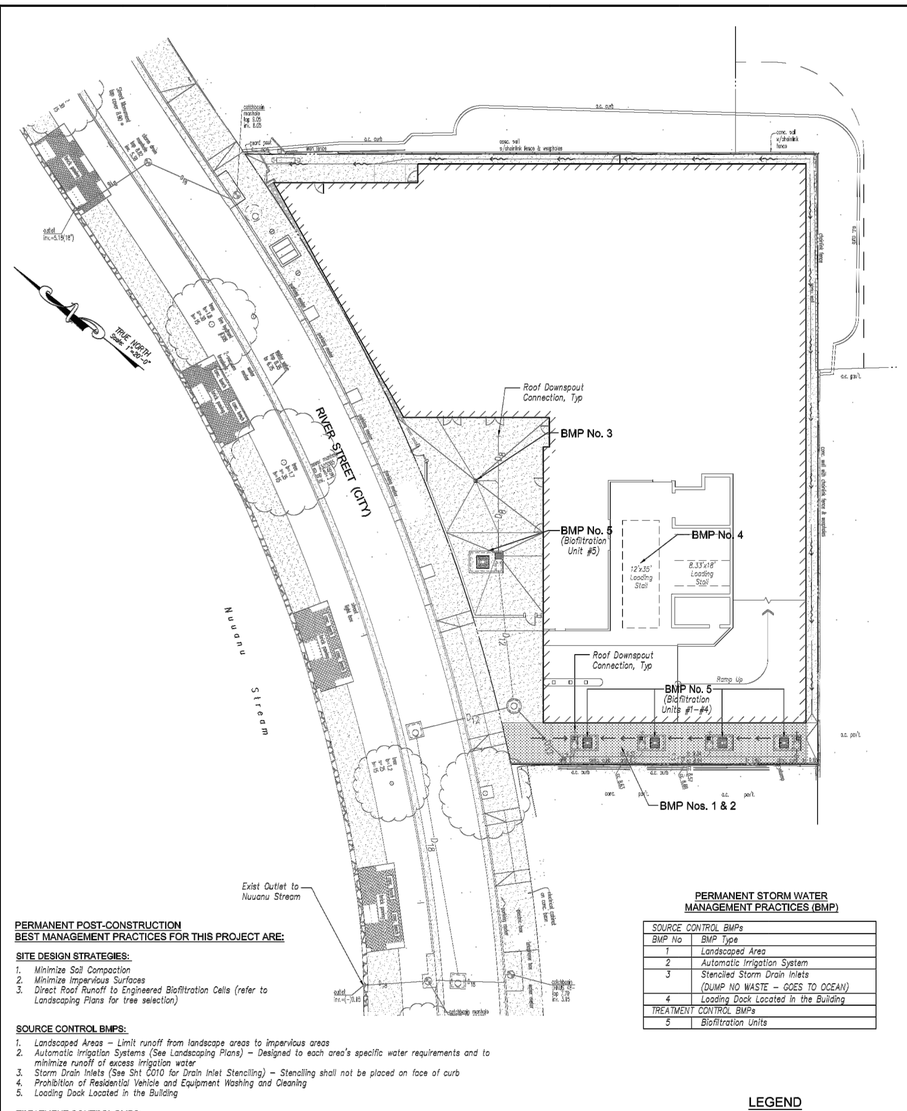
PRE-CONSTRUCTION STRUCTURAL CONTROL BMP'S:

- *Construction Ingress/Egress*
- *Existing Catch Basin Inlet Protection*
- *Temporary Filter Sock Perimeter Control*

DURING CONSTRUCTION STRUCTURAL CONTROL BMP'S:

- *New Catch Basin Inlet Protection*
- *Temporary Stabilization*

POST-CONSTRUCTION BMP'S:



- *Permanent Stabilization BMP'S*

GOOD HOUSEKEEPING BMP'S AND ESCP NOTES:

- *See This Sheet*

LEGEND

- Crushed Rock Construction Road for Ingress/Egress
- Temporary Sediment Control Filter at Exist/New Catch Basin
- Temporary Filter Sock
- Property Line
- Existing Drainline
- New Drainline
- Existing Drainage Flow

PERMANENT POST-CONSTRUCTION BEST MANAGEMENT PRACTICES FOR THIS PROJECT ARE:

SITE DESIGN STRATEGIES:

1. *Minimize Soil Compaction*
2. *Minimize Impervious Surfaces*
3. *Direct Roof Runoff to Engineered Biofiltration Cells (refer to Landscaping Plans for tree selection)*

SOURCE CONTROL BMPS:

1. *Landscaped Areas – Limit runoff from landscape areas to impervious areas*
2. *Automatic Irrigation Systems (See Landscaping Plans) – Designed to each area's specific water requirements and to minimize runoff of excess irrigation water*
3. *Storm Drain Inlets (See Sht C010 for Drain Inlet Stenciling) – Stenciling shall not be placed on face of curb*
4. *Prohibition of Residential Vehicle and Equipment Washing and Cleaning*
5. *Loading Dock Located In the Building*

TREATMENT CONTROL BMPS:

1. *Biofiltration Unit Data (Per Unit)*

Biofiltration Unit #	Drainage Area (Acres)	Water Quality Flow Required	Water Quality Flow Treated*	10-Year Flow	Max Bypass Flow Available*
1-4	0.10	0.054 cfs	0.056 cfs	0.78 cfs	1.4 cfs
5	0.18	0.097 cfs	0.111 cfs	0.98 cfs	1.4 cfs

** Data Provide by Contech Engineered Solutions*

PERMANENT STORM WATER MANAGEMENT PRACTICES (BMP)

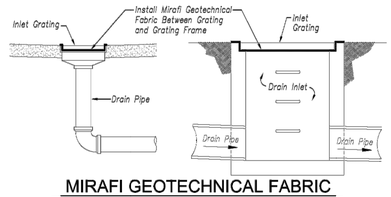
CONSTRUCTION ROAD INGRESS/EGRESS DETAIL

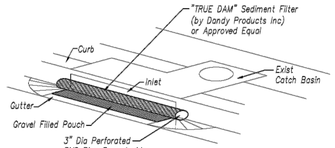
Not to Scale

PLAN



SECTION

NOTES:
1. When joining two sections of Filter Sock, a minimum of 2 feet should be made so that Filter Sock sit side by side.
2. Contractor shall remove any debris in path of Filter Sock to ensure good ground contact.
3. Compost shall not contain biosolids and should be consistent with EPA guidelines.
4. No staking of Filter Sock required when installed on existing sidewalks or on slopes less than 3H:1V. On slopes greated than 3H:1V, wooden stakes shall be installed at 10' on center minimum and at each end of Filter Sock.



FILTER SOCK PLACEMENT DETAIL

Not to Scale

MIRAFI GEOTECHNICAL FABRIC PRIVATE DRAIN INLET DETAIL

Not to Scale

NOTE:
The contractor shall inspect all the catch basins and inlets in the vicinity of the trenching work and remove accumulated silt and debris. Flushing is prohibited.

SEDIMENT CONTROL FILTER AT CATCH BASIN

Not to Scale

EROSION PREVENTION/SEDIMENT CONTROL NOTES:

1. The Contractor shall follow the guidelines in the City and County of Honolulu's "Rules Relating to Water Quality".
2. Owner shall designate an ESCP Coordinator responsible for implementing the ESCP at the project site using form in Appendix A to the Rules Relating to Water Quality (downloaded from the DPP website) prior to issuance of any permits.
3. ESCP Coordinator shall provide to the DPP Director a project schedule of all planned actions and activities on this project at least two weeks prior to commencing of any work.
4. Measures to control erosion and other pollutants shall be in place before any earthwork is initiated.
5. Temporary Stabilization: Required on disturbed areas which are at final grade or when the disturbed area will not be worked for 14 consecutive days or more.
6. Permanent Stabilization: All disturbed areas shall be permanently stabilized using vegetative covering, pavement, or equivalent, prior to removing erosion and sediment measures. Trapped sediment and areas of disturbed soil which result from the removal of the temporary measures shall be immediately and permanently stabilized.
7. Minimize Soil Compaction: Areas where final stabilization or infiltration practices will be installed shall be protected from excessive compaction during construction. Vehicle and equipment use shall be restricted or techniques to condition the soils to support vegetation shall be implemented in the areas that have been compacted and are designated to remain vegetative or post-construction infiltration areas. Clearly mark the area to be avoided with flags or temporary fencing. Where temporary fencing is used, fencing must be adequately supported by posts and maintained in an upright position.
8. Perimeter Controls: Required downslope of all disturbed areas.
9. Inlet protection:
   A. All storm drain inlets onsite and those offsite which may receive runoff from the site shall use an inlet protection device unless they are directed to a sediment basin.
   B. Sediment levels may not exceed one third of the height of a sediment barrier or inlet protection device at any point along the length of the sediment barrier or the inlet protection device.
   C. Sediment barriers and inlet protection devices must be unclogged and cleaned when performance is compromised.
   D. Torn, weathered or sagging sediment barriers or inlet protection devices must be repaired or replaced immediately.
10. Tracking Control:
    A. Minimize sediment track-out onto off-site streets, other paved areas, and sidewalks from vehicles exiting the construction site by restricting vehicle traffic to properly designated areas and using additional controls to remove sediment from vehicle tires prior to exiting the site.
    B. Vehicular parking and movements on project sites must be confined to paved surfaces or predefined parking areas and vehicles paths, which shall be marked with flags or boundary fencing.
    C. All pollutants and materials that are dropped, washed, tracked, spilled, or otherwise discharged from a project site to off-site streets, other paved areas, sidewalks or the MS4 must be cleaned using dry methods such as sweeping or vacuuming.
    D. Washing pollutants and materials that are discharged from the project site to the MS4 into drain inlets or catch basins is prohibited unless the material is sediment and the inlets are directed to a sediment basin or sediment trap.
12. Best management practices (BMP's) shall not be removed until final stabilization is complete for that phase.
13. Refer to City and County of Honolulu Best Management Practices Manual – Construction, for more information on BMP's.
14. The following BMPs were determined to not be applicable based on the site specific conditions. A brief explanation of why each omitted BMP is unnecessary or impracticable has been provided under separate documentation to DPP. As construction progresses, revisions may be necessary and will be provided to DPP Inspectors.
    A. Velocity dissipation devices
    B. Diversion BMPs to divert runoff from upstream areas around disturbed areas of the site
    B. Sediment barriers
    C. Preservation of existing vegetation
    D. Vegetative buffers

EROSION AND SEDIMENT CONTROL PLAN SCHEDULE & RAIN RESPONSE PLAN:

Project Sequence:

Construction activities and implementation of BMP's shall be sequenced to minimize erosion and amount of sediment leaving the site. It is recommended that earth-disturbing activities be scheduled during the dry season. The following is the recommended sequence of operations in normal development and should be followed unless conditions make it impractical. If this is the case, a sequence that provides the most effective erosion control shall be developed.

1. Install stabilized construction entrances, perimeter controls (e.g. temporary filter sock, etc.), inlet protection and clearing and grubbing as necessary for the installation of these BMP's.
2. Clear and grub remainder of the site. When cleared and grubbed areas are not to be graded or disturbed for 14 days or more, seed, plant, or hydrosseed temporary vegetation or use other temporary stabilization methods, unless remaining vegetation provides adequate protection.
3. Relocate, reconstruct and maintain BMP's as needed to keep them effective at all times.
4. Install permanent drainage system with temporary inlet protection.
5. Grade the site as planned. Relocate, reconstruct and maintain BMP's as needed to keep them effective at all times. Initiate temporary stabilization immediately once grading is completed in each phase.
6. Plant or seed temporary vegetative cover or use other temporary stabilization methods as planned.
7. Install temporary or permanent irrigation system for areas in the item above. When a permanent irrigation system is planned, it should be installed prior to seeding.
8. Proceed with construction with least possible disturbance of vegetative areas and temporary structures.
9. Plant permanent ground cover according to the landscaping plans as soon as possible.
10. Remove or dismantle temporary erosion control structures after full establishment of permanent vegetative cover.
11. Practice good housekeeping measures throughout the duration of construction.
12. Inspections will be performed weekly.

Rain Response Plan:

1. The following will be performed when heavy rains, tropical storm or hurricane is imminent or is forecasted in the next 48 hours.
2. Temporary suspension of active grading and trenching.
3. Inspect perimeter controls, and inlet protection devices, and maintain as needed. Reinstall any perimeter controls that were removed due to active work in the area. If a severe storm is expected, remove inlet protection devices to prevent flooding on surrounding streets.
4. Cover or relocate material stockpiles and liquid material containers to avoid contact with rainwater.
5. Place spill pans or oil-only spill pads under construction vehicles to prevent runoff from contacting any spilled petroleum products. Properly dispose of any accumulated oily water after the rain event.
6. Re-inspect after the approaching heavy rains, tropical storm or hurricane and replace or maintain BMP's as needed.

GOOD HOUSEKEEPING BMP'S:

1. Maintenance: Regularly inspect and maintain required erosion and sediment controls to ensure continued performance of their intended function.
2. Dust Control: The contractor at his own expense shall keep the project area and surrounding area free from dust nuisance. The work shall be in conformance with the Hawaii Administrative rules: Title 11, Chapter 60, "Air Pollution Control". Measures may include but not be limited to the installation of dust screens, watering of the site and fill material being place.
3. Street Sweeping and Vacuuming: All pollutants discharged from construction site to off-site areas must be swept or vacuumed each day before leaving the job site.
4. Materials Delivery, Storage and Use Management: Prevent, reduce, or eliminate the discharge of pollutants from material delivery, storage, and use to the storm water system or watercourses by minimizing the storage of hazardous materials onsite, storing materials in a designated area, installing secondary containment. Construction materials, waste, toxic and hazardous substances, stockpiles and other sources of pollution shall not be stored in buffer areas, near areas of concentrated flow, or areas abutting the MS4, receiving waters, or drainage improvements that discharge off-site. Primary and secondary containment controls and covers shall be implemented to the maximum extent practicable.
5. Spill Prevention and Control: Create and implement spill prevention and response plans to eliminate and minimize the discharge of pollutants to the MS4 and receiving waters from leaks and spills by reducing the chance for spills, absorbing, containing, and cleaning up spills and properly disposing of spill materials. At a minimum, all projects shall cleanup all leaks and spills immediately.
6. Hazardous Materials: Prevent or reduce the discharge of pollutants to storm water from hazardous waste through proper material use and waste disposal. In the event that hazardous materials are discharged to the MS4, the property owner or ESCP coordinator shall immediately notify the City Department of Facilities Maintenance, Honolulu Fire Department, and Honolulu Police Department of the discharge by telephone. A written report describing the pollutants that were discharged, the reasons for the discharge, and the measures that have been taken or will be taken to prevent a reoccurrence of the discharge shall be submitted to the Director no less than 3 days after notification by phone.
7. Nonhazardous Materials: In the event that nonhazardous materials are discharged to the MS4, the property owner or ESCP coordinator shall notify the City Department of Facilities Maintenance by telephone no later than the next business day. A written report describing the pollutants that were discharged, the reasons for the discharge, and the measures that have been taken or will be taken to prevent a reoccurrence of the discharge shall be submitted to the Director no less than 3 days after notification by phone.
8. Vehicle and Equipment Cleaning: Eliminate and minimize the discharge of pollutants to storm water from vehicle and equipment cleaning operations by using offsite facilities when feasible, washing in designated, contained areas only, and eliminating discharges to the storm drain system by evaporating and/or treating wash water, as appropriate or infiltrating wash water for exterior cleaning activities that use water only.
9. Vehicle and Equipment Fueling: Prevent fuel spills and leaks by using off-site facilities, fueling only in designated areas, enclosing or covering stored fuel, and implementing spill controls such as secondary containment and active measures using spill response kits.
10. Vehicle and Equipment Maintenance: Eliminate and minimize the discharge of pollutants to storm water from vehicle and equipment maintenance operations by using off-site facilities when feasible, performing work in designated areas only, using spill pads under vehicles and equipment, checking for leaks and spills, and containing and cleaning up spills immediately.
11. Solid Waste Management: Prevent or reduce discharge of pollutants to the land, groundwater, and in storm water from solid waste or construction and demolition waste by providing designated waste collection areas, collect site trash daily, and ensuring that construction waste is collected, removed, and disposed of only at authorized disposal areas.
12. Sanitary/Septic Waste Management: Temporary and portable sanitary and septic waste systems shall be mounted or stoked in, well-maintained and scheduled for regular waste disposal and servicing. Sources of sanitary and/or septic waste shall not be stored near the MS4 or receiving waters.
13. Stockpile Management: Stockpile shall not be located in drainage ways, within 50 feet from areas of concentrated flows, and are not allowed in the City Right-Of-Way. Sediment barriers or silt fences shall be used around the base of all stockpiles to prevent storm water carrying contaminants into drainage systems and State waters. Stockpiles shall not exceed 15 feet in height. Stockpiles greater than 15 feet in height shall require a 8 foot wide benching in accordance with ROH Chapter 14, Article 15. Stockpiles must be covered with plastic sheeting or a comparable material if they will not be actively used within 7 days.
14. Liquid Waste Management: Liquid waste shall be contained in a controlled area such as a holding pit, sediment basin, roll-off bin, or portable tank of sufficient volume and to contain the liquid wastes generated. Containment areas or devices must be impermeable and leak free and should not be located where accidental release of the contained liquid can discharge to water bodies, channels, or storm drains.
15. Concrete Waste Management: Prevent or reduce discharge of pollutants to storm water from concrete waste by conducting washout offsite or performing onsite washout in a designated area constructed and maintained in sufficient quantity and size to contain all liquid and concrete waste generated by washout operations. Plastic lining material should be a minimum of 10 millimeter polyethylene sheeting and should be free of holes, tears, or other defects that compromise the impermeability of the material. Containment areas or devices should not be located where accidental release of the contained liquid can discharge to water bodies, channels, or storm drains. Washout facilities must be cleaned, or new facilities must be constructed and ready for used once the washout is 75 percent full. Once concrete wastes are washed into the designated area and allowed to harden, the concrete should be broken up, removed, and disposed of as solid wastes.
16. Contaminated Soil Management: At minimum contain contaminated soil material by surrounding with impermeable lined berms or cover exposed contaminated material with plastic sheeting. Contaminated soil should be disposed of properly in accordance with all applicable regulations.
17. Dewatering Operations: No dewatering of non-storm water can be discharged from the site without the Contractor obtaining prior notice to and approval from the DPP and the State Department of Health. Dewatering discharges shall be kept on-site using a sediment basin, sediment trap, weir tank, dewatering tank, filtration system or other manufactured system.

2019 Market Study

Ricky Cassiday

April 28, 2019

HALEWAI'OLU SENIOR RESIDENCES

2019 Market Study

Ricky Cassiday

I. OVERVIEW

The **Halewai'olu Senior Development LLC** is proposing to build an affordable senior rental housing project in Honolulu, Hawaii. They have engaged Ricky Cassiday to describe and analyze the market for affordable housing rentals by senior households on the island of Oahu, relative to the guidelines provided by the Hawaii Housing Finance & Development Corporation (HHFDC) for performing such studies.

II. SCOPE OF WORK

As stipulated by the Hawaii Housing Finance and Development Corporation, this Market Study will include:

- A statement of the competence of the market analyst**.**
- A description of the proposed site**.**
- Geographic definition and analysis of the market area**.**
- Identification of the project including location, unit counts, income levels and target population**.**
- Analysis of household sizes and types in market.
- Demographic analysis of the number of households in the market area, which are income eligible, and can afford to pay the rent. Estimate of capture rates for the market areas.
- A description of comparable developments in the market area.
- Analysis of practically available rents, vacancy rates, operating expenses and turnover rates of comparable properties in the market area.
- Analysis of practically available rents, vacancy rates and turnover rates of market rate properties in the market area.
- Expected market absorption of the proposed rental housing, including a description of the effect of the market area.
- Identification and commentary of proposed projects in the market areas.

III. DESCRIPTION OF MARKET ANALYST

Since 1991, Ricky Cassiday has provided the residential l real estate markets of Hawaii with real estate consulting services. A list of clients and studies is attached hereto as Exhibit A.

Note that the data and statements herein are based on independent research and are in no way contingent upon outside findings or recommendations.

IV. DESCRIPTION OF PROPOSED SITE

The subject property is **Halewai'olu Senior Residences,** 1331-1347 River Street, Honolulu, Hawaii, TMK (1) 1-7-006:012

The immediate neighborhood consists of residential housing in an urban setting, with a regional stream running in front of it.

V. GEOGRAPHIC DEFINITION OF AND ANALYSIS OF MARKET AREA

The City and County of Honolulu will serve as the market area for this study. Such a definition was analyzed and deemed appropriate for the following reasons:

- There are no natural boundaries in Honolulu to inhibit relocation;
- The entire island's population lives in close proximity to one another, within a 22-mile radius; and
- There is an acute need for affordably priced shelter on the island.

Further analysis determined that the Principle Market Area (PMA) would encompass the entire island of Oahu.

An analysis of the housing market, rental housing in particular, illustrates that the supply is low while demand continues to rise.

HOUSING DEMAND: Numerous factors affect the demand for housing, the primary being population, household formations and job creation. In the short run, job creation is the most important, as it leads to in-migration (meaning population growth and household formation).

Currently, job creation (as well as income generation, mainly wages) in the island economy is very strong. The table below shows that the rate of unemployment has been steadily falling since 2009-2010. This coincides with the rise in hotel occupancy as well as hotel room rates and is in synch with the general excise tax trend, which is an indicator of overall business activity.

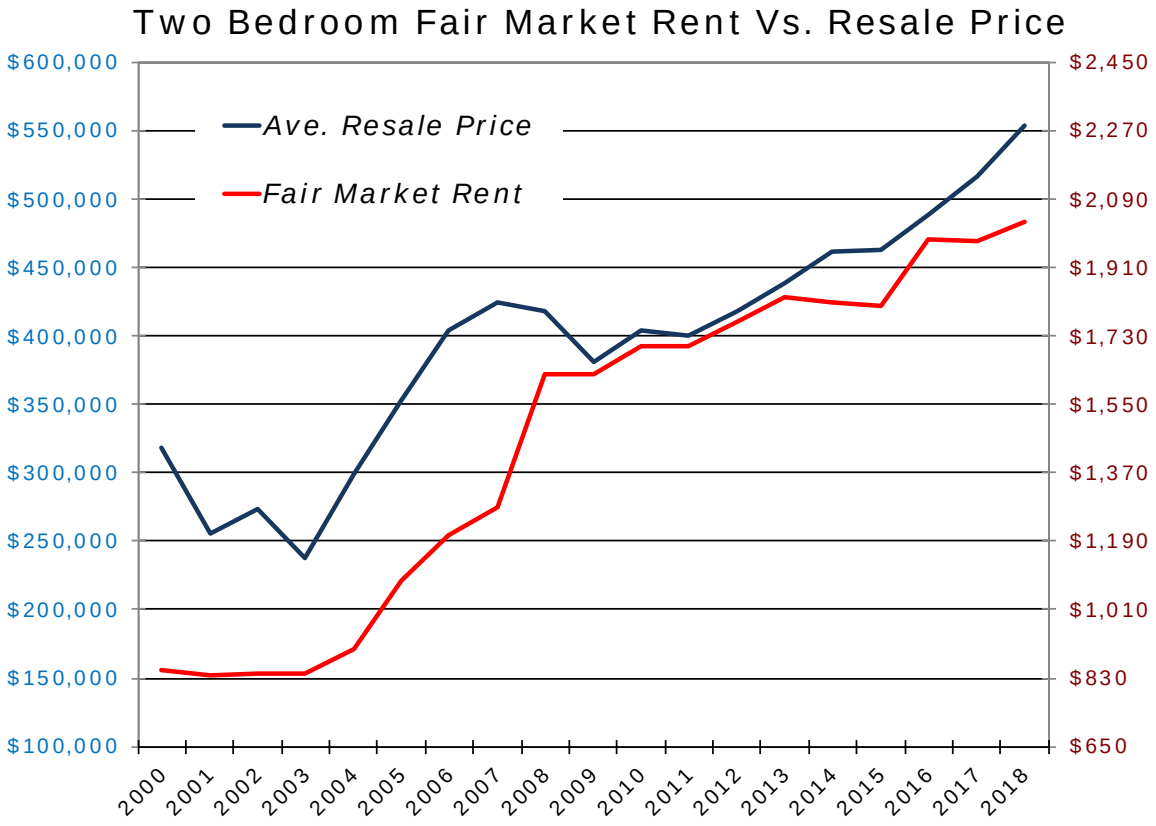
SELECTED HONOLULU ECONOMIC TRENDS

	Unemployment Rate	Hotel Occupancy	Hotel Room Rates	Ave GE Tax ($000)
1995	4.6%	80%	$102	$97,433
2000	4.1%	76%	$115	$110,441
2005	2.8%	86%	$139	$158,946
2006	2.5%	83%	$156	$171,301
2007	2.6%	77%	$168	$180,857
2008	3.9%	75%	$170	$178,448
2009	6.0%	73%	$169	$161,174
2010	6.0%	78%	$150	$168,270
2011	5.9%	81%	$150	$187,260
2012	5.4%	85%	$165	$203,370
2013	4.4%	84%	$183	$208,946
2014	4.1%	85%	$207	$213,399
2015	3.4%	86%	$211	$227,377
2016	3.1%	87%	$221	$231,377
2017	2.2%	89%	$241	$236,538
2018	1.9%	89%	$242	$237,118

Such growth in economic activity has led to growing demand for housing, both for-sale and for-rent units. In addition, this growth exerts pressure on for-sale prices and for-rent rental rates. This makes it more difficult for households with fixed or low-incomes to secure affordable shelter. There are other factors which serve to increase housing demand overall such as vacationers and military households.

HOUSING SUPPLY: The best solution to combat the growing demand is to increase the supply of housing for this segment of the population. Unfortunately, Oahu's housing development process is uncertain, time consuming and expensive, the future supply of units is low. Factors that contribute to such short supply include the scarcity of land as well as the arduous process of zoning for housing under the laws governing land use. Furthermore, construction is costly, labor is tight, and the costs of inputs are high due to the long supply chain.

The aforementioned can be seen in the table below - condo production has been declining since the 1970s, for reasons noted above. This is described in the next section, both island-wide as well as within the urban core.



As such, the combination of inelastic supply and elastic demand lends to this market's extreme volatility over the swing between the bottom and the top of the market where sales can more than triple and prices can more than double. Furthermore, the length of the cycle is usually 5 to 8 years, depending often on external conditions including the direction of interest rates, economic growth in the visitor and offshore buyer markets and the costs of materials.

CURRENT MARKET CONDITIONS: The condominium market is well into the upward swing of the housing cycle in terms of sales activity and price levels (data source is the MLS of the Honolulu Board of Realtors and the Bureau of Conveyances of the State). The last such swing started in 1998 and ended in 2005, ran for some 7 to 8 years and then had 4 to 5 years of falling sales and prices. It turned in 2011-2012, with a reversal of the trend for lower

sales and prices, as demand grew at a time of shrinking inventory. Going forward, we foresee that this cycle's sales and price levels will run for the next several years and exceed the peaks of the last cycle.

This will negatively impact the rental market in a number of ways. Higher for-sale housing prices usually encourage landlords to sell to owner occupants removing rental units from the market. Also, higher housing prices paid by investors for rental units translate into higher rental rates to consumers, as the investor needs a higher cash flow.

The next chart illustrates how sale and rent prices are trending using MLS data for the resale prices and HUD Fair Market Rent data for the rental data. It shows that the prices paid for for-sale two-bedroom units serves as a leading indicator for rental prices for two-bedroom rental units.

Given the County's average wage rate, rents charged are generally above what an average household would like to pay. As such, the need for affordable housing is acutely felt throughout the market highlighting the willingness of renters to relocate. For example, almost 35% of the County's population makes 60% of AMI and below of which 20% are renters.

VII. PROJECT IDENTIFICATION

OVERVIEW: The location is on the edge of Chinatown in the Downtown/Chinatown area of Honolulu, near the Honolulu urban core and the Honolulu Central Business District (CBD), on a tract known as Foster Gardens. The site is landlocked by two adjacent neighbors whose use is commercial. The area surrounding the tract is a mix of commercial and residential uses. The Foster Botanical Garden is located across the site on Vineyard Boulevard. The street fronting the property is River Street, which runs along Nu'uanu Stream. The site was acquired by the City and County of Honolulu with Community Development Block Grant (CDBG) in the 1990s.

The developer is proposing to construct a high-rise affordable senior rental project. The project's proposed unit count and unit mix is detailed in the following table, as well as the target market.

PROJECT UNIT BREAKDOWN, TOTAL

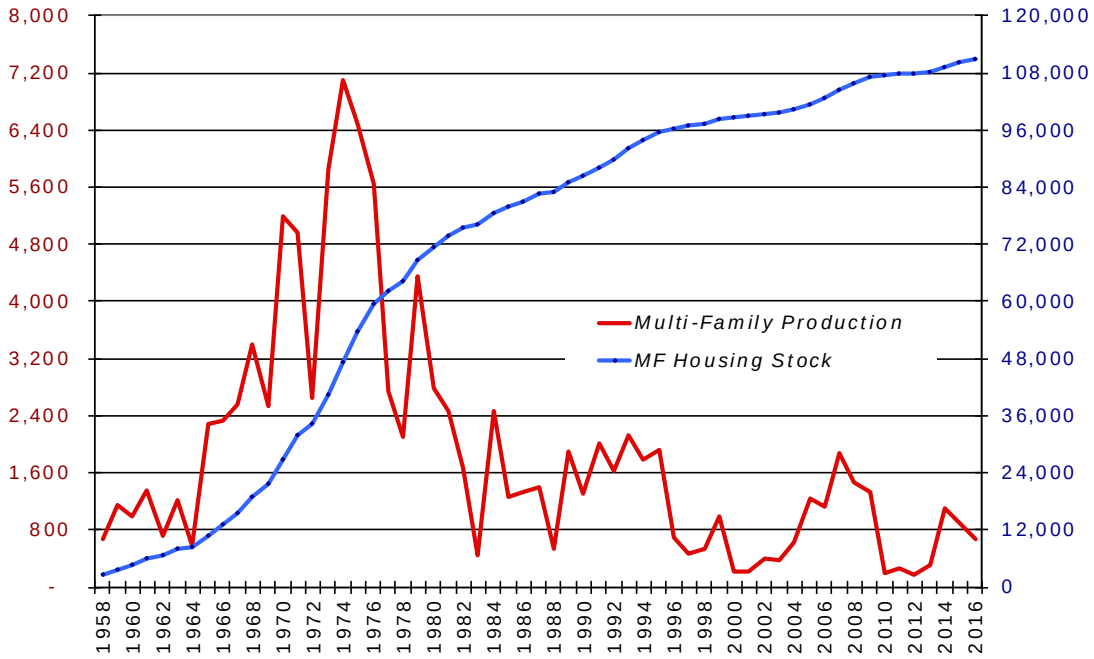
Beds	30% AMI	60% AMI	80%AMI	Total
1-Bedroom	8	115	7	130
2-Bedroom		16	9	25
Total	8	131	16	155

VIII. ANALYSIS OF HOUSEHOLD TYPES IN THE MARKET

The study guidelines call for an analysis of household sizes and types in the market. Thus, the following table describes this.

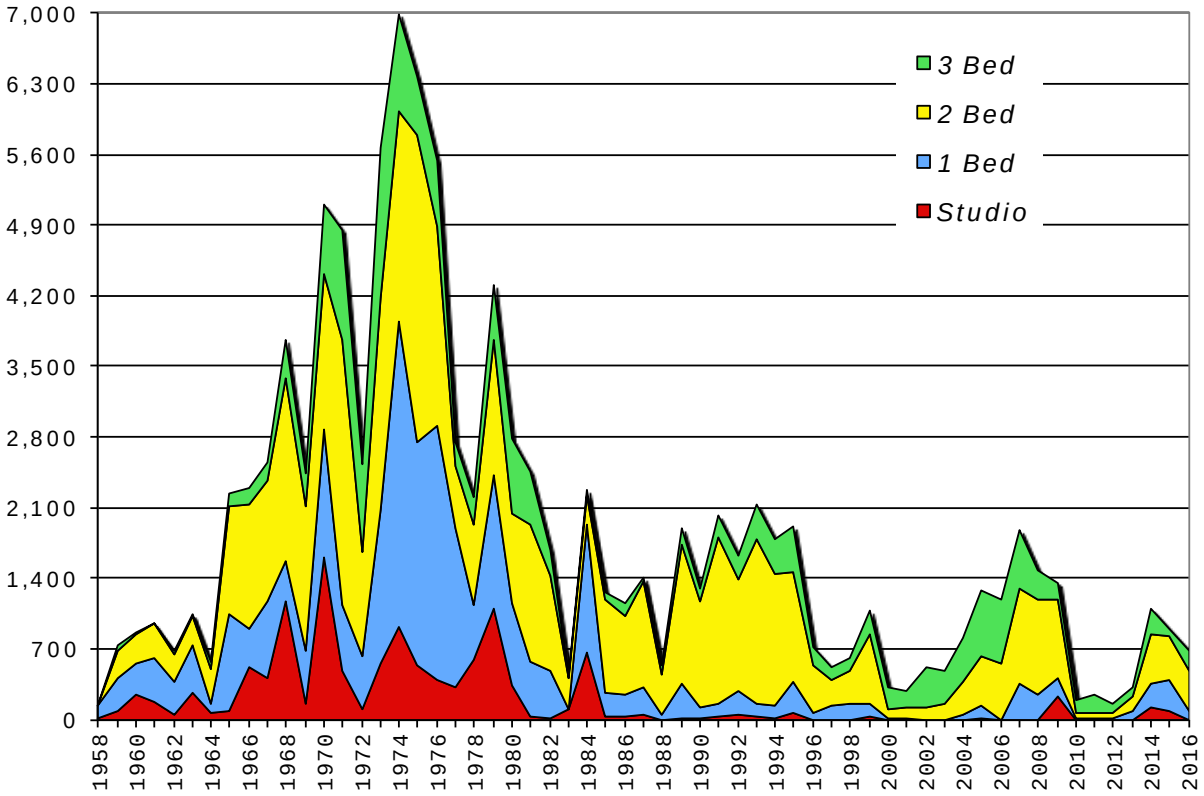
HOUSING STOCK, OAHU, BY AREA, BY TYPE AND BY UNIT COUNT

	Ewa	Kahuku-Kaawa	East Oahu	Central Oahu	North Shore	Waianae	Honolulu	East Honolulu	Total
Single	175,128	2,796	26,403	22,967	11,082	5,658	72,708	13,744	330,485
Condominium	44,375	369	1,628	1,378	423	1,668	35,790	1,237	86,867
Townhouse	23,240	0	2,604	6,737	1,859	595	5,159	1,184	41,378
Apartment	44,436	192	2,315	4,823	1,822	1,622	30,147	813	86,169
Duplex/Multiplex	21,705	30	2,279	842	2,540	2,065	12,897	141	42,499
Co-op	1,661	0	398	38	258	0	967	0	3,322
Other	6,540	302	543	1,493	258	47	3,385	512	13,080
Unreported	374	0	0	0	166	12	161	35	748
Total	317,459	3,688	36,169	38,278	18,408	11,666	161,214	17,666	604,548



Since the project is categorized as attached housing, the study will focus on this type of dwelling. Our analysis of household types and sizes will employ housing statistics provided by the City and County of Honolulu's Real Property Assessment and Property Assessment Division.

The majority of the attached housing stock on the island is old. The table shows that 60% of the attached dwellings on Oahu were built before 1980.



CONDOMINIUM HOUSING PRODUCTION TRENDS, ISLAND WIDE

	Units	Ave. Sq Ftg	Ave. Assessed Values
1955 or less	289	503	$346,326
1960 - 1964	2,429	589	$449,458
1965 - 1969	4,867	618	$410,882
1970 - 1974	13,088	721	$415,926
1975 - 1979	25,730	803	$387,334
1980 - 1984	21,326	714	$379,057
1985 - 1989	9,847	815	$426,401
1990 - 1994	6,440	834	$427,274
1995 - 1999	8,859	917	$448,083
2000 - 2004	4,605	826	$524,536
2005 - 2009	1,836	1,143	$594,289
2010 - 2014	7,024	1,062	$833,913
2015+	2,050	1,056	$892,611

MF Unit Growth & Total Housing Stock

Annual Production of Condos, Oahu

When examining the attached housing stock by bedroom count, one can see that it is comprised primarily of one and two-bedroom units.

CONDOMINIUM HOUSING BEDROOM TYPES, ISLAND WIDE

	Units	Ave. Sq Ftg	Ave. Assessed Values	Ave. Values Per Sq Ft
Studios	8,439	361	$202,080	$561
1 Bed	23,800	582	$309,853	$533
2 Bed	45,103	882	$412,141	$467
3 Bed	16,882	1,245	$493,991	$397
4 Bed	1,623	1,517	$525,142	$346

Hawaii has one of the lowest percentage ownership housing markets in the nation and is among one of the least affordable. Such can be attributed to the limited supply of land, very high costs of production and very strong housing demand, resulting in low housing production and high prices. The problem is exacerbated by the fact that housing prices have exceeded household incomes for over 25 years.

Per the 2010 Census, the total number of housing units in Honolulu was 329,724, with 92% of them occupied. This left some 26,000 units vacant, with about one-third of them or 9,477 accessible to those seeking a residential housing unit. Most of these are in locations and in a condition conducive to high rental rates, such as Waikiki (high visitor demand) and Makiki (high demand for middle- and upper-income households, due to close proximity to employment centers and good schools). Thus, they remained unaffordable to households with low- to moderate-incomes.

Given high demand and low supply, the large numbers of low- to moderate-income households currently have very few options for housing. Further, this condition has existed for over 25 years, since the implementation of land zoning regulations at the county level (supply constraints) and the dramatic rise in the price of housing, fed by the Japanese visitor and housing demand explosion. These conditions, high prices and low supply, continue on today, with Honolulu being named as the least affordable housing market in the nation in a number of studies.

For instance, in 2016, Hawaii ranked #1 in the nation for having the widest gap between wages and the price of rental housing by The National Low-Income Housing Coalition's annual report, Out of Reach. It showed that in 2016, the national Housing Wage is $20.30 for a two-bedroom rental unit, assuming a 40-hour workweek, 52 weeks per year. In comparison, Hawaii's Housing Wage is $32.44 for a two-bedroom rental unit.

HOUSEHOLD CONDITIONS, SIZE AND OWNERSHIP: A major effect of high housing costs on families is that they re-rent part of their shelter to friends or family. The US Census measures evidence of this, and they define crowding as 2 or more persons per bedroom.

They also measure doubling up via surveys and define that as 'more than one family group' in a household. In the last Housing Planning Study, such a survey was performed and the results from Oahu show the following:

CROWDING & DOUBLING UP, ALL OAHU HOUSEHOLDS SURVEYED

	Owners	Renter
Crowded	5.00%	21.60%
Doubled up	12.30%	10.70%
Crowded & Doubled Up	16.50%	26.80%

The following tables show the data by area.

HOUSEHOLDS DOUBLING UP, BY AREA

	Ewa	Central Oahu	Waianae	Honolulu	Total
Yes	4,495	4,096	2,298	18,378	37,778
No	25,875	34,182	9,368	142,836	279,681

OAHU HOUSEHOLDS CROWDING, BY AREA

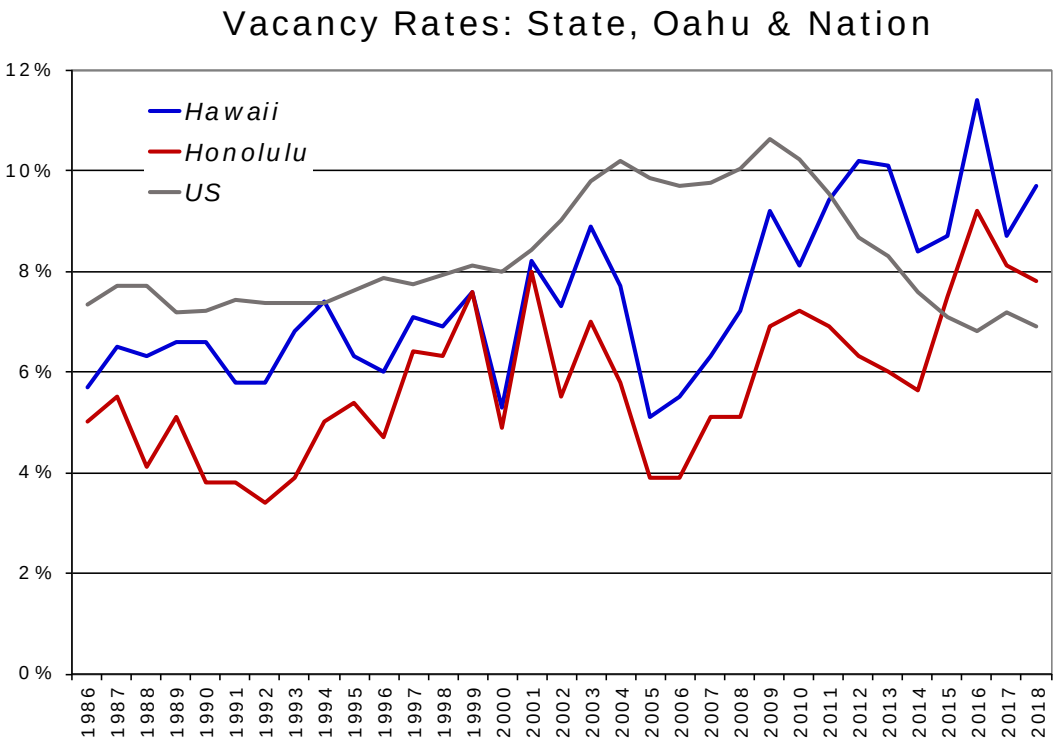
People / Bedroom	Ewa	Central Oahu	Waianae	Honolulu	Total
Less than 2	27,880	35,445	10,091	137,354	281,269
More than 2	2,490	2,833	1,575	23,860	36,190

Another way that this condition is made apparent is the measurement of household size. Indeed, as households cannot afford housing, then overtime pent-up demand increases, household formation is delayed, and the average household size grows. The statewide average for household size increased by 2.8% from 2.88 persons per household to 3.11. This is consistent with a housing market where demand was greater than supply. The following table shows that Oahu had highest increase in average household size over the 10-year period.

HOUSEHOLDS DOUBLING UP & CROWDING, BY AREA

	Population Growth	Household Growth	Housing Size Growth
Hawaii	19.1%	17.0%	0.3%
Honolulu	10.9%	3.5%	8.8%
Kauai	14.3%	11.7%	2.3%

IX. OVERVIEW OF HONOLULU'S RENTAL MARKET

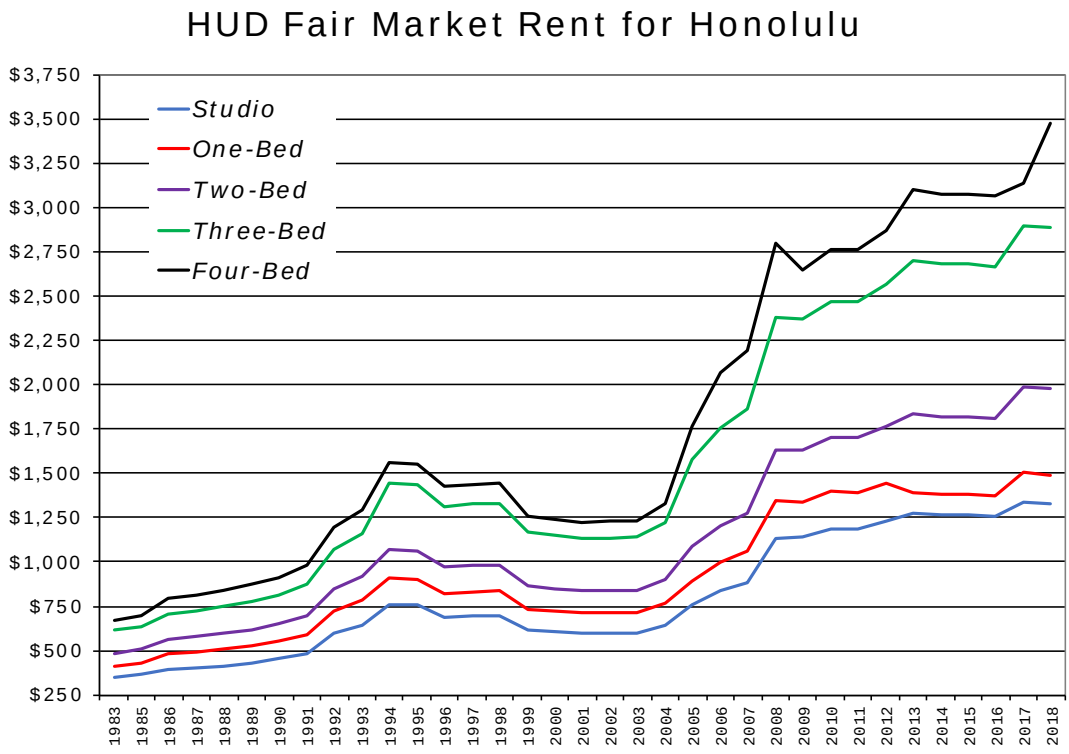


HISTORY: As described above, the rental market in the County is expensive. Unlike most urban areas in the United States where large rental operators are common, the island of Oahu consists of many small developments. Most multifamily development for local renter households occurred on small parcels of land by small groups of local investors due to the ease of financing. As a result, the rental market is predominantly comprised of small rental operations and/or mom-and-pop landlords. The large number of two-story walk-ups most commonly located in and around Moiliili, Kalihi, Makiki, Kapahulu and Kaimuki serve as evidence of such small rental operations.

All of these factors have contributed to Honolulu continually being named one of the least affordable cities in the US (using US Census data). The flipside of that is that, in terms of the vacancy rate of rental units, historically it is one of the lowest in the nation.

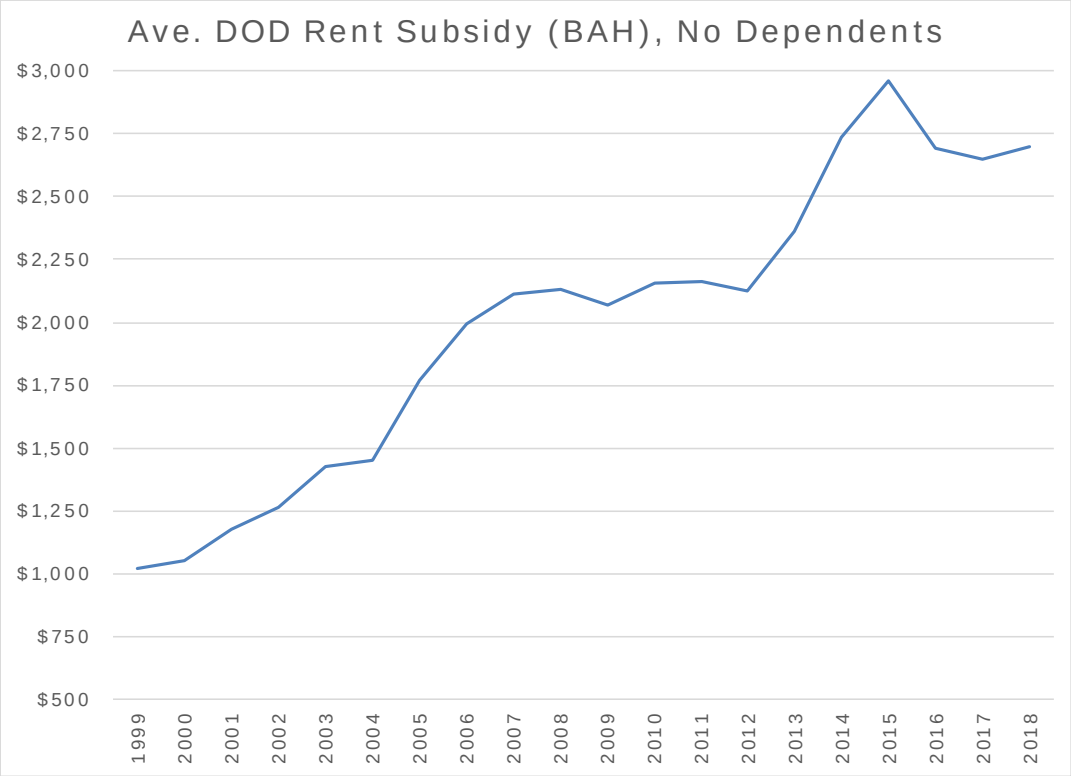
RENTAL MARKET CURRENT CONDITIONS: As previously stated, Honolulu is a small market with very few large rental operators and therefore data describing rental rates of specific projects is not readily available. There are, however, general sources that can be used.

U.S. Public Agencies



The U.S. Census has data detailing rentals of all housing types for Oahu. The following table illustrates the trend for the vacancy rate:

Note that the rates for Honolulu and the state used to be lower than that of the U.S. as a whole. However, that is not the case today – in the aftermath of the Great Depression, this rate has not returned to the levels it enjoyed during the 2005 top of real estate market.



This trendline flies in the face of logic, given high housing costs and extremely low unemployment, existing in Honolulu since 2010 every available unit should be occupied, not vacant. This anomaly leads to speculation that the Census data somehow captures the existence on Oahu of short-term rental units. There are a goodly number of such units, and they produce a very healthy cash flow, better say many landlords than long-term rentals. This should explain why there are such a large percentage of 'vacancies.'

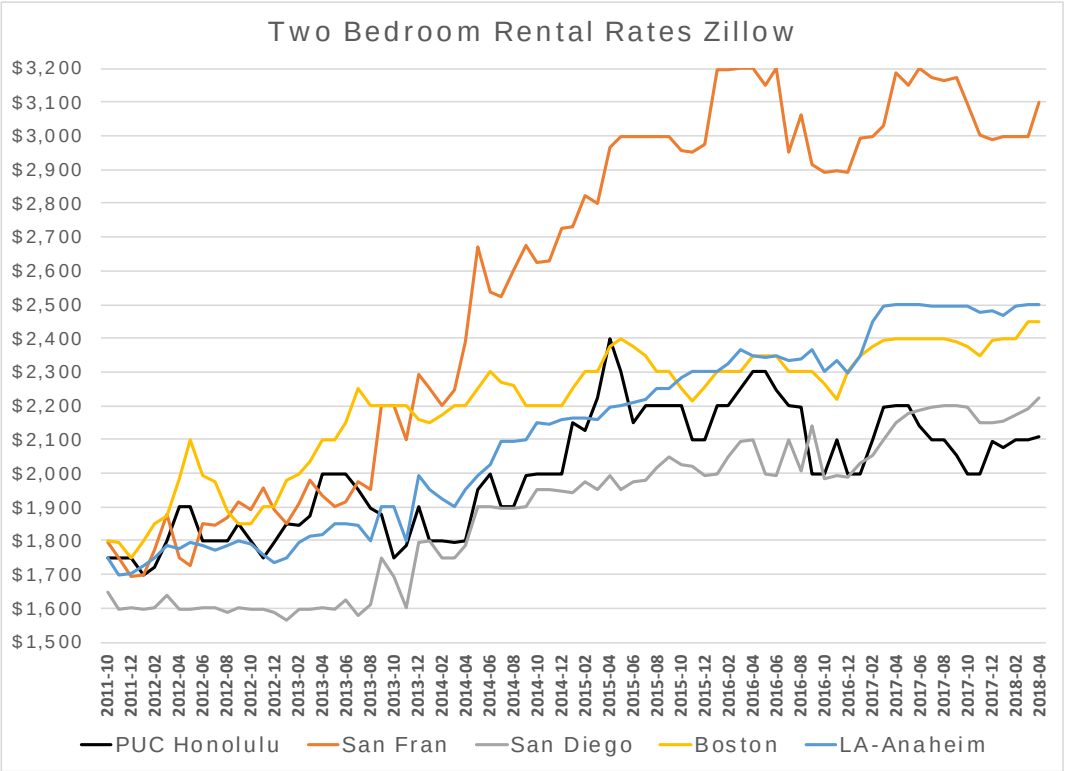
Turning to an examination of the actual rental rates being charged in the market, the best known one is called "Fair Market Rents" (FMR) and comes from the US Housing and Urban Development department (HUD). Every year, HUD analyzes the rental markets across the country, and then publishes a set of gross rent estimates for an area. They include the shelter rent plus the cost of all tenant-paid utilities, minus conveniences, like telephone and Internet. HUD does so by using (to quote them) "the most accurate and current data available" – per(http://www.huduser.org/datasets/fmr.html) - and this data includes the 2010 US Census data, the last American Community Survey (ACS) data, and telephone surveys of eligible recent rental unit movers.

As seen, the trend for HUD-defined rents is generally higher. Note also that these rents are above those proposed by this subject development.

Another source of rental trend information comes from the Department of Defense (DOD). It is called the Base Allowance for Housing (BAH), and it is their description of the rental market rates, done in conjunction with providing their personnel based in the county with a rental allowance. This is done for all counties where military personnel are based and adjusted for a cost of living. The following chart shows the average allowance that the military provides to its households when stationed in Oahu, in this case. As seen, the DOD allowance has moved in an opposite direction to the Fair Market Rent trend for Oahu for the same period (which is curious, looking at the spike up and down the last 3 years).

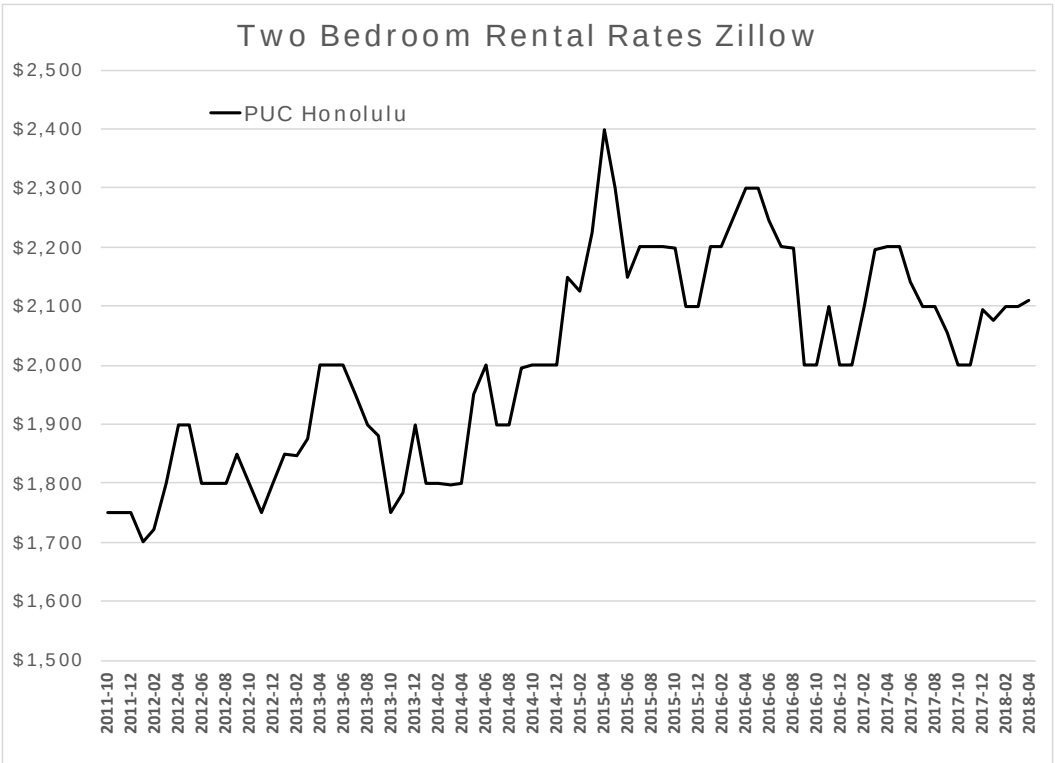
As seen, this data's historical trend is cohesive with the Zillow and the Honolulu Board of Realtor trend.

Given that, rental housing research and researchers have used publicly available data on rental rates to describe the market place. Historically, the best source, in terms of depth, breadth and consistency, was classified advertising in the local newspapers. The listings here provided a wealth of important data, such as asking rents, unit size, unit location, unit features, unit restrictions, etc. This data, when collected over time, then allowed for research to show rental rate and unit availability trends, and do so by location, bed count, rents and other features.



However, the advent of the internet disrupted the classified advertising marketplace by allowing that activity – and information - to migrate from a hard copy print in a newspaper into an electronic data held within a website. Thus, the research done using newspaper classified waned while that done using Internet websites that specialize in rental units in the area.

One that provides rental information most comprehensively is Craigslist. In essence, this website replaced the classified ads in the newspapers in terms of being the clearinghouse for renters and renters. Another source is Zillow.



Zillow Data

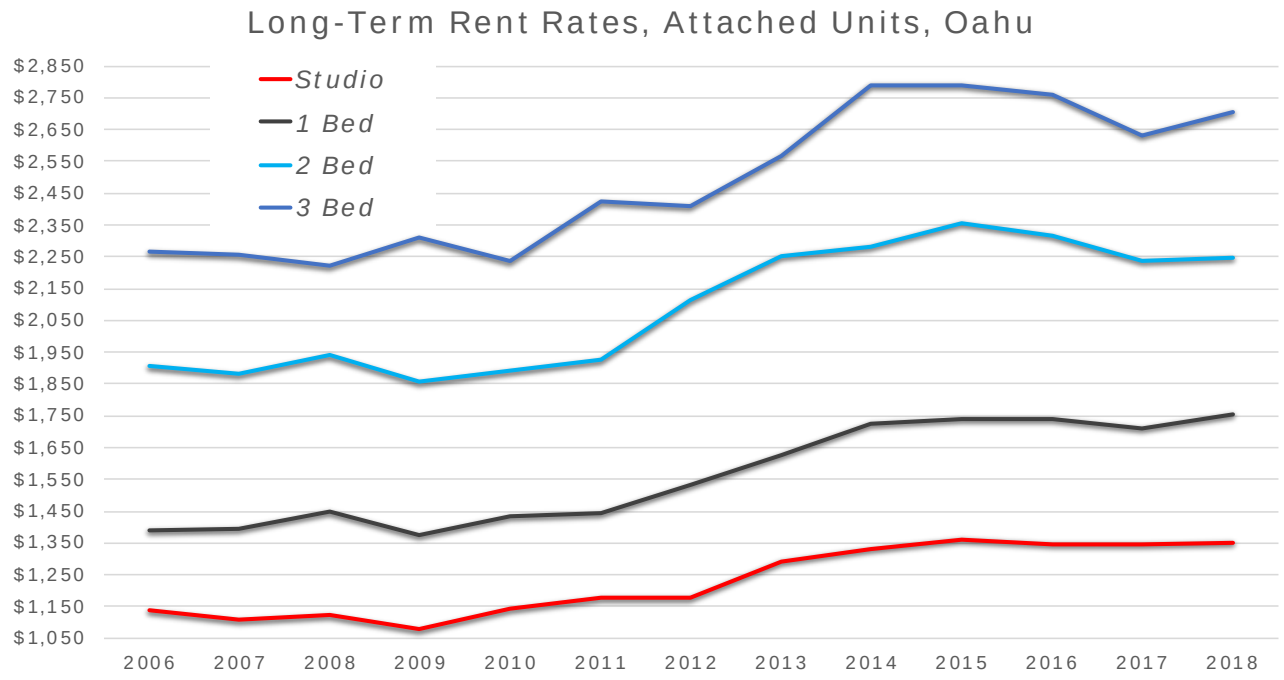
Zillow Group is an online real estate database company that was founded in 2005 by former Microsoft executives. In addition to giving value estimates of homes, it offers several features including value changes of each home in a given time. Where it can access appropriate public data, it also provides basic information on a given home, such as square footage and the number of beds and baths. In December 2009, Zillow expanded its services to include the rental market. The addition of rental listings enabled users to list a home for rent and search for both rental homes and homes for sale.

Zillow rental data consists of listings, listing prices, estimated listing prices per square foot, and can be segmented by county, zip code, city and neighborhood. it breaks the data out by property type – homes vs. condos vs. apartments – it does not allow one to combine townhomes, condominiums and apartments. As such, it is a good tool for looking at the market overview, but not a good one for making fine distinctions and comparisons between the properties in that data.

As seen, the trend is rising, albeit in a volatile fashion.

Honolulu Board of Realtor Data

The best data, in terms of detail and comprehensiveness, is from the Honolulu Board of Realtors (HBR) for attached housing (including townhomes, condominium and apartments). It is very complete, including zip, furnished or not, TMK addresses, starting rent rate, closing rent rates, start of list date and whether the unit listing was rented, expired or is active.



OVERVIEW: We start with an overview of the data, but just the listings that were rented out (with their rented price), and that were partially furnished (which was the largest category numerically – the others were not furnished, fully furnished and negotiable). The other data selection was to exclude single family homes and duplexes, but to lump together town homes, apartments and condos.

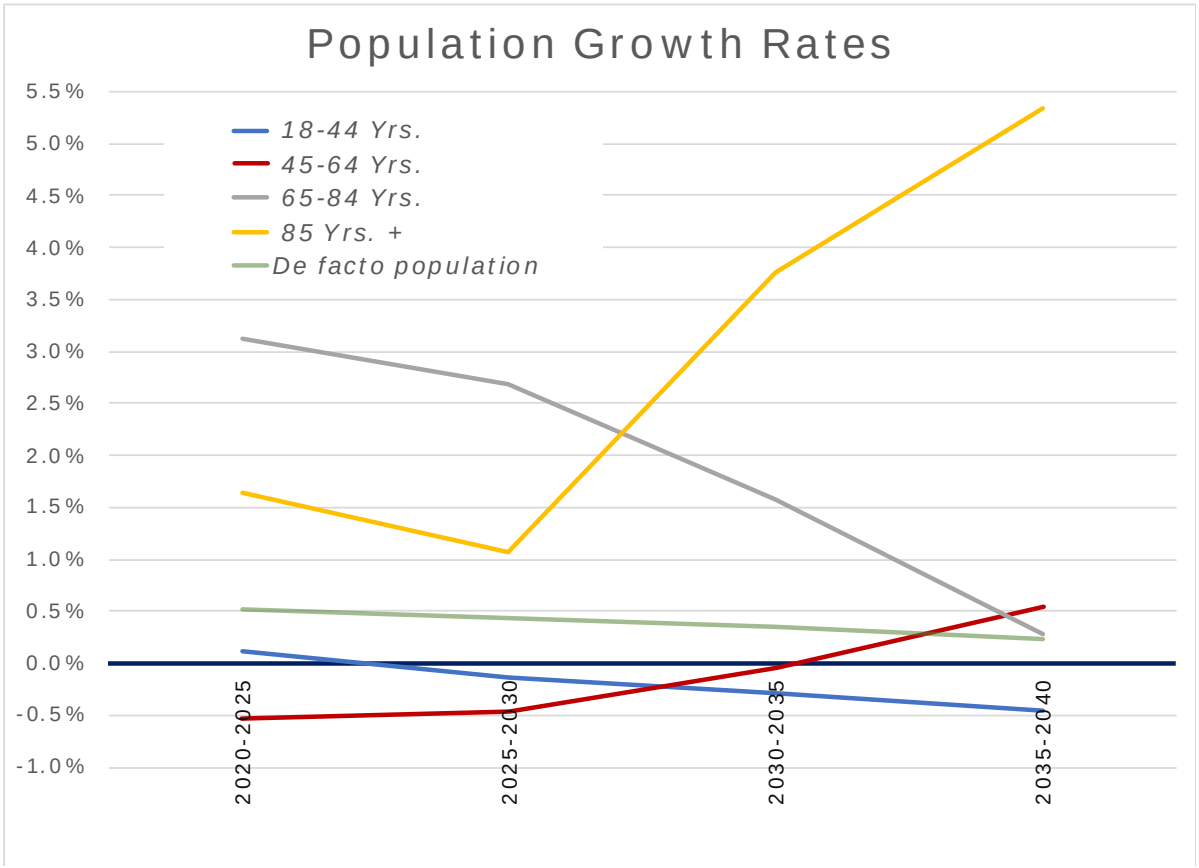
TIME FRAME 2008-2018: The following table gives an overview of the attached housing (including townhomes, condominium and apartments) database, all listings since 2008 by area and by bed counts. Note that this property sits in the TMK Zone 1-9, Ko Olina to Mililani to Aiea.

ALL LISTING COUNTS, FOR ATTACHED DWELLING UNITS, 2008-2018

TMK	Zone1	Studio	1 Bed	2 Bed	3 Bed
1-1	Salt Lake - Downtown	149	494	1,013	236
1-2	Downtown - Waikiki	2,251	5,584	5,659	637
1-3	D Head/Kaimuki - H Kai	169	642	1,204	439
1-4	Waimanalo - Hauula	34	265	944	527
1-5	Hauula – Sunset Beach	43	46	14	8
1-6	Waimea - Mokuleia	3	104	132	5
1-7	Wahiawa	19	99	157	15
1-8	Makaha - W Oahu	81	193	142	53
1-9	Ko Olina - Pearl City	296	1,209	4,954	2,165
1	TOTAL	1,312	4,953	9,541	2,918

The following chart shows the average rents per bed for all multifamily rentals for the past 10 years.

XI HOUSING DEMAND:



Numerous factors affect the demand for housing, the primary being population, household formations and job creation.

In the long run, population growth is the most important determinate of housing demand – although, for Hawaii, housing demand has a strong offshore component. The following table shows population projections by DBEDT for Oahu.

PROJECTED HONOLULU POPULATION TRENDS

	2020	2025	2030	2035	2040
Total resident population	**1,010,123**	**1,032,705**	**1,050,077**	**1,062,059**	**1,069,269**
Population: 0 to 4 years	68,086	69,898	67,117	64,182	62,606
School age children: 5 to 11 years	83,577	86,260	91,316	87,850	83,716
School age children: 12 to 13 years	22,332	23,769	24,516	24,989	23,901
School age children: 14 to 17 years	39,842	41,043	40,320	46,034	44,945
Population: 18 to 44 years	375,683	373,036	367,712	359,283	352,327
Population: 45 to 64 years	235,770	230,332	229,785	236,088	250,365
Population: 65 to 84 years	154,087	175,938	190,301	193,048	190,661
Population: 85 years and over	30,748	32,428	39,011	50,584	60,748
De facto population	**1,070,437**	**1,093,992**	**1,112,667**	**1,125,876**	**1,133,609**

The changes projected over the next 20+ years are shown in the chart below. Clearly, the growth in demand in the next ten years is in the senior component of the population.

X. AREA HOUSEHOLDS DEMOGRAPHIC ANALYSIS

OVERVIEW: Generally, the demographic trend for the island is that the population as a whole is aging. Additionally, the most populous segment of this market is the ones for 45 to 54 years old, followed by the one above it, the 55 to 64 years old.

The scope of work calls for a demographic analysis of the number of households in the market area that are income eligible and can afford to pay the rent. The target market is comprised of those family households who satisfy the income restrictions and other requirements for entering into a rental contract for these units.

The subject property will be producing one and two-bedroom unit rentals for those making 30% to 60% of the Area Median Income (AMI). The project's proposed unit mix is detailed in the following tables.

PROJECT UNIT BREAKDOWN, TOTAL

Beds	30% AMI	60% AMI	80%AMI	Total
1-Bedroom	8	115	7	130
2-Bedroom		16	9	25
Total	8	131	16	155

PROJECT RENT BREAKDOWN, 2018 GUIDELINES

Beds	30% AMI	60% AMI	80%AMI
1-Bedroom	$612	$1,225	$1,634
2-Bedroom		$1,312	$1,750

Next, we take these bedroom sizes and translate them into the households that would qualify to live in them by their household size (number of people) (and then later by AMI).

Per household size, there is an occupancy requirement for the minimum and maximum number of persons in a household buying (or renting) an affordable unit.

OCCUPANCY REQUIREMENT

Bedrooms	Occupancy Range
1 Bedroom	1-2 Persons
2 Bedroom	2-5 Persons

We then look at this, given the income limits of the household. This is given by the HUD 2018 AMI definition. These tax subsidy income limits are described in the table below.

MULTIFAMILY TAX SUBSIDY PROJECT INCOME LIMITS, 2018

AMI	1 Person	2 Person	3 Person	4 Person	5 Person	6 Person	7 Person
30%	$24,510	$27,990	$31,500	$34,980	$37,800	$40,590	$43,380
50%	$40,850	$46,650	$52,500	$58,300	$63,000	$67,650	$72,300
60%	$49,020	$55,980	$63,000	$69,960	$75,600	$81,180	$86,760
80%	$65,360	$74,640	$84,000	$93,280	$100,800	$108,240	$115,680

Using the above guidelines, the table below depicts the total population of households in the County (meaning, on the island) who are renting, categorized by income bracket according to the number of people in the household.

This data comes from Ribbon Demographics, a firm that specializes in taking US Census data and separating it into segments that are useful for projecting the demographic demand for affordable housing. It defines the relevant target markets of the project.

The next step is to determine the number of people in the household who would qualify to live in a unit. This is done relative to the number of bedrooms, per the project's unit supply. The rules regulating the rental of the one bedrooms say that no less than one person and no more than two people can rent a one-bedroom unit. For two-bedroom units, no fewer than two people and no more than five people can rent a unit.

SENIOR RENTER ONLY HOUSEHOLDS BY AMI AND FAMILY SIZE, 2018

AMI	1-Person	2-Person	3-Person	4-Person	5-Person
30%	7,877	2,814	818	589	274
50%	3,588	2,059	941	575	244
60%	1,293	964	510	246	153
80%	2,360	1,515	580	585	125

The next step is to determine the number of people in the household who would qualify to live in a unit. This is done relative to the number of bedrooms, per the project's unit supply.

The rules regulating the rental of the one bedrooms say that no less than one person and no more than two people can rent a one-bedroom unit. For two-bedroom units, no fewer than two people and no more than five people can rent a unit.

From this one can derive the number of households in the market area who make the allowable income or less. This becomes the number of households that constitutes the total potential demand for the project's supply. This analysis begins with deriving the demand for the one-bedroom unit.

ONE BEDROOM UNITS: The supply by bedroom and target AMI is defined below.

PROJECT SUPPLY, BY TARGET AMI

Target AMI	Bed/Bath	Unit Count
30%	1 Bed	8
60%	1 Bed	115
80%	1 Bed	7

The next table describes the maximum income that a household qualifying for a one-bedroom unit can make.

LIMITS OF INCOME BY HOUSEHOLD SIZE

One Bedroom Limits	30% of AMI	60% of AMI	80% of AMI
1 Person	$24,510	$49,020	$65,360
2 Person	$27,990	$55,980	$74,640

With this, one can get to the number of one and two-person households who reside within the market area who satisfy income limit restrictions. This represents the potential demand in terms of the number of households that would be able to rent one of these units.

The table below shows this potential demand for one and two-person households by AMI.

RENTER HOUSEHOLDS POTENTIAL DEMAND FOR ONE BEDROOM UNITS

Target AMI	1-Person	2-Person	Renter Population
30%	7,877	2,814	10,691
60%	1,293	964	2,257
80%	2,360	1,515	3,875

The next table shows the total potential demand relative to the project's actual supply. Using that, it derives the share of market percentage that the unit supply represents verses total potential demand.

And we consider what an appropriate capture rate could be for the units of the project. Given the location of this project, as well as the fact this is new construction, we think the rate easily could be 40% to 60% of total potential demand. We then apply a factor of 50%, the midway point between the ranges, and arrive at the number of households that would apply for these units.

ONE BEDROOM SHARE OF TOTAL POTENTIAL MARKET, BY AMI

Target AMI	Unit Supply	Potential Demand	Capture Rate 50%
30%	8	10,691	5,346
60%	115	2,257	1,129
80%	7	3,875	1,938

Using either total potential demand or lower capture rate potential demand, the demographic composition of the County says that there is more potential demand than supply.

TWO BEDROOM UNITS: Per two-bedroom units, the supply of these units by AMI is detailed below.

PROJECT SUPPLY, BY TARGET AMI

Target AMI	Total Count
60%	16
80%	9

The next table describes the maximum income a household can make for these units.

LIMITS OF INCOME BY HOUSEHOLD SIZE

Two Bedroom Limits	60% of AMI	80% AMI
2 Person	$55,980	$74,640
5 Person	$75,600	$100,800

The next table shows how many two to five-person households existing within the given income limits for the area.

RENTER HOUSEHOLDS POTENTIAL DEMAND FOR 2 BEDROOM UNITS

AMI	Renters
60%	1,657
80%	2,298

The next table defines the project supply, by the number of units, and sets it against the potential demand. With that, we can derive the share of market percentage that the unit supply represents verses total potential demand, below.

Again, we consider what an appropriate capture rate could be for this proposed development's units. Given the location of this project, as well as new construction, we again assign the rate as 50%, to get a final potential demand.

2 BEDROOM CAPTURE RATE, BY AMI

AMI	Total Count	Potential Demand	Capture Rate 50%
60%	16	2,968	1,484
80%	9	2,254	1,127

As with the one bedroom, these tables show that there is more potential demand than supply.

XI. DESCRIPTION OF COMPARABLE UNITS IN THE MARKET AREA

The following tables describe the comparable units in the market area for projects that have one, two and three-bedroom units serving families making 30%, 80% and 100% of AMI.

30% AMI AFFORDABLE RENTAL INVENTORY BY BEDROOM FOR OAHU

Bedrooms in Unit	Count of Projects with Units	Count of Built Units	Average Sq Ft Size	Total Count Project Units
1 Bed	12	279	467	8

60% AMI AFFORDABLE RENTAL INVENTORY BY BEDROOM FOR OAHU

Bedrooms In Unit	Projects With Units	Built Units	Average Sq Ft Size	Total Count Project Units
1 Bed	14	687	513	115
2 Bed	2	13	672	16

80% AMI AFFORDABLE RENTAL INVENTORY BY BEDROOM FOR OAHU

Bedrooms In Unit	Projects With Units	Count of Built Units	Average Sq Ft Size	Total Count Project Units
1 Bed	12	1,144	498	7
2 Bed	1	58	71	9

These tables illustrate how the supply of the proposed subject development compares to the existing housing stock of comparable units, by bedrooms and the AMI of their target market. They describe specifically that – on the supply side - the numbers that will be provided by this proposed development are small (but only relative to the larger number, the existing stock).

XII. ANALYSIS OF COMPARABLE PROPERTIES IN THE AREA.

OVERVIEW: By way of overview, the Oahu marketplace within which “market rate properties” compete is comprised of very few large unit rental properties and a great many small unit properties. Relative to other US urban centers, this is a unique characteristic and has much to do with the development of the visitor industry and the nature of the urbanization (or the lack thereof) on Oahu.

As short a while ago as 40 years, Oahu was primarily an agrarian economy, at least in terms of the dispersion of population near the plantation areas. As such, there was no real urban core around which people lived. Thus, there is no real core area with lots of large condominium projects, other than hotel and luxury units. The main area for that was in Waikiki, which targeted short-term visitors. The rest of condominium development was small-scale, due to the rugged topography on Oahu, due to the lack of capital for building large projects, and due to the lack of land for development (leasehold system). As such, the rental marketplace was dispersed as well as highly fragmented, and the result of that is that Oahu’s rental market contains a great many 10-20 unit two-story ‘walk-ups’ (no elevator necessary, due to the limitation to two stories).

As a practical matter for this study, there are no large operators to call and survey for their rents, vacancy rates, operating expenses and turnover rates. Indeed, almost all of those who were surveyed would not divulge anything more than the asking rent.

ANALYSIS: The following tables describe the comparable units in the market area for projects that have one, two and three-bedroom units serving families making 30%, 60%, 80% and 100% of AMI.

30% AMI INVENTORY BY BEDROOM

Bedroom Count	Existing Projects	Existing Units	Ave Months of Waitlist	Ave Vacancy Rate	Ave Turnover Rate	Total Units
1-Bedroom	12	279	84	0.000	0.02	8

60% AMI INVENTORY BY BEDROOM

Bedroom Count	Existing Projects	Existing Units	Ave. Months of Waitlist	Ave Vacancy Rate	Ave Turnover Rate	Project Units
1-Bedroom	14	687	33	0.007	0.011	115
2-Bedroom	2	13	18	0.000		16

80% AMI INVENTORY BY BEDROOM

Bedroom Count	Existing Projects	Existing Units	Ave. Months of Waitlist	Ave Vacancy Rate	Ave Turnover Rate	Project Units
2-Bedroom	12	1,144	30	0.013	0.02	7
3-Bedroom	1	58	24	0.000	0.02	9

An analysis shows the following trends:

- The lower the income of the households served, the lower the vacancy rate;
- The lower the income of the households served, the lower the turnover rate;

Given that, the market would be most served by having (producing) more units for the lower income households. It would also be beneficial to have more, larger sized units.

XIII. ANALYSIS OF MARKET RATE PROPERTIES IN THE AREA

Again, there are no large operators to call and survey for their rents, vacancy rates, etc. Instead, the Internet was used to research websites that specialize in rental units. The rental averages for rented units below are from the Honolulu Board of Realtors.

AVERAGE RENTAL RATE TRENDS FOR HONOLULU, HBR

Period	One Bedroom	Two Bedroom	Three Bedroom
2016	$1,711	$2,257	$2,751
2017	$1,695	$2,255	$2,740
2018	$1,755	$2,293	$2,809

It shows a slightly rising trend for rents.

Next, we reviewed the listings for rental apartment units on the Internet over the last 2 months, specifically those advertised as being the 'least expensive'. The following tables describe those units, a comparison can be made between those rents to the highest rents for the subject property.

ONE BEDROOM MARKET RENTAL RATES, SELECTED AREA PROJECTS

School Street, no W/D, street parking	Kuakini, Ground Floor, Walk-up, No W/D	Kewalo Street Walk-up, No W/D	Wilder Street, Walk-up, No W/D, no parking	Pensacola Street, Walk-up, no W/D or parking	Kukui Gardens Apartments -	Kewalo Gardens Punahou
$900	$1,310	$1,100	$1,125	$1,250	$1,239	$1,300

TWO-BEDROOM MARKET RENTALS, SELECTED OFFERINGS

728 Kinau Street, Seniors only	1227 Alexander Street, Walkup,	Marin Tower, No W/D	1104 Hoolai Street, Walk-up, No W/D	1426 Keeaumoku Walkup, No W/D	Kokea Gardens, Kalihi, Walkup, NO W/D	Kukui Gardens Apartments
$1,250	$1,260	$1,290	$1,295	$1,395	$1,400	$1,472

Note that these units are priced equal or higher than the proposed project's rents (which, themselves, are priced commensurately as a purpose-built, higher quality, better located community).

XIV. PROPOSED PROJECTS IN THE MARKET AREAS

PROJECTED NEW INVENTORY: Currently there are no affordable senior projects planned for development in the immediate market area. There is minimal land in the market area available for development, and zoning restrictions, entitlements, and other land-related covenants make development of affordable housing challenging.

XV. CONCLUSIONS AND FORECAST

Simply put, the local real estate market is poised to see several years of increased prices for all condominium units, significantly so by the end of this market cycle. Per usual, the market for rental housing will experience a similar trend, and reasonably priced units will become less available and costlier. Finally, the lack of apartment construction should allow the rental market of Honolulu to continue enjoying a decent recovery.

Currently, the market for the proposed development is robust, with the majority of the comparables exhibiting stable occupancies and low vacancy rates. The current rental rate schedule relative to units available to the general public on the open market is competitive.

Based on our demographic information and rental demand analysis, we believe that there is adequate demand in the primary market area for the Subject property as proposed. Therefore, we expect the proposed development will attain and maintain a 99 percent occupancy rate upon stabilization. And, in light of the paltry supply and growing demand for affordable housing, we do not foresee any negative impact on the existing rental housing stock. Further, it is reasonable to expect the project will be achieving 97%-100% occupancy in the first 6 to 9 months, post-completion.

1.1. PROJECT OVERVIEW

Halewai'olu Senior Development, LLC is proposing to construct and operate the Halewai'olu Senior Residences ("HSR"), a 17-story, 155-unit plus one resident manager, senior (62 years and over, age-restricted) rental housing facility in the Chinatown area of Honolulu ("Project"). Construction of the Project will require demolition of an existing two-story building. The property on which the Project will be constructed is owned by the City and County of Honolulu and will be the subject of a long-term lease. The Project will consist of one 17-story residential building with 13 residential floors above a four-story parking podium. Levels one through four will include the building lobby; a courtyard; a multipurpose room, recreation deck, activity rooms, warming kitchen, and management office for building residents; retail; and parking.

1.2. PROJECT LOCATION

The Project is proposed to be located on River Street, Honolulu. The Project site lies south of the River Street Canal, between N Vineyard Boulevard and N Kukui Street, adjacent to the Lum Sai Ho Tong building. The property is currently occupied by a two-story commercial building that will be demolished as part of the proposed Project.

A regional and area map of the proposed site are included as Figure 1-1 and Figure 1-2 below. The Project would be constructed on approximately 0.6 acres of land along River Street, in the location shown in Figure 1-3. The elevation of the subject property is approximately eight feet above mean sea level with an overall downward gradient toward the canal, although the property is relatively flat.

Figure 1-1. Halewai'olu Project Regional Location: Honolulu, Hawaii

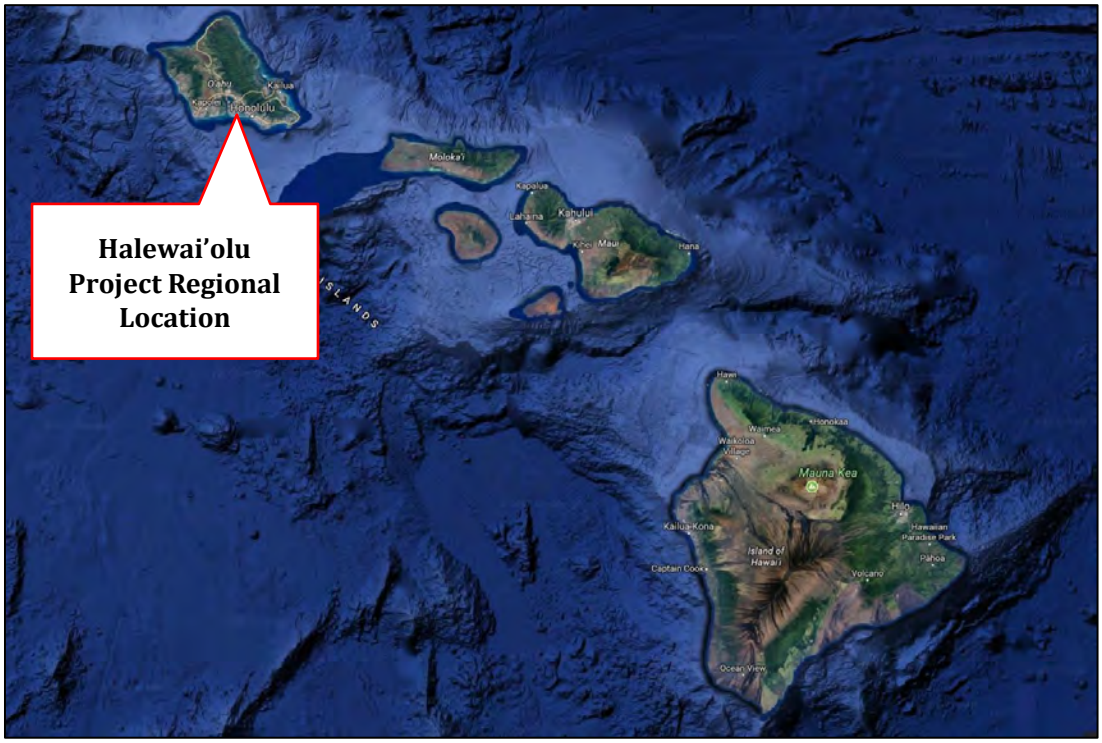

Figure 1-2. Halewai'olu Project Location

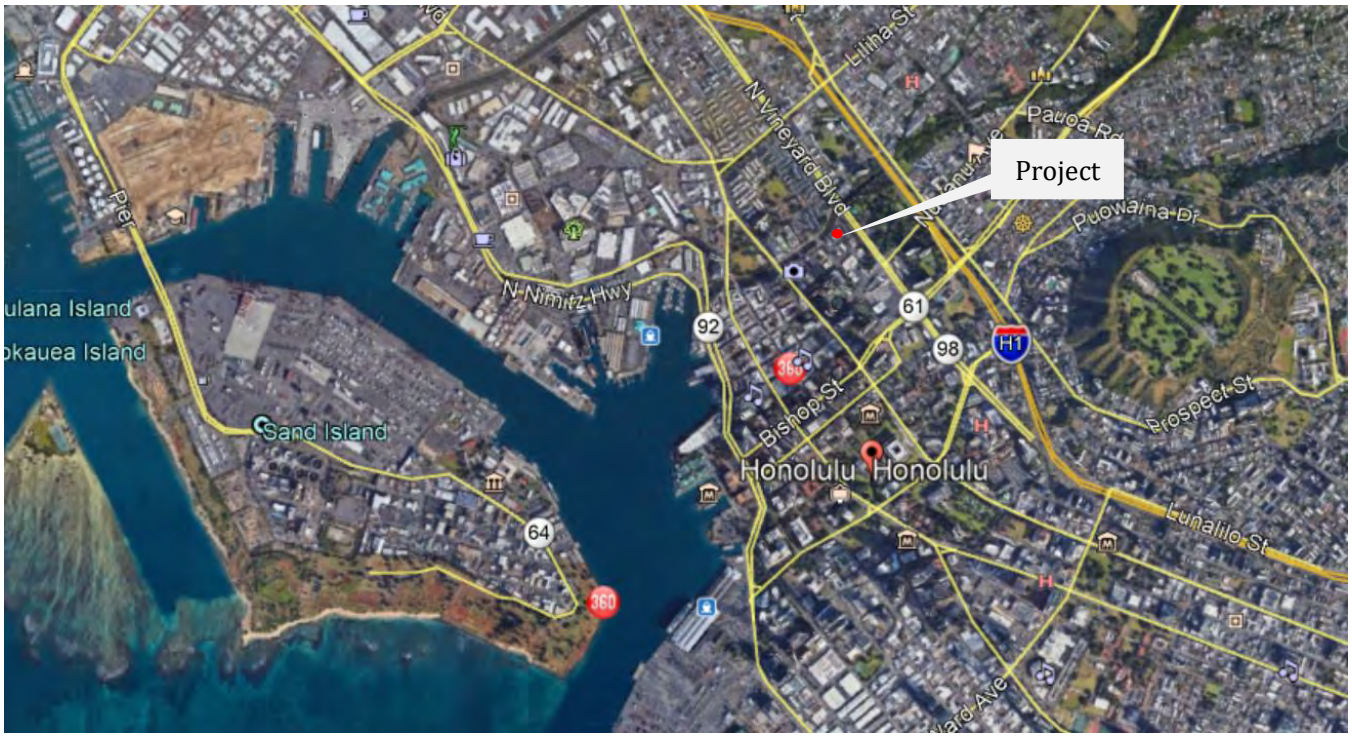

Figure 1-3. Halewai'olu Project Location

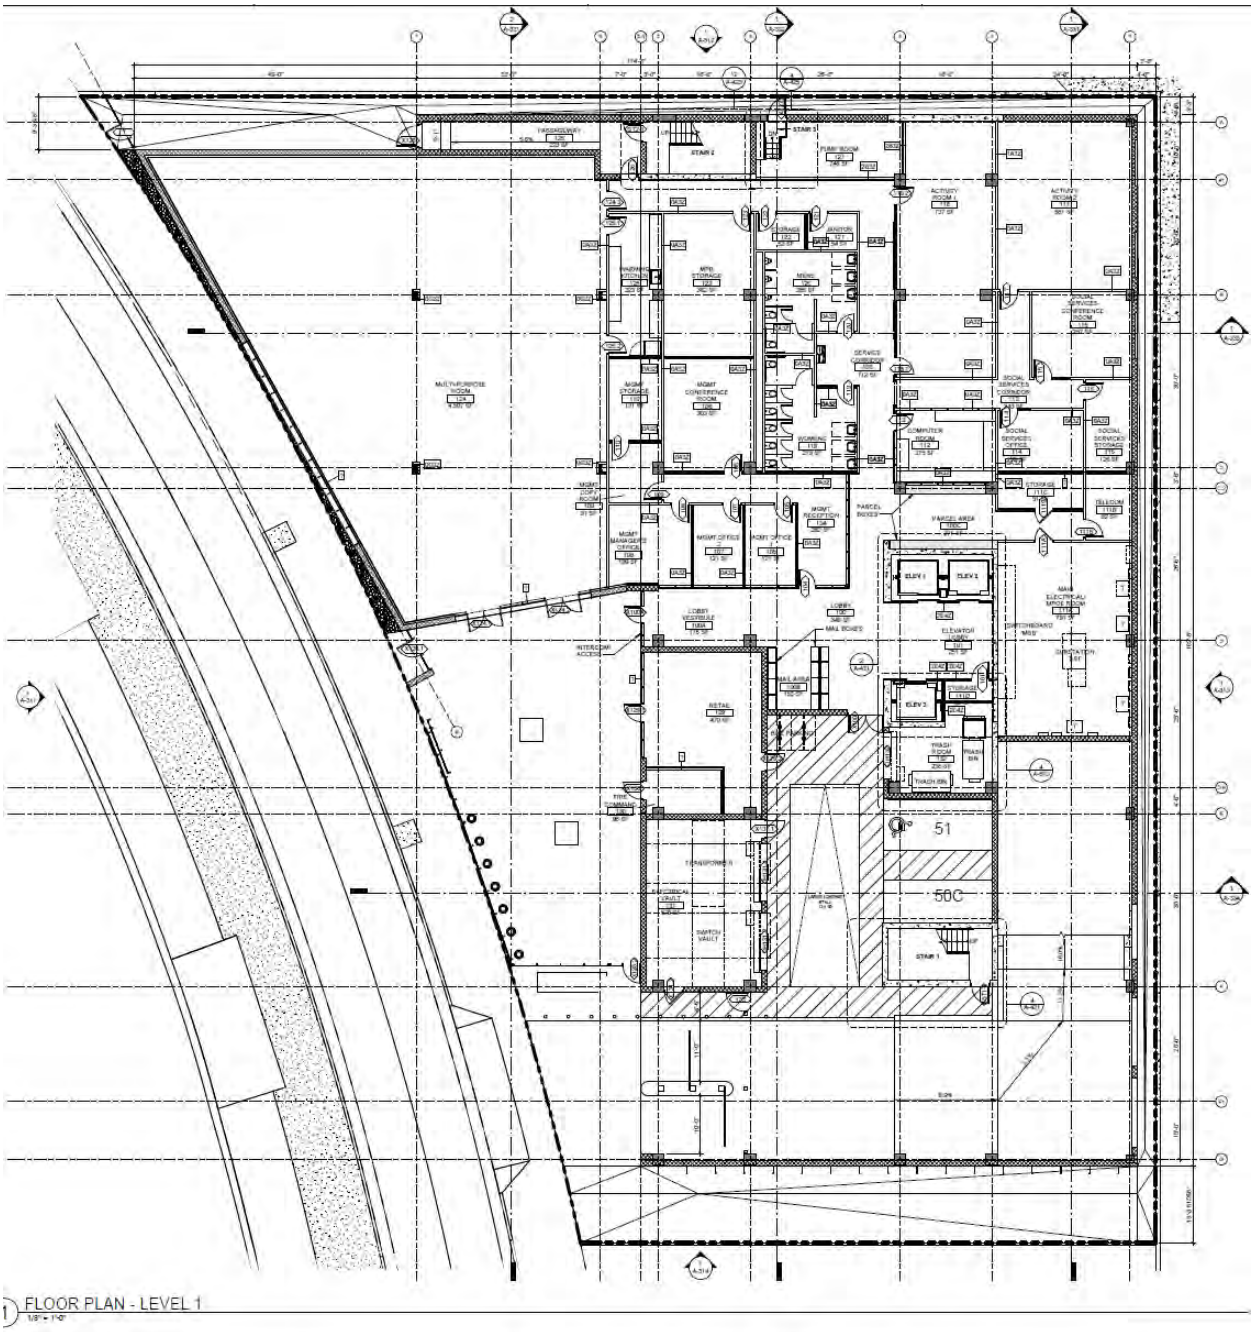
Source: Fehr & Peers, Focused Mobility Analysis Report (MAR) for the Proposed Halewai'olu Senior Residences

1.3. PROJECT DESCRIPTION

The Project will include demolition of the existing two-story commercial building on property, grading and filling, construction of a new foundation, and construction of the new 17-story building. Demolition is scheduled to be completed in the 4th quarter of 2020. Construction will be completed in the 2nd quarter of 2022, with occupancy slated to begin in April of 2022. Figure 1-4 depicts the site plan for the ground floor of the proposed Project.

1.4. GENERAL PLAN DESIGNATION AND ZONING

The proposed site is currently designated in the City and County of Honolulu as "BMX4" – "Central Business Mixed Use"- so no change in zoning is required to accommodate the proposed Project.



1.5. SURROUNDING LAND USES AND SETTING

West of the Project site is River Street and the sidewalks along River Street serve as a promenade along the Nu'uanu Stream called Sun Yat Sen Mall, located approximately 54 feet west of the Project site. Further west and across the stream are the Waena Apartments. The Izumo Taishkyo Mission Shinto shrine, constructed in 1968, is located approximately 322 feet northwest of and across the stream from the Project site. College Walk promenade is on the west side of Nu'uanu Stream.

The Lum Sai Ho Tong temple, constructed in 1953, is located directly adjacent to the existing structure. Approximately 254 feet further south of the Project site is the Chinatown Cultural Plaza, a popular commercial center used for seasonal community events. Alongside the Chinatown Cultural Plaza, a portion of River Street by the stream becomes a pedestrian-only promenade popularly used for recreation by seniors in the Chinatown area.

The Borthwick Mortuary Crematorium and Chapel (Hawaii Department of Health Clean Air Branch Noncovered Source Permit 0422-01-N) are located directly adjacent and to the southeast of the Project site. A portion of its surface parking lot extends north and directly borders the northeast portion of the Project site. The Kuan Yin temple and Foster Botanical Garden are located approximately 246 feet further northeast of the Project site across Vineyard Boulevard. The botanical garden is owned and operated by the City Department of Parks and Recreation (DPR) and is a historic resource listed on the National Registry of Historical Places (NRHP).

Figure 1-4. Site Plan

2.1. AIR QUALITY STANDARDS

The U.S. Environmental Protection Agency (EPA) sets national ambient air quality standards (NAAQS) for ozone (O_3), nitrogen dioxide (NO_2), carbon monoxide (CO), sulfur dioxide (SO_2), particulate matter with an aerodynamic diameter of 10 microns or less (PM_{10}), particulate matter with an aerodynamic diameter of 2.5 microns or less ($PM_{2.5}$), and lead (Pb). These standards establish the maximum concentrations of pollution considered to be acceptable, with an adequate margin of safety, to protect the public health and welfare.

The State of Hawaii has also adopted ambient air quality standards, which in some cases are more stringent than the NAAQS. Hawaii has set state standards for ozone, NO_2, CO, SO_2, PM_{10}, $PM_{2.5}$, Pb, and hydrogen sulfide (H_2S).

Both national and state air quality standards consist of two parts—an allowable concentration of the pollutant, and an averaging time over which the concentration is measured. The allowable concentrations are based on studies of the effects of the pollutants on human health, crops and vegetation, and in some cases, damage to paint and other materials. The averaging times are based on whether the damage caused by the pollutant is more likely to occur during exposure to a high concentration for a short time (e.g., one hour), or to a comparatively lower average concentration over a longer period of time (e.g., 8 hours, 24 hours, or one year). For some pollutants there is more than one air quality standard, reflecting both its short-term and long-term effects. Table 2-1 below presents the national and state ambient air quality standards for selected pollutants.

2.2. BACKGROUND AIR QUALITY

The Project will be located within the City and County of Honolulu, which is among the four counties under the jurisdiction of the State of Hawaii Department of Health (HDOH) Clean Air Branch (CAB). The HDOH CAB acts as the regulatory agency for air pollution control in Honolulu and is the local agency empowered to regulate air pollutant emissions for the Project area.

The nearest monitor to the Project site is HDOH's Downtown Honolulu monitor at 1250 Punchbowl Street, 0.6 mile from the Project. PM_{10}, $PM_{2.5}$, SO_2, and CO are monitored at this location. Ozone is monitored at Sand Island, 1.1 miles from the Project. NO_2 concentrations are monitored at the Kapolei monitoring station at 2052 Lauwiliwili Street. Air quality data collected at these stations (the nearest monitoring stations to the Project site) for the regulated criteria pollutants during the years 2015 through 2017 are presented in Table 2-2. As shown by these data, air quality in the area never exceeded the short-term or long-term national or state standards for any criteria pollutant. The available air quality data indicates that in 2015, 2016, and 2017 (the latest year for which annual reports are available), excluding the exceedances on the island of Hawai'i due to the volcano, the State of Hawaii was in attainment of all NAAQS.

Table 2-1. National and State Ambient Air Quality Standards

Pollutant	Unit	Averaging Period	NAAQS	SAAQS
SO_2	ppb	1 hour	75[a]	--
	ppm	3 hours	0.5[b]	0.5
		24 hours	--	0.14
		1 year	--	0.03
CO	ppm	1 hour	35[c]	9
		8 hours	9[c]	4.4
NO_2	ppb	1 hour	100[d]	--
	ppm	1 year	0.053[c]	0.04
PM_{10}	µg/m³	24 hours	150[e]	150
		1 year	-- [f]	50
$PM_{2.5}$	µg/m³	24 hours (block avg.)	35[g]	--
		1 year	12.0[h]	--
		1 year	15.0[i]	--
O_3	ppm	8 hours (rolling avg.)	0.070[j]	0.08
Pb	µg/m³	3 months (rolling avg.) 3 months (calendar qtr)	0.15[k] --	-- 1.5
H_2S	ppm	1 hour	--	0.025

Notes:
a. The three-year average of the 99th percentile of 1-hour maximum daily concentrations must not exceed the level of the standard.
b. Federal Secondary Standard.
c. Not to be exceeded more than once per year.
d. The three-year average of the 98th percentile of 1-hour maximum daily concentrations must not exceed the level of the standard.
e. Not to be exceeded more than once per year on average over three years.
f. EPA revoked the annual PM_{10} standard effective December 17, 2006, due to a lack of evidence linking health problems to long-term exposure. The State still has an annual standard.
g. 98th percentile, averaged over three years.
h. Annual mean, averaged over three years.
i. Annual mean, averaged over three years. Secondary standard.
j. The three-year average of the fourth highest daily maximum value must not exceed the level of the standard.
k. Rolling three-month average may not exceed the level of the standard.

Under the provisions of the Federal Clean Air Act, the City and County of Honolulu is classified as in attainment with regards to the NAAQS.

3.1. DEMOLITION AND PROJECT CONSTRUCTION

3.1.1. Summary

Short-term emissions will be produced from activities related to Project construction, including demolition of the existing structures, site preparation, and building construction. These emissions will be short in duration so will not have long-term impacts on air quality. Construction emissions will result largely from off-road construction equipment activity and to a lesser extent, on-road motor vehicle trips to and from the proposed Project site. Emissions will also result from fugitive sources such as demolition, grading and road travel activities. This section describes a quantitative analysis of emissions during Project construction and resulting expected impacts on ambient air quality in the vicinity of the Project site. This analysis demonstrates that worst-case air quality impacts of Project construction, if built as proposed, are not expected to cause a significant air quality impact.

3.1.2. Analysis Methodology

The first phase of the Project will be the demolition of the existing two-story building that includes office, retail, and restaurant space, which is vacant. Demolition will involve the removal of the building, foundation, and parking lot, along with transport of the demolition materials to an offsite location where they can be disposed of.

Following the removal of all existing materials from the site, the construction phase will begin. Construction activities will include site preparation, construction of foundations, building construction and paving, and landscaping.

Fugitive dust emissions from the demolition and construction phases of the Project will result from the following activities:

- Demolition, excavation and grading at the Project site;
- Onsite travel on paved and unpaved roads and across the unpaved construction areas;
- Aggregate and soil loading and unloading operations;
- Raw material transfer to and from material stockpiles; and
- Wind erosion of areas disturbed during construction activities.

Engine exhaust will be emitted from the following sources:

- Heavy equipment used for demolition, excavation, grading, and construction of new and existing structures;
- Water trucks used to control dust emissions;
- Diesel- and gasoline-fueled welding machines, generators, air compressors, and water pumps;
- Gasoline-fueled pickup trucks and Diesel-fueled flatbed trucks used onsite to transport workers and materials around the Project site;
- Transport of mechanical and electrical equipment to the Project site; and
- Transport of raw materials to and from stockpiles.

The heavy construction equipment and other vehicles that will be used for this work (e.g., backhoes, cranes, trenchers, delivery and water trucks, etc.) will be powered by internal combustion engines that emit typical exhaust air pollutants. Because construction and demolition activities will take place over a relatively limited

period (less than two years), none of these equipment emissions is expected to add substantially to existing sources of these pollutants.

Excavation, grading, and trenching for the new Project requires the use of large diesel-fueled construction equipment. However, in the case of the proposed Project, the number of pieces of equipment operating at any one time in one location is relatively small. As a result, combustion emissions such as CO, NOx and particulate matter from this equipment are not expected to have a significant effect on air quality.

The soil disturbance caused by excavation, grading, and trenching work generates fugitive dust, which can have a more substantial (albeit temporary) effect on air quality than emissions from the engines themselves. The potential for adverse effects continues until the replacement vegetation has become established or material is placed over the exposed ground. To minimize this potential, HSR plans to limit the amount of grubbing, grading, and vegetation removal to the smallest amount possible, disturbing only the minimum area required (a total of 0.6 acres).

Specific information regarding the equipment that will be used for demolition/site preparation and Project construction will not be available until a construction contractor is selected. Consequently, overall construction emissions can only be estimated at this time. Equipment loadings and operational characteristics were taken from Appendix D of the CalEEMod model[1]. Emission factors were derived from U.S. EPA's MOVES model[2]. Estimated total emissions during demolition and Project construction are summarized in Table 3-1 below. Demolition and construction phase emissions by year are compared with total countywide emissions in Table 3-2 below. Details of the emissions calculations are provided in Appendix A.

HSR will require its contractor to implement the standard mitigation measures listed below, as well as whatever additional measures may be required by the construction-related permits that the contractor must obtain from the City and County of Honolulu.

- Maintain all construction equipment in accordance with manufacturer's specifications.
- Fuel all diesel-powered equipment, including but not limited to bulldozers, graders, cranes, loaders, scrapers, backhoes, generator sets, compressors, and auxiliary power units, with ultra-low sulfur motor vehicle diesel fuel.
- Minimize the extent of disturbed area as much as possible.
- Use water trucks as needed to minimize the amount of airborne dust leaving the site.
- Cover or continuously wet dirt stockpile areas containing more than 100 cubic yards of material to minimize the formation of windblown dust.

- Install construction fencing to minimize the transmission of windblown dust onto roadways and adjacent properties.
- Implement permanent dust control measures identified in the Project plans as soon as possible following completion of any soil disturbing activities.
- Limit vehicle speed for all construction vehicles moving on any unpaved surface at the construction site.
- Cover all trucks hauling dirt, sand, soil, or other loose materials.

The implementation of these mitigation measures will further minimize any potential air quality impacts during the construction phase of the proposed Project. As a result, impacts during Project construction are not expected to be significant.

3.2. OPERATIONAL EMISSIONS

3.2.1. Summary

Once the Project is constructed, its operational emissions and ambient air quality impacts will result largely from motor vehicle trips to and from the proposed facility. This section describes a "semi-quantitative" analysis of Project operational emissions and resulting expected impacts on ambient air quality in the vicinity of the Project site. This analysis demonstrates that worst-case air quality impacts of the Project, if built, would not be expected to cause or contribute to violations of the NAAQS or SAAQS.

3.2.2. Analysis Methodology and Results

Air quality dispersion models are often used to quantify airborne pollutant concentrations and ambient air quality impacts associated with emissions from a proposed project as dictated by ambient conditions and expected emission levels of the project. For this Project, the levels of motor vehicle activity (the primary operational emission source) in the vicinity of the Project were based on estimates from the Final Focused Mobility Analysis report[3] prepared by Fehr & Peers. These incremental vehicle travel levels were combined with vehicle emissions factors (emissions for each pollutant per mile of vehicle travel) using the U.S. Environmental Protection Agency's (EPA's) latest MOVES2014b vehicle emissions model to estimate incremental operational emissions for the Project.

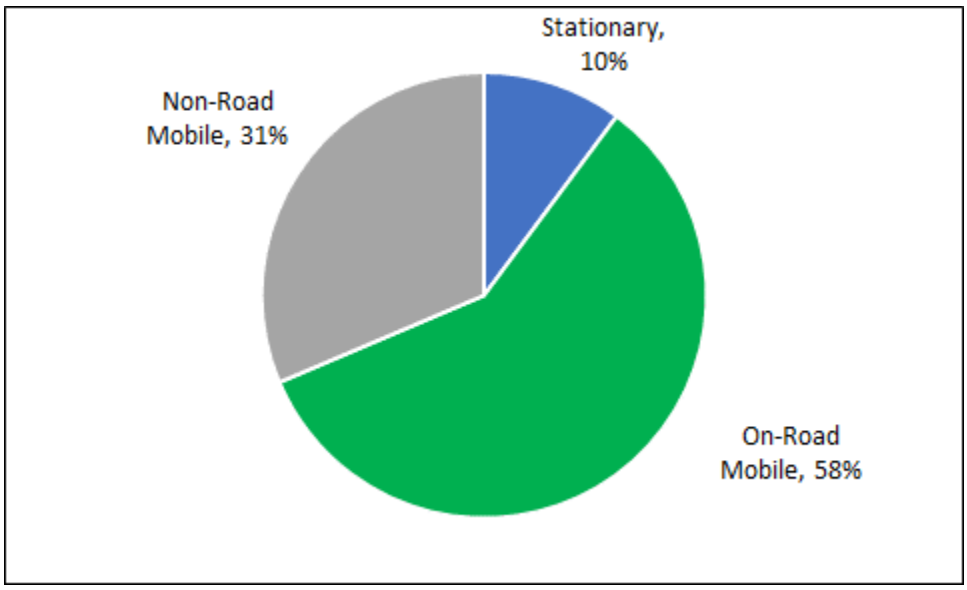
Table 3-3 shows the estimated incremental operational emissions from the Project due to motor vehicle trips to and from the proposed senior residences. The Project operational emissions assume an average trip length of 30 miles (which is conservatively high given the proximity of the Project to groceries, shopping, and restaurants; social, cultural, and medical facilities; and other resources/amenities; that the residences will be seniors; and that mass transit, including rail, is in walking distance from the Project) and reflect the 310 daily vehicle trips forecast by Fehr & Peers to be generated by the proposed Project. Table 3-3 also compares these incremental operational emissions to total 2020 vehicle emissions for the City and County of Honolulu, as projected by MOVES2014b. As shown in the rightmost column of Table 3-3, criteria pollutant emissions from Project operation are expected to be well below one tenth of one percent of total countywide vehicle emissions, so their impact on air quality is expected to be negligible.

[3] "Focused Mobility Analysis Report (MAR) for the Proposed Halewai`olu Senior Residences," Fehr & Peers, August 6, 2019.

Table 3-3. Project Vehicle Emissions and Comparison to Countywide Vehicle Emissions (Calendar Year 2020)

Pollutant	Project Traffic Emissions (tons/day)	City and County of Honolulu Vehicle Emissions (tons/day)	Relative Project Emissions (% of County total)
Volatile Organic Compounds (VOC)	0.0022	6.78	0.03%
Oxides of Nitrogen (NOx)	0.0015	11.83	0.01%
Carbon Monoxide (CO)	0.0325	89.05	0.04%
Fine Particulate Matter ($PM_{2.5}$)	0.0001	0.49	0.02%

To provide context for these incremental Project emissions and to assess the need to perform quantitative dispersion modeling, estimates of regional emissions (covering all source categories) and existing traffic levels were also compiled. In addition, ambient air quality monitoring data from the nearby station at the Hawaii Department of Health (HDOH) building were evaluated to determine whether the anticipated incremental Project operational emissions could be expected to cause violations of the NAAQS.



When dispersion modeling is conducted to evaluate ambient air quality impacts from projects for which the primary emission source is motor vehicles (which is the case for the Project), quantitative impacts are typically assessed only for carbon monoxide (CO). In some cases, especially when significant diesel vehicle activity is involved, particulate matter (PM) impacts are also evaluated through air quality modeling[4]. Project-related motor vehicle trips are expected to include few diesel vehicles; therefore, evaluation of Project impacts on PM is not required.

Figure 3-1 presents a breakdown of the key CO emission sources across the City and County of Honolulu. It was compiled for calendar year 2014 (the most recent year for which emissions data are available) from EPA's National Emission Inventory (NEI)[5]. As shown in Figure 3-1, roughly 90% of county-wide CO comes from mobile sources, with on-road motor vehicles contributing the greatest share. The on-road motor vehicle portion of emissions within downtown Honolulu where the proposed Project is located is even higher than that shown for the entire county, given the dense roadway network and traffic levels.

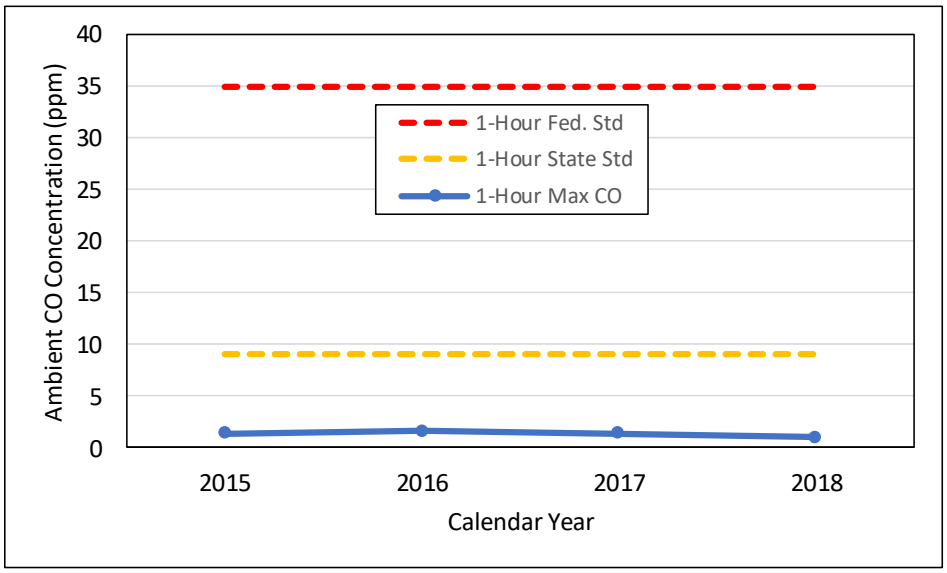
[4] Ozone impacts cannot be quantified for individual projects since it is not directly emitted, but forms in the atmosphere from "precursor" pollutants volatile organic carbon (VOC) and oxides of nitrogen (NOx) in the presence of sunlight. In addition, motor vehicles are not significant sources of two other criteria pollutants, sulfur dioxide or lead. Therefore, quantitative modeling for motor vehicle related project impacts are limited to CO and PM.

[5] https://www.epa.gov/air-emissions-inventories/2014-national-emissions-inventory-nei-data

Figure 3-1. Relative CO Emissions Contributions by Source Sector - City and County of Honolulu (2014 NEI)

As presented earlier in Table 2-2, ambient air quality levels in the Project area are well below the NAAQS for all criteria pollutants. The nearest ambient monitoring site for CO is located at the Hawaii Department of Health (HDOH) building on 1250 Punchbowl Street, only 0.6 miles to the southeast of the Project site in downtown Honolulu. Figure 3-2 and Figure 3-3 present maximum CO levels recorded at this monitor over the last four years and compare them to the federal and state 1-hour and 8-hour CO standards, respectively.

Figure 3-2. Peak Ambient 1-Hour CO Trends at Downtown Honolulu Monitor



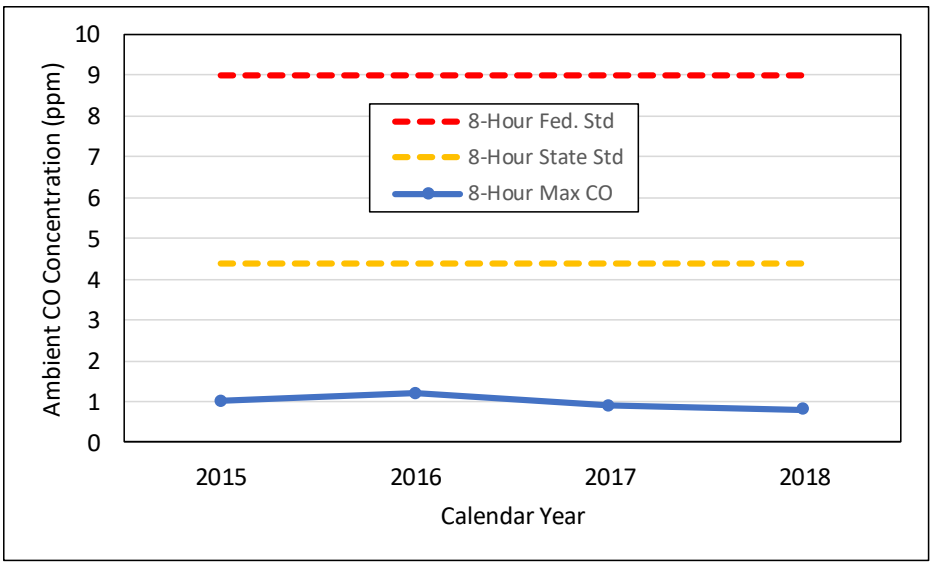


Figure 3-3. Peak Ambient 8-Hour CO Trends at Downtown Honolulu Monitor

As shown in both Figure 3-2 and Figure 3-3, maximum 1-hour and 8-hour average CO concentrations measured in downtown Honolulu over the most recent four years (2015-2018) are well below both the NAAQS (federal) and the state standards. Maximum 1-hour CO concentrations have been less than 5% and less than 18% of federal and state standards, respectively. Peak 8-hour CO concentrations over the last four years have been 13% or less of the federal standard and 27% or less of the state standard.

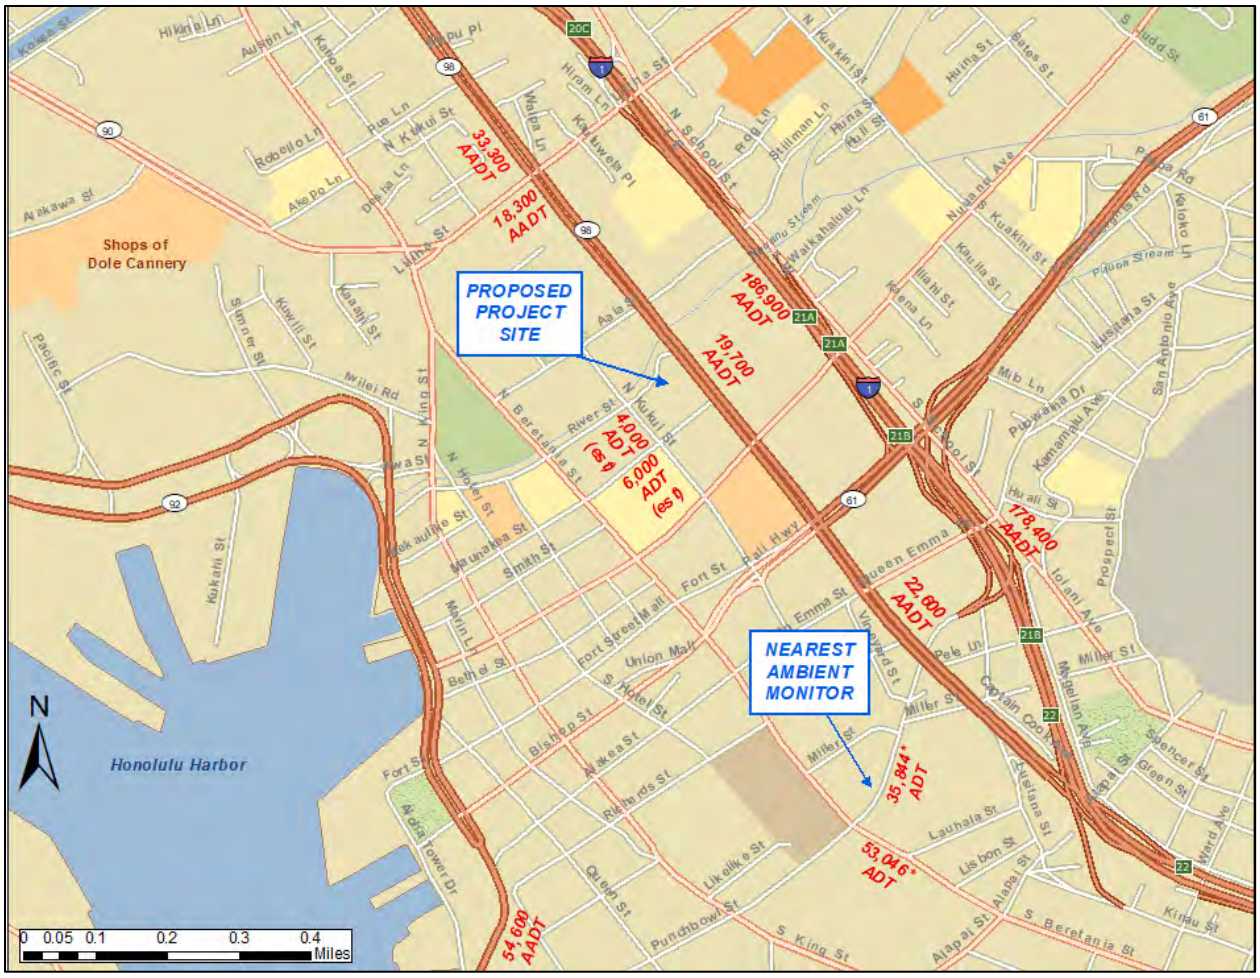
In accordance with EPA guidance, HDOH classifies the downtown Honolulu (1250 Punchbowl Street) monitor as a "Middle Scale" monitor for CO[6]. As defined for CO by EPA[7]:

> *Middle scale measurements are intended to represent areas with dimensions from 100 meters to 0.5 kilometer. In certain cases, middle scale measurements may apply to areas that have a total length of several kilometers, such as "line" emission source areas. This type of emission sources areas would include air quality along a commercially developed street or shopping plaza, freeway corridors, parking lots and feeder streets.* [emphasis added]

Based on this definition, it is reasonable to assume that monitored CO concentrations at the downtown monitor are representative of ambient concentrations at the Project site. To evaluate the spatial extent of the representativeness of the HDOH CO monitor, Figure 3-4 displays the location of both the proposed Project site and the downtown monitor (the nearest ambient CO monitor to the Project site) overlaid on a roadway system base map. Recalling that the dominant source of ambient CO is on-road motor vehicles (especially in high traffic areas such as downtown Honolulu), Figure 3-4 also identifies known existing daily traffic levels in the vicinity of the Project site and the ambient monitor. Traffic levels are shown alongside the roadway they represent. For example, average daily traffic (ADT) along Punchbowl Street near the HDOH monitor is 35,844 vehicles per day.

---

[6] "State of Hawaii 2018 Air Monitoring Network Plan," submitted to U.S. EPA Region 9 by State of Hawaii Department of Health, Document No. HDOH – AMNP – 2018 - v01, July 1, 2018. Available at https://health.hawaii.gov/cab/files/2018/05/2018-Air-Monitoring-Network-Plan.pdf



[7] https://epa.gov/ttnamti1/files/ambient/pm25/qa/vol2appe.doc

Traffic levels shown in Figure 3-4 were compiled from three sources:

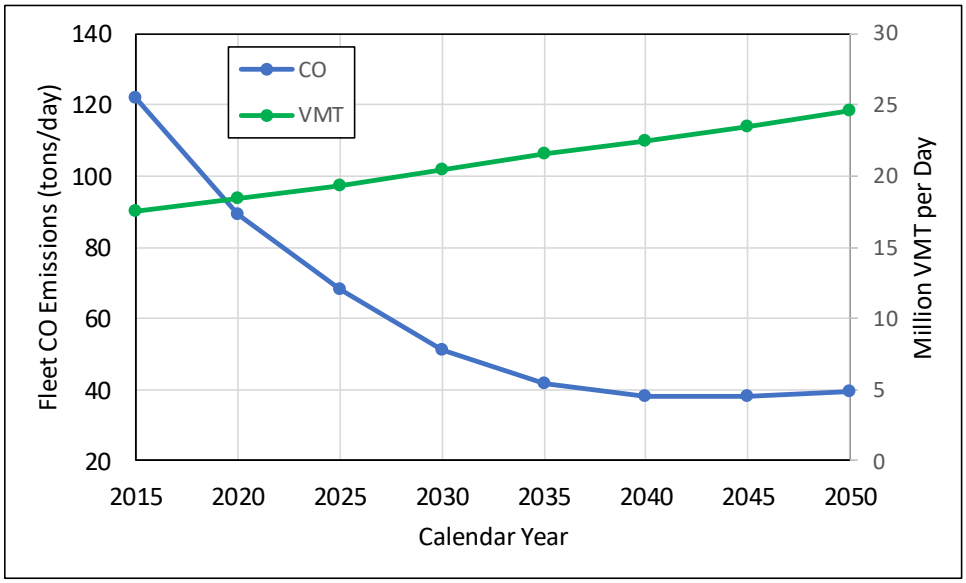
1) the Focused Mobility Analysis Report (MAR)3 (roads in vicinity of Project site);
2) the 2018 Air Network Plan6 (roads in vicinity of the HDOH monitor); and
3) the Hawaii Department of Transportation GIS-based traffic data portal[8].

The MAR-based traffic levels were estimated from peak hour counts collected by Fehr & Peers and projected to daily levels using a factor of 10 (1/0.1) based on a typical "K-Factor" value[9]. Daily traffic from the 2018 Air Network Plan near the monitor were based on 2006 traffic levels developed by the Hawaii Department of Transportation. These traffic data are denoted with an asterisk (*) in Figure 3-4. Finally, the remaining traffic levels shown in Figure 3-4 are based on 2017 Annual Average Daily Traffic (AADT) levels compiled by the Hawaii Department of Transportation.

Figure 3-4. Project Site and Nearby Ambient Monitor Location with Traffic Levels

[8] https://histategis.maps.arcgis.com/apps/MapSeries/index.html?appid=39e4d804242740a89d3fd0bc76d8d7de

[9] https://www.webpages.uidaho.edu/niatt_labmanual/Chapters/roadwaydesign/theoryandconcepts/DesignControlsAndCriteria.htm



A comparison of the traffic levels plotted in Figure 3-4 on the roads in the vicinity of both the Project site and the ambient monitor indicates that traffic (and therefore vehicle emissions) in the immediate area of the Project site is lower than that in the vicinity of the monitor. Traffic levels on along the Vineyard Blvd arterial corridor (shown as Highway 98 in Figure 4-4) are slightly lower near the Project site (19,700 AADT) than further southeastward where it intersects Punchbowl Street (22,600 AADT). Moreover, neighborhood street traffic along N Kukui Street (4,000 ADT) and Maunakea Street (6,000 ADT) near the Project site is much lower than that along Punchbowl Street (35,844 ADT) and Beretania Street (53,046 ADT) near the ambient monitor.

This spatial comparison of vehicle traffic levels coupled with the CO monitoring data presented earlier in Figure 3-2 and Figure 3-3 clearly indicate that existing ambient concentrations at the Project site can be conservatively represented by the HDOH monitor data and are likely to be lower than those recorded at the HDOH site. According to the Fehr & Peers MAR, the proposed Project is estimated to add only 310 daily vehicle trips (and up to 11 peak hour trips). This nominal increase in vehicle traffic will still result in total (existing plus Project) traffic levels in the vicinity of the Project site that remain significantly lower than those in the vicinity of the nearby HDOH ambient monitor, where peak measured CO concentrations are well below all applicable federal and state standards.

Therefore, dispersion modeling was not needed to confirm that worst-case pollutant concentrations in downtown Honolulu will clearly not cause violations of all applicable ambient air quality standards if the Project is built.

Finally, to demonstrate that the risk of violating ambient standards also decreases over time after the Project is built, Figure 3-5 presents trends in CO emissions over time developed for the City and County of Honolulu using EPA's MOVES2014b vehicle emissions model. As seen in Figure 3-5, vehicle CO emissions are projected to drop significantly in future years; emissions in 2050 are forecast to be over 50% lower than current (2020) levels.

Figure 3-5. MOVES2014b-Projected City and County of Honolulu Vehicle Fleet CO Emission Trends

This decrease is the result of the on-going effects of the federal motor vehicle and fuel control programs and is projected to significantly reduce overall fleet emissions over time, even with growth in travel (plotted as VMT on the right axis in Figure 3-5) at roughly 1% per year.

3.3. PUBLIC HEALTH IMPACTS

This section discusses potential impacts and public exposure associated with airborne emissions of hazardous air pollutants (HAPs) from the construction and operation of the proposed Project.

3.3.1. Types of Risks

Cancer risk is the probability or chance of contracting cancer over a human life span (assumed to be 70 years). Carcinogens are assumed to have no threshold below which there would be no human health impact. Any exposure to a carcinogen is assumed to have some probability of causing cancer: the lower the exposure, the lower the cancer risk.

Non-cancer health effects can be either long-term (chronic) or short-term (acute). In determining potential non cancer health risks from air toxics, it is assumed there is a dose of the TAC below which there would be no impact on human health. The air concentration corresponding to this dose is called the Reference Exposure Level (REL). Chronic toxicity is defined as adverse health effects from prolonged chemical exposure, caused by chemicals accumulating in the body. Because chemical accumulation to toxic levels typically occurs slowly, symptoms of chronic effects usually do not appear until long after exposure commences. The lowest no-effect chronic exposure level for a non-carcinogenic air toxic is the chronic REL. Below this threshold, the body is capable of eliminating or detoxifying the chemical rapidly enough to prevent its accumulation. Chronic RELs have been established for 8-hour and 1-year exposure periods. Acute toxicity is defined as adverse health effects caused by a brief chemical exposure of no more than 24 hours. For most chemicals, the air concentration required to produce acute effects is higher than the level required to produce chronic effects because the duration of exposure is shorter.

3.3.2. Health Impacts from the Project

Emissions of HAPs during demolition and construction will consist of combustion emissions from diesel fuel in construction equipment (e.g., cranes, dozers, excavators, graders, front-end loaders, backhoes). The discussion of construction impacts in Section 1.7.1 indicates that emissions of all pollutants during construction are expected be minimal and to last for a short time. No significant public health effects are expected during construction. Strict construction practices that incorporate safety and compliance with applicable laws, regulations, ordinances and standards will be followed. In addition, mitigation measures to reduce air emissions from construction impacts will be implemented as described above.

4.1. GREENHOUSE GAS EMISSIONS AND CLIMATE CHANGE SETTING

Global climate change refers to change in average meteorological conditions on the earth with respect to temperature, precipitation, and storms, lasting for decades or longer. The term "global climate change" is often used interchangeably with the term "global warming," but "global climate change" is preferred by some scientists and policy makers to "global warming" because it helps convey the notion that in addition to rising temperatures, other changes in global climate may occur. Climate change may result from the following influences:

- Natural factors, such as changes in the sun's intensity or slow changes in the Earth's orbit around the sun;
- Natural processes within the climate system (e.g., changes in ocean circulation); and/or
- Human activities that change the atmosphere's composition (e.g., through burning fossil fuels) and the land surface (e.g., deforestation, reforestation, urbanization, and desertification).

There is a general scientific consensus that global climate change is occurring, caused to some degree by increased emissions of greenhouse gases (GHGs) that keep the Earth's surface warm by trapping heat in the Earth's atmosphere. This trapped radiation warms the atmosphere, the oceans, and the earth's surface[10]. While many studies show evidence of warming over the last century and predict future global warming, the precise causes of such warming and its potential effects are far less certain[11]. In its "natural" condition, the greenhouse effect is responsible for maintaining a habitable climate on Earth, but human activity has caused increased concentrations of these gases in the atmosphere, thereby contributing to an increase in global temperatures.

As determined from worldwide meteorological measurements between 1990 and 2005, the primary observed effect of global climate change has been a rise in the average global tropospheric[12] temperature of 0.36 degrees Fahrenheit (°F) per decade. Climate change modeling shows that further warming could occur, which could induce additional changes in the global climate system during the current century. Changes to the global climate system, ecosystems, and the environment of Hawaii could include higher sea levels, drier or wetter weather, changes in ocean salinity, changes in wind patterns or more energetic aspects of extreme weather (e.g., droughts, heavy precipitation, heat waves, extreme cold, and increased intensity of tropical hurricanes).

4.1.1. Greenhouse Gases

Human activities, including fossil fuel combustion and land use changes, release CO_2 and other compounds cumulatively termed greenhouse gases. GHGs are effective at trapping radiation that would otherwise escape the atmosphere. Many scientists believe "most of the warming observed over the last 50 years is attributable to

[10] United States Global Change Research Program (USGCRP). 2014. Climate Change Impacts in the United States: The Third National Climate Assessment. Available at http://nca2014.globalchange.gov/.

[11] https://archive.epa.gov/epa/climate-change-science/future-climate-change.html

[12] The troposphere is the zone of the atmosphere characterized by water vapor, weather, winds, and decreasing temperature with increasing altitude.

human activities."[13] The increased amount of CO_2 and other GHGs in the atmosphere is the alleged primary cause of human-induced warming.

The most important GHGs directly emitted by humans include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and several others. CO_2 is the primary greenhouse gas that is contributing to recent climate change. CO2 is absorbed and emitted naturally as part of the carbon cycle, through plant and animal respiration, volcanic eruptions, and ocean-atmosphere exchange. Human activities, such as the burning of fossil fuels and changes in land use, release large amounts of CO_2, causing concentrations in the atmosphere to rise. Carbon dioxide is removed from the atmosphere (or "sequestered") when it is absorbed by plants as part of the biological carbon cycle.

Methane is produced through both natural and human activities. For example, natural wetlands, agricultural activities, and fossil fuel extraction and transport all emit CH_4. Nitrous oxide is produced through natural and human activities, mainly through agricultural activities and natural biological processes. Fuel burning and some other processes also create N_2O. Chlorofluorocarbons (CFCs), hydrochlorofluorocarbons (HCFCs), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6), together called fluorinated gases, are often used in coolants, foaming agents, fire extinguishers, solvents, pesticides, and aerosol propellants. These fluorinated gases have a long atmospheric lifetime, and some of these emissions will affect the climate for many decades or centuries. GHGs vary considerably in terms of Global Warming Potential (GWP), the comparative ability of each GHG to trap heat in the atmosphere. The GWP is based on several factors, including the relative effectiveness of a gas to absorb infrared radiation and the length of time that the gas remains in the atmosphere ("atmospheric lifetime"). The GWP of each gas is measured relative to CO_2, the most abundant GHG. The definition of GWP for a particular GHG is the ratio of heat trapped by one unit mass of the GHG to the ratio of heat trapped by one unit mass of CO_2 over a specified time period.

4.1.2. Anthropogenic Greenhouse Gas Emissions

The effect each GHG has on climate change is measured as a combination of the quantity of its emissions and its global warming potential and is expressed in terms of how much warming would be caused by the same mass of CO_2. Thus, GHG emissions are typically expressed in terms of pounds or tons of CO_2 equivalents (CO_2e).

4.1.2.1. Global GHG Emissions

Worldwide emissions of GHGs in 2017 were 36.2 gigatonnes (Gt) of CO_2e per year (including emissions from industrial and agricultural sources but excluding emissions from land-use changes).[14]

4.1.2.2. US GHG Emissions

In 2017, sources in the United States emitted about 6.5 Gt of CO_2e, or approximately 25 tons per year (tpy) per person. Over 80 percent of these emissions were CO_2 and about 10% were methane[15]. Of the six major types of

[15] U.S. EPA, "Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2017," available at https://www.epa.gov/sites/production/files/2019-04/documents/us-ghg-inventory-2019-chapter-executive-summary.pdf

sources nationwide (electric power industry, transportation, industry, agriculture, commercial, and residential), the electric power industry and transportation sectors combined account for approximately 62% of the GHG emissions. The majority of the electrical power industry and all of the transportation emissions are generated from direct fossil fuel combustion.

4.1.2.3. GHG Emissions in Hawaii

As of January 2015, the state of Hawaii reported statewide emissions from all sources of 20.2 million metric tons of CO_2e[16]. The majority of these emissions result from energy use, with transportation being the largest contributor. Oahu's 2016 inventory shows about 14.9 million metric tons of CO_2e[17].

4.1.3. Regulatory Programs

GHG emissions are regulated federally through several regulatory programs, including U.S. EPA's fuel economy standards for mobile sources and New Source Review permitting requirements and New Source Performance Standards, and mandatory GHG emissions reporting for certain types of stationary sources.

The state of Hawaii established a Hawaii GHG Program in 2007, with the goal of reducing emissions from stationary sources to 1990 levels by 2020. Hawaii's stationary source permitting program includes requirements for quantification, evaluation and reporting of GHG emissions from large sources of emissions.

The City and County of Honolulu is in the process of developing a Climate Action Plan, with the goals of combating climate change and eliminating fossil fuel emissions to achieve a carbon neutral economy and 100% renewable energy use by 2045.

4.2. GREENHOUSE GAS EMISSIONS AND CLIMATE CHANGE IMPACTS

4.2.1. Project Activities Producing GHG Emissions

Construction and operation of the proposed Project would generate GHG emissions. However, the Project's contribution to total GHG emissions in the City and County of Honolulu is expected to be insignificant, as discussed further below.

Overall, the following activities associated with a typical residential development could contribute to the generation of GHG emissions:

- **Removal of Vegetation**. The net removal of vegetation for construction results in a loss of the carbon sequestration in plants. However, the property on which the Project will be located is already developed, so the Project is expected to have minimal to no vegetation removal. In addition, HSR intends to plant additional vegetation which will result in additional carbon sequestration and lower the carbon footprint of the Project.

---

[16] Hawaii State Department of Health, "Hawaii Greenhouse Gas Emissions Report for 2015," January 2019. Available at https://health.hawaii.gov/cab/files/2019/02/2015-Inventory_Final-Report_January-2019-004-1.pdf

[17] City and County of Honolulu, Office of Climate Change, Sustainability and Resiliency, 2016 Greenhouse Gas Emissions. Available at https://www.resilientoahu.org/2016-inventory

- **Construction Activities**. Construction equipment typically uses fossil-based fuels to operate. The combustion of fossil-based fuels creates GHGs such as carbon dioxide, methane and nitrous oxide.

- **Gas, Electric and Water Use**. Natural gas use results in the emissions of two GHGs: methane (the major component of natural gas) and carbon dioxide from the combustion of natural gas. Methane is released prior to initiation of combustion of the natural gas (as before a flame on a stove is sparked), and from the small amount of methane that is not combusted in a natural gas flame. Although Honolulu is striving to achieve 100% renewable energy use by 2045, most of the island's electricity is still generated by burning fossil fuels. Potable water and wastewater also require energy for supply and treatment.

- **Motor Vehicle Use**. Transportation associated with the proposed Project would result in GHG emissions from the combustion of fossil fuels in daily automobile and truck trips.

4.2.2. Estimated GHG Emissions from the Proposed Project

This section evaluates the emissions of greenhouse gases that may result from implementation of the proposed Project.

- **Construction**. Construction would produce combustion emissions from various sources. During site preparation and construction of the Project, GHGs would be emitted through the operation of construction equipment and from worker and builder supply vendor vehicles, each of which typically use fossil-based fuels to operate. Using the methodology described in Section 1.7.1, it is estimated that the total Project construction emissions would be approximately 1,338 metric tons of CO2e. Details of the calculations are provided in Appendix A.

  Architectural coatings used in construction of the proposed Project may contain volatile organic compounds (VOCs) that are ozone precursors. However, there are no significant emissions of GHGs from architectural coatings.

- **Transportation**. Transportation associated with the Project would result in GHG emissions from the combustion of fossil fuels in daily automobile and truck trips. Transportation is the largest source of GHG emissions in Honolulu. For land use development projects, vehicle miles traveled (VMT) and vehicle trips are the most direct indicators of GHG emissions associated with the Project. As discussed in Section 1.7.2, the VMT generated by the proposed Project are expected to be minimal, resulting in an increase in approximately 4 tons per day of CO2e, or approximately 0.04% of total countywide CO2e from motor vehicles. Details of the calculations are provided in Appendix B.

- **Electricity and Natural Gas**. Buildings represent 39 percent of United States primary energy use and 70 percent of electricity consumption. However, residential energy use accounted for less than 10% of county-wide GHG emissions in 2016. The overall impact of the electricity and natural gas use in the proposed Project is expected to be insignificant.

- **Water and Wastewater**. Energy use and related GHG emissions are based on water supply and conveyance, water treatment, water distribution, and wastewater treatment. Each element of the water use cycle has unique energy intensities (kilowatt hours [kWh]/million gallons). Water usage and wastewater generation accounted for less than one percent of county-wide GHG emissions in Honolulu in 2016. The overall impact of the water and wastewater-related energy use for the proposed Project is expected to be insignificant.

- **Solid Waste Disposal**. Solid waste generated by the Project could contribute to GHG emissions in a variety of ways. Landfilling and other methods of disposal use energy for transporting and managing the waste and they produce additional GHGs to varying degrees. Landfilling, the most common waste management practice, results in the release of CH4 from the anaerobic decomposition of organic materials. CH4 is 25 times more potent a GHG than CO2. However, landfill CH4 can also be a source of energy. In the City and County of Honolulu, all the waste collected from residential and commercial locations is used as fuel in the City's waste-to-energy plant[18]. As a result, the amount of GHGs generated by the Project through solid waste disposal is expected to be minimal.

It is likely that as a result of moving to the Project, the senior residents of the Project will have shorter travel distances; require fewer vehicle trips; walk or use public transit more often, instead of driving; or use overall less energy by virtue of the Project's location in close proximity to groceries, shopping, restaurants, social, cultural, medical and other resources/amenities, and mass transit, including rail the future rail line. If these types of changes occur, overall vehicle miles traveled could be reduced as a result of the Project, and it could be argued that the Project would result in a potential net reduction in GHG emissions, locally and globally.

Finally, the Project has been designed to meet stringent LEED (Leadership in Energy and Environmental Design) standards and is currently in the certification process. LEED-certified buildings are recognized as saving energy, water, and resources and generating less waste than buildings that are not designed and built to LEED standards, and this design approach enhances the Project's sustainability. Overall, the proposed Project's cumulative greenhouse gas emissions contribution would not be significant.

APPENDIX A: DEMOLITION AND CONSTRUCTION PHASE EMISSION CALCULATIONS

Emissions estimates for demolition and construction activities are made up of two parts: activity rates and emission factors. The activity rate is a measure of the activity that produces the emissions per unit of time, such as the number of miles driven in a month, the gallons of fuel combusted in an hour, or the hours of equipment operation in a year. The emission rate is a measure of the emissions produced by each unit of activity. Emission rates are developed in any number of ways. They may be directly measured or monitored, generated using mass balance or computer models, estimated based on measured data from similar sources or processes, or taken from published studies.

Activity Rates

There are three components of emissions estimates for demolition and construction emissions: off-road vehicle exhaust, on-road vehicle exhaust, and fugitive particulates. Activity rates for off-road and on-road vehicles[19] were estimated using California Emissions Estimator Model® (CalEEMod). CalEEMod is a land use emissions computer model designed to provide a uniform platform for government agencies, land use planners, and environmental professionals to quantify potential criteria pollutant and greenhouse gas (GHG) emissions associated with both construction and operations from a variety of land use projects. CalEEMod utilizes default construction equipment loading data that is not specific to California, which can be used when site-specific information is not available for a project. The model also uses California-specific emission factors that are appropriate for use in projects located within California. However, since this Project is not located in California, only the equipment loading portion of the model was used to produce activity rates for this study. Activity rates for off-road and on-road vehicles are shown in Tables A-1 and A-2 below.

Fugitive PM_{10} and $PM_{2.5}$ emissions occur from demolition activities (building demolition and debris loading), grading activities (grading dust, bulldozing, and truck loading), and road travel on unpaved and paved roads. The activity rates developed for on-road and off-road equipment activity were also used to estimate activity rates for use in calculating fugitive particulate emissions.

Emission Factors

Emission factors for off-road and on-road equipment exhaust were developed using Motor Vehicle Emissions Simulator (MOVES2014b). MOVES2014b produces estimates for total activity, total emissions, and equipment properties in Oahu County (based on the engine size, load factor, and number of pieces of each type of equipment as developed using CalEEMod). These estimates were used to estimate emission rates in terms of g/hp-hr. All off-road construction equipment was modeled as diesel except for welders, which were modeled as gasoline. The emission rates for off-road equipment are shown in Table A-3. These emission factors were used in conjunction with the estimated construction equipment and schedule (shown in Table A-1) to calculate the construction equipment emissions.

[19] Off-road vehicles include most construction equipment that is not designed to operate upon a public roadway, while on-road vehicles include conventional trucks (such as pickup trucks, delivery vans, cement mixer trucks and water trucks) that are primarily driven on public roads. Off-road vehicles are not required to meet the same stringent exhaust emission standards that apply to on-road vehicles, so emissions estimates for the two types of vehicles are developed separately.

Appendix Table A-1. Estimated Construction Equipment and Schedule

Phase	Equipment Type	Number of Units	Const. Days 2020	Const. Days 2021	Const. Days 2022	Hrs/Day
Demolition	Concrete/Industrial Saws	1	30	0	0	8

Appendix Table A-2. Estimated On-Road Motor Vehicle Trips and Trip Distance

Vehicle Type*	Demolition trips/day	Site Prep trips/day	Grading trips/day	Building trips/day	Paving trips/day	Coating trips/day	Distance miles/trip
LD	13	8	8	121	13	24	12
HDT	6	6	10	20	0	0	10
HHDT	48	0	14	0	0	0	27

Note:
* LD – Light Duty Vehicles / HDT – Heavy Duty Trucks / HHDT – Heavy Heavy Duty Trucks

MOVES2014b was also used to estimate emission rates for construction-related on-road motor vehicle trips using estimated trip counts and distances. These estimates were used to estimate emission rates in terms of g/mile, as shown in Table A-4. The emission rates included off-network (start emissions) as well as running emissions. PM_{10} and $PM_{2.5}$ emissions from brake wear and tire wear were also calculated using MOVES2014b. The emission rates were used in conjunction with the estimated vehicle trips and distances (shown in Table A-2) to calculate the construction on-road motor vehicle trip emissions.

Building demolition and debris loading were calculated using the square footage of the buildings to be demolished with emission factors and equations from the *Midwest Research Institute – Gap Filling PM_{10} Emission*

Factors for Selected Open Area Dust Sources, 1988. Grading dust and bulldozing emissions were calculated using acres to be graded and bulldozer operating hours with emission factors and equations from *AP-42 Section 11.9*[20]. Truck loading emissions were calculated using the volume of soil to be exported with emission factors and equations from *AP-42 Section 13.2*. Paved and unpaved road travel fugitive emissions were calculated using vehicle miles traveled with emission factors and equations from *AP-42 Section 13.2.1 and 13.2.2*. Fugitive emissions will be mitigated by watering at least three times a day, which is expected to reduce fugitive dust emissions by at least sixty-one percent. Details of the fugitive emissions calculations are shown in Tables A-5, A-6 and A-7.

Appendix Table A-3. Emission Factors and Assumptions for Off-Road Construction and Demolition Equipment

Off-Road Equipment Type	Horsepower Rating	Load Factor	Emission Rates (g/hp-hr)						
			VOC/ROG	CO	NOx	SOx	CO_2	PM_{10}	$PM_{2.5}$

Welders	46	0.45	1.80	35.71	3.02	0.01	1532.89	0.15	0.14

Notes:

a. MOVES2014b was run in the Nonroad scale to estimate emission rates for the construction equipment.

- MOVES produces estimates for total activity, total emissions, and equipment properties in the City and County of Honolulu (engine size, load factor, number of equipment).
- These results are used to estimate emission rates (shown in the Nonroad Emission Rates worksheet), in terms of g/hp-hr.
- Only the activity for the HP bin that included the engine size to be modeled was included.
- All Nonroad Equipment were Diesel except welders, which were modeled as gasoline. (Air compressors can be ignored if modeled as electric.)

b. The emissions for construction equipment are multiplied by the average engine size and the load factor to estimate g/hr emission rates.

1. BACKGROUND

Halewai'olu Senior Development, LLC ("HSR") is proposing to construct and operate a 17-story, 156-unit senior rental housing facility in the Chinatown area of Honolulu ("Project"). The new 17-story building will replace an existing two-story building.

Immediately south of the proposed Project is the Borthwick Mortuary, which includes a crematorium with two double-chambered incinerators. Pursuant to Hawaii Administrative Rules (HAR), Chapter 11-60.1, "Air Pollution Control", the Hawaii Department of Health (HDOH), Clean Air Branch requires that crematories in the state obtain an Air Pollution Control Permit, for which the Borthwick Mortuary complies (Air Pollution Control - Noncovered Source Permit No. 0422-01-N). The HDOH has reportedly received complaints about crematorium nuisances such as occasional odors, ash and smoke from occupants of nearby buildings in the past, however, with crematorium's two chamber incinerator process there should be no nuisance level odors, ash or smoke from the crematorium stacks if operating in compliance with its HDOH permit conditions. If a nuisance level odor, ash or smoke is present, the incineration process is not working correctly and should be addressed by the crematorium to bring the incineration process back into compliance. Based on public records available for review, the crematorium has apparently not received any violations for their cremation process and stack emissions. It is expected that the crematorium will continue to operate within their permitted levels and should not be a source of nuisance level odor, ash or smoke.

Comments received from nearby community members have raised concerns about what effects the proposed building may have on their sites as well as on potential future residents of the Project site. In order to address these concerns, an assessment was conducted to determine whether the construction of the Project would be likely to alter wind flow in the Project area in a manner that would increase pollutant concentrations and result in potentially increased odors, ash or smoke at nearby sensitive receptors and on the Project site.

2. RESULTS

Potential emission concentration impacts were assessed at the Project site and six potential historic locations adjacent to the Project area: Lum Sai Ho Tong, Mun Lun School, Chinese Cultural Plaza, Izumo Taishakyo Mission, Kuan Yin Temple, and Foster Botanical Garden.

Section 3 of this assessment details the technical methodology used to determine the impacts construction of the proposed 17-story building would pose on wind patterns in the immediate area and how these impacts might increase or change the concentration of emissions from the crematorium at receptor points near and on the Project site.

The assessment found that with the Project fully constructed, potential emission concentration impacts from the crematorium stacks to nearby communities were *reduced* at four of the locations and were *unaffected* at two of the locations. Based on these results, it may be concluded that odor, ash and smoke at nearby communities would be reduced or remain the same with the Project fully built. As such, it could be concluded that the construction of the proposed Project would pose no change to current conditions at nearby receptors and may even *improve* conditions at as many as four of the locations modeled.

Some post-project elevated residential receptors at the Project site would have potentially increased emission concentrations when compared to pre-project ground level receptors, but this would occur only if the crematorium were not operating within HDOH permit parameters. Only 18 of the 156 proposed units would have an increase potential of at least 1.5 times the pre-project ground level concentrations, with a maximum increase of a unit at 4.27 times higher. However, these concentrations are based on being outside; these units will not have balconies and will have filtered air-conditioning units installed which would enable residents to close their windows during warmer temperatures.

Finally, and as stated in Section 1 above, the crematorium is required to operate according to their permitted conditions which are designed to prevent nuisance-level odors, ash and smoke from reaching off-site receptors. Therefore, it can be concluded that construction and operation of the proposed Project will have a less than significant impact on the Project site as well as on nearby receptors based on potential nuisances from the nearby crematorium stack emissions. Future occupants of the Project site should not be adversely affected by the crematorium's operation, provided that the Borthwick facility is operated as permitted by the HDOH.

3. STUDY METHOD

Potential nuisance impacts associated with the Project were assessed by modeling pollutant concentrations from incinerator emissions at the nearby Borthwick Mortuary crematorium. The Project site and six locations adjacent to the Project area were modeled to determine how the crematorium's emissions are currently dispersed (without the Project building present) and how they would be dispersed with the Project building constructed. The dispersion model was run twice: once in the pre-Project configuration and once in the post-Project configuration. The resulting change in modeled concentrations was used to determine if the Project building would be expected to cause or contribute to an increase in emissions concentrations that would impact reported nuisance experienced at the specific study locations.

The modeling was performed using the most recent version of the U.S. Environmental Protection Agency's (EPA's) AMS/EPA Regulatory Model – AERMOD (recompiled for Lakes ISC-AERMOD View 9.6.5 (interface). The AERMOD dispersion model is used throughout the United States for ambient air quality impact and health risk assessments to predict the areas where various airborne constituents may be dispersed from a given source. The analysis employed all of the regulatory default AERMOD model keyword parameters, including elevated terrain options.

The goal of this analysis was to determine how the presence of the Project building would be expected to impact emission concentrations in the adjacent area. Therefore, specific pollutant emissions rates were not necessary and unit emission rates were used to determine the effects of the new structure on localized concentrations. A unit emission rate of 1 gram per second was used for both incinerators at the nearby mortuary.

Both models consisted of two point sources representing the mortuary's two incinerators, each with 8.78-meter stack height, 0.5-meter stack diameters, 900 degrees Kelvin exhaust temperature, and exit velocities of 5.6 meters per second.[1] These values represent the operating parameters as permitted by the HDOH. Both models included the two buildings located on the Borthwick property and a building representing the Lum Sai Ho Tong, all of which have the ability to affect the dispersion of emissions from the incinerators. The pre-Project model (Figure 3-1) included the existing 2-story building on the Project site, while in the post-Project model (Figure 3-2) the existing 2-story building was replaced by the new Project structure. All of these buildings have the potential to affect the dispersion of emissions from the incinerators.

[1] Borthwick Mortuary Permit Application - Modification to Existing Permit #P-475-1501 dated 5-19-98.

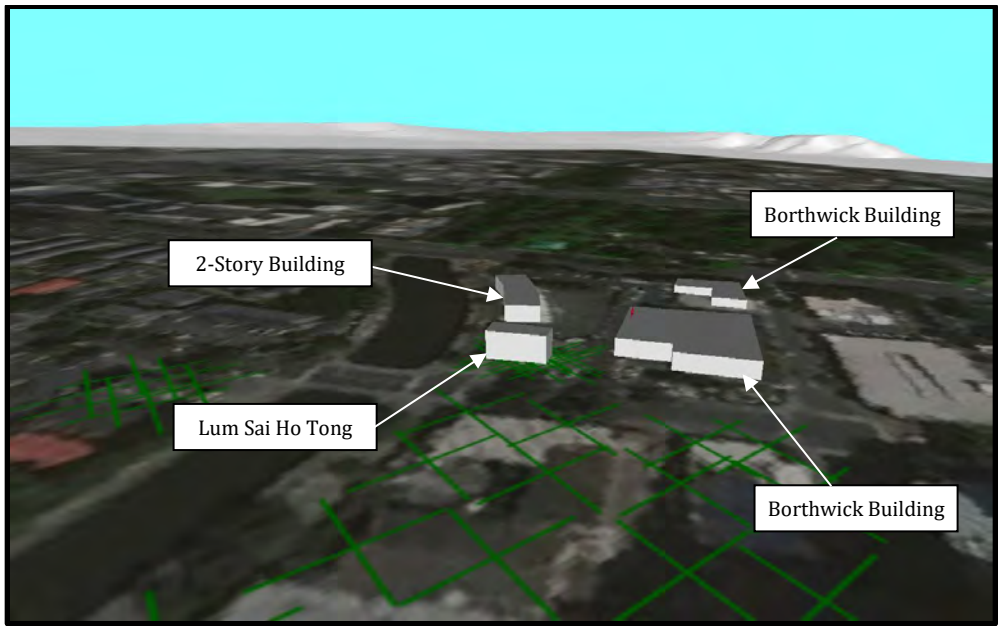

Figure 3-1: Pre-Project Model 3-D Rendering

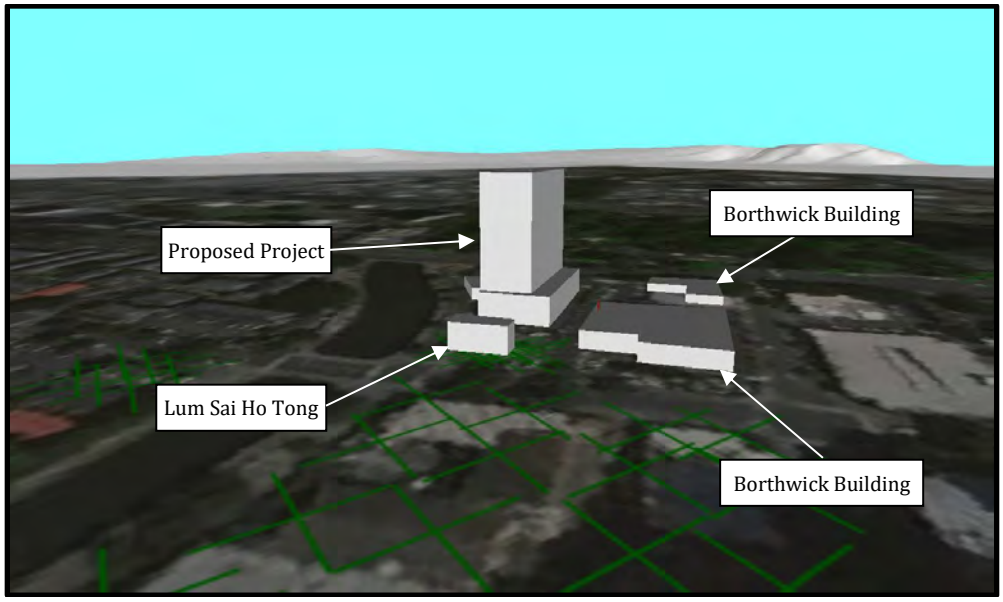

Figure 3-2: Post-Project Model 3-D Rendering

A five-year meteorological dataset for the Honolulu Airport monitoring station, representing calendar years 2012 through 2016, was processed using AERMET with the U-Star option and used with AERMOD. Figure 3-3 is a wind rose that displays the distribution of wind directions and speeds in the meteorological dataset. The wind rose shows that the prevailing winds in the project area are trade winds, which are predominantly from the northeast.

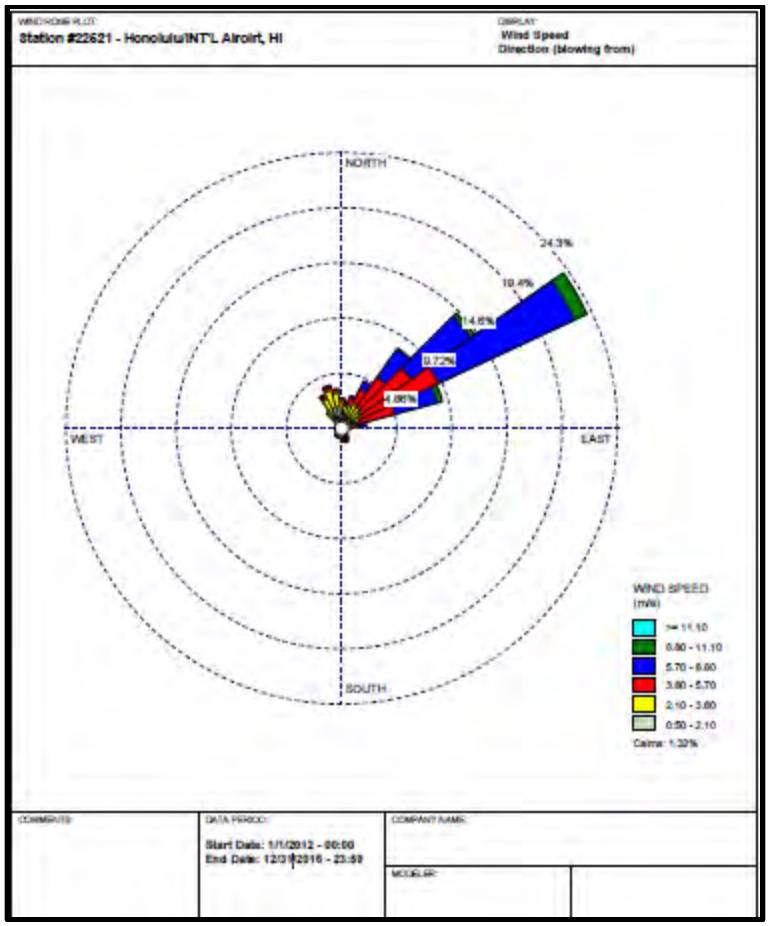

Figure 3-3: Five Year (2012-2016) Met Data Set Wind Rose

Seventy-six (76) discrete receptors were modeled at six potential historic locations adjacent to the Project area: Lum Sai Ho Tong, Mun Lun School, Chinese Cultural Plaza, Izumo Taishakyo Mission, Kuan Yin Temple, and Foster Botanical Garden (Figure 3-4). The pre-project configuration modeled twenty (20) ground level receptors and the post-Project configuration modeled 176 elevated and ground level receptors at the Project site.

Figure 3-4: Discrete Receptors

For each receptor a 1-hour average concentration was modeled and converted into a 10-minute concentration using a 1.65 factor based on the Duffee, O'Brien and Ostojic (1991) stability dependent formula ($C_1 = C_0 \times (t_0/t_1)^n$) to convert modelled values to alternative averaging times and using an average stability class exponent of 0.28.[2] The pre- and post-Project concentrations at each of the six locations are compared in **Table 3-1**.

As demonstrated in **Table 3-1**, each of the nearby locations is either not affected or experiences reduced concentrations as a result of the presence of the Project's building. Therefore, it can be concluded that the Project can be expected to have an overall net benefit to nuisance impacts in the local area.

Table 3-1: **Maximum Modeled Concentrations**

Location	Pre-Project Concentrations 10-min (µg/m³)	Post-Project Concentrations 10-min (µg/m³)	Project Impact 10-min (µg/m³)
Lum Sai Ho Tong	1,934	1,411	-523
Mun Lun School	1,195	939	-256
Chinese Cultural Plaza	1,020	1,020	0
Izumo Taishakyo Mission	750	680	-70
Kuan Yin Temple	693	575	-118
Foster Botanical Garden	1,005	1,005	0
Project Site	1,186	5,068	3,882

[2] Ten-minute concentrations were conservatively evaluated in this odor analyses since Honolulu does not currently have an odor significance threshold. Odor significance thresholds are typically evaluated on time interval concentrations ranges anywhere from 2-minutes to 1-hour.

Executive Summary

The proposed project is a 17-story senior (age-restricted), affordable apartment tower located in the Chinatown neighborhood of Downtown Honolulu, on River Street, between N Vineyard Boulevard and N Kukui Street. The building will consist of 13 residential floors above a four-story parking podium containing a first floor with a lobby, social activities center (SAC), small commercial space, second and third floors of parking, and a fourth floor recreation deck. The residential component will include 155 age-restricted dwelling units and one resident manager unit. 26 of the units will be two-bedrooms. The new residential use will replace an existing primarily vacant two-story building which leased to office, retail, and restaurant space.

The project site plan illustrates the main project driveway on River Street. As River Street is a one-way roadway, vehicles entering the site will utilize N Kukui Street, and vehicles exiting the site will utilize Diamond Head-bound N. Vineyard Boulevard to access other local and regional roadways.

This focused mobility analysis report analyzed the existing operations of two intersections, estimated project trip generation, reviewed site access, and considered the project's potential impacts on pedestrian, bicycle, and transit modes.

This analysis studied two intersections in the project area: Kukui Street/Maunakea Street and Kukui Street/River Street. The existing conditions at both intersections were analyzed using standard traffic engineering methodologies described in the Highway Capacity Manual (HCM). Both intersections function at LOS C or better during the AM and PM peak hours. Both the City and County of Honolulu (C&CH) and the Hawaii Department of Transportation strive for LOS D or better roadway operations where feasible.

The project is estimated to generate 310 net new daily vehicle trips, 5 net new AM peak hour trips (0 inbound/5 outbound), and 11 net new PM peak hour trips (3 inbound/8 outbound). Due to the very low peak hour trip generation, the impact of the addition of project traffic on the surrounding roadway network was not analyzed since any change in traffic operations would be negligible.

The project will not result in any significant impacts to existing or planned pedestrian, bicycle, or transit modes.

1. Introduction

This focused mobility analysis presents the results of the study conducted by Fehr & Peers for the proposed Halewaiolu Senior Residences in the Chinatown neighborhood of the City and County of Honolulu (C&CH) on the island of Oahu. The project site is located on the Diamond Head side of River Street mauka of N Kukui Street and makai of N Vineyard Boulevard. The adjacent roadways are under the jurisdiction of the Highways Division of HDOT (N. Vineyard Boulevard) and the C&CH. This analysis was conducted in accordance with the guidelines and standards of both the C&CH Department of Planning & Permitting (DPP) Traffic Review Branch (TRB) and Department of Transportation Services (DTS), as well as the State of Hawaii Department of Transportation – Highways Division (HDOT). The analysis addresses potential project impacts to all travel modes.

1.1 Project Description

The proposed project is a 17-story senior (age-restricted), affordable apartment tower located in the Chinatown neighborhood of Downtown Honolulu, on River Street, between N Vineyard Boulevard and N Kukui Street. The building will consist of 13 residential floors above a four-story parking podium containing a first floor with a lobby, SAC, and small commercial space on the first floor, second and third floors of parking, and a fourth floor recreation deck. The residential component will include 155 age-restricted units and one resident manager unit. 26 of the units are two-bedrooms. The new residential use will replace an existing primarily vacant two-story building which was leased to office, retail, and restaurant space.

26 of which are two-bedroom units. The new residential use will replace an existing building that includes office, retail, and restaurant uses, most of which are vacant.

The project location is shown on **Figure 1**. The project site plan is illustrated on **Figure 2**.

The project site plan illustrates the main project driveway on River Street. As River Street is a one-way roadway, vehicles entering the site will utilize N Kukui Street and vehicles exiting the site will utilize N. Vineyard Boulevard to access other local and regional roadways.

Project Site Plan - Third Floor

1.2 Project Study Area

Inbound vehicle access to the project site is provided via Kukui Street and River Street. Vehicle egress from the project site is provided via River Street and a stop-controlled right turn movement onto N Vineyard Boulevard. This analysis evaluated the operations at two (2) existing intersections in the vicinity of the proposed project that are listed below.

1. Maunakea Street/N Kukui Street
2. N Kukui Street/River Street

The study intersections and project site are shown on **Figure 1**.

1.3 Study Scenarios

The operation of the study intersections were evaluated during the weekday AM and PM peak hours for the following scenarios:

- **Existing Conditions** – The analysis of existing traffic conditions was based on 2018 counts collected during the typical weekday peak commute hours and existing roadway and intersection configurations. The existing conditions evaluation also includes an overview of current pedestrian, bicycle, and transit facilities and services near the site.

Analysis of the study intersections under future scenarios were not analyzed due to the low project trip generation discussed in **Section 3.1**.

1.4 Traffic Analysis Methodology

The analysis of traffic operations performed for this study is based on procedures presented in the *Highway Capacity Manual* (HCM), published by the Transportation Research Board in 2016 *(HCM 6th Edition)*. The operations of roadway facilities are described with the term level of service (LOS). LOS is a qualitative description of traffic flow based on such factors as speed, travel time, delay, and freedom to maneuver. Six levels are defined from LOS A, with the least congested operating conditions, to LOS F, with the most congested operating conditions. LOS E represents "at-capacity" operations. Operations are designated as LOS F when volumes exceed capacity, resulting in stop-and-go conditions. The methodologies for signalized and unsignalized intersections are described below.

1.4.1 Signalized Intersections

The method described in Chapter 18 of the *HCM 6th Edition* was used to prepare the LOS calculations for the signalized study intersections of N Kukui Street/Maunakea Street. This LOS method analyzes a signalized intersection's operation based on average control delay per vehicle. Control delay alone is used to characterize LOS for the entire intersection or an approach. Control delay includes the initial deceleration delay, queue move-up time, stopped delay, and final acceleration delay. The average control delay for signalized intersections is calculated using Synchro 10.0 analysis software and is correlated to a LOS designation as shown in **Table 1**.

Table 1: Signalized Intersection LOS Definitions

Level of Service	Description	Delay in Seconds
A	Progression is extremely favorable and most vehicles arrive during the green phase. Most vehicles do not stop at all. Short cycle lengths may also contribute to low delay.	≤ 10.0
B	Progression is good, cycle lengths are short, or both. More vehicles stop than with LOS A, causing higher levels of average delay.	> 10.0 to 20.0
C	Higher congestion may result from fair progression, longer cycle lengths, or both. Individual cycle failures may begin to appear at this level, though many still pass through the intersection without stopping.	> 20.0 to 35.0
D	The influence of congestion becomes more noticeable. Longer delays may result from some combination of unfavorable progression, long cycle lengths, or high V/C ratios. Many vehicles stop, and the proportion of vehicles not stopping declines. Individual cycle failures are noticeable.	> 35.0 to 55.0
E	This level is considered by many agencies to be the limit of desirable delay. These high delay values generally indicate poor progression, long cycle lengths, and high V/C ratios. Individual cycle failures are frequent occurrences.	> 55.0 to 80.0
F	This level is considered undesirable with oversaturation, which is when arrival flow rates exceed the capacity of the intersection. This level may also occur at high V/C ratios below 1.0 with many individual cycle failures. Poor progression and long cycle lengths may also be contributing factors to such delay levels.	> 80.0

Source: *Highway Capacity Manual*, Transportation Research Board, 2016.

1.4.2 Unsignalized Intersections

The operations of the unsignalized intersection of N Kukui Street/River Street were evaluated using the method contained in Chapter 19: Two-Way Stop-Controlled Intersections of the *HCM 6th Edition*. LOS ratings for stop-sign-controlled intersections are based on the average control delay expressed in seconds per vehicle. At all-way stop-controlled (AWSC) intersections the overall intersection delay and LOS is reported, and the LOS is characterized solely on control delay. At side-street (SSSC) or two-way stop controlled (TWSC) intersections, the average control delay is calculated for each minor-street stopped movement and

the major-street left turns, not for the intersection as a whole. For approaches composed of a single lane, the control delay is computed as the average of all movements in that lane. For approaches with multiple lanes, the control delay is computed for each movement; the movement with the worst (i.e., longest) delay is presented for TWSC. The average control delay for unsignalized intersections is calculated using Synchro 10.0 analysis software and is correlated to a LOS designation as shown in **Table 2**.

Table 2: Unsignalized Intersection LOS Definitions

Level of Service	Description	Delay in Seconds
A	Little or no delay.	≤ 10.0
B	Short traffic delay.	> 10.0 to 15.0
C	Average traffic delays.	> 15.0 to 25.0
D	Long traffic delays.	> 25.0 to 35.0
E	Very long traffic delays.	> 35.0 to 50.0
F	Extreme traffic delays with capacity exceeded.	> 50.0

Source: *Highway Capacity Manual*, Transportation Research Board, 2016.
Notes: [1] For approach-based and intersection-wide assessments, such as that used for AWSC intersections, LOS is defined solely by control delay.

2. Existing Conditions

This chapter describes the existing mobility network and includes a discussion of the current bicycle, pedestrian, and transit facilities located in the project study area. This chapter also includes a discussion of the existing intersection operational analysis and related results.

2.1 Existing Site

The project site is located on the Diamond Head side of River Street, mauka of N Kukui Street; makai of N Vineyard Boulevard in the Chinatown neighborhood of Honolulu. The site is bounded by: River Street on the Ewa side; the Borthwick Mortuary property Diamond Head and mauka of the site; and the Lum Sai Ho Tong temple property makai of the site. The existing, primarily vacant office, restaurant, and retail building will be demolished with construction of the proposed project.

2.2 Existing Transportation Facilities

New traffic count data was collected as part of this analysis to identify existing transportation conditions in the vicinity of the proposed project. The existing conditions analysis included an inventory of the street system, and assessment of traffic volumes, and determination of operating conditions at the study intersections. Existing pedestrian, bicycle, and public transit service are also described in this section.

2.2.1 Existing Roadway System

The key roadways in the study area are described below.

River Street is a local street that traverses in a mauka-makai direction and provides direct access to the project site. River Street is a one-way, one-lane street under the jurisdiction of C&CH from N Kukui Street to N Vineyard Boulevard. Makai of N Kukui Street, River Street becomes a pedestrian promenade and continues as a vehicular roadway makai of N Beretania Street. The posted speed limit is 25 miles per hour (mph). One-hour parallel parking is permitted along the Diamond Head side of the street from 7:00 AM to 6:00 PM. Congestion was not observed during field observations at the study intersections and queuing at the intersection with N Vineyard Boulevard was extremely limited, with a maximum observed delay of 10 seconds for any one vehicle.

Pedestrian Facilities: Sidewalks are provided along both sides of River Street, with an attached sidewalk on the Diamond Head side fronting the project site and a pedestrian pathway (separated by a landscaped buffer) on the ewa side of the street adjacent to Nuuanu Stream. Marked crosswalks are provided at River

Street's intersections with N. Kukui Street providing access from the site to the River Street promenade. At the intersection with N Vineyard Boulevard a pedestrian signal is present providing a controlled crossing of this six-lane roadway. The *Downtown Neighborhood TOD Plan* proposed pedestrian intersection improvements at both study intersections.

Bike Facilities: Separate or designated bicycle facilities are not currently provided on River Street. Bicyclists are required to share the roadway with vehicles, although some cyclists choose to ride on the pedestrian path on the ewa side of the street. Based on Downtown Neighborhood Transit-Oriented Development (TOD) Plan 2017, published by City and County of Honolulu, a designated bike path will be provided in the future. Further, the *Oahu Bike Plan Update* (2018 Draft) identifies a future bicycle path on the ewa side of the street following the alignment of the existing pedestrian pathway.

N Vineyard Boulevard is a major arterial road within the vicinity of the project site. It is a six-lane arterial that extends between Palama Street and Lunalilo and is under the jurisdiction of HDOT. The posted speed limit is 30 mph. The intersection of N. Vineyard Boulevard at Maunakea Street is signalized. Parking on the mauka side of N Vineyard Boulevard is time-restricted and the parking lane is converted to a travel lane during the AM and PM peak hours. During the PM peak hour, Diamond Head-bound vehicles queue back from the Maunakea Street signal, which intermittently but temporarily impedes the ability for a vehicle to turn right onto N Vineyard Boulevard from River Street.

Pedestrian Facilities: Sidewalks are provided on both sides of the road. Crosswalks and pedestrian countdown signals are provided on the Diamond Head and makai legs of the intersection at Maunakea Street. As mentioned above, a pedestrian signal is provided at the intersection with River Street to provide a protected crossing of N Vineyard Boulevard.

Bike Facilities: Separate or designated bicycle facilities are not provided on Vineyard Boulevard in the vicinity of the project. Bicyclists are required to share the roadway with vehicles. The *Oahu Bike Plan Update* identifies future bicycle lanes on this street near the project site.

Kukui Street traverses an Ewa-Diamond Head direction between Aala Street and Pali Highway. Kukui Street is a two-way, two-lane local street under the jurisdiction of DTS. The posted speed limit of Kukui Street is 25 mph.

Pedestrian Facilities: Sidewalks are provided on both sides of Kukui Street. Crosswalks are provided across all roadway legs of the River Street intersection. Crosswalks and pedestrian countdown signals are also provided on all four legs of the Maunakea Street intersection.

Bike Facilities: Separate or designated bicycle facilities are not provided on Kukui Street. Bicyclists must share the roadway with vehicles. The *Oahu Bike Plan Update* identifies future bicycle lanes on this street near the project site.

Maunakea Street is a two-lane local street that is aligned in a mauka-makai direction. It is located on the Diamond Head side of the project site and connects N Vineyard Boulevard and Kukui Street. The posted speed limit is 25 mph. Maunakea Street is under the jurisdiction of DTS.

Pedestrian Facilities: Sidewalks are provided on both sides of the road. Crosswalks and pedestrian countdown signals are provided at the intersections with Kukui Street and Vineyard Boulevard.

Bike Facilities: Separate or designated bicycle facilities are not provided on Maunakea Street. Bicyclists must share the roadway with vehicles.

2.2.2 Existing Bicycle Activity

Based on the peak period counts conducted, a total of six (6) bicyclists were observed traveling through the N Kukui Street/River Street intersection during the AM peak hour, and five (5) bicyclists were observed in the PM peak hour. At the N Kukui Street/Maunakea intersection, a total of 12 bicyclists were observed traveling through this intersection during the AM peak hour, and seven (7) bicyclists were observed during the PM peak hour.

2.2.3 Existing Pedestrian Activity

Pedestrian counts collected during the peak periods at the two study intersections showed that the highest volumes of pedestrians crossing at a study intersection occurred during the PM peak hour, with 203 people crossing at the N Kukui Street/Maunakea Street intersection. Most pedestrians crossed Maunakea Street on the Diamond Head side of the intersection.

2.2.4 Existing Transit Facilities and Services

TheBus is the main public transportation service on the Island of Oahu, where it served over 63 million riders in the fiscal year of 2017-2018. The bus fleet transports an average of approximately 197,000 riders daily

(weekdays) via fixed-route, express, and paratransit service[1]. The closest bus stops are located 0.1 miles away (or roughly a four-minute walk) from the project site on N Beretania Street at River Street (Stop ID: 439) and Nuuanu Avenue at N. Vineyard Boulevard (Stop ID: 389). These bus stops serve about 25 different routes, which provide transit users good access to most destinations in and around Downtown Honolulu.

2.3 Existing Traffic Volumes and Lane Configurations

Existing lane configurations and traffic signal controls were obtained through field observations. The operations of the existing intersections were evaluated during weekday AM and PM peak periods (6:00 AM – 9:00 AM and 3:00 PM – 6:00 PM). Traffic counts were collected during the weekday AM and PM peak periods at the study intersections in March 2019 under normal traffic and weather conditions. The weekday AM peak hour of traffic for the study intersections occurred between the hours of 7:15 AM and 8:15 AM. During the weekday afternoon, the PM peak hour of traffic occurred between the hours of 5:00 PM and 6:00 PM at the N Kukui Street/River Street intersection, and between 4:45 PM and 5:45 PM at N Kukui Street and Maunakea Street.

Figure 3 presents the existing AM and PM peak hour turning movement volumes, corresponding lane configurations, and traffic control devices. Peak hour intersection count data are provided in **Appendix A**.

2.4 Existing Intersection Levels of Service

Peak hour intersection LOS analysis was performed for the existing study intersections using the methodology described previously and traffic count data collected for this study. **Table 3** shows the results for Existing Conditions LOS. Detailed LOS Worksheets are provided in **Appendix B**.

Table 3: Existing (2019) Intersection Levels of Service (LOS)

Intersection	Traffic Control	Peak Hour	Delay (sec/veh)[1]	LOS[2]
1. N Kukui Street / River Street	Unsignalized	AM	7.6	A
		PM	7.5	A
	Signalized	AM	21.3	C

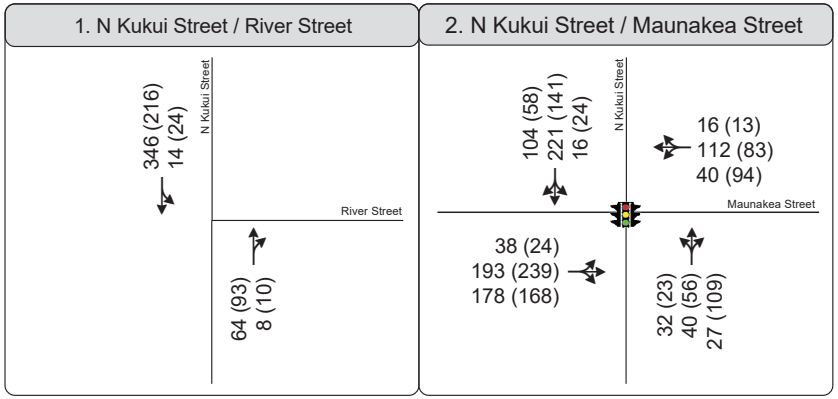
2. N Kukui Street / Maunakea Street		PM	23.5	C

Source: Fehr & Peers, 2019

Notes:

[1] Whole intersection weighted average stopped delay expressed in seconds per vehicle for signalized intersections.
2 LOS calculations performed using the Highway Capacity Manual (HCM), 6th Edition method.

As shown in **Table 3**, both study intersections currently operate at LOS C or better during the AM and PM peak hours.



2.5 Field Observations

During field observations in March 2019, queuing was observed along N Vineyard Boulevard in the PM peak hour to the extent that it affected the ability of right-turning vehicles from River Street to execute the turn onto N Vineyard Boulevard. However, low volumes of vehicles were observed completing the affected movement, and observed delays did not exceed approximately 10 seconds for any one vehicle. Excessive queuing was not observed at either study intersection on N. Kukui Street.

Sight distance at the study intersection and the intersection of River Street/N Vineyard Boulevard were reviewed, and no visual impediments were identified during field observations.

The pedestrian pathways between the project site and the two nearest bus stops were reviewed and were found to provide adequate access in terms of pavement quality and limited conflicts with vehicles.

3. Project Traffic Estimates

This section describes the anticipated number of vehicle trips and directionality of those trips that would result from implementation of the proposed project. Future traffic added to the roadway system by the project is estimated using a three-step process: (1) project trip generation, (2) trip distribution, and (3) trip assignment. The first step estimates the amount of project-generated traffic that would be added to the roadway network. The second step estimates the direction of travel to and from the project site. The new trips are assigned to specific street segments and intersection turning movements during the third step. This process is described in more detail in the following sections.

3.1 Project Trip Generation Estimates

Trip rates presented in the *Trip Generation Manual* (10th Edition, Institute of Transportation Engineers (ITE), 2017) were used to estimate the number of trips forecasted to be generated by the proposed land use. The project's trip generation estimates were developed using MainStreet, a web application developed by Fehr & Peers that uses a Mixed-Use (MXD) Trip Generation Model. The MXD model was developed by Fehr & Peers and the Environmental Protection Agency (EPA), and is based on statistically superior data compared to the methodology used by ITE. The model recognizes that traffic generation for a given land use is significantly affected by the density, diversity, design, destination, accessibility, travel proximity, and scale of development. The MXD model estimates the proportion of daily and peak hour trips that will remain on the project site (due to internal capture), as well as reductions for external trips made via transit, walking, and bicycling. Based on this approach, the trip generation includes the forecasted volume of peak hour and daily trips to be generated by the site, as well as trip reductions associated with the location of the site in a relatively dense environment with multiple destinations located within a reasonable walking, bicycling, and transit travel distances of the project site. Lastly, existing traffic volumes generated by the few active uses on the site were deducted from the project's vehicle trip generation to determine the number of net new trips expected to be added to the adjacent street system.

The estimated project trips are summarized in **Table 4** and the trip rates applied to this project are provided in **Appendix C**.

Table 4: Project Trip Generation Estimates

Project Component	Size	Units[1]	Daily Trips	AM Peak Hour			PM Peak Hour		
				In	Out	Total	In	Out	Total
Senior Adult Housing - Attached	156	DU	577	11	20	31	22	19	41
REDUCTIONS									
Transit/Walk/Bike Trip Reduction[2]			267	-7	-13	-20	-12	-11	-23
Existing Trip Reduction[3]			--	-4	-2	-6	-7	0	-7
TOTAL			**310**	**0**	**5**	**5**	**3**	**8**	**11**

Source: Fehr & Peers, 2019

Notes: [1]DU=Dwelling Units

[2]Internal capture and active/transit trip reductions calculated using MainStreet web app (see text for details).

[3]Existing trip reduction based on project site driveway counts conducted in March 2019.

A daily driveway count was not completed, and a corresponding daily existing trip reduction was not applied. Therefore, the expected volume of 310 net new daily trips is higher than what would actually be generated after project implementation and is a conservative estimation.

Ultimately, as shown in **Table 4**, the project is forecasted to generate 310 net new daily vehicle trips, five (5) net new AM peak hour trips (0 inbound/5 outbound), and 11 net new PM peak hour trips (3 inbound/8 outbound).

3.2 Project Trip Distribution and Assignment

The distribution of traffic generated by the project onto the roadway system was based on access to H-1, existing traffic volumes, and expected traffic flows to destinations in the Ewa, Diamond Head, makai, and mauka directions. Based on these factors, the vehicle trip distribution of the project-generated traffic is estimated to be:

- 35% to/from N Kukui Street Diamond Head of Maunakea Street
- 30% to/from Maunakea Street makai of N Kukui Street
- 20% to/from N Vineyard Boulevard Ewa of River Street
- 5% to/from S Vineyard Boulevard Diamond Head of Nuuanu Avenue
- 5% to/from Nuuanu Avenue mauka of N Vineyard Boulevard
- 5% to/from Aala Street makai of N Kukui Street

The project trip distribution is shown on **Figure 4**.

As described in Section 1.1, access to the proposed project will be provided by a single two-way driveway on River Street. All inbound trips will arrive via N. Kukui Street, and all trips leaving the project site will utilize River Street to access N Vineyard Boulevard and travel in the Diamond Head direction.

Using the estimated trip generation and the distribution patterns discussed, the traffic generated by the proposed project was assigned to the study intersections and individual turning movements. **Figure 5** shows the assignment of trips generated by the project for AM and PM peak hours.

Given the very low volume of traffic added to any one turning movement at any intersection, the change in traffic operations at any street intersection would be negligible and would not be perceived by most drivers. Accordingly, no operations analysis of future traffic operations was conducted.

4. Site Access and On-Site Circulation

This chapter includes a review of the site access, on-site circulation for vehicles, bicyclists, and pedestrians, and on-site parking. An evaluation of off-site active and transit travel modes is presented in **Chapter 5.**

4.1 Site Access and On-Site Vehicle Circulation

Vehicular site access will be provided by a single in and out driveway on River Street at the makai end of the site. This driveway provides access to the project's parking area provided on the second and third stories of the building. In addition, the driveway provides access to a loading area on the first floor that can accommodate one van or single-unit truck for deliveries or passenger loading, as well as two future electric vehicle charging stations. The ramp is designed with a 90-degree turn beyond the loading area before ramping up to the second floor.

To minimize conflicts between vehicles backing into or leaving the loading area and vehicles traveling down the ramp from the parking area, a mirror (or mirrors) should be installed on the makai wall of the ramp. Use of the device(s) would increase visibility of the loading area to drivers traveling down the garage ramp.

Due to the design of the project access driveway and building wall locations, the driveway opening is set back from the sidewalk fronting the site. However, appropriate visual and audible warning devices should be installed to alert pedestrians to vehicles exiting the project driveway.

4.2 Parking

An on-site shared parking area is provided on the second and third floors of the building. Access to the parking area is provided from the project's access driveway. The parking area will be available for residents, guests, and SAC users. Parking spaces in the shared parking area will not be marked or reserved and will be available on a first-come first-shared basis.

The City and County of Honolulu Land Use Ordinance Section 21-5.610A requires special needs housing for the elderly to provide at least one parking stall per four dwelling units, one guest parking stall per 10 dwelling units, and two off-street loading spaces. The project's location in a transit-oriented development area and its proximity to existing transit and the future Chinatown HART station may further reduce the demand for parking in the building. This project applied for a County-level exclusion (201-H) to reduce the number of required parking and loading stalls for the project.

As currently proposed, the two parking levels will provide approximately 51 parking spaces, approximately 10 of which are tandem and will be managed appropriately. Additionally, one space for off-street loading will be provided on the ground floor level as shown on the site plan in **Figure 2**.

4.3 On-Site Pedestrian and Bicycle Circulation

Pedestrian circulation will be provided via the sidewalk fronting the site along River Street, as well as access located on the mauka side of the building providing access to a stairwell. All pedestrian access within the building is provided by stairs or elevators.

Bicycles will need to be dismounted on site. A sufficient number of bicycle parking stalls pursuant to HRS 201H exemption, will be provided on levels 1-4.

5. Multimodal Assessment

The potential impact of the proposed project on the off-site pedestrian, bicycle, and transit facilities and services is addressed in this chapter.

5.1 Transit Facilities and Access

Existing transit facilities and services appear to be sufficient to serve the development. Multiple bus stops are located within a reasonable walking distance of the site, with the two closest bus stops located within a four-minute walk. Pedestrian access to these stops appears to be accessible for a disabled person utilizing a wheelchair or a walking aid. The project is within 800 feet of the proposed HART rail Chinatown station. This station is scheduled to provide rail transit access toward Ala Moana Center and toward East Kapolei by 2025. This service will enhance transit access and further reduce the need for Halewaiolu residents to use a car regularly, or even own one.

5.2 Bicycle Facilities

The Oahu Bike Plan (2012) provides guidance on desired bike facilities across the island of Oahu. This plan is currently being updated. *The Oahu Bike Plan Update (2018 Draft)* identifies a proposed bicycle path on the ewa side of River Street, and proposed bicycle lanes on both sides of N Vineyard Boulevard and N Kukui Street.

The project will not conflict with the installation of these bicycle facilities. As mentioned in **Section 4.3**, on-site bicycle racks and secure bicycle storage should be provided for residents, employees, and visitors.

5.3 Pedestrian Facilities

The *Downtown Neighborhood Transit-Oriented Development (TOD) Plan (2017)* identifies pedestrian intersection improvements that are to be made at River Street's intersections with Kukui Street and N Vineyard Boulevard. A pedestrian signal was recently installed at River Street's intersection with N Vineyard Boulevard.

The project will not conflict with these improvements or significantly affect the existing sidewalk provided along its frontage.

6. Recommendations

Overall, the Halewaiolu Senior Residences project will generate few vehicular trips and is expected to have a negligible impact on traffic operations. Therefore, no roadway improvements are proposed as a part of this development.

Dear **Ms. Seddon:**

Geolabs, Inc. is pleased to submit our report entitled "Geotechnical Engineering Exploration, Halewai`olu Senior Residences, 1331 - 1347 River Street, Honolulu, Oahu, Hawaii" prepared in support of the detailed design of the proposed senior residential project.

Our work was performed in general accordance with the scope of services outlined in our fee proposal dated February 8, 2019.

Please note that the soil and rock samples recovered during our field exploration (remaining after testing) will be stored for a period of two months from the date of this report. The samples will be discarded after that date unless arrangements are made for a longer sample storage period. Please contact our office for alternative sample storage requirements, if appropriate.

Detailed discussion and preliminary recommendations are contained in the body of the report. If there is any point that is not clear, please contact our office.

Very truly yours,

GEOLABS, INC.

SUMMARY OF FINDINGS AND RECOMMENDATIONS

Our field explorations suggest that the original alignment of Nuuanu Stream may have traversed the southern portion of the project site. Boring Nos. 1, 101, and 103 drilled toward the southern portion of the project site encountered a thin layer of surface fills overlying a highly compressible layer of recent alluvium and lagoonal deposits extending to depths of about 25 to 38 feet below the existing pavement surface. Stiff to very stiff alluvial deposits interbedded with dense cobbly boulders were then encountered and extended to the maximum depth explored of about 152.5 feet below the existing pavement surface.

Toward the northern portion of the project site, Boring Nos. 2, 102, and 104 generally encountered a highly compressible layer of recent alluvium and lagoonal deposits between depths of about 1 and 19 feet below the existing pavement surface. Below the compressible deposits, dense cinder sands and very stiff alluvial clays interbedded with basalt formation were encountered to a depth of about 98 feet below the ground surface. Hard to very hard basalt formation was encountered between depths of about 48 and 86 feet below the existing pavement surface.

Based on the subsurface conditions encountered in the borings and the structural load demands on the new high-rise building foundations, we recommend supporting the new high-rise building on a deep foundation system consisting of micropiles with a diameter of 7.625 inches. We recommend casing the upper 30 feet of the micropiles (permanent casing) below the bottom of the foundation cap elevations. The permanent casing should have an OD of at least 7.625 inches (same as the grout bulb size), and the permanent casing should extend 3 feet into the alluvial clay deposits. The micropiles would derive vertical support primarily from skin friction between the foundation element and surrounding supporting geo-materials. In order to achieve an allowable compressive load capacity of 250 kips, the cased micropiles would need to extend to about 75 and 120 feet below the bottom of the foundation cap elevations (assumed at about +2 feet MSL for ease of reference) at the northern and southern portions of the building, respectively.

The text of this report should be referred to for detailed discussion and our design recommendations.

END OF SUMMARY OF FINDINGS AND RECOMMENDATIONS

SECTION 1. GENERAL

This report presents the findings from our geotechnical engineering exploration conducted in support of the detailed design of the Halewai`olu Senior Residences located at 1331 - 1347 River Street in the Chinatown area of Honolulu on the Island of Oahu, Hawaii. The project location and general vicinity are shown on the Project Location Map, Plate 1.

This report summarizes the findings and presents our geotechnical recommendations based on our field exploration, laboratory testing, and engineering analyses. The recommendations presented herein are intended for the design of foundations, slabs-on-grade, retaining structures, site grading, pavements, and underground utility lines only. In addition, general discussions on the excavation and dewatering requirements are included in this report for information purposes. The findings and recommendations presented herein are subject to the limitations noted at the end of this report.

1.1 Project Considerations

The project site is at 1331 - 1347 River Street in the Chinatown area of Honolulu on the Island of Oahu, Hawaii. The parcel (designated as TMK: 1-7-006: 012) is approximately trapezoidal in shape and encompasses approximately 26,925 square feet in land area. A preliminary geotechnical engineering report entitled “Preliminary Geotechnical Engineering Exploration, Halewai`olu Senior Residences, 1333 River Street, Honolulu, Oahu, Hawaii” dated January 17, 2017 was prepared by our office for the proposed housing development. The recommendations contained in this geotechnical engineering report supersede the preliminary geotechnical recommendations contained in the previous report dated January 17, 2017.

Based on the information provided, we understand it is desired to proceed with the detailed design of the affordable senior rental housing project. We anticipate the proposed housing development will consist of an 18-story high-rise building providing a total of approximately 150 living units with some retail space on the ground floor.

Our preliminary field exploration suggests that the site generally is underlain by a highly compressible layer of recent alluvium and lagoonal deposits extending to depths of approximately 14 and 38 feet below the existing ground surface in the two borings drilled toward the northern and southern portions of the site, respectively.

Because of the potentially weak subsurface conditions anticipated at the site, shear wave velocity profiling was conducted during the preliminary field exploration in an effort to more closely analyze the site for seismic design considerations.

We anticipate several minor below-grade structures, such as the elevator pits, likely will be required. Due to the presence of soft lagoonal deposits and shallow groundwater, we anticipate excavation shoring and dewatering operations likely will be required for the deeper excavations during construction.

As part of the field exploration program, four infiltration tests were performed in accessible areas across the project site to evaluate the infiltration characteristics of the subsurface materials for design of the storm water runoff disposal system in order to meet the drainage requirements for Low Impact Development (LID).

1.2 Purpose and Scope

The purpose of our field exploration was to obtain an overview of the surface and subsurface conditions to develop a generalized subsurface data set to formulate geotechnical recommendations for design of foundations, slabs-on-grade, retaining structures, site grading, pavements, and underground utility lines only. The scope of work for this exploration included the following tasks and work efforts:

1. Coordination of boring stakeout and underground utility toning by various utility companies and government agencies.

2. Mobilization and demobilization of a truck-mounted drill rig and two operators to the project site and back.

3. Drilling and sampling of four additional borings extending to depths of about 79 to 152.5 feet below the existing pavement surface. In addition, four shallow borings were drilled to a depth of about 5 feet below the existing pavement surface for infiltration testing.

4. Coordination of the field exploration and logging of the borings by our geologist.

5. Performance of four field infiltration tests to evaluate the hydraulic characteristics of the subsurface materials to provide information in support of the design of the storm water runoff disposal system.

6. Laboratory testing of selected soil samples and rock cores obtained during the field exploration as an aid in classifying the materials and evaluating their engineering properties.

7. Analyses of the field and laboratory data to formulate preliminary geotechnical recommendations for the detailed design of the proposed project.

8. Preparation of this geotechnical engineering report summarizing our work on the project and presenting our findings and geotechnical recommendations in support of the detailed design of the proposed development.

9. Coordination of our overall work on the project by our senior engineer.

10. Quality assurance of our work and client/design team consultation by our principal engineer.

11. Miscellaneous work efforts such as drafting, word processing, and clerical support.

Detailed descriptions of our field exploration methodology and the Logs of Borings are presented in Appendix A. Results of the seismic shear wave velocity testing conducted during the preliminary field exploration is presented in Appendix B. Laboratory test results of selected soil and core samples obtained from the current field exploration are presented in Appendix C. Results of the infiltration tests performed at selected locations are presented in Appendix D. Photographs of the core samples are presented in Appendix D. The pertinent geotechnical data from the preliminary field exploration, including logs of borings, laboratory test results, and photographs of the core samples, are presented in Appendix F.

END OF GENERAL

SECTION 2. SITE CHARACTERIZATION

The Island of Oahu was built by the extrusion of basaltic lavas from the Waianae and Koolau Shield Volcanoes. The older Waianae Volcano is estimated to be middle to late Pliocene in age and forms the bulk of the western one-third of the island. The younger Koolau Volcano is estimated to be late Pliocene to early Pleistocene (Ice Age) in age and forms the majority of the eastern two-thirds of the island. The Koolau Volcano reached the end of its main shield-building phase about 2 million years ago.

The project site is situated next to the southern bank of Nuuanu Stream on the Honolulu Coastal Plain. This plain is composed of interbedded marine, terrestrial, and volcanic deposits on the southwest side of the former Koolau Volcano.

The base member encountered in our exploration consists of basaltic lava flow from the Honolulu Volcanic Series. This basalt was deeply scoured by stream erosion at a time when the sea level was as much as 300 feet below its present elevation. As the great continental glaciers of the Ice Age melted and the sea level rose, erosion of the basalt ceased and extended periods of deposition followed. The deposits generally consisted of alluvium and ash transported from Nuuanu Valley upstream of the site.

Subsequently, the alluvium was covered by sandy beach deposits and coralline reef formation, which developed when the sea level rose to an elevation higher than its present level. As the continental glaciers formed again, the sea level dropped, the reef and alluvial deposits were eroded. When the sea level rose again to its present level, the stream channel was filled with fine-grained organic soils deposited in a quiet lagoonal environment. More recent alluvial deposits continued to accumulate over the lagoonal sediments. Finally, in the past century, the area was filled for development.

2.1 Site Description

The proposed senior residential development is located at 1331 - 1347 River Street in the Chinatown area of Honolulu on the Island of Oahu, Hawaii. The parcel (designated as TMK: 1-7-006: 012) is approximately trapezoidal in shape and encompasses approximately 26,925 square feet in land area.

The project site is currently occupied by a two-story structure of Concrete Masonry Unit (CMU) construction alongside River Street. The remaining areas consist of an open parking lot paved with asphaltic concrete. Based on our field reconnaissance and topographic survey map provided, the existing topography across the project site is relatively flat with existing ground surface elevations between about +8 and +10 feet Mean Sea Level (MSL).

2.2 Subsurface Conditions

To obtain an overview of the subsurface conditions at the subject parcel, we conducted a preliminary geotechnical exploration program consisting of two borings, designated as Boring Nos. 1 and 2, extending to depths of about 86 and 121.2 feet below the existing pavement surface. Our current field exploration program in support of the detailed design consisted of drilling and sampling four additional test borings, designated as Boring Nos. 101 through 104, extending to depths ranging from about 79 to 152.5 feet below the existing pavement surface. The approximate locations of the current drilled borings are shown on the Site Plan (Plate 2). The boring locations from the 2017 preliminary field exploration also are shown on the same plan for reference purposes.

Based on the results obtained from our preliminary (2017) and current (2019) field explorations, the original alignment of Nuuanu Stream appears to have traversed the southern portion of the project site. Boring Nos. 1, 101, and 103 drilled toward the southern portion of the project site encountered a thin layer of surface fills overlying a highly compressible layer of recent alluvium and lagoonal deposits extending to depths of about 25 to 38 feet below the existing pavement surface. Stiff to very stiff alluvial deposits interbedded with very dense cobbly boulders were then encountered and extended to the maximum depth explored of about 152.5 feet below the existing pavement surface.

Toward the northern portion of the project site, Boring Nos. 2, 102, and 104 generally encountered a highly compressible layer of recent alluvium and lagoonal deposits between depths of about 1 and 19 feet below the existing pavement surface. Below the compressible deposits, dense cinder sands and very stiff alluvial clays interbedded with basalt formation were encountered to a depth of about 98 feet below

the ground surface. Hard to very hard basalt formation was encountered between depths of about 48 and 86 feet below the existing pavement surface.

For illustration purposes only, two Generalized Geologic Cross Sections depicting the interpreted subsurface conditions at the project site are provided on Plates 3.1 and 3.2. The approximate surface projections of the subsurface profiles prepared for this report are shown on the Site Plan, Plate 2.

We encountered groundwater at depths of about 7.2 to 8 feet below the existing pavement surface at the time of our field explorations. The groundwater levels encountered generally correspond to about Elevations +1.1 to +2.5 feet MSL at the time of our field exploration. It should be noted that groundwater levels can fluctuate depending on surface water runoff and seasonal precipitation (due to the proximity of the project site to Nuuanu Stream), groundwater withdrawal and/or injection, and other factors.

Detailed descriptions of the field exploration methodology are presented in Appendix A. Descriptions and graphic representations of the materials encountered and water levels observed in the borings are presented on the Logs of Borings in Appendix A. Results of the shear wave velocity profiling conducted within one of the borings are presented in Appendix B. Laboratory tests were performed on selected soil samples and rock cores, and the test results are presented in Appendix C. Results of the infiltration tests performed at selected locations are presented in Appendix D. Photographs of the rock cores are provided in Appendix E.

2.3 Seismic Design Considerations

Based on the International Building Code, 2006 Edition (IBC 2006), the project site may be subject to seismic activity and seismic design considerations will need to be addressed. The following sections provide discussions on the seismicity, the potential for liquefaction at the project site, and the soil profile for seismic design.

2.3.1 Earthquakes and Seismicity

In general, earthquakes that occur throughout the world are caused solely by shifts in the tectonic plates. In contrast, earthquake activity in Hawaii is linked primarily to volcanic activity. Therefore, earthquake activity in Hawaii generally

occurs before or during volcanic eruptions. In addition, earthquakes may result from the underground movement of magma that comes close to the surface but does not erupt. The Island of Hawaii experiences thousands of earthquakes each year, but most of the earthquakes are so small that they can only be detected by sensitive instruments. However, some of the earthquakes are strong enough to be felt, and a few cause minor to moderate damage.

In general, earthquakes (associated with volcanic activity) are most common on the Island of Hawaii. Earthquakes that are directly associated with the movement of magma are concentrated beneath the active Kilauea and Mauna Loa Volcanoes on the Island of Hawaii. Because the majority of the earthquakes in Hawaii (over 90 percent of earthquakes) are related to volcanic activity, the risk of high seismic activity and degree of ground shaking diminishes with increased distance from the Island of Hawaii. The Island of Hawaii has experienced numerous earthquakes greater than Magnitude 5 (M5+); however, earthquakes are not confined only to the Island of Hawaii.

To a lesser degree, the Island of Maui has experienced numerous earthquakes greater than Magnitude 5. Therefore, moderate to strong earthquakes have occurred in the County of Maui. The effects of earthquakes occurring on the Islands of Hawaii and Maui may be felt on the Island of Oahu. For example, several small landslides occurred on the Island of Oahu as a result of the Maui Earthquake of 1938 (M6.8). In addition, some houses on the Island of Oahu were reportedly damaged as a result of the Lanai Earthquake of 1871 (M7+).

Due to the relatively short period of documented earthquake monitoring in the State of Hawaii, information pertaining to earthquakes that were felt on the Island of Oahu may not be complete. In general, over the last 150 years of recorded history, we are not aware of reported earthquakes greater than Magnitude 6 occurring on the Island of Oahu. Based on available information, we understand that an earthquake of about Magnitude 5.6 occurred on June 28, 1948 in the vicinity of the Island of Oahu, possibly along the hypothesized and controversial Diamond Head Fault feature.

The Diamond Head Fault feature is believed to extend northeasterly away from the southeastern tip of the Island of Oahu. The Diamond Head Fault feature may be related to the widely documented Molokai Fracture Zone located on the sea floor in the vicinity of the Hawaiian Islands. Despite only the moderate tremor intensity, the resulting damage was reportedly widespread and included broken windows, ruptured masonry building walls, and a broken underground water main. In addition, some areas on the Island of Oahu, including the Tantalus, Iwilei, and Tripler areas, reported more intense ground shaking, severe enough to have cracked reinforced concrete.

2.3.2 Soil Profile

Because of the variable subsurface conditions anticipated across the site as discussed above, it was desired to perform seismic shear wave velocity profiling in an effort to more closely analyze the subsurface conditions for seismic design considerations. Shear wave velocity profiling was performed in Boring No. 1 using seismic cone penetration testing (SCPT) equipment. Based on the subsurface conditions encountered in Boring No. 1, the weighted average shear wave velocity for the materials within the upper 100 feet of the soil profile within the alluvial stream channel is on the order of about 657 feet per second. A small lense of loose granular soils was encountered; however, the subsurface profile encountered did not encounter extensive zones of loose granular soils that would be considered susceptible to soil liquefaction.

Based on the subsurface materials encountered at the project and the shear wave velocity profiling performed, we believe the project site may be classified from a seismic analysis standpoint as being a “Stiff Soil Profile” corresponding to a Site Class D soil profile type based on the International Building Code (Table No. 1613.5.2), 2006 Edition. Based on a Site Class D soil profile, the following seismic design parameters were estimated and may be used for the seismic analysis of the building planned for the project.

SEISMIC DESIGN PARAMETERS INTERNATIONAL BUILDING CODE 2006 EDITION	
Parameter	**Value**
Peak Bedrock Acceleration, PBA (Site Class B)	0.266
Spectral Response Acceleration (Site Class B), S_S	0.614

2.3.3 Liquefaction Potential

Based on the 2006 International Building Code IBC 2006 (code adopted by the City and County of Honolulu), the project site may be subjected to seismic activity and the potential for soil liquefaction at the project site will need to be evaluated.

Soil liquefaction is a condition where saturated cohesionless soils located near the ground surface undergo a substantial loss of strength due to the build-up of excess pore water pressures resulting from cyclic stress applications induced by earthquakes. In this process, when the loose saturated sand deposit is subjected to vibration (such as during an earthquake), the soil tends to densify and decrease in volume causing an increase in pore water pressure. If drainage is unable to occur rapidly enough to dissipate the build-up of pore water pressure, the effective stress (internal strength) of the soil is reduced. Under sustained vibrations, the pore water pressure build-up could equal the overburden pressure, essentially reducing the soil shear strength to zero and causing it to behave as a viscous fluid. During liquefaction, the soil acquires sufficient mobility to permit both horizontal and vertical movements, and if not confined, will result in significant deformations.

Soils most susceptible to liquefaction are loose, uniformly graded, fine-grained sands and loose silts with little cohesion. The major factors affecting the liquefaction characteristics of a soil deposit are as follows:

FACTORS	LIQUEFACTION SUSCEPTIBILITY
Grain Size Distribution	Fine and uniform sands and silts are more susceptible to liquefaction than coarse or well-graded sands.
Initial Relative Density	Loose sands and silts are most susceptible to liquefaction. Liquefaction potential is inversely proportional to relative density.
Magnitude and Duration of Vibration	Liquefaction potential is directly proportional to the magnitude and duration of the earthquake.

As mentioned above, the subsurface profile encountered did not encounter extensive zones of loose granular soils that would be considered susceptible to soil liquefaction. Therefore, the potential for soil liquefaction is not a design consideration for this project.

END OF SITE CHARACTERIZATION

SECTION 3. DISCUSSION AND RECOMMENDATIONS

Our field explorations suggest that the original alignment of Nuuanu Stream may have traversed the southern portion of the project site. Boring Nos. 1, 101, and 103 drilled toward the southern portion of the project site encountered a thin layer of surface fills overlying a highly compressible layer of recent alluvium and lagoonal deposits extending to depths of about 25 to 38 feet below the existing pavement surface. Stiff to very stiff alluvial deposits interbedded with very dense cobbly boulders were then encountered and extended to the maximum depth explored of about 152.5 feet below the existing pavement surface.

Toward the northern portion of the project site, Boring Nos. 2, 102, and 104 generally encountered a highly compressible layer of recent alluvium and lagoonal deposits between depths of about 1 and 19 feet below the existing pavement surface. Below the compressible deposits, dense cinder sands and very stiff alluvial clays interbedded with basalt formation were encountered to a depth of about 98 feet below the ground surface. Hard to very hard basalt formation was encountered between depths of about 48 and 86 feet below the existing pavement surface.

Based on the subsurface conditions encountered in the borings and the structural load demands on the new high-rise building foundations, we recommend supporting the new high-rise building on a deep foundation system consisting of micropiles with a diameter of 7.625 inches. We recommend casing the upper 30 feet of the micropiles (permanent casing) below the bottom of the foundation cap elevations. The permanent casing should have an OD of at least 7.625 inches (same as the grout bulb size), and the permanent casing should extend 3 feet into the alluvial clay deposits. The micropiles would derive vertical support primarily from skin friction between the foundation element and surrounding supporting geo-materials. In order to achieve an allowable compressive load capacity of 250 kips, the cased micropiles would need to extend to about 75 and 120 feet below the bottom of the foundation cap elevations (assumed at about +2 feet MSL for ease of reference) at the northern and southern portions of the building, respectively. The text of this report should be referred to for detailed discussion and geotechnical recommendations for the proposed project.

3.1 Micropile Foundations

Based on the subsurface conditions encountered in the borings and the structural load demands on the new high-rise building foundations, we recommend supporting the new high-rise building on a deep foundation system consisting of cased micropiles. The load supporting capacity of the micropile foundation would derive primarily from skin friction between the micropile bonded zone and the alluvial clays with cobbles and boulders and/or hard to very hard basalt formation anticipated across the project site.

A micropile consists of a small diameter (usually less than 12 inches) drilled and grouted pile with a center reinforcing steel bar. The micropile foundation typically is constructed by drilling a borehole, placing reinforcing steel in the hole, and grouting the borehole. Micropiles are desirable because they can be installed readily in access restrictive environments and in numerous soil types and ground conditions. In addition, installation of the micropiles generally causes minimal disturbance to adjacent structures, the adjacent soils, and the environment.

We envision a micropile system with a minimum OD (outside diameter) of 7.625 inches should be used. We recommend designing each micropile based on an allowable compressive load capacity of 250 kips per pile with an allowable tensile load 175 kips. The allowable compressive and tensile load capacities of the micropiles may be increased by up to one-third (⅓) when designing for short-term loads, such as demands due to seismic or wind reactions.

Lateral load resistance contribution from the micropile should be discounted due to the relatively small diameter of the foundation element. Passive earth pressure acting against the near-vertical faces of the foundation caps and/or grade beams may be estimated using an equivalent fluid pressure of 300 and 150 pounds per square foot per foot of depth (pcf) for above and below groundwater conditions, respectively. The static groundwater level at the project site may be assumed to be at about Elevation +3 feet MSL for design purposes.

Based on the anticipated subsurface conditions at the site, we recommend extending the micropiles through the soft and/or loose lagoonal deposits and derive load bearing support from the alluvial deposits and/or basalt formation encountered across

the project site. To achieve the allowable compressive load capacity with a factor of safety of 2, we believe each micropile would need to extend a depth of about 45 and 90 feet into the competent materials, or approximately 75 and 120 feet below the bottom of pile cap elevation, for the northern and southern portions of the project site, respectively. We also recommend providing a permanent steel casing for the upper 30 feet of the micropiles. The permanent steel casing should have an OD of at least 7.625 inches (same as the grout bulb size), and the permanent steel casing should extend 3 feet into the alluvial clay deposits. The center reinforcing steel bar should consist of a Grade 80 No. 20 reinforcing bar with a cross sectional area of 4.91 square inches. The following table provides a summary of the micropile recommendations for ease of reference.

CASED MICROPILE SYSTEM RECOMMENDATIONS	
Micropile Outside Diameter of Casing	7.625 inches minimum
Micropile Casing Thickness	0.375 inches minimum
Micropile Casing Tip Elevation	See Table Below
Diameter of Micropile Bonded Length	7.625 inches minimum
Micropile Bonded Length	See Table Below
Micropile Total Length	See Table Below
Center Reinforcing Bar (Full Depth)	No. 20 (ASTM A615 Grade 80)
Grout Minimum Compressive Strength	6,500 psi (water-cement ratio of 0.40 or less)

SUMMARY OF MICROPILE FOUNDATIONS			
Location	**Cased Length** (feet)	**Bonded Length** (feet)	**Total Length** (feet)
Northern Portion	30	45	75
Southern Portion	30	90	120
Note: All lengths provided above are measured from the bottom of the pile cap elevations assumed at +2 feet MSL or lower.			

To facilitate the micropile drilling and ensure the quality of the grouting, we recommend advancing the steel casing to the bottom of the micropile during the drilling

operation. The steel casing may be withdrawn during the grouting operation while a minimum of 10 feet grout head is maintained above the bottom of the casing at all times. The casing should be withdrawn above the design casing depth (minimum 3 feet) and plunged back to the design casing depth (3 feet into the alluvial deposits). In general, the micropiles should have a minimum center-to-center spacing of about 24 inches to avoid reduction in vertical load capacity due to group action and to facilitate drilling of the micropiles. Micropiles within 5 feet of a recently completed micropile should not be drilled or grouted until the grout in the recently completed micropile has been allowed to cure for at least 24 hours to avoid disturbing or compromising the recently completed micropile.

It should be noted that the bond stress between the grout bulb and the soil is highly dependent on the drilling procedures and the grouting methods employed by the contractor to install the micropile. Therefore, the bond stress between the grout bulb and the soil may vary considerably between different contractors and micropile foundation systems. In order to determine whether the contractor's methods of micropile installation are adequate and to determine the ultimate compressive load capacity, we recommend performing two pre-production compressive load tests on sacrificial micropiles. In general, the purpose of the pre-production load test on a micropile is to fulfill the following objectives:

1. To examine the adequacy of the methods and equipment proposed by the contractor to install the micropiles to the depths required.

2. To confirm or modify the estimated minimum depth of the micropiles by determining the ultimate grout-to-soil bond stress.

3. To assess the contractor's method of drilling and grouting.

In general, the pre-production load tests should be performed in accordance with ASTM D1143, as modified herein. Based on experience, we believe the load test should be conducted no earlier than seven days after completion of the micropile installation to allow the grout adequate time to cure. Two additional micropiles may be used for reaction during the compressive load testing of the pre-production load test micropile.

The reaction micropiles may be installed to depths as deep as the load test micropile to provide adequate reaction in uplift (to be determined by the contractor).

The load test micropile should be loaded gradually to at least 200 percent of the allowable design load in compression. We recommend holding the maximum test load (200 percent of the design load) for a minimum of 4 hours (up to a maximum of 8 hours) depending on the recorded movements of the load test micropile. The pre-production load test is an integral part of the design of the micropile foundation system. Therefore, we recommend a Geolabs representative observe the pre-production load test.

In addition to the pre-production load test, we also recommend performing pullout tests (proof tests) on selected micropiles during construction to confirm the load carrying capacity of the installed micropiles. We recommend testing a minimum 5 percent of the total number of micropiles for pullout. The pullout tests should consist of subjecting the micropile to at least 125 percent of the design load. The micropile should be loaded in 12.5% design load increments, and each load should be held for at least 5 minutes. The maximum test load should be held for a minimum of 10 or 60 minutes. Pullout test on the selected micropiles is an integral part of the design of the micropile foundation system. Therefore, we recommend conducting the pullout tests under the observation of a Geolabs representative.

A specialty contractor experienced in the construction of a micropile foundation system (minimum five projects) should perform the installation of the micropiles. Due to the specialized nature of the micropile foundation construction, observation and testing of the micropile foundation system should be designated as a “Special Inspection” item. Therefore, a Geolabs representative (Special Inspector) should be present to observe the geotechnical aspects of the micropile foundation installation and testing.

Settlements of the micropiles will result primarily from elastic compression of the micropile member and subgrade response. We estimate the total settlement of the micropile-supported foundations to be 0.5 inches or less with differential settlements between micropiles not exceeding about one-half of the total settlement. We believe these settlements are essentially elastic and should occur as the loads are applied.

3.2 Shallow Foundations

In general, we believe shallow spread and/or continuous strip footings may be used to support minor structures planned at the project site. It should be noted that where these minor structures (supported on a shallow foundation system) abut the new building structure (supported on a deep foundation system), differential movement between the two structures should be expected and accepted. Therefore, structural connections should not be provided where differential movement between the two structures supported on different foundation systems is expected. Otherwise, shallow foundations should not be used for the minor structures. Based on our evaluation, we recommend supporting the one-story retail spaces located on the north side of the project site on micropile foundations similar to the high-rise tower structure.

An allowable bearing pressure of up to 2,000 pounds per square foot (psf) may be used for the design of footings bearing on the recompacted on-site materials or compacted fill. This bearing value is for dead-plus-live loads and may be increased by one-third (⅓) for transient loads, such as those caused by wind or seismic forces. In general, the bottom of foundations should be embedded a minimum of 18 inches below the lowest adjacent finished grade. Footings constructed near tops of slopes or on sloping ground should be embedded deep enough to provide a minimum horizontal setback distance of 6 feet measured from the outside edge of the footings to the face of the slope.

Foundations next to other foundations, utility trenches, or easements should be embedded below a 45-degree imaginary plane extending upward from the bottom edge of the utility trench, or the footings should extend to a depth as deep as the inverts of the utility lines. This requirement is necessary to avoid surcharging adjacent below-grade structures with additional structural loads and to reduce the potential for appreciable foundation settlement.

If soft and/or loose materials are encountered at the bottom of footing excavations, the soft and/or loose materials should be over-excavated until dense and/or stiff materials are exposed in the footing excavations. The over-excavation should be backfilled with select granular fill materials moisture-conditioned to above the

optimum moisture content and compacted to a minimum of 90 percent relative compaction. Alternatively, the bottom of footing may be extended down to bear directly on the underlying competent materials.

If the foundations for the new structures are designed and constructed in strict accordance with our recommendations, total settlement of foundations is estimated to be on the order of 1.5 inches with differential settlements on the order of about 0.75 inches.

Lateral loads acting on the structure may be resisted by friction between the base of the foundation and the bearing materials and by passive earth pressure developed against the near-vertical faces of the embedded portion of foundations. A coefficient of friction of 0.30 may be used for foundations bearing on the recompacted on-site materials or compacted fill. Resistance to lateral loads due to passive earth pressure may be calculated using an equivalent fluid pressure of 300 pounds per foot per foot of depth (pcf) for foundations embedded in the on-site materials and/or compacted structural fill materials. These values assume the soils around the foundations are well compacted. Unless covered by pavements or slabs, the passive pressure resistance in the upper 12 inches below the finished grade should be neglected.

3.3 Slabs-On-Grade

We anticipate the ground floor slabs for the new building construction will consist of concrete slabs-on-grade. Surface fills consisting of clayey silts are present at the ground surface at the project site. The near-surface clayey fills encountered may exhibit a slight to moderate expansion potential when subjected to moisture fluctuations. To reduce the potential of structural distress to the lightly loaded slabs, we recommend over-excavating the clayey subgrade soils and providing 12 inches of select granular fill below the ground floor slabs. The over-excavation and replacement with 12 inches of select granular fill should extend a minimum of 2 feet laterally beyond the edge of the slab.

The subgrades for concrete slabs-on-grades (not subjected to vehicular traffic) should be scarified to a depth of at least 8 inches, moisture-conditioned to at least 2 percent above the optimum moisture, and compacted to no less than 90 percent

relative compaction. The compaction requirement for subgrades of slabs-on-grades subjected to vehicular traffic, such as the ground floor level parking (if provided), should be increased to a minimum of 95 percent relative compaction. Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density of the same soil determined in accordance with ASTM D1557. Optimum moisture is the water content (percentage by dry weight) corresponding to the maximum dry density.

Select granular fills should consist of imported granular materials such as crushed coral, basaltic gravel, or cinder sands. The materials should be well graded from coarse to fine with particles no larger than 3 inches in largest dimension. The materials should have a laboratory California Bearing Ratio (CBR) value of 20 or higher, and a swell potential of 1 percent or less when tested in accordance with ASTM D1883. The material also should contain between 10 and 30 percent particles passing the No. 200 sieve. The select granular fill materials should be moisture-conditioned to above the optimum moisture content and compacted to at least 90 percent relative compaction. The slab subgrade should be kept moist until covered by the select granular fill.

For the interior building slabs (not subjected to vehicular traffic), we recommend placing a minimum 4-inch thick layer of cushion fill consisting of open-graded gravel (ASTM C33, No. 67 gradation) directly below the slabs. The open-graded gravel cushion fill would serve as a capillary moisture break and would provide for the uniform support of the slabs. To reduce the potential for future moisture infiltration through the slab and subsequent damage to floor coverings, an impervious moisture barrier is recommended on top of the open-graded gravel cushion layer. We also recommend designing interior walls to incorporate some flexibility to accommodate a small amount of possible ground movements.

Where the slabs will be subjected to vehicular traffic, such as the parking garage slabs, we recommend placing a 6-inch layer of aggregate subbase below the slabs in lieu of the 4-inch thick gravel cushion layer. The aggregate subbase should consist of crushed basaltic aggregates compacted to a minimum of 95 percent relative

compaction. Where slabs are intended to function as rigid pavements for trucks, a minimum slab thickness of 6 inches may be used for preliminary design purposes. In addition, provisions should be made for proper load transfer across the slab joints that will be subjected to vehicular traffic. For the design of structural slabs supported on 6 inches of aggregate subbase, a modulus of subgrade reaction of about 200 pounds per square inch per inch of deflection (pci) may be used for the slab resting on the compacted aggregate subbase.

Exterior concrete slabs, such as walkways and patios, also may be required for the project. In general, we recommend providing a minimum 6-inch thick cushion fill layer consisting of select borrow subbase below exterior concrete slabs that will not be subjected to vehicular traffic. The select borrow subbase should be moisture-conditioned to above the optimum moisture and compacted to at least 90 percent relative compaction. The select borrow subbase should be increased to a minimum of 12 inches if expansive clayey soils are encountered at the slab subgrade level. To reduce the potential for significant slab cracking due to concrete shrinkage, crack control joints should be provided at intervals equal to the width of the walkways with expansion joints at right-angle intersections.

The thickened edges of slabs adjacent to unpaved areas should be embedded at least 12 inches below the lowest adjacent grade. It should be emphasized that the areas adjacent to the slabs should be backfilled tightly against the edges of the slabs with relatively impervious soils (well-graded on-site granular soils). These areas also should be graded to divert water away from the slabs and to reduce the potential for water ponding around the slab edges.

3.4 Retaining Structures

Based on the information provided, we understand that retaining structures, such as elevator pits, with a retained height of up to 8 feet will be required for the project. The following general guidelines are provided for design of the retaining structures as described herein.

3.4.1 Retaining Structure Foundations

Parameters for design of foundations for retaining structures that are structurally connected to (or abutting) the high-rise building should be designed in accordance with the "Micropile Foundations" section herein.

For site retaining walls and other retaining structures that are not structurally connected to (or abutting) the new structures, retaining structure foundations may be designed in accordance with the "Shallow Foundations" section herein. Wall footings should have a minimum width of 24 inches. In addition, the bottom of wall footings on relatively flat areas should be embedded a minimum depth of 24 inches below the lowest adjacent finished grade. The bottom of footing elevations also should be limited to Elevation +3 feet MSL or higher to reduce the potential for encountering soft soils at the footing subgrade levels.

In the event that soft subgrade conditions are encountered at the bottom of footing elevations, Geolabs should be contacted to review the exposed conditions and provide supplemental recommendations for treatment of the soft subgrade soils below footings supported on grade.

3.4.2 Static Lateral Earth Pressures

Retaining structures should be designed to resist the lateral earth pressures due to the adjacent soils and surcharge effects. The recommended lateral earth pressures for design of retaining structures expressed in equivalent fluid pressures of pounds per square foot per foot of depth (pcf), are presented below.

LATERAL EARTH PRESSURES FOR DESIGN OF RETAINING STRUCTURES			
Backfill Condition	**Earth Pressure Component**	**Active** (pcf)	**At-Rest** (pcf)
Level Backfill (Above Groundwater)	Horizontal	40	60
	Vertical	None	None
Level Backfill (Below Groundwater)	Horizontal	80	90
	Vertical	None	None

It is assumed that the on-site soils with a maximum particle size of 3 inches or less or select granular fill materials will be used to backfill behind the walls. It is assumed that the backfill behind retaining structures will be compacted to between 90 and 95 percent relative compaction. Over-compaction of the retaining structure backfill should be avoided.

In general, an active condition may be used for gravity retaining walls and walls that are free to deflect by as much as 0.5 percent of the wall height. If the tops of the walls are not free to deflect beyond this degree, or are restrained, the walls should be designed for the at-rest condition. The lateral earth pressures presented do not include hydrostatic pressures that might be caused by groundwater trapped behind the walls.

Surcharge stresses due to areal surcharges, line loads, and point loads within a horizontal distance equal to the depth of the wall should be considered in the design. For uniform surcharge stresses imposed on the loaded side of the wall, a rectangular distribution with a uniform pressure equal to 36 percent of the vertical surcharge pressure acting over the entire height of the wall, which is free to deflect (cantilever), may be used in design. For walls that are restrained, a rectangular distribution equal to 53 percent of the vertical surcharge pressure acting over the entire height of the wall may be used for design. Additional analyses during design may be needed to evaluate the surcharge effects of point loads and line loads.

3.4.3 Drainage

In general, retaining structures should be well drained to reduce the potential for build-up of hydrostatic pressures, especially due to seepage water and/or perched groundwater. A typical drainage system for retaining walls would consist of a minimum 12-inch wide zone of permeable material, such as open-graded gravel (ASTM C33, No. 67 gradation), placed immediately around a perforated pipe (perforations facing down) at the base of the retaining wall. The perforated pipe should discharge to an appropriate outlet.

As an alternative to the use of permeable material, a prefabricated drainage product, such as MiraDrain 6200, may be used instead of the permeable drainage material. The prefabricated drainage product also should be hydraulically connected to a perforated pipe at the base of the retaining wall. The perforated pipe should discharge to an appropriate outlet. Unless covered by concrete or asphaltic concrete, the upper 12 inches of backfill (above the permeable drainage material and/or prefabricated drainage product) should consist of relatively impervious materials, such as the on-site silty and clayey soils, to reduce the potential for significant water infiltration behind the walls.

For site retaining walls, the typical drainage system may consist of 1 to 2 cubic foot of permeable material, such as open-graded gravel (ASTM C33, No. 67 gradation), wrapped with non-woven filter fabric (Mirafi 180N or equivalent) placed at each of the weep hole locations. The weep holes should be spaced not more than 6 feet apart. The backfill from the bottom of the wall to the bottom of the weep hole should consist of relatively impervious material to reduce the potential for significant water infiltration into the subsurface. In addition, the upper 12 inches of the retaining wall backfill should consist of relatively impervious material to reduce the potential for significant water infiltration behind the retaining structure unless covered by concrete slabs at the surface.

3.5 Site Grading

Based on the existing topography, we anticipate minimal site grading work will be required for the project construction. In general, foundation excavations and subsequent backfills of up to about 12 feet deep may be required for construction of the building foundations and elevator pits. It should be noted that placement of new fills at this site likely will induce some consolidation of the soft and/or loose lagoonal deposits underlying the site. Therefore, it is important to place the new fills as soon as practical to allow the ground settlements to occur first prior to construction of improvements, such as the slab-on-grade construction, to reduce the potential for adverse effects resulting from ground settlements. The following site grading items are addressed in the succeeding subsections:

1. Site Preparation
2. Fills and Backfills
3. Fill Placement and Compaction Requirements

A Geolabs representative should monitor the grading operations to observe whether undesirable materials are encountered during the excavation and scarification process, and to confirm whether the exposed soil conditions are similar to those encountered in our field exploration.

3.5.1 Site Preparation

At the on-set of earthwork, areas within the contract grading limits should be cleared and grubbed thoroughly. Vegetation, debris, deleterious materials, existing structures to be demolished, and other unsuitable materials, should be removed and disposed of properly off-site to reduce the potential for contaminating the excavated materials.

Soft and yielding areas encountered during clearing and grubbing below areas designated to receive fill and/or future improvements should be over-excavated to expose firm natural material, and the resulting excavation should be backfilled with well-compacted fill. The excavated soft soils should not be re-used as fill materials and should be properly disposed of off-site.

In general, the over-excavated subgrades and areas designated to receive fills should be scarified to a depth of about 8 inches, moisture-conditioned to above the optimum moisture content, and recompacted to a minimum of 90 percent relative compaction. The compaction requirement of the finished subgrades for areas subjected to vehicular traffic should be increased to a minimum of 95 percent relative compaction. Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density as determined by ASTM D1557. Optimum moisture is the water content (percentage by dry weight) corresponding to the maximum dry density.

3.5.2 Fills and Backfills

In general, the near-surface clayey silt soils encountered during our field exploration should be suitable for use as general fill materials, provided that the

maximum particle size is less than 3 inches in largest dimension. The on-site materials generated from the excavations may be used as a source of general fill or backfill materials provided that they are free of vegetation and deleterious materials and screened of the over-sized materials and/or processed to meet the above gradation requirements (less than 3 inches in largest dimension).

Imported materials to be used as select granular fill should be non-expansive granular material, such as crushed coral or basalt. The select granular fill should be well graded from coarse to fine with particles no larger than 3 inches in largest dimension. The material should have a California Bearing Ratio (CBR) value of 20 or higher, and a swell potential of 1 percent or less when tested in accordance with ASTM D1883. The material also should contain between 10 and 30 percent particles passing the No. 200 sieve. Imported fill materials should be tested for conformance with these recommendations prior to delivery to the project site for the intended use.

Where groundwater is encountered (within the excavations), backfill materials should consist of free-draining granular materials, such as No. 3B Fine gravel (ASTM C33, No. 67 gradation), wrapped on all sides with non-woven filter fabric. The free-draining granular materials should be used up to a level of about 12 inches above the groundwater level to facilitate compaction of the fill materials.

Aggregate base and subbase courses required for the project should consist of crushed basaltic aggregates and should meet the requirements of Sections 31 and 30 of the City and County Standard Specifications (September 1986). Imported fill materials should be tested for conformance with these recommendations prior to delivery to the project site for the intended use.

3.5.3 Fill Placement and Compaction Requirements

In general, fills and backfills should be moisture-conditioned to above the optimum moisture content, placed in level lifts not exceeding 8 inches in loose thickness and compacted to at least 90 percent relative compaction. The compaction requirement for the last lift of fill (finished subgrade) below areas

subjected to vehicular traffic should be increased to at least 95 percent relative compaction.

Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density as determined by ASTM D1557. Optimum moisture is the water content (percentage by dry weight) corresponding to the maximum dry density. Compaction should be accomplished by sheepsfoot rollers, vibratory rollers, or other types of acceptable compaction equipment. Water tamping, jetting, or ponding should not be allowed to compact the fills.

3.6 Excavation

As mentioned above, we anticipate excavations on the order of up to about 13 feet below the ground surface may be required for construction of the building foundations and elevator pits. Based on the subsurface conditions encountered and the limited working space, we envision temporary shoring of some of the deeper excavations may be required.

The field exploration encountered a surface fill layer underlain by soft and/or loose lagoonal deposits near the existing ground surface. Therefore, we envision that conventional excavation techniques using a backhoe excavator may be used for the planned excavations. In general, we believe interlocking steel sheet piling may be used for temporary shoring purposes, especially where dewatering of the excavations will be necessary. However, it should be noted that use of a vibratory hammer to install the interlocking steel sheet piles should be avoided to reduce the potential for inducing a liquefaction condition in the underlying very soft and/or loose lagoonal deposits, which would cause some settlements of the ground adjacent to the sheet pile shoring.

We also recommend the contractor develop and implement a monitoring program to detect ground movement and/or subsidence adjacent to the excavations, which may result in damage to nearby structures and pavements. It should be noted that minor settlements of the adjacent ground may occur during and after installation of the interlocking steel sheet piles. Therefore, we recommend the contractor retain a qualified geotechnical engineer to design and evaluate the shoring system planned.

In general, the contractor should determine the method and equipment to be used for excavations, subject to practical limits and safety considerations. Based on the field exploration, the surface fill materials and underlying soft and/or loose lagoonal deposits encountered in the borings may be excavated with conventional earthmoving equipment. However, some localized areas of hard materials and/or obstructions may be encountered at the site. Therefore, the contractor may encounter difficult excavation conditions at localized areas, which should be expected considering the urban nature of the project site.

3.7 Dewatering

Dewatering of excavations will be necessary where the existing groundwater level is above the bottom of the proposed excavation. We encountered groundwater in our drilled borings at depths of about 7.2 to 8.0 feet below the ground surface at the time of our field exploration. The groundwater levels encountered generally correspond to about Elevations +1.1 to +2.5 feet MSL.

Based on the groundwater levels anticipated and the generally permeable nature of some of the silty sand soils below the surface fills to be encountered within the excavations, dewatering will be required at the planned excavations of the project construction. Therefore, dewatering provisions will need to be included in the contract documents for the proposed construction. Because the excavation may involve discharge of groundwater, a National Pollutant Discharge Elimination System (NPDES) permit may be required for this discharge. The contractor should consult their independent consultant for the latest regulations and information pertaining to the permit application.

Because of the granular nature of some of the subsurface soils, we anticipate the granular soils encountered below the surface fills are relatively permeable. Therefore, dewatering of the excavation may involve moderate volumes of water. Because of the presence of loose and/or soft soils, we do not recommend dewatering by means of a well point system along the outside of the excavations. The resultant areal depression of the natural groundwater table could induce consolidation of the compressible subsurface soils resulting in potential ground settlements, which could affect the

adjacent existing structures. The potential impact of the dewatering system selected on depressing the natural groundwater table must be carefully evaluated by the contractor prior to dewatering.

It is our opinion that a cut-off wall system, such as interlocking steel sheet piles, should be considered to aid in dewatering the excavation. However, sumps will be needed to collect water that percolates up into the base of the excavation or infiltrates through the sheet piles. The sheet piles should be driven to a sufficient depth to reduce the potential for areal ground subsidence and to reduce the amount of dewatering needed within the excavations in areas underlain by granular subsurface soils with moderate permeability. Use of an interlocking sheet pile shoring support system with jet-grouted soils (or tremie concrete plug) is relatively watertight, which should allow the groundwater levels outside the excavations to be maintained close to the original pre-construction levels. Therefore, some type of groundwater control requirement should be specified in the contract documents.

It should be noted that installation of the sheet pile shoring to the desired depths at the site may require predrilling of the sheet pile locations. The presence of these predrilled holes directly adjacent to the sheet pile shoring may serve as conduits for groundwater to infiltrate the sheet pile shored excavation. This condition could result in large volumes of seepage water to infiltrate the shored excavation requiring additional dewatering efforts and disposal of the dewatered effluent. Therefore, the contractor should take precautionary measures to avoid these conditions, which could contribute significantly to the dewatering requirements for the project.

The contractor is responsible for dewatering for construction and disposal of the dewatered effluent. The selection of equipment and methods of dewatering should be left up to the contractor, and he/she should be aware that modifications to the dewatering system may be required during construction depending on the conditions encountered. The dewatering method selected should have minimal impact on the groundwater level surrounding the proposed excavation. The dewatering operations should be coordinated with the shoring support such that the stability of the excavations

is not jeopardized. The operations should be carried-out without softening the bottom of the excavations.

It is our opinion that the definition of "Dewatering" in the contract documents should be written to include works or systems required to lower the natural groundwater table and/or to exclude water from the excavations to allow construction of the proposed structures under safe and dry conditions. These works or systems may include, but are not limited to, pumping, cut-off walls, tremie concrete plugs, etc.

3.7.1 Subsurface Soil Permeability

Based on our borings, the near-surface clayey silt fill soils were underlain by lagoonal deposits consisting of relatively thin layer of loose silty sands overlying a thick deposit of soft organic silts. The permeability of the subsoils at the site may be considered moderately permeable based on the materials encountered. Therefore, the contractor should pay attention to the site-specific dewatering plan for the proposed excavations.

3.7.2 Dewatering Considerations

We suggest considering the following three basic criteria in selection of a suitable method of dewatering:

a. The dewatering method should result in the least disturbance or damage to existing buildings, roads, and environment.

b. The dewatering method should maintain stability of, and also provide safe and dry working conditions in, the excavation.

c. The dewatering method should be sufficiently flexible to allow modifications to accommodate various ground conditions.

3.7.3 Dewatering Precaution and Monitoring

The contractor must carefully evaluate the potential impact of the dewatering system selected on depressing the natural groundwater table prior to dewatering. The contractor should retain a qualified geotechnical engineer to design and evaluate the dewatering system used.

The contractor should be solely responsible for the impact and safety of the dewatering operations. His/her qualified representative, who should be continuously present on-site during dewatering activities, will have the best opportunity to promptly observe the effects of dewatering during construction and to implement, as soon as possible, necessary precautionary or remedial measures including, but not limited to, slowing down or stopping the dewatering operations.

Where encountered at the bottom of excavations, permeable granular soils may be susceptible to piping and “quick” conditions. The dewatering operations should be carried-out without creating a “quick” condition or softening at the excavation bottoms. Therefore, the project dewatering operations should be performed without pumping out soil fines (pumping clear water only) and should be coordinated with the shoring installation such that the excavation stability is not adversely affected. Excessive pumping, which removes soil fines, may result in “blowing” or heaving of the excavation bottom or sides.

Groundwater drawdown outside the excavation will cause additional settlement resulting from consolidation of the soft and/or loose compressible soils. Therefore, the use of a deep well system outside the excavations to draw down the groundwater level should not be allowed.

Special caution also should be taken to avoid dewatering utility trenches connected to the excavations. If this occurs, the granular bedding and/or backfill in the utility trenches could act as subdrains and cause significant areal groundwater drawdown. Significant areal groundwater drawdown would result in appreciable ground settlements and potential damage to utility lines and/or other adjacent existing structures.

3.8 Underground Detention/Infiltration System

In accordance with the City’s storm water requirements, infiltration tests and test pits/borings are required to support the on-site disposal design. To provide information for the design of the detention/filtration system, we advanced four boreholes to a depth of about 5 feet below the pavement surface and installed temporary casing in the

boreholes. The infiltration tests were conducted through the bottom of the cased boreholes in general accordance with the procedures described in the Maryland Storm Water Management manual.

Each boring was pre-soaked with water for approximately two hours prior to testing. Water was introduced into the boring to a depth of about 2 feet above the bottom of the boring; and, the drop of the water level in the boring was measured with respect to time for a falling head test consisting of four individual one hour trials per test. The water level was refilled, as necessary, for each trial.

The tests were carried out in several increments until achieving a steady-state with a relatively constant water infiltration rate. Results of the final infiltration rates are presented in the following table. Detailed testing data and results are presented on Plates D-1 through D-4.

SUMMARY OF BOREHOLE INFILTRATION TESTING		
Boring No.	**Depth** (feet)	**Final Infiltration Rate** (inches/hour)
I-1	5	2.75
I-2	5	0
I-3	5	4.25
I-4	5	0

The percolation test results indicated that the infiltration rates at the site may vary from 0 to 4.25 inches per hour. It should be noted that each percolation test was conducted through a 4-inch borehole, which may not represent the actual infiltration condition within a typical infiltration chamber footprint or an open basin. It should be further noted that these tests were conducted on a preliminary basis and their locations were based on the information provided by the project Civil Engineer and site accessibility.

3.9 Pavement Design

We envision that entry driveways and parking areas will be constructed for the new development. In general, we anticipate the vehicle loading for the new pavements

would consist of primarily passenger vehicles and light trucks with occasional heavy trucks. Therefore, we assumed generally light to medium traffic loading conditions for pavement design purposes. We have made our preliminary pavement design assuming the pavement subgrade soil will consist of the medium stiff clayey silt soils encountered in the borings during our field exploration. On this basis, we recommend utilizing the following pavement design for this project.

Flexible Pavement for Parking Areas

2.0-Inch Asphaltic Concrete
6.0-Inch Aggregate Base Course (95 Percent Relative Compaction)
6.0-Inch Aggregate Subbase Course (95 Percent Relative Compaction)
14.0-Inch Total Pavement Thickness on a Moist Compacted Subgrade

Flexible Pavement for Entry Driveways and Loading Zones

3.0-Inch Asphaltic Concrete
6.0-Inch Aggregate Base Course (95 Percent Relative Compaction)
6.0-Inch Aggregate Subbase Course (95 Percent Relative Compaction)
15.0-Inch Total Pavement Thickness on a Moist Compacted Subgrade

Rigid Pavement for Loading Zones

6.0-Inch Portland Cement Concrete
12.0-Inch Aggregate Subbase (95 Percent Relative Compaction)
18.0-Inch Total Pavement Thickness on a Moist Compacted Subgrade

Pavement restoration for River Street should follow the “Flexible Pavement for Entry Driveways and Loading Zones” presented above or match the existing pavement section, whichever is greater.

The subgrade soils under the pavement areas should be scarified to a minimum depth of 8 inches, moisture-conditioned to above the optimum moisture, and compacted to at least 95 percent relative compaction. If the pavement subgrade soils are pumping during the compaction operation, a layer of woven geotextile fabric, such as Mirafi 500X or equivalent, should be provided between the aggregate subbase and the underlying subgrade soils. CBR tests and/or field observations should be performed on the actual subgrade soils during construction to confirm that the above design sections are adequate. The aggregate base and subbase courses should consist of crushed basaltic aggregates compacted to a minimum of 95 percent relative compaction.

In addition, paved areas should be sloped, and drainage gradients should be maintained to carry the surface water off the site. Surface water ponding should not be allowed on-site during or after construction. Concrete curbs used to isolate landscaping in or adjacent to the pavement areas should extend a minimum of 2 inches into the soils below the aggregate base course layer to reduce the potential for migration of excessive landscape water into the pavement section. Alternatively, a subdrain system could be constructed to collect the excess water from landscaping irrigation. For long-term performance, we recommend constructing a subdrain system adjacent to the paved/landscaped areas.

3.10 Underground Utility Lines

We envision new on-site utility lines (i.e., water, sewer, and drain lines) and utility line connections adjacent to the project site may be required for the development. We anticipate most of the utility line trenches will be excavated in the fills and/or soft/loose lagoonal deposits. In general, we recommend using granular bedding consisting of 6 inches of free-draining granular materials (ASTM C33, No. 67 gradation) below the pipes for uniform support. Free-draining granular materials, such as No. 3B Fine gravel (ASTM C33, No. 67 gradation), also should be used for the initial trench backfill up to about 12 inches above the pipes.

It is critical to use this free-draining material to reduce the potential for formation of voids below the haunches of the pipes and to provide adequate support for the sides of the pipes. Improper backfill material around the pipes and improper placement of the backfill could result in backfill settlement and pipe damage. Where groundwater is encountered, the bedding should be wrapped on all sides by non-woven filter fabric (Mirafi 180N or equivalent).

We envision soft and/or loose lagoonal deposits will be encountered at or near the invert elevations along some of the on-site utility lines planned. Therefore, we recommend providing a subgrade stabilization layer consisting of 24 inches of No. 2 Rock (ASTM C33, No. 4 gradation) wrapped in a non-woven filter fabric (Mirafi 180N or equivalent) below the bedding layer for uniform support. The stabilization layer should extend beyond the sides of the pipe a minimum width of

one-fourth the outside diameter of the pipe or 12 inches, whichever is greater. This 2-foot thick stabilization layer also may be used for support of the 18-inch RCP drain line, drain manholes, and other below-grade structures, such as large meter boxes (8' x 7.5' x 5' deep), biofilter concrete vaults (11' x 7' x 4.6' deep), and electrical concrete encasements (2' high x 1.5'). A typical trench detail is provided on Plate 4.

In general, we anticipate utility lines with an invert elevation deeper than about +1 foot MSL would encounter the soft and/or loose lagoonal deposits and likely will require the use of the stabilization layer. It should be noted that some of the lagoonal deposits at the site are highly sensitive and may be subjected to appreciable settlement due to disturbance caused by construction activities and shoring installation and/or extraction. Therefore, it may be necessary to support some of the more sensitive utility lines (specifically gravity sewer lines) and below-grade structures on jet-grouted column foundations (similar to pile foundations) or ACIP piles depending on the invert depths and pipe materials. Further discussions are presented in the following "Jet-Grouted Column Foundation Support System" section.

The upper portion of the trench backfill from a level of 12 inches above the pipes to the top of the subgrade or finished grade may consist of the excavated granular materials with a maximum particle size of 6 inches or select granular fill materials. The backfill material should be moisture-conditioned to above the optimum moisture content, placed in maximum 8-inch level loose lifts, and mechanically compacted to at least 90 percent relative compaction. In areas where trenches will be in paved areas, the upper 3 feet of the trench backfill below the pavement finished grade should be compacted to no less than 95 percent relative compaction.

3.11 Jet-Grouted Column Foundation Support System

As mentioned above, the lagoonal deposits at the site are highly sensitive and may be subjected to appreciable settlement due to disturbance caused by construction activities and shoring installation and/or extraction. Therefore, it may be necessary to support some of the more sensitive utility lines (specifically gravity sewer lines) and below-grade structures on jet-grouted column foundations (similar to pile foundations) depending on the invert depths and pipe materials.

Jet grouting is a technique utilizing a special drill bit and injection monitor with radial horizontal nozzles to produce stabilized soil-cement columns. The jet-grouting technique is a process that produces soil-cement columns by pumping neat cement grout slurry through horizontal jets injected at high pressures. The horizontal jets of cement grout slurry cuts and mixes the surrounding in-situ materials with the neat cement slurry grout as the drill bit is slowly rotated and withdrawn to form a soil-cement column.

We envision some of the new gravity sewer line inverts may be located within the soft and/or loose lagoonal deposits anticipated at shallow depths. In order to provide support for the new gravity sewer lines from appreciable future settlements, we recommend installing jet-grouted column foundations under the pipes along the new gravity sewer line alignments. The jet-grouted column foundations would derive vertical support from end bearing and skin friction along the sides of the jet-grouted column foundations with the surrounding soils.

The following subsections provide detailed discussions on these utility lines and below-grade structures. In addition, several items of the jet-grouted column foundations also are addressed in the following subsections:

1. Off-Site Gravity Sewer Line
2. On-Site Utility Lines
3. Below-Grade Structures
4. Jet-Grouted Column Foundations
5. Jet Grouting Equipment
6. Jet Grouting Test Program
7. Construction Considerations

3.11.1 Off-Site Gravity Sewer Line

The off-site gravity sewer lines (or any sewer lines) to be dedicated to the City and County of Honolulu, as well as the portions of sewer lines (including manhole structures) extending up to the first sewer line manhole within private property, should be supported by jet-grouted columns following the strict guidelines by the City and County of Honolulu where settlement of the sewer line is not tolerable. Therefore, we recommend installing jet-grouted column foundations with a minimum diameter of 36 inches at a maximum center-to-center spacing of 10 feet

along these sewer line alignments. We also anticipate the new sewer lines likely will be constructed using PVC pipes, which generally come in 20-foot long pipe sections.

The top of the jet-grouted columns should be installed up to 6 inches below the new sewer line inverts to allow for placement of the gravel bedding material wrapped in a non-woven geotextile fabric (Mirafi 180N or equivalent. For estimating purposes, the tip of the jet-grouted columns may be assumed at a depth of about 40 feet below the existing ground surface. A Geolabs representative should be present during the jet-grouted column installation to confirm the foundation bearing material at each of the jet-grouted column locations.

As an alternate, the off-site gravity sewer lines may be supported on the 24-inch thick stabilization layer (in addition to the 6-inch thick bedding) as discussed above provided that the off-site gravity sewer lines remain private and are not dedicated to the City and County of Honolulu. In addition, it is advisable that the slopes for these gravity sewer lines be increased (ideally 2% slope or greater) to account for potential settlements in the line. If the owner elects to support the gravity sewer lines on the 24-inch thick stabilization layer, some additional maintenance of the lines should be anticipated and expected due to the potential for settlement of the installed lines.

3.11.2 On-Site Utility Lines

We recommend providing a 24-inch thick stabilization layer for the on-site underground utility lines and manhole structures because we anticipate the majority of the inverts of the underground utility lines will be near or within the soft and/or loose lagoonal deposits encountered below a depth of about 5 to 7 feet below the existing ground surface. Use of the 24-inch thick stabilization layer for the on-site underground utility lines assumes that some amount of utility line settlement (1 to 3 inches) is considered to be acceptable. Where competent ground conditions are exposed at about the utility line invert elevations, the 24-inch thick stabilization layer may be omitted.

The requirement for the 24-inch stabilization layer should be determined in the field based on the exposed ground conditions at the pipe invert elevations. Therefore, a Geolabs representative should observe the exposed trench subgrade conditions before placement of the pipe bedding to evaluate if the 24-inch thick stabilization layer below the on-site underground utility lines is necessary.

3.11.3 Jet-Grouted Column Foundations

Based on our experience with similar projects, the jet-grouted column foundations should have a minimum diameter of 36 inches. In addition, the grout mix should have a specific gravity of at least 1.5 and should be able to produce jet-grouted column foundations with a 7-day unconfined compressive strength of at least 150 pounds per square inch (psi) and a 28-day unconfined compressive strength of at least 300 psi.

In general, the jet-grouted column foundations should extend to a depth of about 40 feet below the existing ground surface. It should be noted that local variations in the subsurface profile should be anticipated. Because the depths of each column foundation will vary depending on the subsurface conditions and the depth to the invert at each column foundation location, a Geolabs representative should be present to observe the jet grouting operations.

The jet-grouted column foundations should be installed up to about 6 inches below the new utility line inverts to allow for the placement of the gravel bedding material. For preliminary design and cost estimation purposes, an allowable compressive load capacity of up to 30 tons with a column foundation tip elevation of about -34 feet MSL may be used for the recommended jet-grouted column foundation design.

3.11.4 Jet Grouting Equipment

Based on the subsurface conditions anticipated at the site, we recommend using the single fluid method of jet grouting for support of the new utility lines for this project. The drilling equipment should be capable of advancing the jetting rods to the depth required and working in limited headroom conditions. The drilling

equipment also should be equipped with automated controls necessary to slowly rotate and withdraw the jetting rods at those rates determined necessary for the formation of the jet-grouted column foundations. Rates of rotation and withdrawal of the jetting rods for each column foundation should be recorded by the contractor and confirmed by a Geolabs representative.

Grout mixers, holding tanks, and associated equipment should be capable of continuously producing a uniform grout mixture required for the formation of the jet-grouted column foundations. Uniformity of the grout mixture should be measured and recorded by the contractor by taking unit weight (density) measurements of the mixed grout by mud balance at least once every 2,000 gallons of grout mixed and pumped.

High-pressure pumps for the jet grouting operations should be capable of delivering grout at a minimum pressure of 4,000 psi. The high-pressure pumps should be equipped with the necessary gauges to measure and record grout pumping pressures, flow rate, and total grout used for each column foundation.

3.11.5 Jet Grouting Test Program

We recommend undertaking a jet grouting test program to evaluate the proposed grouting methods and the ability of the proposed grout mix to produce jet grout column foundations meeting the depth, diameter, and material property requirements. The test program should be conducted and evaluated; including the results of 28-day unconfined compressive strength tests, prior to starting production jet grouting work.

To achieve these objectives, we recommend constructing at least one test section consisting of a minimum of three jet grout column foundations using the same procedures proposed for the production jet grouting work. The jet grout columns should extend to a depth of about 40 feet below the existing ground surface. The test columns should be installed up to near the existing ground surface to allow for later excavation to below the groundwater level for physical inspection. Excavation to expose the grout columns of the test section should not be sooner than 14 days after the jet grout columns have been constructed.

After the jet grout test columns have set up sufficiently, at least two continuous core samples should be obtained from the full depth of the test columns. In general, we recommend employing triple tube core barrels with thin walls to obtain continuous core samples of the jet grout columns. The core barrel should have a nominal inside diameter of at least 3 inches or greater. The core sample should be obtained from the outer half of the jet grout column radius.

The core samples should be inspected and checked for segregation. A minimum of four compression tests should be performed on each of the core samples in accordance with ASTM D1633 or ASTM D2850, as appropriate.

We recommend a Geolabs representative be present during the jet grouting test program to observe and evaluate the field performance of the proposed jet grouting equipment and methods. Therefore, observation of the jet grouting operations by Geolabs is necessary and should be designated a “Special Inspection” item.

3.11.6 Construction Considerations

Existing underground utilities may be present along the new utility line alignments. The contractor should be responsible for locating and avoiding the underground utility lines during the jet-grouted column foundation installation.

The subsurface conditions generally consist of fills, lagoonal deposits, and older alluvial materials. It should be noted that cobbles and boulders are present below the lagoonal deposit across the project site. If dense cobbles and boulders are encountered above the design tip elevation, drilling of the jet-grouted columns may be terminated earlier by deriving its load bearing capacity from end-bearing onto the cobble and boulder deposits.

Some of the new utility lines may run adjacent to existing sidewalks and travelway. Therefore, grout, soil, and water spoil returns produced during the jet grouting operations should be contained and disposed of properly by the contractor.

3.12 Design Review

Final drawings and specifications for the proposed construction should be forwarded to Geolabs for review and written comments prior to bid solicitation and/or construction. This review is necessary to evaluate conformance of the plans and specifications with the intent of the foundation and earthwork recommendations provided herein. If this review is not made, Geolabs cannot assume responsibility for misinterpretation of the recommendations presented herein.

3.13 Post-Design Services/Services During Construction

It is highly recommended to retain Geolabs for geotechnical engineering support and continued services during construction. The following are critical items of construction monitoring that require "Special Inspection" as stipulated in Section 1704 of IBC 2006.

1. Review of micropile foundation installation submittals
2. Observation of the load test pile installation and load testing
3. Observation of the production micropile installation
4. Observation of shallow foundation excavations
5. Review of jet-grouting submittals
6. Observation of jet-grouting test program
7. Observation of jet-grouted column installation
8. Observation of the subgrade soil preparation
9. Observation of fill placement and compaction

A Geolabs representative should monitor the other aspects of the earthwork construction. This is to observe compliance with the intent of the design concepts, specifications, or recommendations and to expedite suggestions for design changes that may be required in the event that subsurface conditions differ from those anticipated at the time this report was prepared. The recommendations provided herein are contingent upon such observations.

If the actual subsurface conditions encountered during construction are different from those assumed or considered in this report, then appropriate modifications to the design should be made.

END OF DISCUSSION AND RECOMMENDATIONS

SECTION 4. LIMITATIONS

The analyses and recommendations submitted herein are based in part upon information obtained from the field borings. Variations of the subsurface conditions between and beyond the field borings may occur, and the nature and extent of these variations may not become evident until construction is underway. If variations then appear evident, it will be necessary to re-evaluate the recommendations presented herein.

The locations of the field borings indicated in this report are approximate, having been estimated by taping from visible features shown on the Site Plan transmitted by Gray, Hong, Nojima & Associates, Inc. on May 7, 2019. Elevations of the borings were interpolated based on the spot elevations shown on the same plan. The locations and elevations of the field borings should be considered accurate only to the degree implied by the methods used.

The stratification breaks shown on the graphic representations of the borings depict the approximate boundaries between soil and/or rock types and, as such, may denote a gradual transition. Water level data from the borings were measured at the times shown on the graphic representations and/or presented in the text of this report. These data have been reviewed and interpretations made in the formulation of this report. However, it must be noted that fluctuation may occur due to variation in tides, rainfall, perched groundwater conditions, groundwater withdrawal, and other factors.

This report has been prepared for the exclusive use of Halewai`olu Senior Development, LLC and their project consultants for specific application to the *Halewai`olu Senior Residences* project in Honolulu on the Island of Oahu as described herein in accordance with generally accepted geotechnical engineering principles and practices. No warranty is expressed or implied.

This report has been prepared solely for the purpose of assisting the architects and engineers in the preparation of the design documents for the new office building project. Therefore, this report may not contain sufficient data, or the proper information, for use to form the basis for preparation of construction cost estimates or contract

bidding. A contractor wishing to bid on this project should retain a competent geotechnical engineer to assist in the interpretation of this report and/or performance of site-specific exploration for bid estimating purposes.

The owner/client should be aware that unanticipated subsurface conditions are commonly encountered. Unforeseen subsurface conditions, such as perched groundwater, soft deposits, hard layers, or cavities, may occur in localized areas and may require additional probing or corrections in the field (which may result in construction delays) to attain a properly constructed project. Therefore, a sufficient contingency fund is recommended to accommodate these possible extra costs.

This geotechnical engineering exploration conducted at the project site was not intended to investigate the potential for presence of hazardous materials existing at the project site. It should be noted that the equipment, techniques, and personnel used to conduct a geo-environmental exploration differ substantially from those applied in geotechnical engineering.

END OF ADDITIONAL SERVICES AND LIMITATIONS

CLOSURE

The following plates and appendices are attached and complete this report:

APPENDIX A

APPENDIX A

Field Exploration

Our preliminary field exploration at the project site consisted of drilling and sampling two test borings, designated as Boring Nos. 1 and 2, extending to depths of about 121.2 and 86 feet below the existing pavement surface, respectively. The current field exploration program consisted of drilling and sampling four additional test borings, designated as Boring Nos. 101 through 104, extending to depths of about 79 to 152.5 feet below the existing pavement surface. In addition, four shallow borings to a depth of about 5 feet were drilled for the performance of infiltration testing. The approximate locations of the drilled borings from the preliminary and current field explorations are shown on the Site Plan (Plate 2). The borings were drilled using a truck-mounted drill rig equipped with continuous flight augers and rotary coring tools.

Our geologists classified the materials encountered in the borings by visual and textural examination in the field in general accordance with ASTM D2488, Standard Practice for Description and Identification of Soils, and monitored the drilling operations on a near-continuous (full-time) basis. These classifications were further reviewed visually and by testing in the laboratory. Soils were classified in general accordance with ASTM D2487, Standard Practice for Classification of Soils for Engineering Purposes (Unified Soil Classification System), as shown on the Soil Log Legend, Plate A-0.1. Deviations made to the soil classification in accordance with ASTM D2487 are described on the Soil Classification Log Key, Plate A-0.2. Graphic representations of the materials encountered are presented on the Logs of Boring, Plates A-1 thru A-8.

Relatively “undisturbed” soil samples were obtained in general accordance with ASTM D3550, Ring-Lined Barrel Sampling of Soils, by driving a 3-inch OD Modified California sampler with a 140-pound hammer falling 30 inches. In addition, some samples were obtained from the drilled boring in general accordance with ASTM D1586, Penetration Test and Split-Barrel Sampling of Soils, by driving a 2-inch OD standard penetration sampler using the same hammer and drop. The blow counts needed to drive the sampler the second and third 6 inches of an 18-inch drive are shown as the “Penetration Resistance” on the Logs of Boring at the appropriate sample depths. The penetration resistance shown on the logs of boring indicates the number of blows required for the specific sampler type used. The blow counts may need to be factored to obtain the Standard Penetration Test (SPT) blow counts.

Pocket penetrometer tests were performed on selected cohesive soil samples in the field. The pocket penetrometer test provides an indication of the unconfined compressive strength of the sample. Results of the pocket penetrometer tests are summarized on the Logs of Borings at the appropriate sample depths.

Core samples of the rock materials encountered at the project site were obtained by using diamond core drilling techniques in general accordance with ASTM D2113, Diamond Core Drilling for Site Investigation. Core drilling is a rotary drilling method that

uses a hollow bit to cut into the rock formation. The rock material left in the hollow core of the bit is mechanically recovered for examination and description. Rock cores were described in general accordance with the Rock Description System, as shown on the Rock Log Legend, Plate A-0.2. The Rock Description System is based on the publication “Suggested Methods for the Quantitative Description of Discontinuities in Rock Masses” by the International Society for Rock Mechanics (March 1977).

Recovery (REC) may be used as a subjective guide to the interpretation of the relative quality of rock masses, where appropriate. Recovery is defined as the actual length of material recovered from a coring attempt versus the length of the core attempt. For example, if 3.7 feet of material is recovered from a 5.0-foot core run, the recovery would be 74 percent and would be shown on the Logs of Borings as REC = 74%.

The Rock Quality Designation (RQD) is also a subjective guide to the relative quality of rock masses. RQD is defined as the percentage of the core run in rock that is sound material in excess of 4 inches in length without any discontinuities, discounting any drilling, mechanical, and handling induced fractures or breaks. If 2.5 feet of sound material is recovered from a 5.0-foot core run in rock, the RQD would be 50 percent and would be shown on the Logs of Borings as RQD = 50%. Generally, the following is used to describe the relative quality of the rock based on the "Practical Handbook of Physical Properties of Rocks and Minerals” by Robert S. Carmichael (1989).

Rock Quality	**RQD** (%)
Very Poor	0 – 25
Poor	25 – 50
Fair	50 – 75
Good	75 – 90
Excellent	90 – 100

The excavation characteristics of a rock mass or coral formation is a function of the relative hardness of the coral/rock, its relative quality, brittleness, and fissile characteristics. A dense formation with a high RQD value would be very difficult to excavate or drill and would probably require more arduous methods of excavation.

GEOLABS, INC.

Geotechnical Engineering

Soil Classification Log Key

(with deviations from ASTM D2488)

GEOLABS, INC. CLASSIFICATION*

GRANULAR SOIL (- #200 <50%)

- **PRIMARY** constituents are composed of the largest percent of the soil mass. Primary constituents are capitalized and bold (i.e., **GRAVEL, SAND**)
- **SECONDARY** constituents are composed of a percentage less than the primary constituent. If the soil mass consists of 12 percent or more fines content, a cohesive constituent is used (**SILTY** or **CLAYEY**); otherwise, a granular constituent is used (**GRAVELLY** or **SANDY**) provided that the secondary constituent consists of 20 percent or more of the soil mass. Secondary constituents are capitalized and bold (i.e., **SANDY** GRAVEL, **CLAYEY** SAND) and precede the primary constituent.
- **accessory descriptions** compose of the following:
  with some: >12%
  with a little: 5 - 12%
  with traces of: <5%
  accessory descriptions are lower cased and follow the Primary and Secondary Constituents
  (i.e., SILTY GRAVEL **with a little sand**)

COHESIVE SOIL (- #200 ≥ 50%)

- **PRIMARY** constituents are based on plasticity. Primary constituents are capitalized and bold (i.e., **CLAY, SILT**)
- **SECONDARY** constituents are composed of a percentage less than the primary constituent, but more than 20 percent of the soil mass. Secondary constituents are capitalized and bold (i.e., **SANDY** CLAY, **SILTY** CLAY, **CLAYEY** SILT) and precede the primary constituent.
- **accessory descriptions** compose of the following:
  with some: >12%
  with a little: 5 - 12%
  with traces of: <5%
  accessory descriptions are lower cased and follow the Primary and Secondary Constituents
  (i.e., SILTY CLAY **with some sand**)

EXAMPLE: Soil Containing 60% Gravel, 25% Sand, 15% Fines. Described as: **SILTY GRAVEL** with some sand

RELATIVE DENSITY / CONSISTENCY

Granular Soils			Cohesive Soils			
N-Value (Blows/Foot)		Relative Density	N-Value (Blows/Foot)		PP Readings (tsf)	Consistency
SPT	MCS		SPT	MCS		
0 - 4	0 - 7	Very Loose	0 - 2	0 - 4		Very Soft
4 - 10	7 - 18	Loose	2 - 4	4 - 7	< 0.5	Soft
10 - 30	18 - 55	Medium Dense	4 - 8	7 - 15	0.5 - 1.0	Medium Stiff
30 - 50	55 - 91	Dense	8 - 15	15 - 27	1.0 - 2.0	Stiff
> 50	> 91	Very Dense	15 - 30	27 - 55	2.0 - 4.0	Very Stiff
			> 30	> 55	> 4.0	Hard

MOISTURE CONTENT DEFINITIONS

Dry: Absence of moisture, dry to the touch

Moist: Damp but no visible water

Wet: Visible free water

ABBREVIATIONS

WOH: Weight of Hammer

WOR: Weight of Drill Rods

SPT: Standard Penetration Test Split-Spoon Sampler

MCS: Modified California Sampler

PP: Pocket Penetrometer

GRAIN SIZE DEFINITION

Description	Sieve Number and / or Size
Boulders	> 12 inches (305-mm)
Cobbles	3 to 12 inches (75-mm to 305-mm)
Gravel	3-inch to #4 (75-mm to 4.75-mm)
Coarse Gravel	3-inch to 3/4-inch (75-mm to 19-mm)
Fine Gravel	3/4-inch to #4 (19-mm to 4.75-mm)
Sand	#4 to #200 (4.75-mm to 0.075-mm)
Coarse Sand	#4 to #10 (4.75-mm to 2-mm)
Medium Sand	#10 to #40 (2-mm to 0.425-mm)
Fine Sand	#40 to #200 (0.425-mm to 0.075-mm)

Soil descriptions are based on ASTM D2488-09a, Visual-Manual Procedure, with the above modifications by Geolabs, Inc. to the Unified Soil Classification System (USCS).

	**CLINKER**		**SILTSTONE**
	**COBBLES**		**TUFF**
	**CORAL**		**VOID/CAVITY**

ROCK DESCRIPTION SYSTEM

ROCK FRACTURE CHARACTERISTICS

The following terms describe general fracture spacing of a rock:

Massive: Greater than 24 inches apart

Slightly Fractured: 12 to 24 inches apart

Moderately Fractured: 6 to 12 inches apart

Closely Fractured: 3 to 6 inches apart

Severely Fractured: Less than 3 inches apart

DEGREE OF WEATHERING

The following terms describe the chemical weathering of a rock:

Unweathered: Rock shows no sign of discoloration or loss of strength.

Slightly Weathered: Slight discoloration inwards from open fractures.

Moderately Weathered: Discoloration throughout and noticeably weakened though not able to break by hand.

Highly Weathered: Most minerals decomposed with some corestones present in residual soil mass. Can be broken by hand.

Extremely Weathered: Saprolite. Mineral residue completely decomposed to soil but fabric and structure preserved.

HARDNESS

The following terms describe the resistance of a rock to indentation or scratching:

Very Hard: Specimen breaks with difficulty after several "pinging" hammer blows.
Example: Dense, fine grain volcanic rock

Hard: Specimen breaks with some difficulty after several hammer blows.
Example: Vesicular, vugular, coarse-grained rock

Medium Hard: Specimen can be broked by one hammer blow. Cannot be scraped by knife. SPT may penetrate by ~25 blows per inch with bounce.
Example: Porous rock such as clinker, cinder, and coral reef

Soft: Can be indented by one hammer blow. Can be scraped or peeled by knife. SPT can penetrate by ~100 blows per foot.
Example: Weathered rock, chalk-like coral reef

Very Soft: Crumbles under hammer blow. Can be peeled and carved by knife. Can be indented by finger pressure.
Example: Saprolite

APPENDIX B

APPENDIX B

Seismic Shear Wave Velocity Test

Seismic shear wave velocity profiling of the subsurface materials at the project site was performed using Seismic Cone Penetration Testing (SCPT) equipment. The purpose of the seismic shear wave velocity profiling of the subsurface materials was to more closely analyze the seismic design considerations for the project. Shear wave velocity testing using seismic cone penetration testing equipment was performed at a selected boring location, designated as B-1(SW), located within the old alluvial stream channel as shown on the Site Plan (Plate 2). The seismic shear wave velocity profiling was performed at various depths extending to a maximum depth of about 120 feet below the existing pavement surface.

To conduct the seismic shear wave velocity test in the boring, the test boring was advanced utilizing rotary coring methods to the maximum depth of the boring. A log of the materials encountered in the boring is presented in the Logs of Borings in Appendix A. After the boring was advanced to the maximum depth of the borehole, the bored hole was backfilled with 0.25-inch diameter coated bentonite pellets. The temporary casing from the coring operations was used as a tremie pipe to place the bentonite pellets starting from the bottom and advancing upward. When the bentonite pellets are in contact with the groundwater in the borehole, the pellets started to hydrate slowly. As the bentonite pellets hydrate, they swell and soften. The probe was then pushed through the softened bentonite extending to a depth of about 120 feet below the existing pavement surface using seismic cone testing equipment (SCPT).

The seismic shear wave velocity test consists of hydraulically pushing a 10-ton steel electronic subtraction cone with an apex angle of 60 degrees and a projected surface area of 1.55 square inches (10 square centimeters) into the bored hole. The cone carries a uniaxial horizontal accelerator geophone to detect the arrival of a shear wave generated and propagated from the ground surface. The seismic measurements were made when the SCPT had stopped and a shear wave was sent into the subsurface. A shear wave was generated at the surface by striking a loaded plank with a switched hammer. The propagation time of the wave from the hammer blow to the cone was measured at each discrete depth interval. The vector difference of these depths divided by the time difference for the shear wave to arrive at the various depths gave provided the average shear wave velocity over the depth interval.

The seismic shear wave velocities measured and the weighted average seismic shear wave velocity calculated for the top 100 feet of the soil profile at the test location are presented on Plates B-1.1 thru B-1.5 in Appendix B. The weighted average shear wave velocity was calculated based on the average shear wave velocity method described in Section 1615.1.5 of the International Building Code (2006 Edition).

APPENDIX C

APPENDIX C

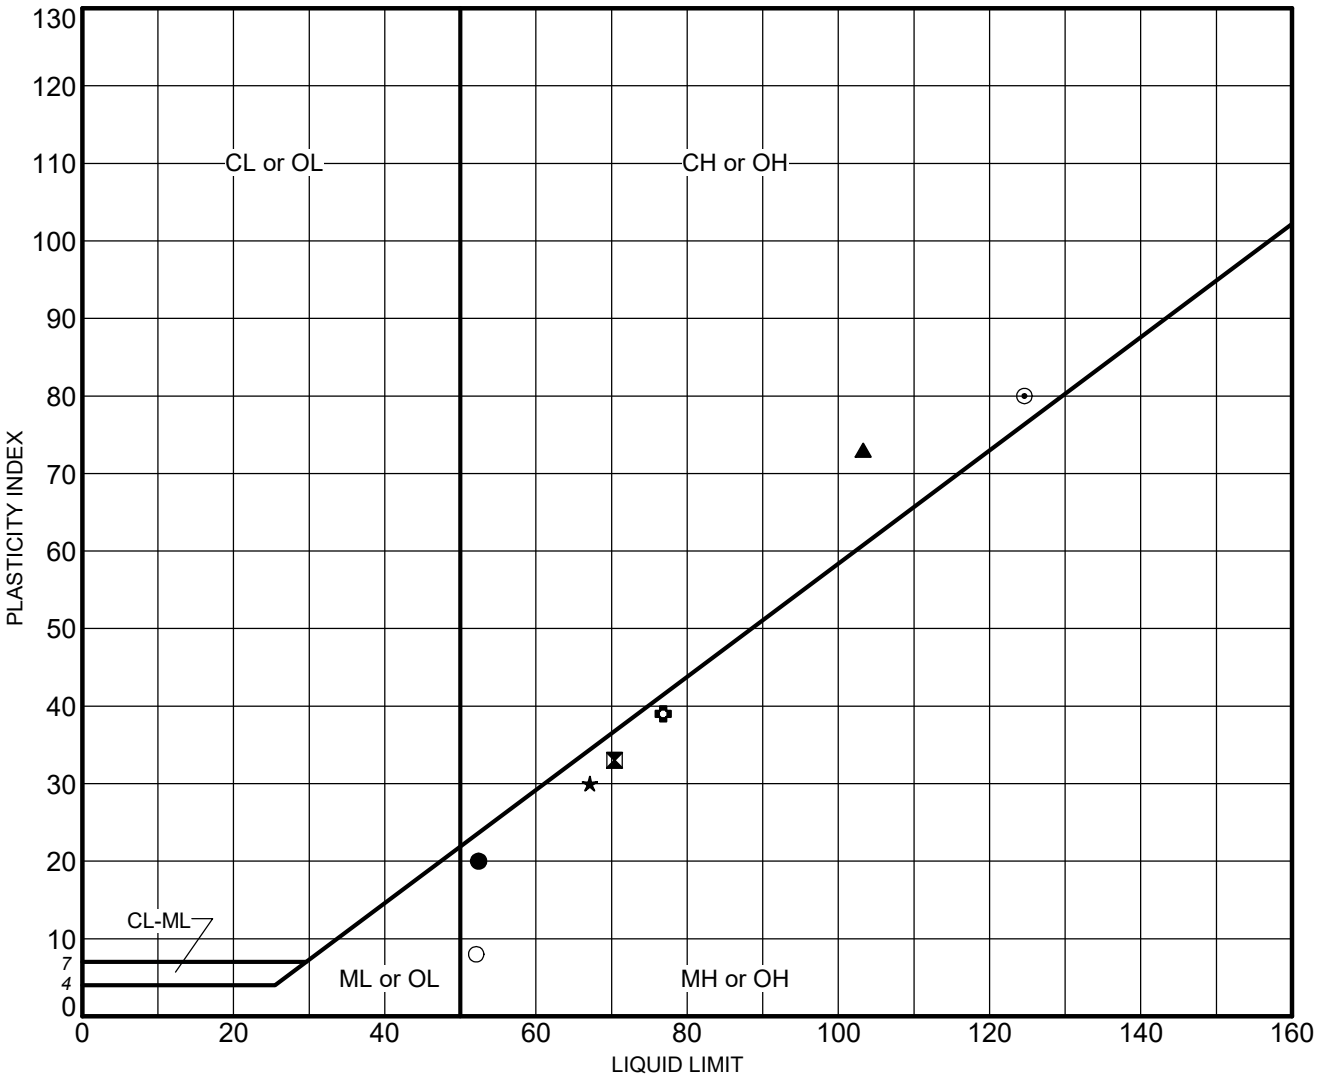
Laboratory Tests

Moisture Content (ASTM D2216) and Unit Weight (ASTM D2937) determinations were performed on selected samples as an aid in the classification and evaluation of soil properties. The test results are presented on the Logs of Boring at the appropriate sample depths.

Seven Atterberg Limits tests (ASTM D4318) were performed on selected soil samples to evaluate the liquid and plastic limits to aid in soil classifications. The test results are summarized on the Logs of Borings at the appropriate sample depths. Graphic presentations of the test results are provided on Plate C-1.

Three Sieve Analysis tests (ASTM C117 and C136) were performed on selected soil samples to evaluate the gradation characteristics of the soils and to aid in soil classification. In addition, two hydrometer tests (ASTM D422) were conducted on the samples to further evaluate the finer grain materials of the soils. Graphic presentations of the grain size distribution of the soils are provided on Plate C-2.

Three one-inch Ring Swell tests were performed on relatively undisturbed samples to evaluate the swelling potential of the near-surface soils. The test results are summarized on Plate C-3.



Four Uniaxial Compression tests (ASTM D7012, Method C) were performed on selected core samples to evaluate the unconfined compressive strength of the basalt formation encountered. The test results are presented on Plate C-4.

Thirteen Unconsolidated Undrained Triaxial Compression tests (ASTM D2850) were performed on selected soil samples to evaluate the undrained shear strength of the in-situ soils. The approximate in-situ effective overburden pressure was used as the applied confining pressure for the relatively “undisturbed” soil sample. The test results and the stress-strain curves are presented on Plates C-5 through C-17.

One Modified Proctor compaction test (ASTM D1557) was performed on a bulk sample of the near-surface soils to evaluate the dry density and moisture content relationships. The test results are presented on Plates C-18.

Two laboratory California Bearing Ratio tests (ASTM D1883) were performed on bulk samples of the near-surface soils to evaluate the pavement support characteristics of the soils. The test results are presented on Plates C-19 and C-20.

Two sets of Corrosivity tests, including pH (ASTM G51), Minimum Resistivity (ASTM G57), Chloride Content (EPA 300.0), and Sulfate Content (EPA 300.0), were performed by our office and TestAmerica Laboratories, Inc. on selected soil samples obtained from our field exploration. The test results are summarized on Plate C-21.

Attention: Questor Lau, AIA
Development Officer

Subject: April 2019 Noise Study Report ; Halewai`olu Senior Residences; 1221 River Street

Dear Mr. Lau:

In my noise study report dated April 2019, I had assumed that project build-out would be in Year 2021. The forecasted traffic noise levels in Year 2021 at the faces of the project's residential tower were shown in Table 5 on Page 21 of my report. As indicated in my report, receptors at the residential tower's mauka face (Locations T1 Mauka) were predicted to have the highest traffic noise levels in 2021, ranging as high as 64 to 65 DNL.

When rounding to the nearest 0.1 DNL, the Year 2021 noise level predictions in Table 5 ranged from 64.3 to 64.9 DNL along the residential tower's mauka face. Traffic noise levels are expected to increase by 0.5 DNL from Year 2021 to Year 2029 as indicated in the noise study report, with annual increases being approximately 0.06 DNL per year between Year 2021 and Year 2029. The extrapolated Year 2022 noise level predictions then fall within a range of values from 64.4 to 65.0 DNL along the residential tower's mauka face, when rounded to the nearest 0.1 DNL.

The results of the calculations above indicate that the DNL forecasts for Year 2022 at receptors located closest to the 65 DNL exposure level zone should be identical to the Year 2021 values of Table 5 on Page 21 of my report when rounded to the nearest 1 DNL unit. For this reason, traffic noise mitigation measures should also not be required in Year 2022.

Sincerely,

Yochi Ebisu, P.E.

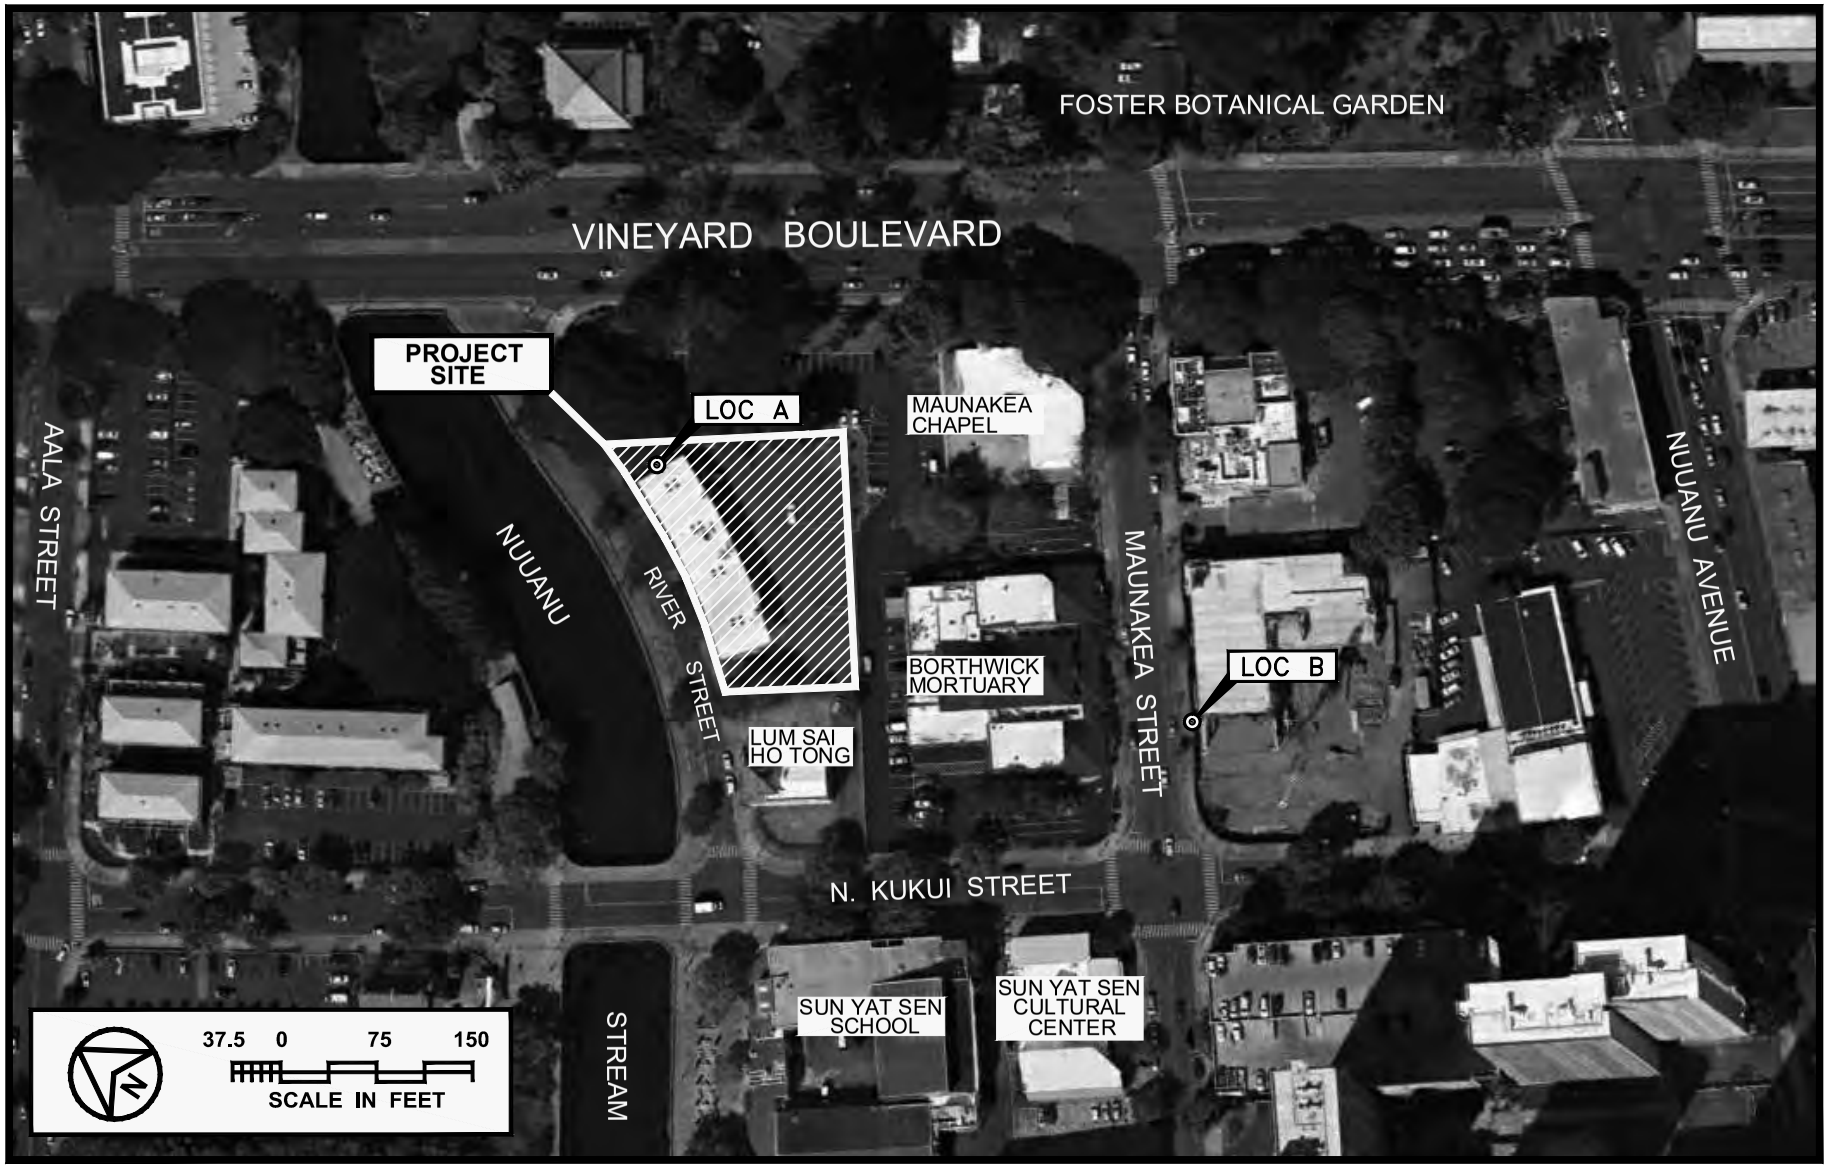
CHAPTER I. SUMMARY



The existing and future traffic noise levels in the vicinity of the proposed Halewai`olu Senior Residences Project (see Figure 1) were evaluated for their potential impacts and their relationship to the current FHA/HUD (Federal Housing Administration/Housing and Urban Development) noise standard. The traffic noise level increases along the access roadways to and from the project site were calculated. No significant increases in traffic noise are predicted to occur along Vineyard Boulevard River Street, North Kukui Street, or Maunakea Street as a result of project plus non-project traffic following project build-out by CY 2021. The increases in future traffic noise levels resulting from project traffic are predicted to range from 0.0 to 0.2 DNL (Day-Night Average Sound Level). Traffic noise from Vineyard Boulevard will continue to control background ambient noise levels in the immediate project environs.

Future traffic noise levels are predicted to not exceed the FHA/HUD standard of 65 DNL at all units of the project's proposed residential tower building through 2021. Noise mitigation measures in the form of the use of sliding windows and consideration of the use of selected building materials at the residential units is recommended to minimize potential noise impacts from future traffic noise. Compliance with the FHA/HUD 65 DNL noise standard may be possible by CY 2029, but will require traffic noise mitigation measures at any residential unit located along the mauka (north) face of the proposed tower building. These required mitigation measures include the use of a solid mauka wall and non-operable windows or doors along the mauka face of the tower, or the use of closure and air conditioning of all rooms which are located along the mauka wall of the residential tower.

The Halewai`olu Senior Residences Project traffic will not increase the future traffic noise along a high volume and high noise level roadway such as Vineyard Boulevard because of the very low volume of project traffic anticipated to use that roadway. The total increases in future traffic noise levels along this high volume roadway resulting from project and non-project traffic are predicted to be 0.0 and 0.2 DNL, respectively, by CY 2021. An additional increase of 0.5 DNL by 2029 is predicted along Vineyard Boulevard as a result of non-project traffic.

Similar increases in traffic noise levels of 0.2 to 0.4 DNL are predicted to occur along North Kukui and Maunakea Streets as a result of project and non-project traffic by CY 2021. Increases of 3.1 and 0.2 DNL are anticipated along River Street as a result of non-project and project traffic, respectively. However, these increases will be difficult to measure or perceive. The 3.1 DNL increase along River Street is not considered to be significant because of the relatively low existing noise levels along that roadway.

Unavoidable, but temporary, noise impacts may occur during the excavation and building erection activities within the project area, and particularly during the earthwork activities on the project site. Because construction activities are predicted to be audible

PROJECT LOCATION MAP AND NOISE MEASUREMENT LOCATIONS

FIGURE 1

within the project site and at adjoining properties, the quality of the acoustic environment may be degraded to unacceptable levels during periods of construction. Mitigation measures to reduce construction noise to inaudible levels will not be practical in all cases, but the use of quiet equipment is recommended as a standard mitigation measure. The implementation of Hawaii State Department of Health permit procedures and curfew periods for construction activities is also expected for this project.

CHAPTER II. PURPOSE

The primary objective of this study was to describe the existing and future noise environment in the environs of the proposed Halewai`olu Senior Residences Project on the island of Oahu. Traffic noise level increases and impacts associated with the proposed development were to be determined along the public roadways which are expected to service the project related traffic. A specific objective was to determine future traffic noise level increases associated with both project and non-project traffic, and the potential noise impacts associated with these increases.

Potential noise impacts at planned senior housing and commercial units of the project due to traffic noise were also evaluated. Assessments of possible future impacts from short term construction noise at the project site were also included as noise study objectives. Recommendations for minimizing identified noise impacts were also to be provided as required.

CHAPTER III. NOISE DESCRIPTORS AND THEIR RELATIONSHIP TO LAND USE COMPATIBILITY

The noise descriptor currently used by federal agencies (such as FHA/HUD) to assess environmental noise is the Day-Night Average Sound Level (Ldn or DNL). This descriptor incorporates a 24-hour average of instantaneous A-Weighted Sound Levels as read on a standard Sound Level Meter. By definition, the minimum averaging period for the DNL descriptor is 24 hours. Additionally, sound levels which occur during the nighttime hours of 10:00 PM to 7:00 AM are increased by 10 decibels (dB) prior to computing the 24-hour average by the DNL descriptor. A more complete list of noise descriptors is provided in Appendix B to this report.

Table 1, derived from Reference 1, presents current federal noise standards and acceptability criteria for residential land uses. Land use compatibility guidelines for various levels of environmental noise as measured by the DNL descriptor system are shown in Figure 2. As a general rule, noise levels of 55 DNL or less occur in rural areas, or in areas which are removed from high volume roadways. In urbanized areas which are shielded from high volume streets, DNL levels generally range from 55 to 65 DNL, and are usually controlled by motor vehicle traffic noise. Residences which front major roadways are generally exposed to levels of 65 DNL, and as high as 75 DNL when the roadway is a high speed freeway. In the project area, traffic noise levels along the Rights-of-Way of Vineyard Boulevard are greater than 65 DNL due to the large volumes of traffic and heavy vehicles (trucks and buses) on this major thoroughfare.

For purposes of determining noise acceptability for funding assistance from federal agencies (FHA/HUD and VA), an exterior noise level of 65 DNL or less is considered acceptable for residences and other noise sensitive uses. This standard is applied nationally (Reference 2), including Hawaii. Because of our open-living conditions, the predominant use of naturally ventilated dwellings, and the relatively low exterior-to-interior sound attenuation afforded by these naturally ventilated structures, an exterior noise level of 65 DNL does not eliminate all risks of noise impacts. Because of these factors, and as recommended in Reference 3, a lower level of 55 DNL is considered to be the "Unconditionally Acceptable" (or "Near-Zero Risk") level of exterior noise. However, after considering the cost and feasibility of applying the lower level of 55 DNL, government agencies such as FHA/HUD and VA have selected 65 DNL as a more appropriate regulatory standard.

For commercial, industrial, and other non-noise sensitive land uses, exterior noise levels as high as 75 DNL are generally considered acceptable. Exceptions to this occur when naturally ventilated office and other commercial establishments are exposed to exterior levels which exceed 65 DNL.

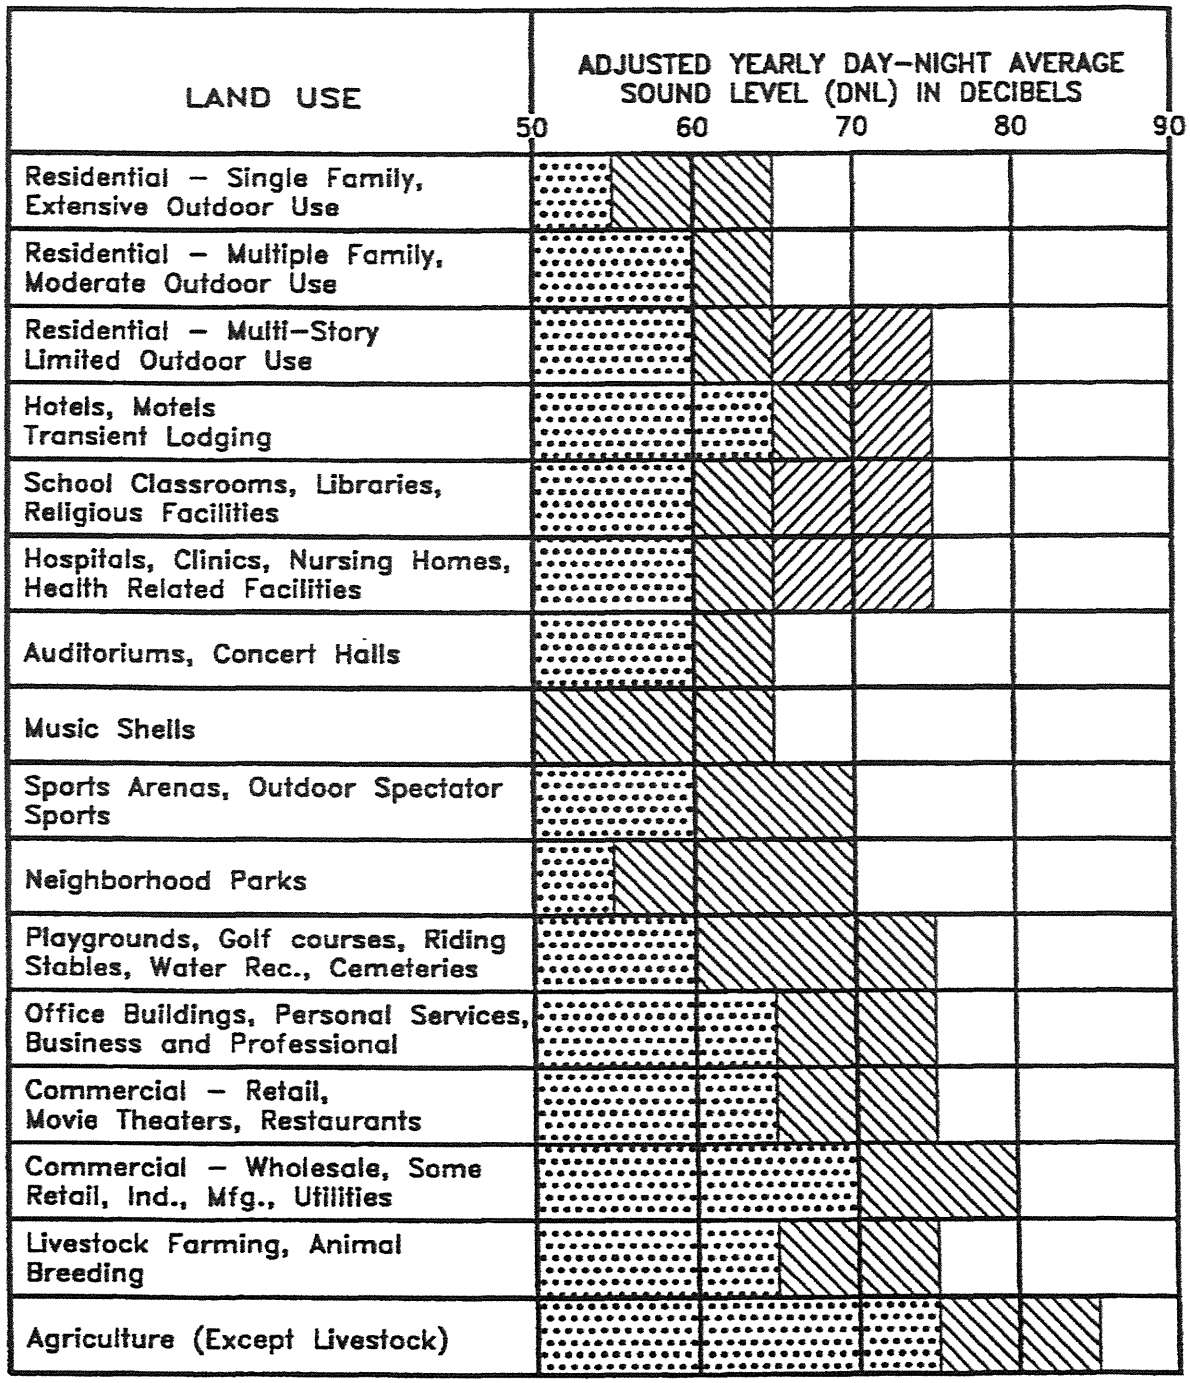


TABLE 1

EXTERIOR NOISE EXPOSURE CLASSIFICATION (RESIDENTIAL LAND USE)

NOISE EXPOSURE CLASS	DAY–NIGHT SOUND LEVEL	EQUIVALENT SOUND LEVEL	FEDERAL (1) STANDARD
Minimal Exposure	Not Exceeding 55 DNL	Not Exceeding 55 Leq	Unconditionally Acceptable
Moderate Exposure	Above 55 DNL But Not Above 65 DNL	Above 55 Leq But Not Above 65 Leq	Acceptable(2)
Significant Exposure	Above 65 DNL But Not Above 75 DNL	Above 65 Leq But Not Above 75 Leq	Normally Unacceptable
Severe Exposure	Above 75 DNL	Above 75 Leq	Unacceptable

Notes: (1) Federal Housing Administration, Veterans Administration, Department of Defense, and Department of Transportation.

(2) FHWA uses the Leq instead of the Ldn descriptor. For planning purposes, both are equivalent if: (a) heavy trucks do not exceed 10 percent of total traffic flow in vehicles per 24 hours, and (b) traffic between 10:00 PM and 7:00 AM does not exceed 15 percent of average daily traffic flow in vehicles per 24 hours. The noise mitigation threshold used by FHWA for residences is 67 Leq.

LAND USE COMPATIBILITY WITH YEARLY AVERAGE DAY-NIGHT AVERAGE SOUND LEVEL (DNL) AT A SITE FOR BUILDINGS AS COMMONLY CONSTRUCTED.
(Source: American National Standards Institute S12.9-1998/Part 5)

FIGURE 2

On the island of Oahu, the State Department of Health (DOH) regulates noise from fixed mechanical equipment and construction activities. State DOH noise regulations are expressed in maximum allowable noise limits rather than DNL (see Reference 4). Although they are not directly comparable to noise criteria expressed in DNL, State DOH noise limits for single family residential lands equate to approximately 55 DNL. For multifamily residential, commercial, and resort lands, the State DOH noise limits equate to approximately 60 DNL. For light and heavy industrial lands, the State DOH noise limits equate to approximately 76 DNL. Construction activities, which are typically noisier than the State DOH noise limits, are regulated through the issuance of permits for allowing excessive construction noise during limited time periods.

CHAPTER IV. GENERAL STUDY METHODOLOGY

Existing traffic and background ambient noise level measurements were obtained in the project environs during March 2019. These readings were used to provide a basis for describing the existing noise environment in the project environs. Traffic noise measurements along Vineyard Boulevard and Maunakea Street were obtained at Locations A and B, respectively, as shown in Table 2. The locations of these two measurement sites are shown in Figure 1. Location A was at the second floor landing of an existing commercial building on the project site. Location B was at ground level fronting Maunakea Street.

Traffic noise calculations for the existing conditions as well as noise predictions for CY 2021 were performed using the Federal Highway Administration (FHWA) Traffic Noise Model Version 2.5 (Reference 5). Traffic data entered into the noise prediction model were: roadway and receiver locations; hourly traffic volumes, average vehicle speeds; estimates of traffic mix; and "Loose Soil" and "Pavement" propagation loss factors. The traffic data and forecasts for the project (References 6 and 7) were the primary sources of data inputs to the model. Hourly traffic volume and vehicle classification counts for Vineyard Boulevard provided by the State Department of Transportation, Highways Division (HDOT, References 8 and 9) were used to describe existing traffic volumes and traffic noise levels along Vineyard Boulevard. Appendix C summarizes the AM and PM peak hour traffic volumes for CY 2019 and 2021 which were available from the project's traffic study and the HDOT data for Vineyard Boulevard. For existing and future traffic along the streets surrounding the project site, it was assumed that the average noise levels, or Leq(h), during the PM peak traffic hour were approximately 1.0 greater than the 24-hour DNL, and during the AM peak traffic hour were equal to the 24-hour DNL. These assumptions were based on calculated traffic noise levels using the traffic and classification counts from References 8 through 9, which are shown graphically in Figure 3. In Figure 3, the HDOT hourly traffic volumes for April 18, 2018 were used in conjunction with the average hourly vehicle mixes developed from the HDOT April 17 and 18, 2019 classification data.

Traffic noise calculations for both the existing and future conditions in the project environs were developed for ground level and elevated receptors. Traffic noise levels were also calculated for future conditions with (Build Alternative) and without (No Build Alternative) the proposed project. Along Vineyard Boulevard, it was assumed that the addition of project traffic would not alter future traffic traffic noise levels along that roadway in 2021 or 2029. The forecasted changes in traffic noise levels over existing levels were calculated with and without the Halewai`olu Senior Residences Project, and noise impact risks evaluated. The relative contributions of the project's traffic to the total noise levels along the roadways surrounding the project site were also calculated, and an evaluation of possible traffic noise impacts was made.

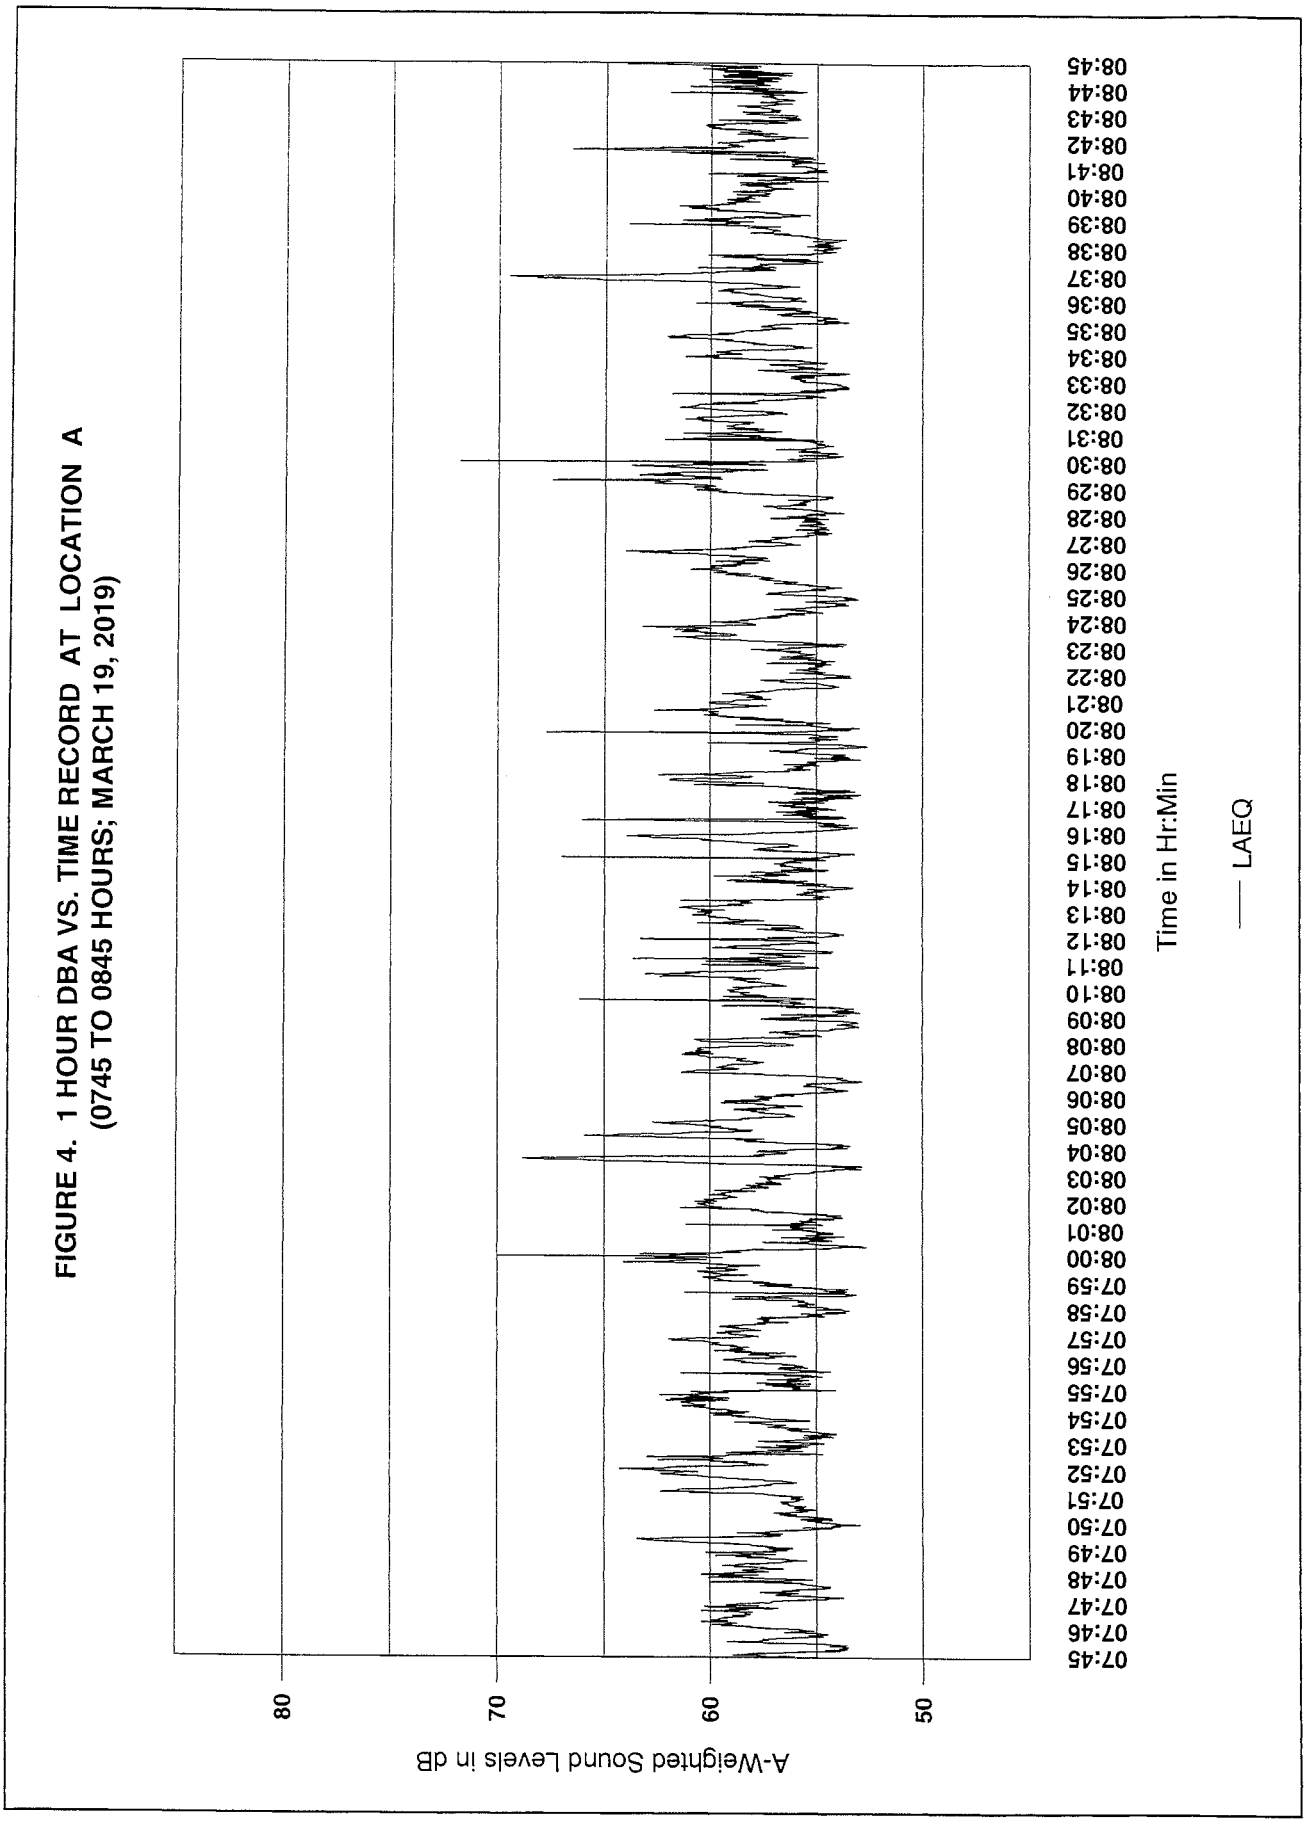
activities were performed for typical naturally ventilated and air conditioned dwellings. Predicted noise levels were compared with existing background ambient noise levels, and the potential for noise impacts was assessed.

V. EXISTING ACOUSTICAL ENVIRONMENT

The major contributor to the existing background ambient noise levels within the project area are traffic along Vineyard Boulevard. The typical hourly variations in noise levels within the immediate project area are controlled by motor vehicle traffic along Vineyard Boulevard. Although a 100+ foot buffer exists between the project site and Vineyard Boulevard, minimal noise shielding exists on the mauka side of the project site. Traffic noise levels tend to be lowest during the early morning hours between 3:00 and 4:00 AM, and tend to be highest during the AM and PM peak commuting hours. Figures 4 and 5 present the measured variations of traffic noise levels obtained at Location A during the AM and PM peak traffic hours, respectively. Figures 6 and 7 present the measured variations of traffic noise levels obtained at Location B during the AM and PM peak traffic hours, respectively.



The existing AM or PM peak hour traffic volumes and their noise contributions at 50, 75, and 100 feet setback distances from the centerlines of the roadways servicing the proposed Halewai`olu Senior Residences Project are shown in Appendix C and Table 3. The corresponding setback distances from the roadways' centerlines to their corresponding 65, 70, and 75 DNL traffic noise contours for ground level receptors are shown in Table 4. Based on the results shown in Tables 3 and 4, as well as the measured sound levels at Locations A and B, it was concluded that existing background noise levels in the project environs currently do not exceed 65 DNL at ground level on the project site or at existing buildings along River Street, North Kukui Street, and Maunakea Street. The existing traffic noise levels at essentially all existing buildings which front Vineyard Boulevard probably exceed 65 DNL.

At low and mid-rise receptor locations which are partially shielded from distant traffic noise, existing background ambient noise levels can be lower due to the noise shielding effects of the buildings. Noise reductions of 5 to 15 dBA can be expected from these noise shielding effects.

Table 5 presents the calculations of existing traffic noise levels in DNL at various locations on the project site and at the various faces of the proposed Halewai`olu Senior Residences tower for various receptor elevations up to 144 feet above ground level. The beneficial effects of shielding from existing buildings, as well as the additive noise contributions from the adjoining streets, are included in the existing sound level calculations shown in Table 5. Figure 8 depicts the various receptor locations of Table 5 in relationship to the various faces of the planned Halewai`olu Senior Residences Project buildings.

As indicated in Table 5, the existing noise levels at the proposed faces of the proposed tower building are highest on the Vineyard Boulevard (north or mauka) side, and are lowest on the south (or makai) side. Existing traffic noise levels at the high elevations on the east, west, and south faces (without the tower structure in place) are currently less than 65 DNL, and are expected to decrease following construction of the

FIGURE 8

tower due to noise shielding effects from the tower.

Existing traffic noise levels on the mauka face of the proposed tower are currently less than 65 DNL, and should also decrease following construction of the tower due to noise shielding effects from the tower of traffic noise sources along Vineyard Boulevard, and River, North Kukui, and Maunakea Streets.

CHAPTER VI. FUTURE NOISE ENVIRONMENT

Predictions of future traffic noise levels were made using the traffic volume assignments of References 6 and 7 for CY 2021 with and without the proposed project. The future projections of non-project and project traffic volumes for the No Build and Build Alternatives are shown in Appendix C.

Table 6 contains the CY 2021 traffic volumes and noise levels at 50, 75, and 100 feet from the roadways' centerlines for the Build Alternative during the AM or PM peak hour. Table 4 contains the setback distances to the 65, 70, and 75 DNL contours for CY 2021 under the Build Alternative. Table 5 presents the predicted future traffic noise levels on the project site for the Build Alternative. Future average vehicle speeds and traffic mixes along all roadways were assumed to be identical to those used for CY 2019 (see Table 3). Although not shown in the tables, CY 2029 traffic volume forecasts for Vineyard Boulevard were also used to predict the CY 2029 traffic noise levels along Vineyard Boulevard. Assuming average vehicle speeds and traffic mixes remain unchanged, the predicted CY 2029 traffic noise levels along Vineyard Boulevard were 0.5 DNL higher than those shown for CY 2021. This 0.5 DNL increase may also be applied to the CY 2021 DNL values shown on the mauka face of the proposed tower building in Table 5, which will increase from 65 to 66 DNL by CY 2029.

In CY 2021, the dominant traffic noise sources in the immediate project area will continue to be traffic noise from Vineyard Boulevard. This situation will continue to occur with or without the proposed project.

Table 7 presents the predicted increases in future traffic noise levels associated with non-project and project related traffic by CY 2021. The traffic noise contributions from the Halewai`olu Senior Residences Project have been separated from the non-project contributions in Table 7. The predicted increases in traffic noise from the Halewai`olu Senior Residences project traffic should not exceed 0.2 dB (or DNL) along the street sections shown in Table 7.

Calculations of future traffic noise levels following project build-out in CY 2021 and at the faces of the proposed Halewai`olu Senior Residences tower building were performed as shown in Table 5. The receptor locations where the calculations were performed are shown in Figure 8. As indicated in Table 5, traffic noise levels at all locations on the faces of the proposed tower building are not expected to exceed 65 DNL by CY 2021. The traffic noise reduction effects resulting from noise shielding by the tower building are apparent in Table 5, where future traffic noise level contributions from Vineyard Boulevard on the east, west, and south building faces are expected to be reduced.

As indicated in Table 5, future traffic noise levels at all of the residential units of the project should not exceed 65 DNL by CY 2021, and after adding the 0.5 DNL additional increase between CY 2021 and 2029, the 65 DNL FHA/HUD threshold will only be exceeded at any unit on the mauka face of the tower by CY 2029.

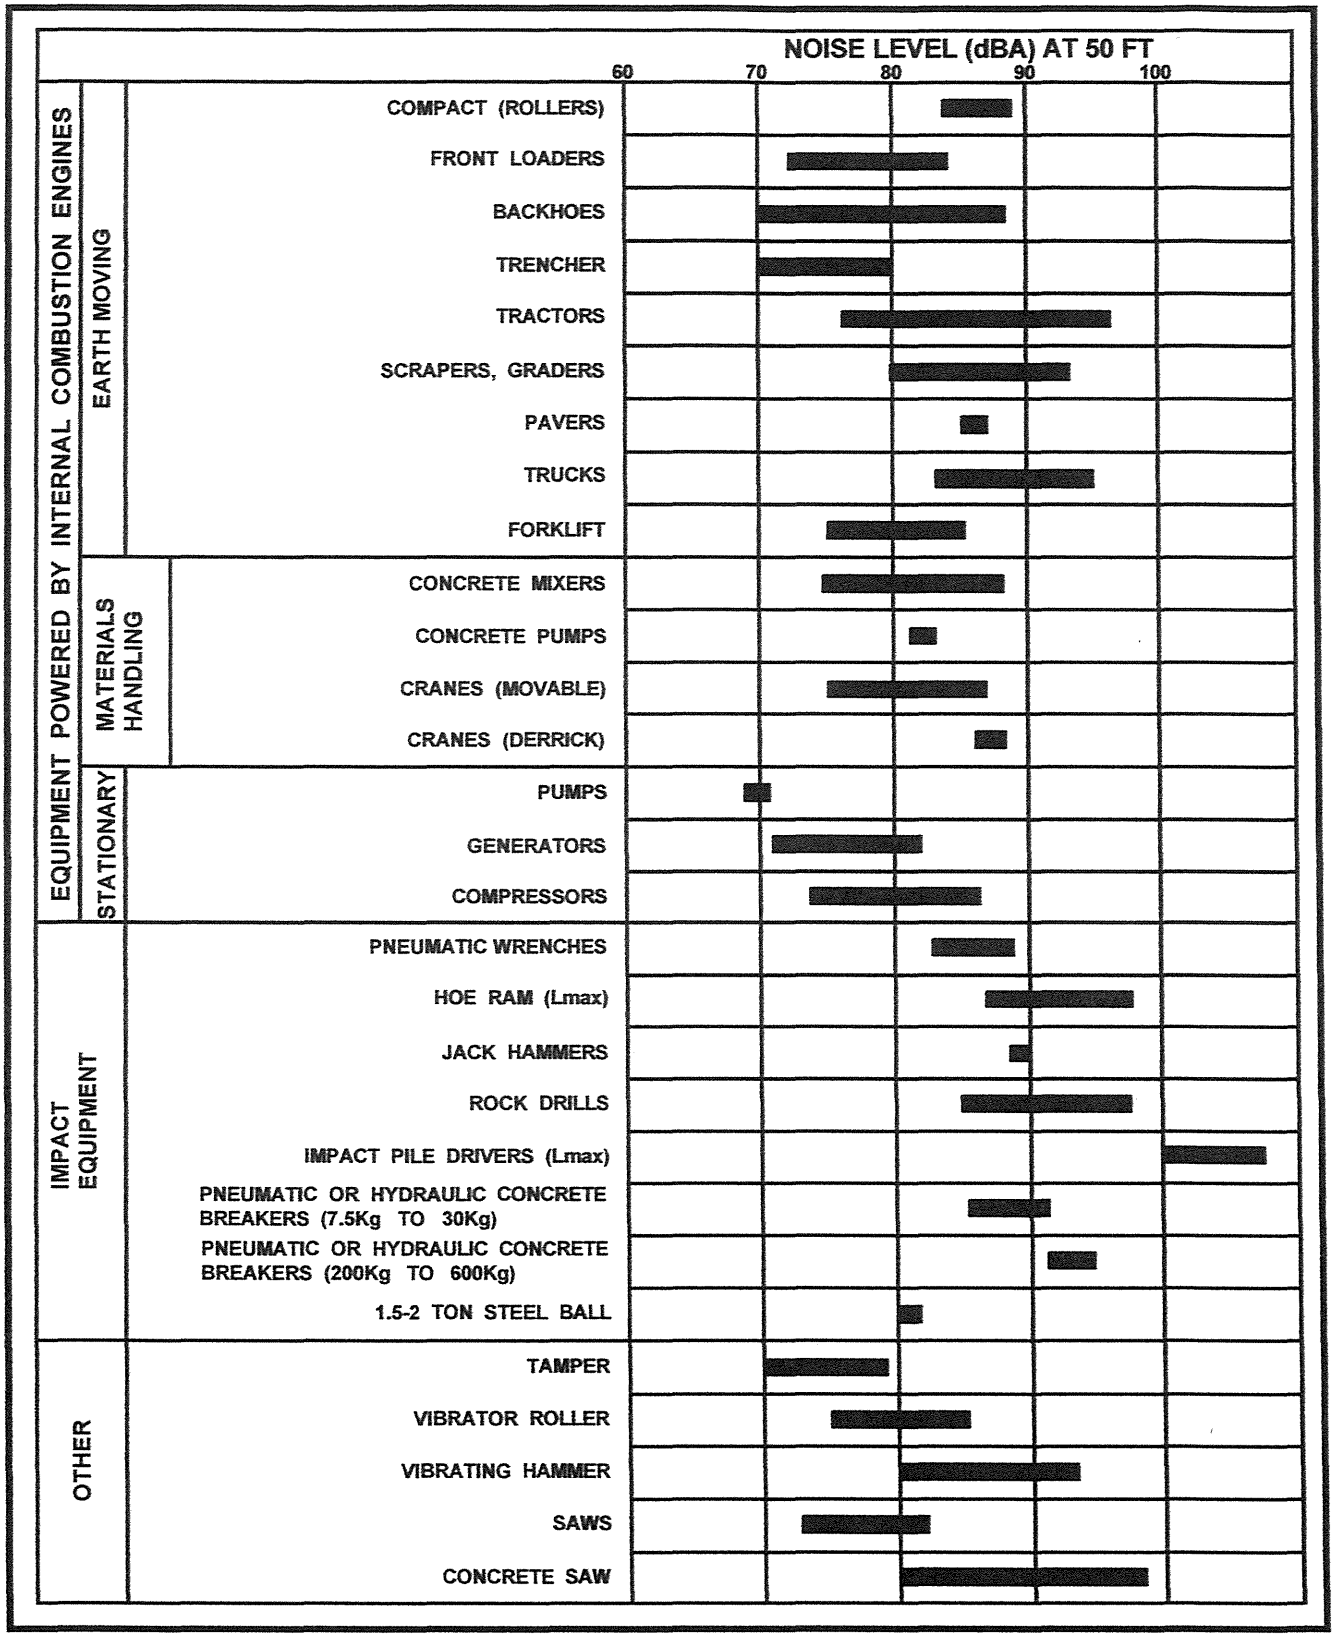
CHAPTER VII. DISCUSSION OF PROJECT-RELATED NOISE IMPACTS AND POSSIBLE MITIGATION MEASURES

Traffic Noise. Noise impacts at existing noise sensitive receptors from existing and future traffic with or without the project are not expected to be discernible. At all roadways surrounding the project site, except for River Street, predicted increases in future traffic noise levels by CY 2021 are less than 0.5 DNL, with project traffic noise contributions being 0.1 DNL or zero. Along River Street, existing traffic noise levels are very low, and the 3.1 to 3.3 DNL increase anticipated by CY 2021 will result in future traffic noise levels below 55 DNL. Based on these results, off-site traffic noise mitigation measures should not be required as a result of the proposed project.

At future noise sensitive receptor locations within the new project building, exceedances of the 65 DNL standard should not occur by 2021. Although mitigation measures are not required by CY 2021, traffic noise mitigation measures may still be desired by some residents in the tower building, particularly those which face Vineyard Boulevard. Traffic noise mitigation measures in the form of closure and air conditioning of the units would be acceptable, but the use of air conditioning in these living units may not be feasible due to recurring cost considerations. If exterior walls with minimum STC 45 rating, and operable exterior widows with minimum STC 35 glazing can be used at these affected units, it should be possible to meet the minimum 5 dB additional exterior-to-interior noise reduction requirement of FHA/HUD (see Reference 2) with operable windows approximately 17 percent opened. The use of sliding exterior windows or lanai doors would allow for more precise control of the ventilation openings for noise attenuation. If inclusion of these features are not cost prohibitive, it may be possible to meet the spirit of the FHA/HUD sound attenuation requirements at the naturally ventilated residential units.

By CY 2029, the FHA/HUD 65 DNL standard could be exceeded by 0.4 DNL at any tower residences with natural ventilation openings located on the mauka face of the tower. All residences located at least one unit from the mauka corner units on the Ewa and Diamond Head faces of the tower should be acceptable with exterior noise levels not exceeding the 65 DNL threshold. If residential units must be located on mauka face of the tower building, the use of solid walls and/or fixed glazing on the mauka walls of those units should be adequate noise mitigation measures to strictly meet the FHA/HUD noise mitigation requirements. Alternately, the use of closure and air conditioning of those residential units' rooms with exterior walls on the mauka side of the tower may also be applied to meet the FHA/HUD noise mitigation requirements. Relocation of the tower's mauka wall by approximately 26 feet toward the south would be required to not exceed the 65 DNL FHA/HUD threshold by 2029.

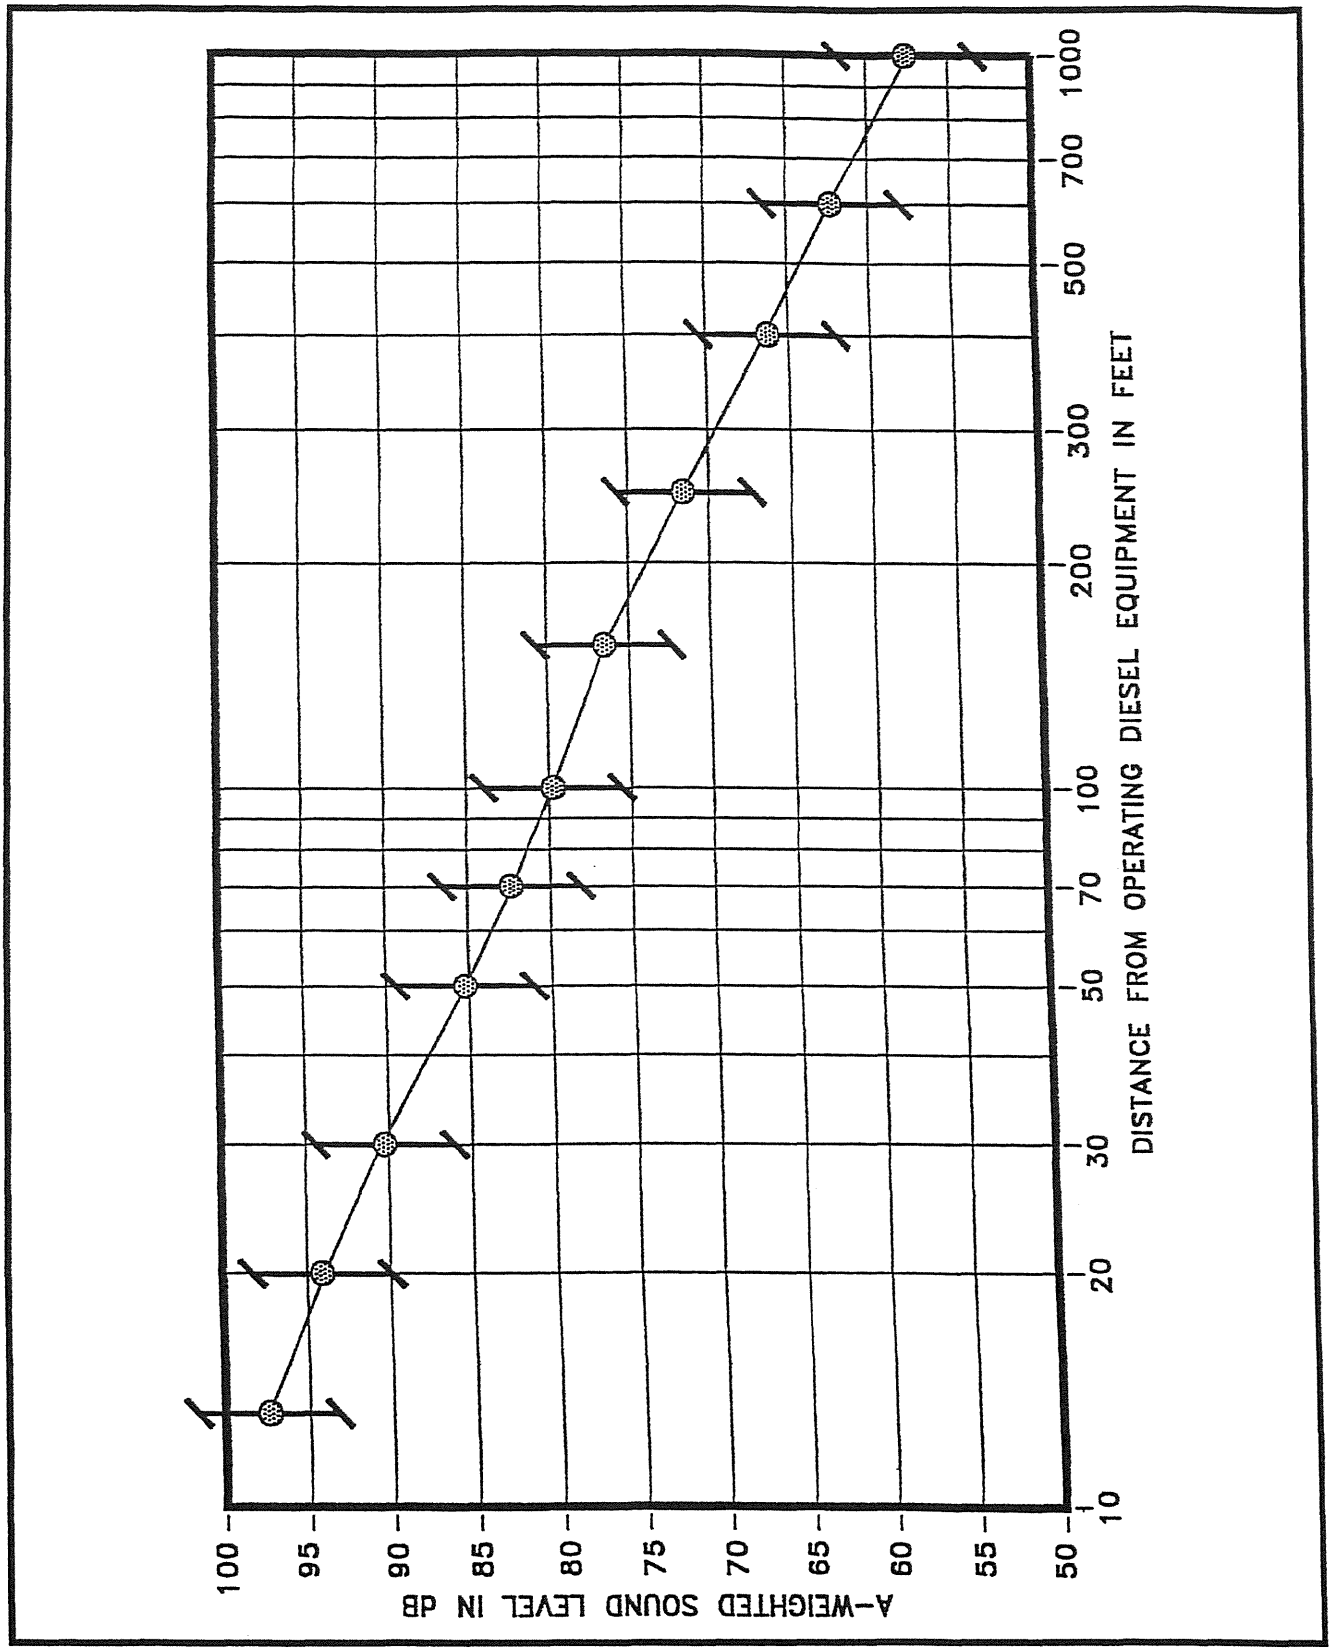
Potential noise impacts from tire squeal within the project's parking structure should be minimized through the use of coarse finishes for the circulation driveway surfaces within the parking structure.



General Construction Noise. Audible construction noise will probably be unavoidable during the entire project construction period. The total time period for construction of the project is not known. It is expected that actual construction work will be moving from one location on the project site to another during that period. Actual length of exposure to construction noise at any receptor location will probably be less than the total construction period for the entire project. Figure 9 depicts the range of noise levels of various types of construction equipment when measured at 50 feet distance from the equipment.

Typical levels of exterior noise from construction activity (excluding pile driving activity) at various distances from the job sites are shown in Figure 10. Figure 10 is useful for predicting exterior noise levels at short distances (within 100 feet) from the work when visual line of sight exists between the construction equipment and the receptor. Direct line-of-sight distances between the work areas and the closest neighboring receptors range from 40 feet to 300+ feet, with corresponding average noise levels of 88 to 69 dBA (plus or minus 5 dBA). For receptors along a cross-street, the construction noise level vs. distance curve of Figure 10 should be reduced by approximately 8 dBA when the work is occurring at the intersection with the cross street, and should be reduced by 15 dBA when work is occurring at least 100 feet from the intersection (and the visual line-of-sight is blocked by intervening buildings). Typical levels of construction noise inside naturally ventilated and air conditioned structures are approximately 10 and 20 dB less, respectively, than the levels shown in Figure 10.

Noise sensitive receptors who are predicted to experience the highest noise levels during construction activities are located at the Borthwick Mortuary and Lum Sai Ho Tong Temple. Predicted maximum construction noise levels at these buildings during the site preparation and earthwork phases of construction ranged from 88 to 86 dBA (plus or minus 5 dBA). The highest noise levels at existing residences during site preparation and building erection work are expected to occur at the existing Waena Apartments across Nuuanu Stream, where minimum buffer distances are moderately large (in the order of 200 feet). Adverse impacts from construction noise are not expected to be in the "public health and welfare" category due to the temporary nature of the work, and due to the administrative controls available for regulation of construction noise. Instead, these impacts will probably be limited to the temporary degradation of the quality of the acoustic environment in the immediate vicinity of the project site.

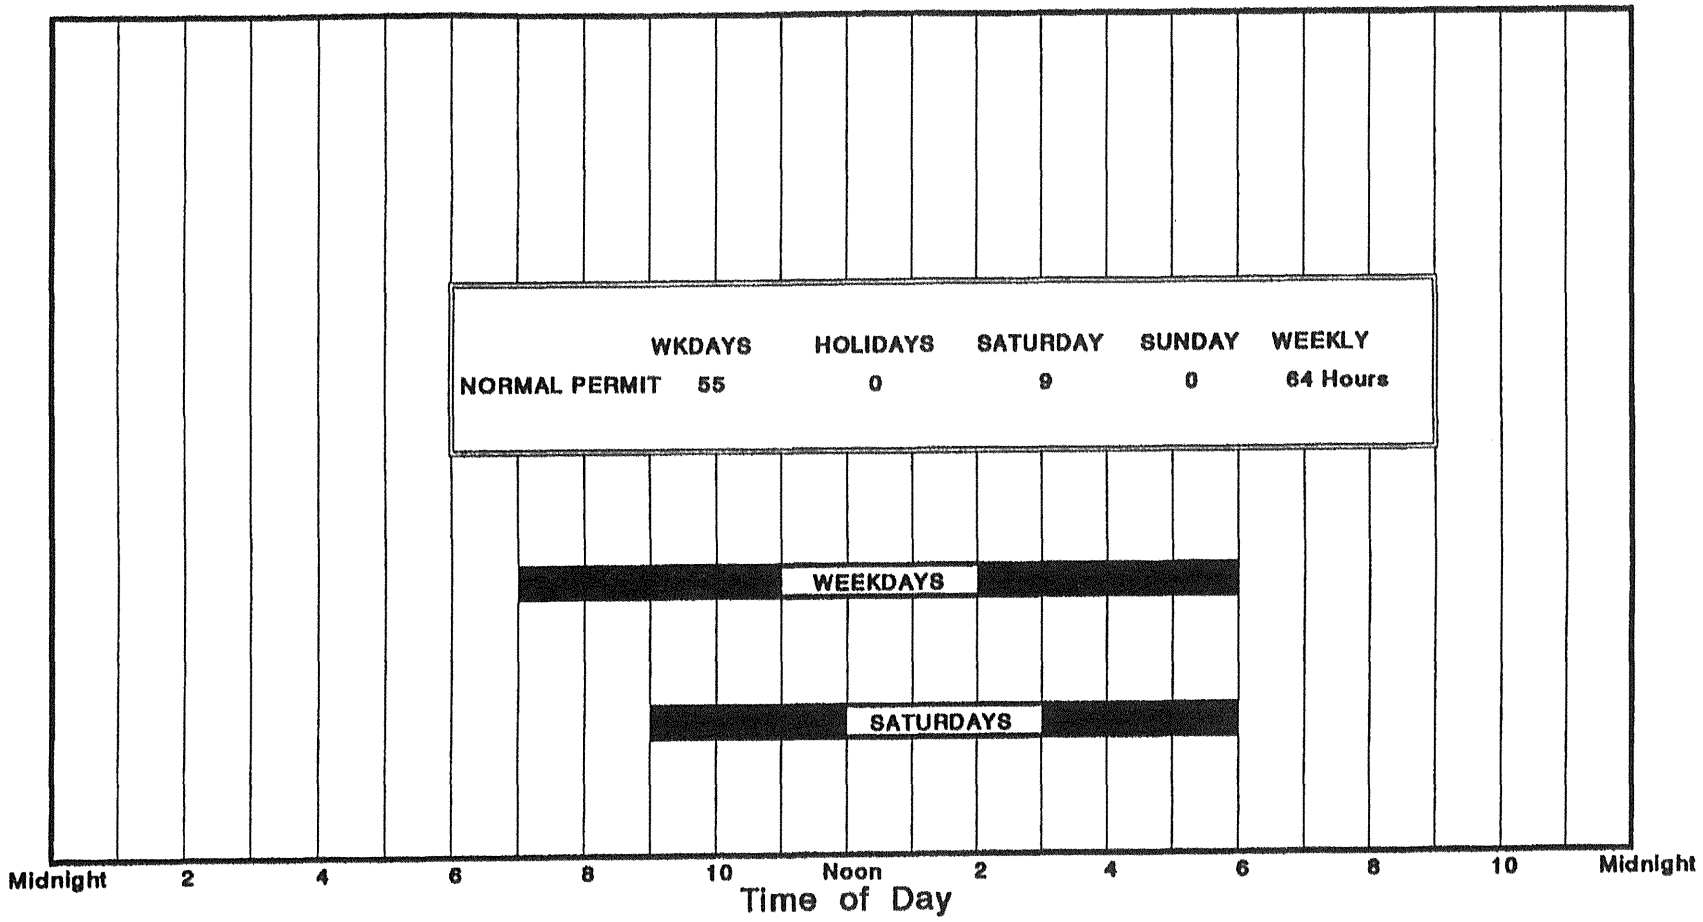


Mitigation of construction noise to inaudible levels will not be practical in all cases due to the intensity of construction noise sources (80 to 90+ dB at 50 feet distance), and due to the exterior nature of the work (excavation, grading, trenching, concrete pouring, hammering, etc.). The use of properly muffled construction equipment should be required on the job site.

Severe noise impacts are not expected to occur inside air conditioned structures which are beyond 70 to 450 feet from the project construction sites. Inside naturally

RANGES OF CONSTRUCTION EQUIPMENT NOISE LEVELS

FIGURE 9



ANTICIPATED RANGE OF CONSTRUCTION NOISE LEVELS VS. DISTANCE

FIGURE 10

ventilated structures, interior noise levels (with windows or doors opened) are estimated to range between 73 to 55 dBA at 70 feet to 450 feet distances from the construction site. Closure of all doors and windows facing the construction site would generally reduce interior noise levels by an additional 5 to 10 dBA.

The incorporation of State Department of Health construction noise limits and curfew times, which are applicable throughout the State of Hawaii (Reference 4), is another noise mitigation measure which is normally applied to construction activities. Figure 11 depicts the normally permitted hours of construction, which are typically limited to the normal working hours. Noisy construction activities are not allowed on Sundays and holidays, during the early morning, and during the late evening and nighttime periods under the DOH permit procedures.

AVAILABLE WORK HOURS UNDER DOH PERMIT PROCEDURES FOR CONSTRUCTION NOISE

APPENDIX B

EXCERPTS FROM EPA'S ACOUSTIC TERMINOLOGY GUIDE

Descriptor Symbol Usage

The recommended symbols for the commonly used acoustic descriptors based on A-weighting are contained in Table I. As most acoustic criteria and standards used by EPA are derived from the A-weighted sound level, almost all descriptor symbol usage guidance is contained in Table I.

Since acoustic nomenclature includes weighting networks other than "A" and measurements other than pressure, an expansion of Table I was developed (Table II). The group adopted the ANSI descriptor-symbol scheme which is structured into three stages. The first stage indicates that the descriptor is a level (i.e., based upon the logarithm of a ratio), the second stage indicates the type of quantity (power, pressure, or sound exposure), and the third stage indicates the weighting network (A, B, C, D, E.....). If no weighting network is specified, "A" weighting is understood. Exceptions are the A-weighted sound level and the A-weighted peak sound level which require that the "A" be specified. For convenience in those situations in which an A-weighted descriptor is being compared to that of another weighting, the alternative column in Table II permits the inclusion of the "A". For example, a report on blast noise might wish to contrast the LCdn with the LAdn.

Although not included in the tables, it is also recommended that "Lpn" and "LepN" be used as symbols for perceived noise levels and effective perceived noise levels, respectively.

It is recommended that in their initial use within a report, such terms be written in full, rather than abbreviated. An example of preferred usage is as follows:

The A-weighted sound level (LA) was measured before and after the installation of acoustical treatment. The measured LA values were 85 and 75 dB respectively.

Descriptor Nomenclature

With regard to energy averaging over time, the term "average" should be discouraged in favor of the term "equivalent". Hence, Leq, is designated the "equivalent sound level". For Ld, Ln, and Ldn, "equivalent" need not be stated since the concept of day, night, or day-night averaging is by definition understood. Therefore, the designations are "day sound level", "night sound level", and "day-night sound level", respectively.

The peak sound level is the logarithmic ratio of peak sound pressure to a reference pressure and not the maximum root mean square pressure. While the latter is the maximum sound pressure level, it is often incorrectly labelled peak. In that sound level meters have "peak" settings, this distinction is most important.

"Background ambient" should be used in lieu of "background", "ambient", "residual", or "indigenous" to describe the level characteristics of the general background noise due to the contribution of many unidentifiable noise sources near and far.

With regard to units, it is recommended that the unit decibel (abbreviated dB) be used without modification. Hence, DBA, PNdB, and EPNdB are not to be used. Examples of this preferred usage are: the Perceived Noise Level (Lpn was found to be 75 dB. Lpn = 75 dB). This decision was based upon the recommendation of the National Bureau of Standards, and the policies of ANSI and the Acoustical Society of America, all of which disallow any modification of bel except for prefixes indicating its multiples or submultiples (e.g., deci).

Noise Impact

In discussing noise impact, it is recommended that "Level Weighted Population" (LWP) replace "Equivalent Noise Impact" (ENI). The term "Relative Change of Impact" (RCI) shall be used for comparing the relative differences in LWP between two alternatives.

Further, when appropriate, "Noise Impact Index" (NII) and "Population Weighed Loss of Hearing" (PHL) shall be used consistent with CHABA Working Group 69 Report Guidelines for Preparing Environmental Impact Statements (1977).

TABLE I

A-WEIGHTED RECOMMENDED DESCRIPTOR LIST

	TERM	SYMBOL
1.	A-Weighted Sound Level	L_A
2.	A-Weighted Sound Power Level	L_{WA}
3.	Maximum A-Weighted Sound Level	L_{max}
4.	Peak A-Weighted Sound Level	L_{Apk}
5.	Level Exceeded x% of the Time	L_x
6.	Equivalent Sound Level	L_{eq}
7.	Equivalent Sound Level over Time (T) (1)	$L_{eq(T)}$
8.	Day Sound Level	L_d
9.	Night Sound Level	L_n
10.	Day-Night Sound Level	L_{dn}
11.	Yearly Day-Night Sound Level	$L_{dn(Y)}$
12.	Sound Exposure Level	L_{SE}

(1) Unless otherwise specified, time is in hours (e.g. the hourly equivalent level is $L_{eq(1)}$). Time may be specified in non-quantitative terms (e.g., could be specified a $L_{eq(WASH)}$ to mean the washing cycle noise for a washing machine).

BIOLOGICAL RESOURCES SURVEY
HALEWAI'OLU SENIOR RESIDENCES
HONOLULU, OAHU HAWAII

INTRODUCTION

The Halewai′olu Senior Residences Project is located at 1331 River Street in Honolulu, TMK (1) 1-7-060:012, on 0.618 acres of land (see Figure 1). This biological resource study was initiated by Michaels Development for the project situated on City and County of Honolulu land.

SITE DESCRIPTION

This 0.618 acre project area lies within an urban setting in the Chinatown area of Honolulu. The property includes a dilapidated two-story residential structure and an asphalt parking lot. A few trees and ornamental plants grow along the perimeter in small grassy planters. The lower Nu′uanu Stream channel is located across River Street. The entire project area is level and at an elevation of about 16 feet. The soil is characterized as Ewa Silty Clay Loam, Shallow, 0-2% slopes (EmA) (Foote et al, 1972), which is a well-drained soil lying over a 20-50 inch deep limestone substrate. Annual rainfall averages 30 inches with most occurring during the winter months.

SURVEY OBJECTIVES

This report summarizes the findings of a biological resources survey of the proposed Halewai′olu Senior Residences Project which was conducted in March 2019. The objectives of the survey were to:

1. Document what plant and animal species occur on the property or may likely occur in the existing habitat.

2. Document the status and abundance of each species.

3. Determine the presence or likely occurrence of any native flora and fauna species, particularly any that are federally listed as Threatened or Endangered. If such species occur, identify what features of the habitat may be essential for these species.

4. Determine if the project area contains any special habitats which if lost or altered might result in a significant negative impact on the flora and fauna in this part of the island.

BOTANICAL SURVEY REPORT

SURVEY METHODS

A walk-through botanical survey method was used, selecting routes to cover the entire area and all habitat types. Areas most likely to harbor native or rare plants were more intensively examined. Notes were made on plant species, distribution and abundance as well as on terrain and substrate.

DESCRIPTION OF THE VEGETATION

The vegetation consisted of a few small to medium sized trees in planter areas around the perimeter of the parking area. A variety of grasses and urban weeds grow beneath these plants and are subject to periodic mowing.

A total of 45 plant species were recorded on the project area. Nine of these were of uncommon occurrence: plains bluestem (*Bothriochloa bladhii*), common sandbur (*Cenchrus echinatus*), swollen fingergrass (*Chloris barbata*), Bermuda grass (*Cynodon dactylon*), oleander (*Neriu oleander*), straggler daisy (*Calyptocarpus vialis*), pink tecoma (*Tabebuia heterophylla*), Geiger tree (*Cordia sebestina*) and false mallow (*Malvastrum coromandelianum*). The remaining thirty-six species were all of rare occurrence.

No native plant species were found on the project area.

DISCUSSION AND RECOMMENDATIONS

All of the plants growing on the project area were not native to Hawaii and were either ornamental trees, shrubs or grasses planted into the landscape, or were adventitious weeds. None of these are of any special conservation concern. No federally Endangered, Threatened or otherwise rare native plants were recorded, and no special native plant habitats were found either (USFWS, 2019).

Because of the above existing conditions, it has been determined that there is little of botanical concern in the project area, and that the anticipated disturbances associated with the proposed redevelopment work are not expected to have a significant negative impact on the botanical resources in this part of O′ahu.

It is recommended, however, that coastal and lowland native plant species might be incorporated into future landscape designs.

PLANT SPECIES LIST

Following is a checklist of all those vascular plant species inventoried during the field studies. Plant families are arranged alphabetically within three groups: Ferns, Monocots and Dicots. Taxonomy and nomenclature of the flowering plants are in accordance with Wagner et al. (1999) and Staples & Herbst (2005), and the Ferns are in accordance with Palmer (2003).

For each species, the following information is provided:

1. Scientific name with author citation.

2. Common English or Hawaiian name.

3. Bio-geographical status. The following symbols are used:

   endemic = native only to the Hawaiian Islands; not naturally occurring anywhere else in the world.

   indigenous = native to the Hawaiian Islands and also to one or more other geographic area(s).

   Polynesian introduction = plants introduced to Hawai'i in the course of Polynesian migrations and prior to western contact.

   non-native = all those plants brought to the islands intentionally or accidentally after western contact.

4. Abundance of each species within the project area:

   abundant = forming a major part of the vegetation within the project area.

   common = widely scattered throughout the area or locally abundant within a portion of it.

   uncommon = scattered sparsely throughout the area or occurring in a few small patches.

   rare = only a few isolated individuals within the project area.

SCIENTIFIC NAME	COMMON NAME	STATUS	ABUNDANCE
FERNS			
POLYPODIACEAE (Polypody Fern Family)

VERBENACEAE (Verbena Family)			
Citharexylum spinosum L.	fiddlewood	non-native	rare

FAUNA SURVEY REPORT

SURVEY METHODS

A walk-through fauna survey method was conducted in conjunction with the botanical survey. All parts of the project area were covered. Field observations were made with the aid of binoculars and by listening to vocalizations. Notes were made on species, abundance, activities and location as well as observations of trails, tracks, scat and signs of feeding. In addition an evening visit was made to the area to record crepuscular activities and vocalizations and to see if there was any evidence of occurrence of the Endangered ʻōpeʻapeʻa or Hawaiian hoary bat (*Lasiurus semotus*) in the area.

RESULTS

MAMMALS

No mammals were seen in the project area during two site visits. While not seen, the following non-native mammals could occur here occasionally: domestic dogs (*Canis familaris*), domestic cats (*Felis catus*), mongoose (*Herpestes auropunctatus*), rats (*Rattus* spp.) and mice *(Mus domesticus*). Taxonomy and nomenclature follow Tomich (1986).

An evening survey was conducted with the use of a bat detector (Batbox IIID) set to the frequency of 27,0000 Hertz that the ʻōpeʻapeʻa are known to emit when echolocating for nocturnal flying insect prey. No bat activity was detected with the use of this device.

BIRDS

Bird life was modest in the diversity of species observed but fairly well represented in individuals recorded. Taxonomy and nomenclature follow American Ornithologists' Union (2019). Two native species and two non-native species were observed during two site visits. The two non-native species, the zebra dove (*Geopelia striata*) and the common pigeon (*Columba livia*), were both common in and around the project area.

The manu o kū or white tern (*Gygis alba rothschildi*) were seen regularly flying above the project area in small numbers and were judged to be uncommon. This tern is indigenous tin Hawaii as well as in many islands in the Pacific. Two indigenous migratory kōlea or Pacific golden-plovers (*Pluvialis fulva*) were seen as individuals in the project area and were judged to be rare.

INSECTS

There were almost no insects found on this concrete and asphalt dominated project area. Just one non-native species was recorded, the dung fly (*Musca sorbens*). Taxonomy and nomenclature follows Nishida et al, (1992).

DISCUSSION AND RECOMMENDATIONS

The Halewai′olu Senior Residences Project area, as it presently exists, consists of one dilapidated two-story concrete multi-residential structure surrounded by an asphalt parking lot and a small amount of peripheral landscaping. This sterile environment discourages many types of wildlife from utilizing the site. All mammals, birds and insects were poorly represented. Only a few hardy species, adapted to human activities, were observed. Just two species of indigenous native birds were seen.

The kōlea is a migratory bird that spends its summers breeding and raising its young on arctic tundra, then flies south to spend its winters on Pacific islands. Many thousands winter in Hawaii where they can be found in almost all habitats from sea level to mountain tops. Kōlea are quite common here and carry no special Endangered or Threatened protected status.

The manu o kū is an indigenous seabird that is found on many Pacific islands and atolls. Many breed and nest in the Papahānaumokuākea Marine Monument on these remote atolls. Prior to 1959 these white terns were not known to breed in the main Hawaiian islands. That year the first pairing was found at Koko Head here on O′ahu. For many years they were found to be rare here. But, their numbers have been growing and in the last two decades they have been increasing in numbers and spreading around O′ahu. They can now be seen regularly in greater Honolulu, flying among tall buildings and landing in trees. They have now successfully adapted to an urban environment. Several were seen flying above the project area. These terns carry no special Protected, Endangered or Threatened status.

No protected waterbird, the ae′o or Hawaiian stilt (*Himantopus mexicanus knudseni*), ′alae ke′oke′o or Hawaiian coot (*Fulica alai*), ′alae ′ula or common moorhen (*Gallinula chloropus sandvicensis*) or the koloa or Hawaiian duck (*Anas wyvlliana*) were seen during the survey and no suitable wetland habitat occurs on the project area.

Hawaiian petrels (*Pterodroma phaeopygia sandwichensii*) and Newell's shearwaters (Puffinus newelli), (collectively known as seabirds) may transit over the project area when flying between the ocean and nesting sites in the mountains during their breeding season (March through November). Fatalities to these seabirds resulting from collisions with artificial structures that extend above the surrounding vegetation have been documented in Hawai′i where high densities of transiting seabirds occur. Additionally, artificial lighting such as floodlighting for construction work can adversely impact seabirds by causing disorientation which may result in collision with utility lines, buildings, fences and vehicles. Fledgling seabirds are especially affected by artificial lighting and have a tendency to exhaust themselves while circling the light sources and become grounded. Too weak to fly, these birds become vulnerable to predation by predators such as mongoose, cats and dogs. These threats can be minimized by the shielding of any outdoor lighting so that the light is visible only from below.

No other recommendations regarding wildlife are deemed necessary.

Because of the above existing conditions, it has been determined that there is little of wildlife concern in the project area, and that the anticipated disturbances associated with the proposed redevelopment work are not expected to have a significant negative impact on the wildlife resources in this part of O′ahu.

ANIMAL SPECIES LIST

Following is a checklist of the animal species inventoried during the field work. Animal species are arranged in descending abundance within three groups: Mammals, Birds and Insects. For each species the following information is provided:

1. Common name.

2. Scientific name.

3. Bio-geographical status. The following symbols are used:

   endemic = native only to Hawai′i; not naturally occurring anywhere else in the world.

   indigenous = native to the Hawaiian Islands and also to one or more other geographic area(s).

   non-native = all those animals brought to Hawai′i intentionally or accidentally after western contact.

   migratory = spending a portion of the year in Hawai′i and a portion elsewhere. In Hawai′i the migratory birds are usually in the overwintering/non-breeding phase of their life cycle.

4. Abundance of each species within the project area:

   abundant = many flocks or individuals seen throughout the area at all times of day.

   common = a few flocks or well scattered individuals throughout the area.

   uncommon = only one flock or several individuals seen within the project area.

   rare = only one or two seen within the project area.

Subject: Informal Consultation for the Proposed Halewai‘olu Senior Residences, River Street, Honolulu, O‘ahu

Dear Ms. Tanabe:

The U.S. Fish and Wildlife Service (Service) received your letter on July 22, 2019, requesting our concurrence with your determination that the proposed demolition and construction of the Halewai‘olu senior residences, located on River Street in Honolulu, O‘ahu, may affect, but is not likely to adversely affect the federally endangered Hawaiian petrel (*Pterodroma sandwichensis*), threatened Newell’s shearwater (*Puffinus auricularis newelli*), endangered Hawai‘i DPS band-rumped storm-petrel (*Oceanodroma castro*) (hereafter collectively referred to as Hawaiian seabirds); endangered Hawaiian hoary bat (*Lasiurus cinereus semotus*); endangered Hawaiian stilt (*Himantopus mexicanus knudseni)*, endangered Hawaiian gallinule (*Gallinula galeata sandvicensis*), endangered Hawaiian coot (*Fulica alai*), and endangered Hawaiian duck (*Anas wyvilliana*) (hereafter collectively referred to as Hawaiian waterbirds). Our findings and recommendations in this consultation are based on your letter and other information available to us. Our response is in accordance with section 7 of the Endangered Species Act of 1973 (ESA), as amended (16 U.S.C. 1531 *et seq*.).

Project Description

The proposed construction project is located on the island of O‘ahu and consists of approximately 0.62 acres (26,925 square feet) of property on River Street in Chinatown, Honolulu. Construction of the proposed project would encompass the entire 0.62-acre project site, including potential staging and stockpile areas. No night work is expected, and no in-water work is proposed for this project. The purpose of this project is to provide affordable housing for senior citizens in the Chinatown community. The project involves the demolition of an existing two-story structure, and construction of a new 17-floor housing facility. The new facility will include one and two bedroom units, and are earmarked for seniors earning 80% of the area median income or below.

Avoidance and Minimization Measures

The following avoidance and minimization measures will become enforceable, in addition to compliance with the project plans, throughout the project timeframe:

a. Trimming of trees greater than 15-feet tall will not occur between June 1 and September 15, and barbed wire will not be used for fencing.
b. All outdoor lights shall be fully sheilded so that the bulb can only be seen from below bulb height and used when needed, and automatic motion sensors shall be installed or turned off when human activity is not occuring in the lighted area. The prosposed project will take place during daylight hours.
c. Erosion control for earth distrubing activities will be employed to ensure that sediments are not delivered to drainages or waterways as a result of the proposed activity.
d. All project proponents present at the construction site will be informed of potential endangered species that may occur within or transit through the project area and that any intentional physical interactions with identified endangered species will be explicitly prohibited.
e. Any incidental take will be immediately reported to the Service.

Effects Analysis

Hawaiian seabirds

Hawaiian seabirds may traverse the project area at night during the breeding, nesting and fledging seasons (March 1 to December 15). Nighttime construction is not anticipated for this project. If nighttime work becomes necessary, construction will be avoided during seabird fledgling season and any outdoor lighting used during construction will be sensor activated or turned off. While fallout from ESA listed seabirds on the island of O‘ahu does occur, an increase in light pollution in urban Honolulu will be indisinguishable as a result of this project, and is not likely to increase seabird fallout. Because night construction is not planned, disorientation and subsequent fallout due to nighttime lighting is not probable, and therefore discountable. Because effects from the action are discountable, the proposed project is not likely to adversely affect Hawaiian seabirds.

Hawaiian hoary bat

The Hawaiian hoary bat may roost and leave their young pups unattended in trees and shrubs when they forage. If trees or shrubs 15 feet or taller are cleared during the pupping season (June 1 through September 15), there is a risk that young bats could inadvertently be harmed or killed since they are too young to fly or may not move away. You have indicated that any woody plants or trees greater than 15 feet will not be removed or disturbed during pup rearing season. By implementing these conservation measures, it is not probable that Hawaiian hoary bat pups would be in tree unable to fly or move away, and therefore, the impacts proposed project are discountable. Additionally, a bat detector placed at the project site by an environmental consultant, was not able to confirm the presence of bats in the area. Because impacts from the proposed project are discountable, we concur with your determination that the proposed project may affect, but is not likely to adversely affect the Hawaiian hoary bat.

Hawaiian waterbirds
Hawaiian waterbirds are found in fresh and brackish-water marshes and natural or man-made ponds. Hawaiian stilts may also be found wherever ephemeral or persistent standing water may occur. If there is driving of heavy machinery or the placement of construction materials in areas where Hawaiian waterbird nests or chicks occur, there is a risk that adults could be disturbed and fly off the nest leaving them exposed to predation or nest failure. Also, there is a risk if chicks are not seen, not able to fly, and potentially crushed. The project site does occur near the concrete chanelized Nu‘uanu stream, but this area is not suitable habitat for Hawaiian waterbirds, and their occurence in the project area has not been observed. It is not probable that Hawaiian waterbird nests or chicks would be crushed as a result of the proposed project, as they are not known to occur within the project area. Therefore, the impacts are discountable. Because impacts from the proposed project are discountable, we concur with your determination that the proposed project may affect, but is not likely to adversely affect the Hawaiian waterbirds.

Summary
Based upon the information you provided, also with the implementation of the aforementioned avoidance and minimization measures impacts from the proposed project are discountable. Therefore, the Service concurs with your determination that the proposed action may affect, but is not likely to adversely affect Hawaiian seabirds, Hawaiian hoary bats, and Hawaiian waterbirds. Unless the project description changes, or new information reveals that the action may affect listed species in a manner or to an extent not considered, or a new species or critical habitat is designated that may be affected by the proposed action, no further action pursuant to section 7 of the ESA is necessary.

We appreciate your efforts to conserve protected species. If you have questions regarding this letter, please contact Narrissa Spies, Fish and Wildlife Biologist (phone: 808-792-9400, email: Narrissa_Spies@fws.gov). When referring to this project in correspondence or emails, please include the following reference number: 01EPIF00-2019-I-0399.

Sincerely,

Island Team Manager
O‘ahu, Kaua‘i, Northwestern Hawaiian Islands, and American Samoa

Civil Attachment C-6	Department of Planning & Permitting Approved Sewer Connection Application dated January 29, 2019
Electrical Attachment E-1	Correspondence with Utility Companies (Hawaiian Electric Co. and Hawaiian Telcom)

Chapter 1 – INTRODUCTION

1.1 INTRODUCTION

A new affordable housing community located in the Chinatown area of Honolulu (refer to Attachments C-1 and C-2), is being proposed by The Michaels Development Company. The 0.62-acre parcel is presently owned by the City and County of Honolulu and will be developed as Halewai'olu Senior Residences. It will consist of approximately 156 one- and two-bedroom rental apartment units in an 18-story high-rise tower as shown in the conceptual rendering below (Photograph 1). Amenities include a rooftop garden, activity deck, courtyard, community center, covered tenant parking and guest parking, bicycle parking, laundry facilities, recycling center, solar hot water and solar photovoltaic energy for common areas.

The property is located at 1331 River Street (designated as TMK 1-7-006:012), between North Kukui Street and Vineyard Street. The site is currently occupied by a two-story office/retail building and paved parking lot, all which will be demolished as part of the project. This preliminary engineering report addresses both on-site and off-site infrastructure requirements, including roadways, drainage, sewer, water, electrical, telecommunications, cable television and roadway/area lighting system improvements necessary to support the development.

Photograph 1: Conceptual rendering of the proposed Halewai'olu Senior Residences

Chapter 2 – DESCRIPTION OF EXISTING INFRASTRUCTURE

2.1 ROADWAYS

Current access to the property is via two driveways off of River Street (Photographs 2 and 3). The driveways are asphalt concrete with concrete aprons. The northern driveway is approximately 12-feet wide; the southern driveway, approximately 24-feet wide. River Street is a one-way, single-lane road that is accessed via North Kukui Street and travels in the northeast direction, eventually connecting to North Vineyard Boulevard. It is an approximately 22-foot wide asphalt-concrete roadway with curb/gutters, bordered by a 21-foot wide concrete and grassed pedestrian walkway to the west and a 12-foot wide concrete sidewalk to the east. Metered street parking is available on the east side of the roadway. River Street and North Kukui Street are owned by the City and County of Honolulu while North Vineyard Boulevard falls under the jurisdiction of the State of Hawaii. All three are maintained by the City and County of Honolulu.

Photograph 2: Driveway access, north of property

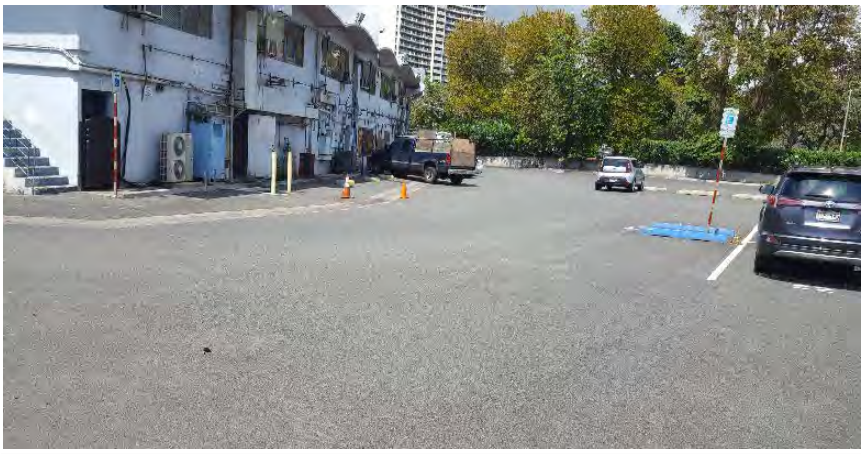
Photograph 3: Driveway access, south of property

2.2 POTABLE WATER

The existing Board of Water Supply (BWS) potable water system consists of an 8-inch diameter water line which runs within River Street. There are currently nine water meter boxes located within the concrete sidewalk fronting the property. All water meter boxes are empty and appear to be abandoned. According to a letter from the BWS, dated March 7, 2019, there are four water laterals leading from the 8-inch water main serving the property (refer to Attachment C-3). One fire hydrant is located on the west-side of River Street, within the grassed planting area. Refer to Attachment C-4 for locations of existing utilities.

The letter from the BWS also states that "the existing water system is adequate to accommodate the domestic demands and offsite fire protection for the proposed development." However, the final decision on the availability of water will be confirmed at the time of the building permit application approval process.

2.3 WASTEWATER FACILITIES



As indicated in the "Due Diligence Evaluation for Development of Halewaiolu Senior Residence" prepared by Community Planning and Engineering, Inc., dated October 2016, sanitary service will be available via an existing 12-inch sewer main located in River Street. The sewer main is owned and maintained by the City and County of Honolulu.

One 8-inch sewer lateral is provided from the sewer main to service the property (refer to Attachment C-4). The lateral is located approximately at the midpoint of the western boundary fronting River Street.

2.4 STORM WATER/DRAINAGE

2.4.1 EXISTING INFRASTRUCTURE

Currently, the 1331 River Street property is almost entirely covered by impervious asphalt surfaces. Storm water runoff from the property flows toward a concrete swale near the south driveway and into a catch basin on River Street. (Refer to Attachments C-2 and C-4, and Photographs 4 and 5.)

Photograph 4: Parking lot and concrete swale towards the left

The existing drainage system fronting the project site consists of concrete gutters running along both sides of River Street and curb inlets/catch basins located at the northwest boundary of the property and near the intersection of River Street and North Kukui Street, fronting the Lum Sai Ho Tong building. Underground 18-inch diameter reinforced concrete pipes run from the catch basins, under River Street, and discharge into Nuuanu Stream.

Photograph 5:
Concrete swale and drain pipe, makai driveway

2.4.2 FLOOD HAZARD

The project site is located in an area designated as Zone X on the Flood Insurance Rate Map (Map No. 15003C0354G dated January 19, 2011). Zone X is defined as "Areas determined to be outside the 0.2% annual chance floodplain."

2.5 ELECTRICAL AND COMMUNICATION FACILITIES

2.5.1 ELECTRICAL SYSTEM

There are underground Hawaiian Electric (HECO) ductlines routed along River Street, Maunakea Street, North Kukui Street and North Vineyard Boulevard. An existing 167 KVA, 120/240V, single phase, pad-mounted HECO transformer is located at the southern driveway and serves the existing property.

A HECO handhole located on the sidewalk next to the southern driveway distributes primary utility power to the property and will be the point of connection for the new residential community. Refer to Photograph 6 for location of existing HECO handhole.

2.5.2 TELECOMMUNICATIONS SYSTEM

Spectrum delivers telecommunications services to the property using the Hawaiian Telecom (HT) underground conduit system. Spectrum uses the HT pullbox located next to the southern driveway near the HECO handhole to deliver telephone and internet services. According to a will serve letter from Hawaiian Telcom (HT) documented in September 27, 2016, HT has existing facilities and infrastructures in the area to provide telephone and high-speed internet services. See Attachment E-1 for the HT will serve letter. The HT pullbox will be the point of connection for both HT and Spectrum services. Refer to Photograph 6 for location of existing HT pullbox.

Photograph 6: HECO Handhole, HECO Transformer, and HT Pullbox

2.5.3 CABLE TELEVISION SYSTEM

Spectrum delivers telecommunications services to the property using the HT underground conduit system. Spectrum uses the HT pullbox located next to the southern driveway near the HECO handhole to deliver cable television services. According to their will serve letter mentioned above, HT has existing facilities and infrastructures in the area to provide digital television services (refer to Attachment E-1). The HT pullbox will be the point of connection for both HT and Spectrum services (refer to Photograph 6 for location of existing HT pullbox).

Chapter 3 – PROJECTED FUTURE DEMANDS

3.1 POTABLE WATER

Potable Water Demand (*Water System Standards*, 2002)

Total Number of Units = 156 multifamily units (130 1-bedroom, 26 2-bedroom units)

Average Daily Demand per unit = 400 gallons/unit

Average Daily Demand = 156 units x 400 gallons/unit = 62,400 gallons/day (GPD)

Maximum Daily Demand = 1.5 x 62,400 = 93,600 GPD

Peak Hour = 3.0 x 62,400 = 187,200 GPD

Fire Flow = 2,000 GPM @ 2-hour duration

3.2 WASTEWATER FLOWS

Wastewater design flows will computed be based on the *Wastewater System Design Standards, City and County of Honolulu (July 2017)* as follows:

Number of Units = 156 multifamily units

Person/Multifamily = 2.8 persons/unit

Number of Persons = 156 x 2.8 = 716.8 persons

Average Daily per Capita Flow = 70 gallons per capita per day (GPCD)

Base Sanitary Flow = 716.8 x 70= 50,176 GPD

Maximum Flow Factor = 2.5

Peak Base SanitaryFlow = 2.5 x 50,176 = 125,440 GPD

Groundwater Infiltration = 35 GPCD x 716.8 persons = 25,088 GPD

Average Dry Weather Flow = 50,176 + 25,088 = 75,264 GPD

Peak Dry Weather Flow = 125,440 + 25,088 = 150,528 GPD

Wet Weather Infiltration/Inflow = 3,000 GPD/acre x 0.62 acre = 1,860 GPD

Design Flow = 150,528 + 1,860 = 152,388 GPD = 0.15 MGD

3.3 STORM WATER RUNOFF

In accordance with the City and County of Honolulu's *Rules Relating to Storm Drainage Standards*, dated August 2017 , the rational formula was used to compute storm water runoff for the developed site for areas less than 100 acres as follows:

Q = C x I x A, cubic feet/second (CFS)

C = Runoff coefficient

I = Rainfall intensity, inches/hour

A = Area, acres

T_m = 10 years (no sump or tailwater effect)

Rainfall Intensity, I_{10} = 2.32 inches/hour, 10 year 1-hour rainfall (per NOAA Atlas 14)

Runoff Coefficient, C = 0.85 for apartment/business area

Time of Concentration, Tc = 7.5 minutes (380 feet at 1.0% slope, paved surface)

CF = 2.5 (Correction Factor for rainfall intensity duration equal to Tc)

Area, A = 0.62 acres, total property area

$Q_{10} = C \times (I_{10} \times CF) \times A = 0.85 \times (2.32 \times 2.5) \times 0.62 = 3.06$ CFS

3.4 STORM WATER QUALITY

Project Site Basic Information:

Property Area = 26,925 square feet = 0.62 acres (from Tax Map Key)

Other estimated areas based on WRNS Architectural Drawings (Consolidated Application, dated 2/9/18):

- Pervious Area = 1,720 square feet
- Impervious Area = 94%
- Roof Area (including parking areas) = 15,780 SF or 0.36 acres

In accordance with the City and County of Honolulu Administrative Rules, Title 20, Department of Planning and Permitting, Chapter 3, *Rules Relating to Water Quality* (the "Rules"), the project is defined as Priority B1. Priority B1 projects are defined as "any new Development and Redevelopment project that results in 5,000 square feet or greater of Impervious Surface area that may have significant water quality impacts due to its location or associated land use activities" (Rules §20-3-48(a)(2)).

Post-construction storm water requirements for Priority B1 projects are as follows (Rules §20-3-49(b)):

- Retain on-site by Infiltration, Evapotranspiration or Harvest/Reuse, as much as the Water Quality Volume or "WQV" as feasible, with appropriate Low Impact Development (LID) Retention Post-Construction Treatment Control BMPs.
- Biofilter the remaining portion of the WQV that is not retained on-site with appropriate LID Biofiltration Post-Construction Treatment Control BMPs as much as feasible.
- If it is demonstrated to be Infeasible to retain and/or biofilter the WQV by criteria in the Rules §20-3-63, one of the following alternative compliance measures is required:
  1) Treat (by detention, filtration, or settling) and Discharge with appropriate Alternative Compliance Post-Construction Treatment Control BMPs, any portion of the WQV that is not retained on-site or biofiltered.
  2) Retain or biofilter at an offsite location, the volume of runoff from a non-tributary drainage area equivalent to the difference between the Project's WQV and the amount retained on-site or biofiltered.

In accordance with the Rules §20-3-63 *Feasibility Criteria*, infiltration BMPs are likely to be deemed infeasible for this site due to low infiltration rates, a seasonally high groundwater table (approximately +3.0 feet MSL), and the proximity of any proposed infiltration measures to the proposed building's footprint and/or existing property lines. Harvest/Reuse BMPs are also considered infeasible due to the demand being inadequate to reuse the required volume of water.

It is anticipated that biofiltration will be accomplished via a vegetated biofilter (aka bioretention filter) based on the current architectural site plan. In accordance with §20-3-58 *Treatment Control BMPs numeric sizing criteria* of the Rules, water quality volume (WQV) will be calculated as follows:

For Vegetated Biofilters:

WQV = P x A x C x 3630/43,560 (acre-feet)

P = design storm runoff depth, inches = 1.5 inches

A = total drainage area, acres

C = volumetric runoff coefficient = .05 + (0.009 x I)

I = percentage impervious cover, expressed as percentage (0 to 100%)

Therefore, WQV = 1.5 x 0.62 x [0.05 + (0.009 x 93.6)] x 3630
= 3,013 CF
= 0.07 acre-ft

3.5 PROPOSED ROADWAYS/DRIVEWAYS

As mentioned in Section 2.1, access to the development shall be from River Street, via North Kukui Street. The proposed driveway into the property shall be approximately in the same location as the existing southeastern driveway. This driveway will be widened from 24 feet to approximately 36 feet in width and will provide two-way traffic circulation. The driveway will be constructed of asphalt concrete pavement with a concrete driveway apron. The other existing driveway closer to the Vineyard Boulevard side of the property will no longer be required as part of the new development, thus, it will be removed.

No other modifications or improvements are planned to this portion of River Street nor to the intersections at Vineyard Boulevard / River Street or North Kukui Street / River Street. A bike path is proposed along the Ewa side of River Street, running parallel to Nuuanu Stream where the current pedestrian pathway is located.

3.6 CONCEPTUAL GRADING AND UTILITY PLAN

As mentioned previously, the proposed development is an 18-story high-rise affordable housing rental for seniors. Conceptual grading and utilities layouts are shown on Attachment C-5. Site grading is expected to be minimal, providing adequate pipe cover over the proposed utilities and positive draining away from the building following the existing site drainage concept.

Preliminary geotechnical recommendations have been provided by Geolabs, Inc. (January 17, 2017) as follows. Based on the site's existing topography, it is anticipated that minimal grading work will be required. It is assumed that construction of the building's foundations and elevator pits will require some excavation and backfill. Due to the soft and/or loose lagoonal soils underlying the site, placement of new fills will likely induce consolidation of the onsite material. It

is therefore recommended that new fill be placed as soon as practical to allow for ground settlement to occur prior to start of construction improvements.

The existing BWS potable water system will be utilized to provide fire and domestic water services for the development. An 8-inch compound water meter will be provided in the concrete sidewalk area fronting the development and will connect to the existing water main in River Street via a new 8-inch underground pipe. New underground 8-inch pipe will also be utilized onsite to provide water flow into the proposed development. The water system will be design in accordance with the *Water System Standards, 2002.*

As mentioned previously, sanitary service will be available via an existing 12-inch sewer main located in River Street. It is anticipated that a new 8-inch sewer lateral will be constructed to service the development. The lateral will lead from a sewer service cleanout located within the proposed courtyard area to an existing sewer manhole located within River Street.

Much of the developed site will be under the roofline of the proposed building. It is estimated that approximately 94% of the site will be impervious surfaces of either paved or roof topped areas. Stormwater shall be collected via rooftop drains and directed towards the makai side of the property, where it shall be then be collected by an onsite drainage system consisting of a series of drain inlets, biofiltration cells and underground drainage pipes. It is anticipated that the onsite underground drainage pipes will range in size from 8 to 12 inches in diameter and will connect to an existing catch basin located in River Street.

3.7 PROPOSED ELECTRICAL AND COMMUNICATION IMPROVEMENTS

3.7.1 OFFSITE IMPROVEMENTS

Electrical System

Depending on the property demand load, offsite Hawaiian Electric Company (HECO) underground ductlines and circuits may need to be upgraded, according to a will serve letter from HECO documented in September 29, 2016. This will include extending new underground conduits, installing new handholes and manholes, and upsizing primary utility conductors. See Attachment E-1 for the HECO will serve letter.

Telecommunications System

Offsite telecommunication system improvements will include extending new underground conduits, installing new pullboxes, handholes and manholes, and supplementing the existing underground support structure, depending on the size of the development. The site will be provisioned with fiber optic cables to deliver telephone and high-speed internet services. If Spectrum were to secure fiber optic services to the property, Hawaiian Telephone (HT) will first need to approve of their use of the HT underground conduit system through an application process.

Digital Television System

Offsite telecommunication system improvements will include extending new underground conduits, installing new pullboxes, handholes and manholes, and supplementing the existing underground support structure, depending on the size of the development. The site will be provisioned with fiber optic cables to deliver digital television services. If Spectrum were to secure

fiber optic services to the property, HT will first need to approve of their use of the HT underground conduit system through an application process.

Public Roadway Lighting System

Public Roadway Lighting improvements are not anticipated for this project.

3.7.2 ONSITE IMPROVEMENTS

Electrical System

The existing HECO transformer will be demolished and a new transformer vault will be located within the new building footprint. The HECO handhole will be relocated to avoid being in the path of the new driveway. From the handhole, new underground conduits and cabling will be extended to the demarcation point as identified by HECO.

Telecommunications System

New underground conduits and fiber optic cabling will be extended as required from the HT pullbox to the demarcation point as identified by the service providers. Interface Engineering will provide the telecommunications requirements within the building. The pullbox will be upgraded depending on the design of the project and the quantity of facilities required for provisioning the site.

Cable Television System

New underground conduits and fiber optic cabling will be extended as required from the HT pullbox to the demarcation point as identified by the service providers. The pullbox will be upgraded depending on the design of the project and the quantity of facilities required for provisioning the site.

Area Lighting System

Building-mounted exterior lighting and parking structure lighting will be provided.

Photovoltaic System

Photovoltaic System is not anticipated for this project.

Electric Vehicle Charging System

Electric Vehicle Charging System will be provided within the building footprint.

Chapter 4 – CONFIRMATION OF INFRASTRUCTURE REQUIREMENTS

4.1 WATER

The Honolulu Board of Water Supply has confirmed that the existing water system is adequate to accommodate the proposed residential development (see Attachment C-3 for BWS letter dated March 7, 2019).

4.2 SEWER

A Sewer Connection Permit for the proposed development has been issued by the City and County of Honolulu, Department of Planning & Permitting (see Attachment C-6 for approved Sewer Connection Application dated January 29, 2019).

201 Merchant Street, Suite 1900
Honolulu, Hawaii 96813-2926

Dear Ms. Nojima:

Subject: Your Letter Dated January 29, 2019 Requesting Water Availability to the Proposed Halewaiolu Affordable Senior Residence, Located at 1331-1347 River Street – Tax Map Key: 1-7-006: 012

Thank you for your email regarding the proposed 156-unit affordable housing rental for seniors.

The existing water system is adequate to accommodate the domestic demands and offsite fire protection to the proposed development. However, please be advised that this information is based upon current data, and therefore, the Board of Water Supply (BWS) reserves the right to change any position or information stated herein up until the final approval of the building permit application. The final decision on the availability of water will be confirmed when the building permit application is submitted for approval.

When water is made available, the applicant will be required to pay our Water System Facilities Charges for resource development, transmission and daily storage.

Water conservation measures are recommended for all proposed developments. These measures include low flow plumbing fixtures, utilization of non-potable water for irrigation using rain catchment and chiller/air handler condensate, cooling tower conductivity meters and water softening recycling systems, drought tolerant plants, xeriscape landscaping, efficient irrigation systems and the use of Water Sense labeled ultra-low-flow water fixtures and toilets.

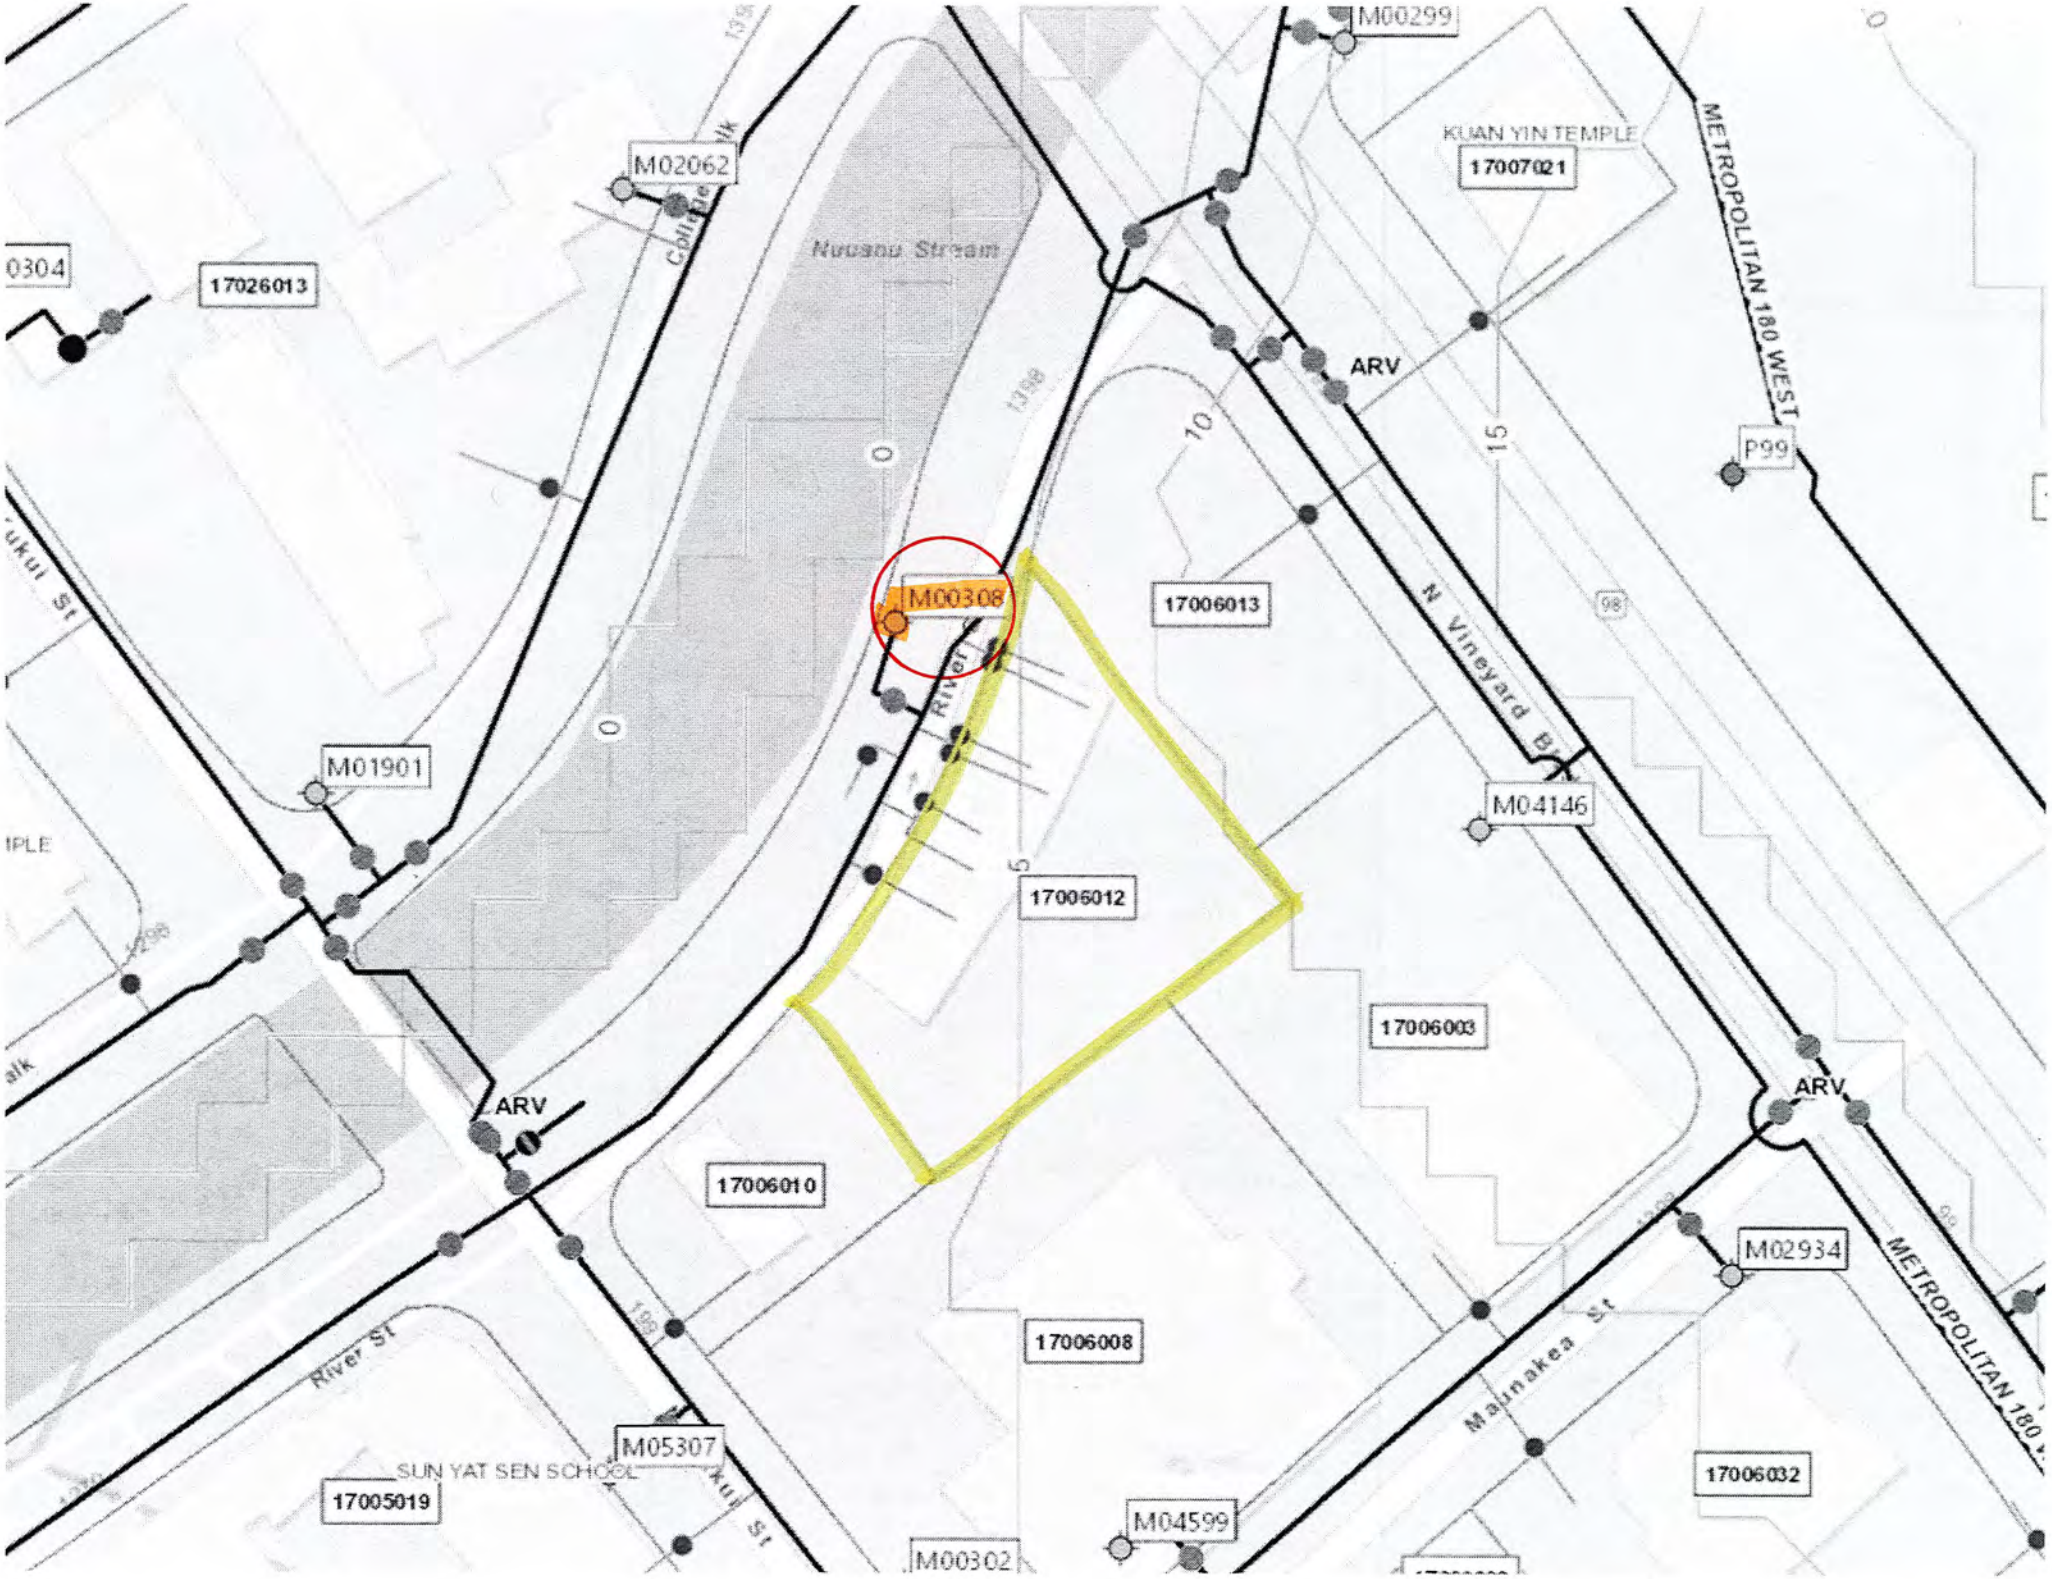
High-rise buildings with booster pumps will be required to install water hammer arrestors or expansion tanks to reduce pressure spikes and potential main breaks in our water system.

The BWS has suspended fire flow tests on fire hydrants as a water conservation measure. However, you may use the following calculated flow data for Fire Hydrant No. M00308 located along River Street:

Static Pressure	80 psi
Residual Pressure	69 psi
Flow	2,000 gpm

The data are based on the existing water system, and the static pressure represents the theoretical pressure at the point of calculation with the reservoir full and no demands on the water system. The static pressure is not indicative of the actual pressure in the field. Therefore, in order to determine the flows that are available to the site, you will have to determine the actual field pressure by taking on-site pressure readings at various times of the day and correlating that field data with the above hydraulic design data.

The map showing the location of the fire hydrant is attached.



The on-site fire protection requirements should be coordinated with the Fire Prevention Bureau of the Honolulu Fire Department.

If you have any questions, please contact Robert Chun, Project Review Branch of our Water Resources Division at 748-5443.

Very truly yours,

ERNEST Y. W. LAU, P.E.
Manager and Chief Engineer

Mr. Masaru Kawaharada
Ronald N.S. Ho & Associates
2153 N. King Street #201
Honolulu, HI. 96819

Dear Mr. Kawaharada:

Re: Halewai'olu Senior Affordable Housing Development
1331 River Street, Honolulu HI

This is in response to your request for a "Will Serve" letter for the above project location.

We have existing distribution circuits on River Street and Kukui Street that could potentially be used to serve your future project. Please keep in mind that these circuits may need to be upgraded depending on the size of this project's load. At this time, we do not have sufficient information and detailed plans to make this determination.

We request that you keep us informed on the status of your project. As soon as you have detailed plans, please create a Service Request with us, and be sure to allow sufficient time for us to work on the project.

Please let us know if we can be of assistance in any other way. Should you have any questions, please call me at 543-7590.

Sincerely,

Eric Shimono
Sr. Engineer
Planning & Design Division
Customer Installation Dept.

ES/GF:ks

Hawaiian Telcom

September 27, 2016

Ronald N. S. Ho & Associates, Inc.
2153 North King Street #201
Honolulu, Hawaii 96819-4554
Attention: Mr. Masaru Kawaharada

Dear Mr. Kawaharada:

Subject: **Halewaiolu Senior Affordable Housing Due Diligence**
Hawaiian Telcom Will Serve Request

In response to your email dated September 13, 2016, we have determined that Hawaiian Telcom will serve the proposed project site from its Alakea Central Office located on Bishop Street.

The existing facilities and infrastructure in the vicinity of this parcel have sufficient capacity for the proposed development. Any related distribution systems throughout the development may also require underground conduits, pullboxes, handholes and manholes. Hawaiian Telcom specifications require 2- or 4-inch conduits, 2'x 4' or 3'x 5' pullboxes, 4'x 6' handholes, and 5'x 10' manholes. The types and amounts will be dependent upon the design of the development.

The Developer's off-site and on-site improvement costs to provide service to the project site will include supplementing the existing underground support structures and/or extending new underground support structures. The responsibility of the costs belongs to the Developer.

Potential service connection points to the project are along River Street. The site will be provisioned with fiber optic cable that will provide access to Hawaiian Telcom's phone, high speed internet and digital television services.

If you have any questions or require assistance in the future on this project, please call me at 546-7761.

Sincerely,

Les Loo
Network Engineer - Outside Plant Engineering

1.0 INTRODUCTION

Halewaiolu Senior Development, LLC (HSD) retained Ford & Associates, Inc. (FAI) to provide a hazardous materials assessment survey for the Halewaiolu Residences Project Site, located at 1331-1347 River Street, in Honolulu, Oahu, Hawaii (the "project site"). The project site consists of a two-story multi-tenant commercial structure on grade. Entry and exit driveways are to the south and north of the structure, with an open parking lot to the rear (east).

The purpose of this project was to conduct a hazardous materials assessment survey of interior and exterior portions of the project site prior to the future planned redevelopment activities. This survey included the collection and laboratory analyses of bulk samples of suspect asbestos-containing materials (ACM) and lead-based paint (LBP). In addition, FAI conducted a visual assessment for materials-containing lead (MCL) (i.e., lead vent shields), and fluorescent light fixtures to assess for the presence of suspect polychlorinated biphenyl (PCB)-containing lighting ballasts and mercury-containing fluorescent light bulbs. Furthermore, FAI visually identified other potentially hazardous environmental concerns present which will impact the future planned redevelopment activities. The roof of the project structure and exterior site areas were included in the survey.

On March 14, 2019, Mr. Todd Sakuda and Mr. Don Gacusan, representatives with FAI, conducted a walkthrough assessment and sampling of the project site. Mr. Sakuda and Mr. Gacusan are certified by the State of Hawaii Department of Health (DOH) and accredited by the United States Environmental Protection Agency (EPA) as Asbestos Building Inspectors (Certification Nos.: HIASB-0361 and HIASB-3137, respectively). In addition, Mr. Sakuda and Mr. Gacusan are certified by the DOH and accredited by the EPA as a Lead-Based Paint Risk Assessor and Lead-Based Paint Inspector (Certification Nos. PB-0281 and PB-0805, respectively). Site access was provided by Mr. Richard Char with Hawaiian Properties Limited.

During the assessment, FAI conducted a visual assessment of the project site and noted areas where friable and non-friable materials suspected of containing asbestos were located. A friable material is one which, when dry, can be crumbled, pulverized, or reduced to powder by hand pressure.

FAI collected representative bulk samples of suspect ACM and paint chip samples of suspect LBP observed throughout interior and exterior portions of the project site. FAI also visually assessed for other potential hazardous materials and units throughout the project site.

2.0 SAMPLING AND ANALYSIS ASSESSMENT

On March 14, 2019, FAI conducted the walkthrough assessment and sampling of the project site. FAI's assessment resulted in the identification, bulk sample collection, and laboratory analyses of suspect hazardous materials throughout the project site.

Bulk samples collected for asbestos analysis and paint samples collected for lead analysis were cataloged, packaged, and shipped to NVL Laboratories Inc. (NVL), an American Industrial Hygiene

Association (AIHA), National Voluntary Laboratory Accreditation Program (NVLAP), and Environmental Lead Laboratory Accreditation Program (ELLAP)-accredited laboratory located in Seattle, Washington.

The following sections describe the sampling and analytical procedures for the collection of suspect-ACM and LBP, and the visual assessment to identify other potentially hazardous materials.

2.1 DESCRIPTION OF ASBESTOS ASSESSMENT

During the assessment, a total of 40 types of suspect ACM were identified, and 141 samples were collected from the project site.

These materials included:

- Painted plaster interior wall and ceiling
- Various colored 4-inch vinyl cove base with associated mastic/adhesive (six types)
- Various ceramic wall and floor tile with associated grout (three types)
- Gypsum wallboard systems with associated joint compound and tape (two types)
- Various colored door caulking (two types)
- Various sized and designed vinyl floor tiles (VFT) and vinyl sheet flooring (VSF) with associated mastics (15 types/variations)
- Various acoustical ceiling panels (two types)
- Various colored sink undercoating (three types)
- White thermoplastic olefin (TPO) roofing system
- White roof coating over black asphaltic roof coating
- Roof penetration and protrusion mastic/sealant
- Roof-top duct seam sealant
- Asphalt concrete (AC) pavement

During the assessment, suspect ACM samples were collected from the project site using hand tools, including chisels, hammers, razor knives, and a core sampler for base roofing materials. Extracted samples were approximately 1- by 1-inch in size and were collected down to the underlying substrates, placed in sealed container, and labeled with unique sample numbers.

The EPA and State of Hawaii Department of Health (DOH) define ACM as materials that contain greater than one percent (1%) asbestos fibers. In accordance with Hawaii Administrative Rules (HAR) Title 11, Chapter 501, Standard for Demolition and Renovation, a minimum of three (3) samples of every homogenous suspect material was collected, per building, per floor, for laboratory analysis. Suspect materials sampled and analyzed are described in Table 2, located behind the Tables tab.

Samples were analyzed for asbestos content using EPA Method 600R-93/116 polarized light microscopy (PLM) for determining asbestos fibers in bulk materials. The analytical laboratory reports are included in Appendix A.

2.2 DESCRIPTION OF LEAD PAINT AND MATERIALS CONTAINING LEAD ASSESSMENT

During the current survey, supplemental paint samples were collected from painted surfaces throughout the interior and exterior of the project site. Paint chips were collected using hand tools, including chisels and razor scrapers. To collect the paint samples, the painted surface (including all sublayers) was scraped down to the underlying substrate (approximately 2- by 2-inches in size), the removed paint chips/shavings were placed in sealed plastic containers, and labeled with unique sample numbers.

The EPA, United States Housing and Urban Development (HUD), and DOH define paint or other surface coatings as LBP when it contains 0.5% or more lead by weight or equal to or greater than one milligram per square centimeter (mg/cm^2). The results for this assessment are reported in % by wt. Paint sample descriptions and locations are presented in Table 3, located behind the *Tables* tab.

The paint samples were analyzed for total lead content using the EPA Method 7000B Atomic Adsorption Spectrometry (AAS). The analytical laboratory reports are included in Appendix B.

In addition, FAI performed a visual assessment of the project site for other materials that may contain lead, such as lead vent shields commonly used in roofing construction, which will be impacted during the future planned redevelopment activities.

2.2 DESCRIPTION OF OTHER HAZARDOUS MATERIALS ASSESSMENT

The following subsections describe other potentially hazardous materials assessed.

2.2.1 Polychlorinated Biphenyls Assessment

FAI disassembled and visually inspected representative, readily accessible fluorescent lighting fixtures throughout the project site to assess for the presence of suspect PCB-containing lighting ballasts.

PCB waste generated in the State of Hawaii must be shipped to an approved waste depository facility located in the United States mainland for final disposal.

2.2.2 Mercury-Containing Material Assessment

FAI inspected the fluorescent lighting fixtures for suspect mercury-containing fluorescent lamps/bulbs. Mercury-containing light lamps/bulbs and/or mercury-containing materials are considered universal waste under Hawaii Administrative Rule (HAR) 11-273 and are managed in accordance with the 40 Code of Federal Regulations (CFR) Part 273. However, the DOH strongly encourages such lamps to be recycled, where feasible.

2.2.3 Other Potentially Hazardous Materials

FAI conducted a visual assessment of readily accessible equipment and units that may contain hazardous material components. FAI assessed areas and existing equipment for potential hazardous material and environmental concerns, and recorded field observations and/or available information.

3.0 SURVEY RESULTS

3.1 RESULTS OF ASBESTOS ASSESSMENT

The survey resulted in the collection of 141 total bulk samples of suspect ACM from the project site that will be impacted during the future planned redevelopment activities. The suspect ACM samples from the current survey were shipped to NVL for Polarized Light Microscopy (PLM) analysis.

Based on the laboratory results, FAI confirmed nine materials that contain asbestos above the regulatory level of 1%. The confirmed ACM include the following:

First Floor

- Approximately 1,850 square feet (SF) of black mastic, located beneath existing VFT in the Uptown Café dining room, office, and Hanagasa Inn dining room
- Approximately 250 SF of light brown mastic beneath 4-by 4-inch blue and white ceramic wall tile, located throughout the Uptown Café, men's restroom
- Approximately five SF of inaccessible sink undercoating (assumed ACM), located in the Uptown Café, dining room, service counter

Second Floor

- Approximately 5,400 SF of 9-by 9-inch brown VFT, located throughout all second-floor suites and hallways
- Approximately 520 linear feet (LF) of 4-inch brown vinyl cove base, located throughout second floor baseboards in suites 204, 205, 207, 212, 213, 215 (restroom included), and 216 (restroom only)
- Approximately five SF of remnant black mirror mastic, located on the restroom door in Suite 205
- Approximately 12,200 SF of painted interior wall plaster, located throughout the second-floor interior walls and partitions

Roof

- Approximately 30 SF of black sealant, located throughout roof penetrations and protrusions
- Approximately 750 SF of black coating beneath white roof coating, located throughout the west side, lower eyebrow roof (awning)

Because the confirmed and assumed ACM will be disturbed during the future planned redevelopment activities, these materials must be properly removed and disposed prior to general demolition/construction activities. A licensed asbestos abatement contractor should conduct the removal and disposal work under the supervision of a qualified industrial hygiene professional.

This asbestos assessment was limited to readily accessible portions of the project site under the conditions present during FAI's site assessment. FAI conducted a thorough assessment; however, additional suspect ACM may exist underground or behind permanent structures such as fixed walls, solid ceilings, or inaccessible/sealed pipe chases. If additional suspect ACM are discovered during the renovation/demolition activities, additional sampling and analysis of the suspect ACM should be conducted.

Table 2, located behind the *Table* tab, show suspect ACM descriptions, locations, analytical results, and sample identification (ID) numbers. Materials confirmed as ACM are described in Table 1, also located behind the *Tables* tab. Estimated affected areas are identified on Figures 2 through 4, located behind the *Figures* tab. Photographs of the confirmed and presumed ACM are presented in the photo log, located behind the *Photographs* tab.

3.2 RESULTS OF LEAD-BASED PAINT ASSESSMENT

The surveys resulted in the collection of 14 total paint samples of suspect LBP from the project site that will be impacted during the future planned redevelopment activities.

Based on laboratory results, none of the paint samples contained lead concentrations above the EPA/HUD regulatory level of 0.5% lead by weight, which defines LBP.

However, seven paint samples reported lower concentrations of lead below the EPA/HUD LBP threshold. Therefore, these paint sample results are considered lead-containing paint (LCP). These paint sample results are shown with an asterisk (*) next to the result on Table 3, located behind the *Tables* tab.

The identified LCPs were observed ranging from poor to good condition with varying degrees of delamination. Although these paints do not meet the EPA/HUD definition of LBP, contractors and subcontractors must follow the OSHA lead standards 29 Code of Federal Regulation (CFR) 1910.1025 (General Industry Standard) and 29 CFR 1926.62 (Construction Standard) when workers have a potential to be exposed to any amount of lead during work activities (i.e., cutting, drilling, sanding, grinding, etc.).

The remaining seven paint sample results were reported below the laboratory reporting limit (RL) and are considered not to contain lead. No special handling or disposal will be required when disturbing these paints.

Table 3, located behind the *Tables* tab, presents all previous and current paint sample descriptions, locations, analytical results, and sample ID numbers.

3.3 RESULTS OF OTHER HAZARDOUS MATERIALS ASSESSMENT

The following subsections describe the field observation and/or sampling for other potentially hazardous materials assessed. FAI's observations are listed as follows:

3.3.1 Polychlorinated Biphenyls-Containing Units

FAI disassembled and visually inspected representative fluorescent lighting fixtures observed throughout the project site. During the assessment, FAI observed all of the inspected light ballasts labeled "No PCBs." However, FAI recommends that all fluorescent light ballasts be inspected prior to the planned demolition activities. All ballasts not displaying the "No PCBs" indication should be removed from the light fixture, placed in a State of Hawaii Department of Transportation (DOT)-approved waste container/drum, properly labeled, and disposed as PCB waste. PCB waste generated in the State of Hawaii must be shipped to an approved waste depository facility located in the Continental United States for final disposal.

In addition, FAI also observed high intensity discharge (HID) light fixtures located on the exterior of the building. These fixtures contain suspect PCB ballasts and should be inspected, removed, and properly disposed prior to the future planned redevelopment activities.

FAI also observed a pad-mounted Hawaiian Electric-owned electrical transformer located on the northwest corner of the project site, along the entry driveway. Based on a letter from Hawaiian Electric, the transformer is a non-PCB unit. A copy of the Hawaiian Electric letter is attached as Appendix C. If this transformer will be affected by the future planned redevelopment activities, the owner should provide Hawaiian Electric advance notice to decommission or relocate the unit prior to the planned redevelopment activities.

3.3.2 Mercury-Containing Materials

FAI also inspected the lighting fixtures for mercury-containing fluorescent bulbs. All fluorescent light bulbs/tubes should be considered mercury-containing, considered universal waste under Hawaii Administrative Rule (HAR) 11-273, and managed in accordance with the 40 Code of Federal Regulations (CFR) Part 273. Furthermore, DOH strongly encourages bulbs/lamps to be recycled, if possible.

In addition, FAI also observed high intensity discharge (HID) lamps throughout the warehouse ceiling and in select locations at the project site. These lamps should also be considered mercury-containing and be properly removed, recycled or disposed in accordance with current regulatory requirements.

3.3.3 Other Potentially Hazardous Materials

FAI assessed areas/equipment of potential concern, and recorded field observations and/or available information, as follows:

Chlorofluorocarbon (CFC)-Containing Air-Conditioning (AC) Units

FAI visually identified two pad-mounted, split-system air-conditioning (AC) units located on the rear of Uptown Café and a variety of window-mounted AC units located throughout the project building. Since these AC units will be affected by the future planned redevelopment activities, the CFC-containing units should be removed/purged/recycled prior to demolition of the abandoned units.

Ionizing Radiation Smoke Detectors

FAI visually observed ceiling-mounted smoke detectors located throughout the project building. Each of these smoke detectors contains a small radioactive source (typically Americium 241). Therefore, since these smoke detectors will be affected by the planned redevelopment activities, they should be removed, properly packaged, and disposed in accordance with current regulatory requirements.

Emergency Exit Light Fixtures

FAI visually observed a few emergency exit-light fixtures located at strategic locations throughout the project site. These light fixtures contain a rechargeable lead-acid battery and should be properly removed and disposed prior to the future planned redevelopment activities.

4.0 LIMITATIONS

This report is for the exclusive use of Halewaiolu Senior Development, LLC and no other party shall have any right to rely on any service provided by FAI without prior written consent. The information and opinions expressed in this report are given in response to a limited assignment and should be considered and implemented only in light of that assignment.

The services provided by FAI in completing this project were consistent with normal standards of the profession. No other warranty, expressed or implied, is made. FAI will not distribute or publish this report without consent except as required by law or court order.

Project No. 19-1439
Sample Collection Date: March 14, 2019

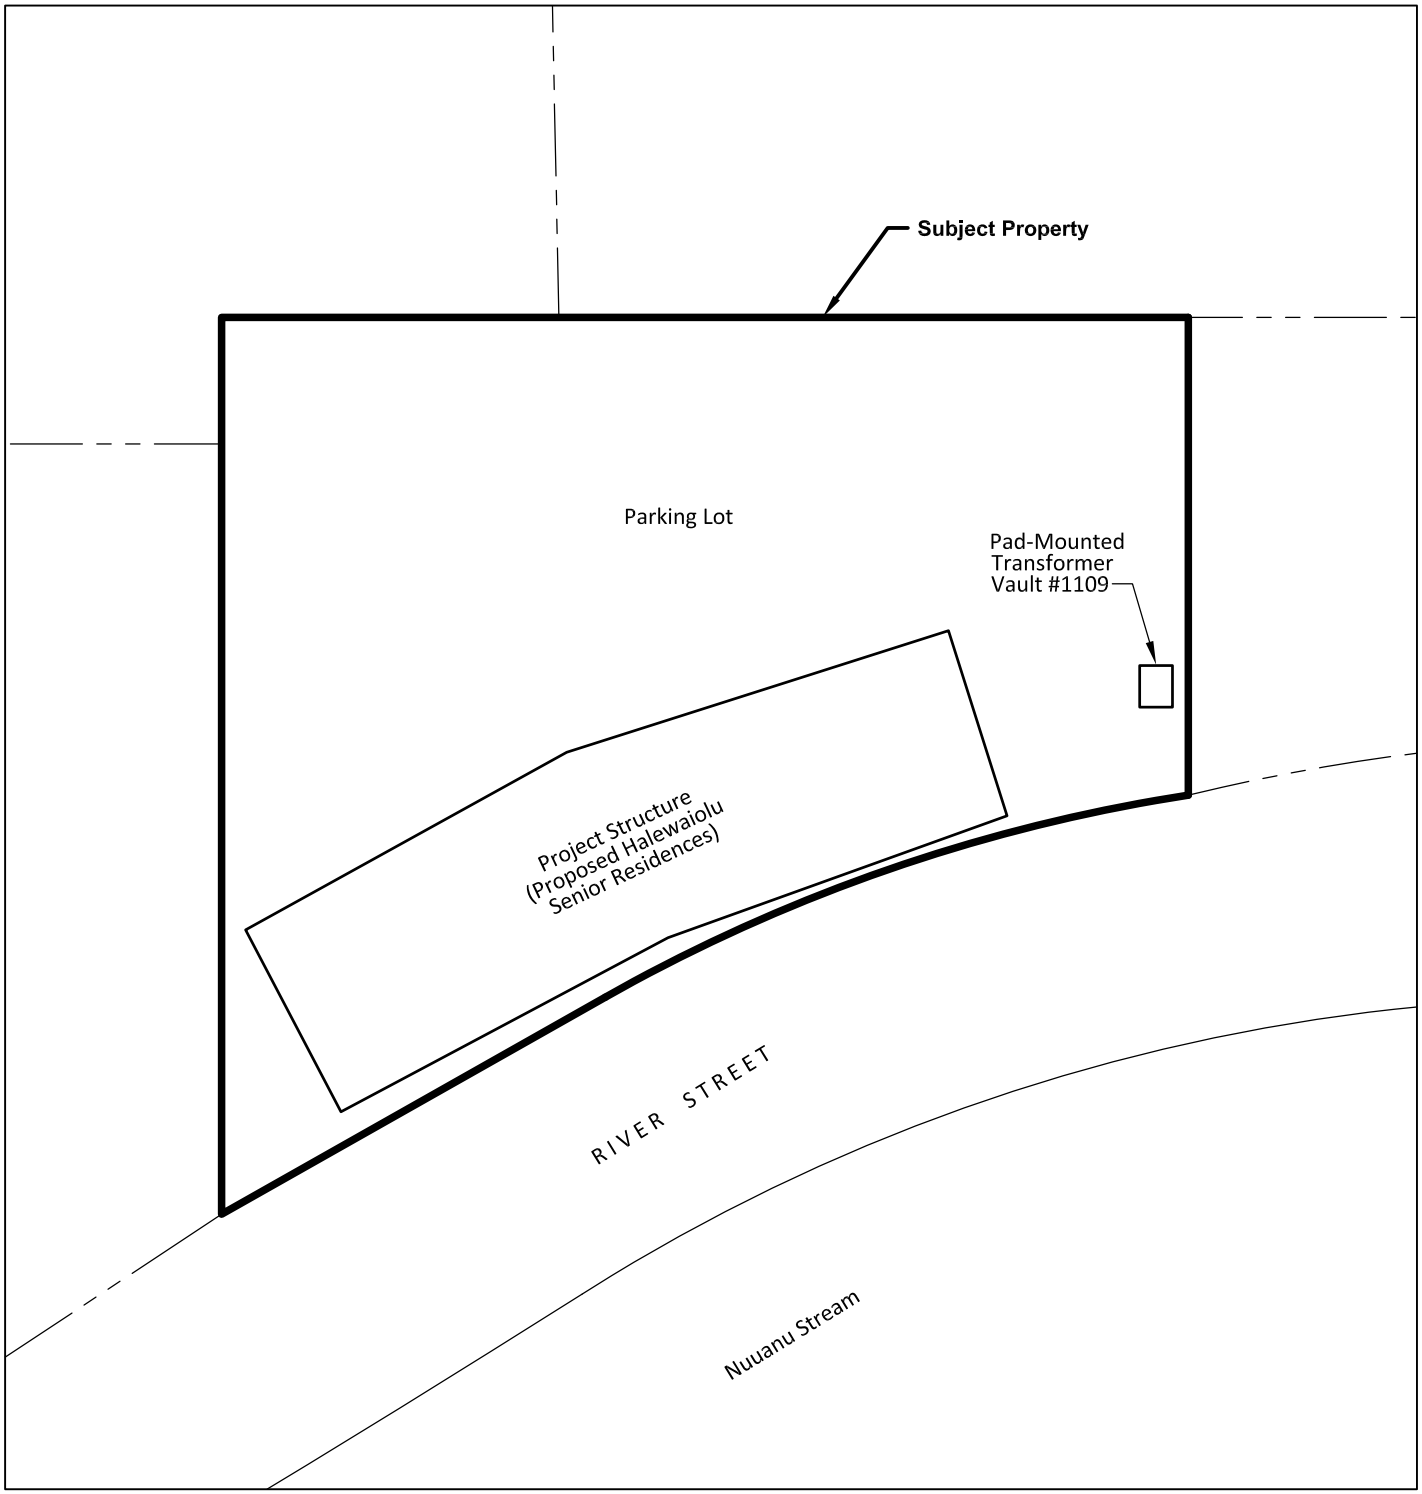
Paint Description / Location	Sampling Location	Lead Content (% by WT)	Sample ID
First Floor			
White paint / located throughout interior, gypsum board walls	Chikara Mochi, interior, north wall	<0.0064	HR-P01
Blue paint / located throughout interior/exterior, wooden doors and frames	Chikara Mochi, interior, front door	0.30*	HR-P02
Beige paint / located throughout interior, plaster walls and ceilings	Miki's Florist, interior, north wall	0.0052*	HR-P03
White paint / located throughout interior, columns and walls	Hanagasa Inn, interior, column, west side wall	<0.0050	HR-P04
Black paint (over white paint) / located throughout interior, wooden trim	Hanagasa Inn, interior, rear door trim	0.025*	HR-P05
Second Floor			
White paint / located throughout 2nd floor, interior, walls and ceilings	Suite 212, interior, north wall	<0.0052	HR-P06
White paint / located throughout 2nd floor, interior, doors and doorframes	Suite 212, entry door	0.014*	HR-P07
Exterior			
Yellow paint / located on exterior, parking bollards	Parking lot, rear of Uptown Café, on parking bollards	<0.0078	HR-P08
Blue paint / located on exterior, rear doors and doorframes	Miki's florist, exterior, rear doorframe	0.25*	HR-P09

Table 3 (continued)

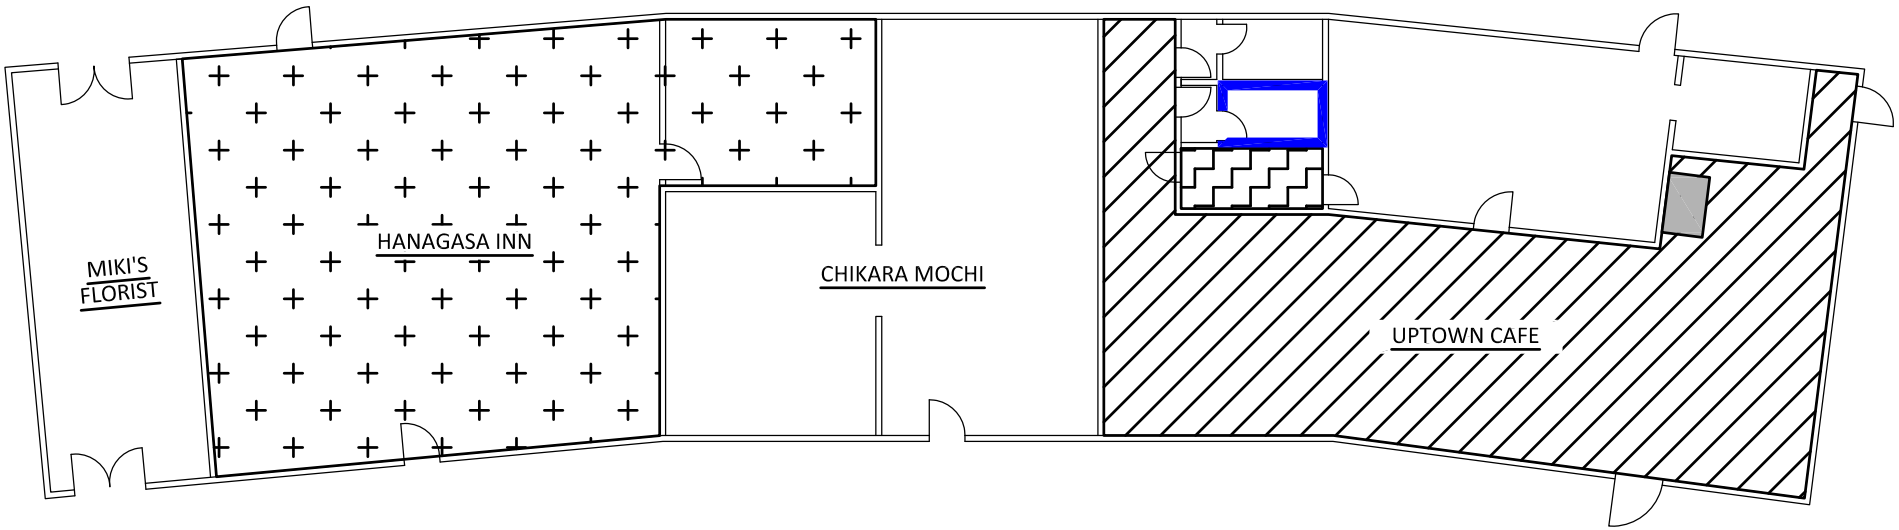
Paint Description / Location	Sampling Location	Lead Content (% by WT)	Sample ID
Exterior (continued)			
Black paint (over gray paint) / located on exterior, stairway, handrails	Stairway, south side, on handrail	0.12*	HR-P10
Blue paint / located on exterior, stairway, threads and risers	Stairway, south side, on threading	0.056*	HR-P11
Yellow paint / located on exterior, parking lot, on parking stops	Parking lot, middle, on parking stop	<0.0054	HR-P12
Handicap blue / located on exterior, parking lot, on parking stops	Parking lot, middle, on parking stop	<0.015	HR-P13
White striping paint / located on exterior, parking lot, stalls	Parking lot, middle, on parking stalls	<0.0043	HR-P14



NOTES:

Occupational Safety and Health Administration (OSHA) regulations for worker protection apply to any paint with a detectable concentration of lead. None of the paints tested are considered lead-based paint (LBP).

* = Detectable concentration(s) of lead above the laboratory reporting limit (RL) but below the regulatory level of 0.5% lead by weight, which defines LBP. These lead-containing paints are subject to OSHA regulations.



< = Below laboratory reporting limit (RL)
% by WT = Percent by weight

LABORATORY ANALYTICAL REPORTS FOR ASBESTOS SAMPLING

March 22, 2019

Don Gacusan
Ford & Associates, Inc.
928 Nuuanu Ave. Suite 505
Honolulu, HI 96813

RE: Bulk Asbestos Fiber Analysis; NVL Batch # 1905329.00

Client Project: 19-1439
Location: Halewaiolu Residences

Dear Mr. Gacusan,

Enclosed please find test results for the 30 sample(s) submitted to our laboratory for analysis on 3/19/2019.

Examination of these samples was conducted for the presence of identifiable asbestos fibers using polarized light microscopy (PLM) with dispersion staining in accordance with both **EPA 600/M4-82-020**, Interim Method for the Determination of Asbestos in Bulk Insulation Samples and **EPA 600/R-93/116** Method for the Determination of Asbestos in Bulk Building Materials.

For samples containing more than one separable layer of materials, the report will include findings for each layer (labeled Layer 1 and Layer 2, etc. for each individual layer). The asbestos concentration in the sample is determined by calibrated visual estimation.

For those samples with asbestos concentrations between 1 and 10 percent based on visual estimation, the EPA recommends a procedure known as point counting (NESHAPS, 40 CFR Part 61). Point counting is a statistically more accurate means of quantification for samples with low concentrations of asbestos.

The detection limit for the calibrated visual estimation is <1%, 400 point counts is 0.25% and 1000 point counts is 0.1%

Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. Please do not hesitate to call if there is anything further we can assist you with.

Sincerely,

Matt Macfarlane, Asbestos Lab Supervisor

RE: Bulk Asbestos Fiber Analysis; NVL Batch # 1905333.00

Client Project: 19-1439
Location: Halewaiolu Residences

Dear Mr. Gacusan,

Enclosed please find test results for the 30 sample(s) submitted to our laboratory for analysis on 3/19/2019.

Examination of these samples was conducted for the presence of identifiable asbestos fibers using polarized light microscopy (PLM) with dispersion staining in accordance with both **EPA 600/M4-82-020**, Interim Method for the Determination of Asbestos in Bulk Insulation Samples and **EPA 600/R-93/116** Method for the Determination of Asbestos in Bulk Building Materials.

For samples containing more than one separable layer of materials, the report will include findings for each layer (labeled Layer 1 and Layer 2, etc. for each individual layer). The asbestos concentration in the sample is determined by calibrated visual estimation.

For those samples with asbestos concentrations between 1 and 10 percent based on visual estimation, the EPA recommends a procedure known as point counting (NESHAPS, 40 CFR Part 61). Point counting is a statistically more accurate means of quantification for samples with low concentrations of asbestos.

The detection limit for the calibrated visual estimation is <1%, 400 point counts is 0.25% and 1000 point counts is 0.1%

Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. Please do not hesitate to call if there is anything further we can assist you with.

Sincerely,

Matt Macfarlane, Asbestos Lab Supervisor

RE: Bulk Asbestos Fiber Analysis; NVL Batch # 1905334.00

Client Project: 19-1439
Location: Halewaiolu Residences

Dear Mr. Gacusan,

Enclosed please find test results for the 30 sample(s) submitted to our laboratory for analysis on 3/19/2019.

Examination of these samples was conducted for the presence of identifiable asbestos fibers using polarized light microscopy (PLM) with dispersion staining in accordance with both **EPA 600/M4-82-020**, Interim Method for the Determination of Asbestos in Bulk Insulation Samples and **EPA 600/R-93/116** Method for the Determination of Asbestos in Bulk Building Materials.

For samples containing more than one separable layer of materials, the report will include findings for each layer (labeled Layer 1 and Layer 2, etc. for each individual layer). The asbestos concentration in the sample is determined by calibrated visual estimation.

For those samples with asbestos concentrations between 1 and 10 percent based on visual estimation, the EPA recommends a procedure known as point counting (NESHAPS, 40 CFR Part 61). Point counting is a statistically more accurate means of quantification for samples with low concentrations of asbestos.

The detection limit for the calibrated visual estimation is <1%, 400 point counts is 0.25% and 1000 point counts is 0.1%

Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. Please do not hesitate to call if there is anything further we can assist you with.

Sincerely,

Matt Macfarlane, Asbestos Lab Supervisor

RE: Bulk Asbestos Fiber Analysis; NVL Batch # 1905337.00

Client Project: 19-1439
Location: Halewaiolu Residences

Dear Mr. Gacusan,

Enclosed please find test results for the 30 sample(s) submitted to our laboratory for analysis on 3/19/2019.

Examination of these samples was conducted for the presence of identifiable asbestos fibers using polarized light microscopy (PLM) with dispersion staining in accordance with both **EPA 600/M4-82-020**, Interim Method for the Determination of Asbestos in Bulk Insulation Samples and **EPA 600/R-93/116** Method for the Determination of Asbestos in Bulk Building Materials.

For samples containing more than one separable layer of materials, the report will include findings for each layer (labeled Layer 1 and Layer 2, etc. for each individual layer). The asbestos concentration in the sample is determined by calibrated visual estimation.

For those samples with asbestos concentrations between 1 and 10 percent based on visual estimation, the EPA recommends a procedure known as point counting (NESHAPS, 40 CFR Part 61). Point counting is a statistically more accurate means of quantification for samples with low concentrations of asbestos.

The detection limit for the calibrated visual estimation is <1%, 400 point counts is 0.25% and 1000 point counts is 0.1%

Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. Please do not hesitate to call if there is anything further we can assist you with.

Sincerely,

Matt Macfarlane, Asbestos Lab Supervisor

Note: If samples are not homogeneous, then subsamples of the components were analyzed separately. All bulk samples are analyzed using both EPA 600/R-93/116 and 600/M4-82-020 Methods with the following measurement uncertainties for the reported % Asbestos (1%=0-3%, 5%=1-9%, 10%=5-15%, 20%=10-30%, 50%=40-60%). This report relates only to the items tested. If sample was not collected by NVL personnel, then the accuracy of the results is limited by the methodology and acuity of the sample collector. This report shall not be reproduced except in full, without written approval of NVL Laboratories, Inc. It shall not be used to claim product endorsement by NVLAP or any other agency of the US Government

RE: Bulk Asbestos Fiber Analysis; NVL Batch # 1905344.00

Client Project: 19-1439
Location: Halewaiolu Residences

Dear Mr. Gacusan,

Enclosed please find test results for the 21 sample(s) submitted to our laboratory for analysis on 3/19/2019.

Examination of these samples was conducted for the presence of identifiable asbestos fibers using polarized light microscopy (PLM) with dispersion staining in accordance with both **EPA 600/M4-82-020**, Interim Method for the Determination of Asbestos in Bulk Insulation Samples and **EPA 600/R-93/116** Method for the Determination of Asbestos in Bulk Building Materials.

For samples containing more than one separable layer of materials, the report will include findings for each layer (labeled Layer 1 and Layer 2, etc. for each individual layer). The asbestos concentration in the sample is determined by calibrated visual estimation.

For those samples with asbestos concentrations between 1 and 10 percent based on visual estimation, the EPA recommends a procedure known as point counting (NESHAPS, 40 CFR Part 61). Point counting is a statistically more accurate means of quantification for samples with low concentrations of asbestos.

The detection limit for the calibrated visual estimation is <1%, 400 point counts is 0.25% and 1000 point counts is 0.1%

Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. Please do not hesitate to call if there is anything further we can assist you with.

Sincerely,

Matt Macfarlane, Asbestos Lab Supervisor

LABORATORY ANALYTICAL REPORTS FOR LEAD PAINT SAMPLING

March 20, 2019

Don Gacusan
Ford & Associates, Inc.
928 Nuuanu Ave. Suite 505
Honolulu, HI 96813

RE: Metals Analysis; NVL Batch # 1905348.00

Dear Mr. Gacusan,

Enclosed please find the test results for samples submitted to our laboratory for analysis. Preparation of these samples was conducted following protocol outlined in EPA Method SW 846 -3051 unless stated otherwise. Analysis of these samples was performed using analytical instruments in accordance with U.S. EPA, NIOSH, OSHA and other ASTM methods.

For matrix materials submitted as paint, dust wipe, soil or TCLP samples, analysis for the presence of total metals is conducted using published U.S. EPA Methods. Paint and soil results are usually expressed in mg/Kg which is equivalent to parts per million (ppm). Lead (Pb) in paint is usually expressed in mg/Kg (ppm) , Percent (%) or mg/cm^2 by area. Dust wipe sample results are usually expressed in ug/wipe and ug/ft^2. TCLP samples are reported in mg/L (ppm). For air filter samples, analyses are conducted using NIOSH and OSHA Methods. Results are expressed in ug/filter and ug/m^3. Other matrix materials are analyzed accordingly using published methods or specified by client. The reported test results pertain only to items tested and are not blank corrected.

For recent regulation updates pertaining to current regulatory levels or permissible exposure levels, please call your local regulatory agencies for more details.

This report is considered highly confidential and will not be released without your approval. Samples are archived for two weeks following analysis. Samples that are not retrieved by the client are discarded after two weeks.

Thank you for using our laboratory services. if you need further assistance please feel free to call us at 206-547-0100 or 1-888-NVLLABS.

Sincerely,

Shalini Patel, Lab Supervisor

REPORT TEXT

(This page intentionally left blank.)

EXECUTIVE SUMMARY

Halewai'olu Senior Development, LLC (HSD) proposes to develop the Halewai'olu Senior Residences at 1331-1347 River Street in downtown Chinatown in Honolulu, island of O'ahu (Project). This executive summary describes the economic and fiscal impacts of the Project within the City and County of Honolulu (County) and the State of Hawai'i (State).

The following chapters provide more information on the study background, project parameters, and analyses.

STUDY BACKGROUND

On May 17, 2016, HSD entered into a Development Agreement with the County regarding certain development rights and an intended lease related to a 26,925 square foot parcel of land owned by the County. The property is located at 1331-1347 River Street and identified as TMK (1) 1-7-006: 012 (the Property). The Property is within the City's Downtown Neighborhood Transit Oriented Development (TOD) plan area, due to its location within a ½-mile radius of the City's planned Chinatown and Iwilei rail stations. The Property is not within the City's Chinatown Special District, but to the extent practicable, design is expected to align with the intent of that designation, as set forth in the County's Land Use Ordinance.

R.M. Towill Corporation (Towill) is assisting HSD in preparing an Environmental Assessment (EA) pursuant to the National Environmental Policy Act (NEPA) and other necessary environmental documentation. Towill is also processing a "201H" application for zoning and other exemptions pursuant to Chapter 201H, Hawai'i Revised Statutes (HRS). This statute allows eligible 201H projects to seek exemptions from certain fees, statutes, ordinances and rules of any governmental agency relating to planning, zoning and construction standards in exchange for providing affordable housing, so long as the project does not negatively affect the health and safety of the general public and does not contravene standards, rates and fees approved by the public utilities commission.

HSD and Towill sought this economic and fiscal impact assessment to support the EA and 201H entitlement documents. A NEPA EA seeks to address a project's "cumulative impact", which is defined by the Council on Environmental Quality as:

> *"the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-federal) or person undertakes such other actions*" (40 CFR § 1508.7)[1].

The Project is one of several residential developments anticipated within the downtown and Chinatown areas, in relationship to the initiation of rail service and other projects anticipated in the area. As reflected in a July 2019 study on market demand and capacity in transit oriented areas prepared for the City and County of Honolulu, the Chinatown and downtown areas of the "Downtown Neighborhood," as defined therein, has capacity for 1,470 and 1,680 more residential units, respectively, including this Project (Strategic Economics, 2019).[2] Thus, the impacts of the Halewai'olu Senior Residences have been

[1] 40 CFR § 1508.7

[2] Strategic Economics, "Honolulu TOD Demand Analysis and Market Projections", July 2, 2019.

accounted for within the context of other residential and public infrastructure investments in the area.

THE PROJECT

The Halewai'olu Senior Residences entails demolition of an existing two-story commercial building on-site and construction of a 17-story senior housing project with 155 affordable rental units, plus one unit for resident manager. The Project is also expected to include a multipurpose room, a recreation deck and garden area, approximately 500 square feet of retail/commercial area, and a two-story parking structure. All tenants shall have incomes at or below 80% of the area median income (AMI) for the County, as adjusted for family size. After development, HSD or its related entity will manage and operate the Project for a maximum term of 75 years, pursuant to the ground lease terms.

Development of the Halewai'olu Senior Residences is already underway, with design, financing and permitting. These planning efforts are projected to conclude by September 2020, with construction commencing immediately thereafter and extending to approximately April 2020. Leasing could be completed by July 2022, with all operations stabilized within a year thereafter.

In order to approximate the above schedule, this economic and fiscal assessment is presented in periods that correspond to the County and State's fiscal years, with the development period represented as FY2020 to FY2022 (July 2019 to June 2022), and the first year of full operations represented as FY2023 (July 2022 to June 2023). Operations are assumed to be stabilized by FY2024 (July 2023 to June 2024).

In operational terms, the key Project elements evaluated in this economic and fiscal impact assessment are as follows.

Table 1: Project Elements Evaluated

	FY2019-FY2022 (Development)	FY2023 (Full operations)	Total/Stabilized Operations
Apartments:		**156 apartments**	**156 apartments**

Commercial space (sq. ft.)	-	500	**500 square feet**

Source: The Michaels Development Company, 2019. See also Exhibit 2-1.

DEVELOPMENT COST AND SUMMARY IMPACTS

This study uses results of the State's Input-Output model (DBEDT 2016)[3] and other factors to estimate various economic and fiscal impacts of the Halewai'olu Senior Residences. The total (including direct, indirect and induced)[4] statewide impacts of the Project are summarized below. HSD estimates overall development costs of $85.6 million, of which $78.6 million is estimated to support direct benefits for Hawai'i. This excludes certain non-

[3] State of Hawai'i, Department of Business, Economic Development and Tourism, "The Hawaii State Input-Output Study: 2012 Benchmark Report", March 2016. See Chapter 4 for discussion of terminology.

[4] State of Hawai'i, Department of Business, Economic Development and Tourism, "The Hawaii State Input-Output Study: 2012 Benchmark Report", March 2016. See Chapter 4 for definition of this terminology.

construction related costs in the development budget such as operating and lease-up reserves, developer fees, and entitlement expenses. As of October 2019, before obtainment of final entitlements, HSD had already expended some $2.9 million of these funds, demonstrating the company's commitment to the Project and to providing affordable housing and social services in the County.

The existing two-story building on the Property is no longer occupied and no longer generates employment, real property taxes or other revenues for the County or State. Therefore, all economic and fiscal impacts estimated herein for the Halewai'olu Senior Residences are considered to be net new.

The table following provides a summary of the anticipated economic and fiscal impacts to be generated by these investments.

Table 2: Summary of Economic and Fiscal Impacts (2019 dollars)

	2020-2022 (Development period)	2023 (Operations)	Total/Stabilized Operations
Hawai'i development costs	$78.6 million	$0	**$78.6 million**

For the State	27.8	1.4	**1.5**

Source: PBR HAWAII, 2019. See also Exhibit 1-1.

[5] Average annual direct, indirect and induces impacts; FTE = Full-time equivalent, defined as 40 hours per week or 2,080 hours per year.

[6] On-site estimates reflect direct employment only; other categories reflect total (direct, indirect and induced) impacts on a statewide basis.

[7] Earnings are defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance, and reflect total (direct, indirect and induced) impacts on a statewide basis.

The goal of this Project is to increase and enhance the supply of affordable rental housing for seniors on an unutilized County property that is located in an established urban area already served by utilities, services and numerous commercial and other enterprises. Social services to be provided at the Project are also intended to enhance the lives of its residents and the surrounding community.

While employment is not a driving motivation of the Halewai'olu Senior Residences, the Project is expected to generate substantial employment during its development, with some 260 FTE positions supported per year over about three years. Operational employment impacts are likely to be modest, with about 5 FTE positions created on-site, or perhaps 12 island-wide, when the impacts of off-site spending are accounted for. The latter could include jobs that are directly created by Halewai'olu Senior Residences off-site, such as for elevator maintenance, utility services, and the like, as well as those supported through indirect and induced effects.

As a 100% affordable housing development, the Project is not conceived as a means of generating income for County or State governments. In fact, through the 201H process, and the County and State's various incentives for affordable housing, the Project is expected to seek common tax and other exemptions considered key to the feasibility of such affordable housing developments. Consistent with this, the assessment shows net additional tax revenues of around $900,000 per year for the State during its development (largely income tax revenues on development employment earnings), but essentially zero net additional government revenues for the State during operations, and none for the County throughout the analysis period.

Accordingly, the ratio of net additional government revenues to expenditures is high for the State during the Project's development, at 27.8, but the ratios ranges from about 1.4 to 1.5 during operations. For the County, the Project could generate slightly less revenue than the costs of providing government services to its potential new residents. The analysis points to a County revenue to expenditure ratio of about 0.3 to 0.4, owing largely to its expected exemption from real property taxes.

These conclusions are discussed further in Chapter 2.

1 – INTRODUCTION

REPORT ORGANIZATION

The remainder of this report is organized as follows:

The report text is presented in three chapters:

1. Introduction - Study objectives and key parameters of the analysis.
2. Projected Impacts – Detailed study findings relating to the economic, population and fiscal impacts of the Halewai'olu Senior Residences.
3. Study Conditions and Terminology – Definitions and other important factors underlying the study.

Exhibits and Appendices follow the text and offer more detailed analyses and findings.

STUDY OBJECTIVE

The objective of this study is to estimate the economic and fiscal impacts of the Halewai'olu Senior Residences (Project) within the City and County of Honolulu (County) and the State of Hawai'i (State), to inform community members, public agencies and other interested parties, and to accompany the requests for discretionary approvals and entitlements as described in the Executive Summary. Factors evaluated include:

- **Economic impacts**:
  - Development-related employment
  - Operations-related employment
  - Personal earnings deriving from development and operations
- **Population impacts:**
  - Persons who may move between islands or from outside of the State because of residential opportunities generated by the Project
  - Employees who relocate to the County or State because of a work opportunity generated by the Project
- **Fiscal impacts:**
  - Real property tax and other County government revenues
  - General excise tax, income tax, and other State government revenues
  - County and State government operating expenditures
  - County and State net fiscal impacts and revenue/expenditure ratios

DOLLAR DENOMINATION

Unless otherwise stated, all dollar amounts referenced are stated in 2019 dollars.

REPORTING PERIODS

This analysis begins in FY2020 (July 2019 to June 2020), after major discretionary approvals were presumed to have been obtained. The conclusions are presented with respect to three time periods:

- **Development activities: planning and design (FY2020 to FY2022)** – While various planning and design efforts are already underway, the analysis begins in July 2019 so as to exclude the majority of the entitlement period. This first three-year period encompasses final Project planning, design, engineering and permitting. This stage is expected to conclude by September 2020. Thereafter, demolition of the existing building, site preparation, and new construction are targeted to begin, with commercial and residential leasing initiated soon thereafter. The Project's certificate of occupancy is targeted for April 2022.
- **Full operations: (FY2023)** – The Project is expected to be fully leased by July 2022, thus FY2023 (July 2022 to June 2023) is treated as its first year of full operations for purposes of this model.
- **Stabilization (FY2024 on)** – The final "period" considered depicts the long-term impacts of the Halewai'olu Senior Residences, after the organizational impacts of initial leasing have subsided and all operations are stabilized.

Note that the first period encompasses three years, while others are evaluated in terms of single years. Thus, care should be taken when comparing totals for each period.

2 – PROJECTED IMPACTS

The Halewai'olu Senior Residences will generate employment, earnings and fiscal benefits during its development and operations. For details of impacts by development element, the reader is referred to the exhibits noted below each table. More information on the current study methodology and definition of key terms such as "direct", "indirect" and "induced" impacts, are provided in Chapter 3.

The analyses undertaken herein reflect economic multipliers and coefficients derived from the State of Hawai'i, Department of Business, Economic Development and Tourism (DBEDT), "The Hawai'i State Input-Output Study: 2012 Benchmark Report," March 2016 (DBEDT 2016).

DEVELOPMENT COSTS

The Halewai'olu Senior Residences is expected to represent an investment of over $85 million, of which some $78.6 million is anticipated to be infused into the Hawai'i economy, and is therefore the focus of this analysis. The differential is due to exclusion of certain non-construction related costs in the development budget, such as operating and lease-up reserves, developer fees, and entitlement expenses. This adjustment is made to best align the analyses with assumptions used in DBEDT 2016.

Most development expenditures are for demolition and construction, representing "hard costs" such as for labor and materials. However, development budgets also cover design, engineering, legal and other professional services, as well as permitting, insurance, administrative and office costs, etc. Substantial shares of these professional services and "other" budgets would be incurred during the planning period prior to groundbreaking.

The table below presents estimated Hawai'i-based costs in total, as well as the average annual estimates projected during the development planning and construction periods.

Table 3: Order of Magnitude Development Costs (2019 dollars, in millions)

	Total	**Average annual** (FY2020-FY2022)
Professional services	$3.3	$1.1
Construction	$64.7	$21.6
Other	$10.6	$3.5
Total	**$78.6**	**$26.2**

Source: The Michaels Development Company, 2019. See Exhibits 3-1 and 3-2 for further detail.

All development expenditures are assumed for projection purposes to occur within the County.

EMPLOYMENT

The Halewai'olu Senior Residences will generate new employment through direct, indirect and induced economic impacts. Employment opportunities are segregated into those temporary effects that would originate from the Project's development, and those permanent effects that would be supported by its operations.

Development-Related

The Halewai'olu Senior Residences is estimated to generate up to 370 full-time equivalent (FTE) jobs per year as a direct effect, and up to 780 annually when considering positions supported directly and indirectly by development expenditures. While some development activities are already underway, the greatest impacts would be felt during the construction period, between FY2020 and FY2022, as represented.

In any given year, this jobs generation could represent some 122 FTE jobs of direct employment, or 260 in total.

Table 4: FTE Development Employment

	Total person-years	Average annual (2020-2022)
Direct	370	122
Indirect and induced	410	137
Total	**780**	**260**

Source: PBR HAWAII, 2019. See also Exhibit 3-3.

Operations-Related

The employment impacts of a real estate development are often thought of as those that occur on-site or at its new facilities. While this is important, and many on-site jobs represent new employment opportunities, others may be jobs that would have existed elsewhere in the County and/or State whether or not the development occurred, and the development may also create employment opportunities off-site. Therefore, assessment of the Project's operations-related employment impacts is presented two ways: (1) in terms of on-site employment and (2) in terms of additional employment statewide. Since this Project entails no discontinuation of existing operations, the new employment it generates is considered "net new".

By definition, on-site operating employment will be located in Honolulu, and all such jobs are considered direct impacts. On the other hand, the Project's statewide impact is considered in terms of employment supported by direct purchases from vendors or other impacts of additional spending the Halewai'olu Senior Residences generates. Such jobs could be located anywhere in the state, although it is assumed that the majority will be on-island. Additionally, this net new employment will have multiplier effects and can therefore be considered in terms of direct, indirect and induced employment.

- **On-site** (direct impacts only) - When the Project is fully operational and leased in 2023, the Project is expected to support some 5 FTE direct jobs on-site.
- **Statewide** – The Halewai'olu Senior Residences is expected to support about 12 ongoing FTE jobs statewide, once the new facilities are stabilized, including its direct, indirect and induced impacts.

Operating employment impacts would include technical and staff positions at the new residential and commercial facilities themselves, as well as other positions in that can be expected to be generated throughout the State's economy via indirect and induced economic factors. Most such positions can be expected to be realized by persons who are already residents of the State.

Table 5: Average Annual FTE Operational Employment			
	FY2020 to FY2022	**FY2023 (full operations)**	**FY2024+ (stabilized)**
ON-SITE			
Direct impacts	0	5	5
STATEWIDE			
Direct	0.4	7	7
Indirect and induced	0.4	5	5
Total (rounded)	1	12	12

Source: PBR HAWAII, 2019. See also Exhibits 3-6 and 3-7.

EARNINGS

Evaluation of personal earnings is based on the statewide impacts shown above. This study defines earnings in alignment with the framework of the DBEDT 2016 models, where earnings include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance. Earnings exclude gratuities and bonuses that may also apply to certain types of work.

Development-Related

Development-related positions attributable to the Project are expected to support total earnings of some $53.6 million over the three-year period evaluated, representing an average of about $17.9 million per year. These earnings are estimated to average $81,000 per direct FTE job, and $58,000 per indirect and induced job, for an overall average of $69,000.

Table 6: Personal Earnings Attributable to Development Employment (2019 dollars)		
	Total	**Average annual (FY2020-FY2022)**
Direct	$29.9 million	$10.0 million
Total (direct, indirect & induced)	$53.6 million	$17.9 million
Average per FTE job (Total)		*$69,000*

Source: PBR HAWAII, 2019. See also Exhibits 3-4 and 3-5.

Operations-Related

During the development period, initial leasing activity could generate a small amount of personal earnings, budgeted at $77,500 in total or some $0.03 million per year. Once operations are stabilized and initial leasing is concluded, average annual ongoing earnings are anticipated to represent some $0.9 million per year, including direct, indirect and induced effects.

On average, these net new FTE positions, including direct, indirect and induced impacts, are expected to earn about $75,000 per FTE job at stabilization.

Table 7: Personal Earnings Attributable to Statewide Operational Employment (2019 dollars)			
	FY2020 to FY2022 (initial leasing)	**FY2023 (full operations)**	**FY2024+ (stabilized)**
Direct	$0.03 million	$0.4 million	$0.4 million
Total (direct, indirect & induced, rounded)	$0.1 million	$0.9 million	$0.9 million
Average per FTE job (Total)	*$68,000*	*$74,000*	*$75,000*

Source: PBR HAWAII, 2019. See also Exhibits 3-7 and 3-8.

POPULATION

Resident population movements could be driven by the Project's residential or employment opportunities, as well as its ongoing operations. Population impacts are of interest in themselves and are also evaluated because more population tends to require additional State and County resources and services, as addressed in the fiscal impacts section of this report.

Project Tenants Moving From Off-Island

The vast majority of Halewai'olu Senior Residences tenants are expected to be existing residents of O'ahu. However, for modelling purposes, a very small number, about 5% or some 6 to 10 persons, are projected to move from a neighbor island or from out-of-State because of the new residential opportunities at the Project.

Resident Population Change Due to Employment

In-migrant employee impacts are assessed for the Project's direct employment impacts only.

In theory, employment opportunities created by Halewai'olu Senior Residences could encourage some out-of-state residents, including former Hawai'i residents, to move to O'ahu. Others may commute to O'ahu from another island on a daily or longer basis. Based on recent construction and development management experiences, 96% of the development labor force is expected to be filled by persons who are already established residents of O'ahu. Conversely, 4% could commute from, or move from outside of the County to take a temporary development-related position created by the Halewai'olu Senior Residences. Because of the size and diversity of O'ahu's construction labor force, these movers are generally anticipated to be from out-of- state rather than from other islands.

With respect to operational positions, due to the well-developed and experienced labor force resident in Hawai'i, the majority of operations-related positions are expected to be filled by persons who are already established residents of O'ahu and/or the State. Given the small size of the Project labor force, it is assumed for projection purposes that no population impacts are generated by this means.

De Facto Population Change Due to Visitation

Because the Halewai'olu Senior Residences does not have facilities catering to off-island visitors or tourists, it is not expected to have any additional de facto population impact.

Summary Population Impacts

Combining the potential movements of population due to the Project's residential and employment opportunities, its average daily impact on State and County population levels are nominal but are considered because they could generate carrying costs for government entities, as explained in the section below.

Table 8: Average Daily Population Impact

	FY2020 to FY2022 (development)	FY2023 (full operations)	FY2024+ (stabilized)
To the County	5	10	10
To the State	5	6	6

Source: PBR HAWAII, 2019. See also Exhibit 4-1.

FISCAL IMPACTS

This section presents the fiscal impacts of the Project, in terms of new revenues and expenses for the County and State governments.

County

The County's main source of revenue is real property taxes. However, based on its status as an affordable housing development, the Halewai'olu Senior Residences would be eligible for exemption from real property taxes throughout the regulated affordability period agreed to with the County.[8] For modelling purposes, it is assumed that the Project will continue to be exempt from real property taxes thereafter as well.

An additional source of revenue for the County is a 0.5% surcharge Honolulu is allowed on qualifying State Gross Excise Tax (GET) collections. However, the Project's status as affordable housing is also expected to make its development expenditures exempt from GET, this potential source is also expected to yield little if any County tax revenues.

- **Net additional revenues** – Net additional revenues for the County are nominal. However, the Property is not known to be generating any real property taxes or other County revenues at this time, so the various exemptions would not represent a loss of revenues for the County.
- **Revenue to expenditure ratio** – After considering the government carrying costs of the Project's slight population impacts to the County, the revenue to expenditure ratio attributable to development of the Project is estimated to range from about 0.3 to 0.4.

State

With the State government's more diverse and far-reaching taxing powers, the Halewai'olu Senior Residences' fiscal impacts are expected to be more substantial than the County's.

- **Net additional revenues** – While construction of the Halewai'olu Senior Residences is expected to be exempt from GET, other sources of State taxes would include GET

[8] The real property exemption is among the affordable housing incentives established by the Revised Ordinances of Honolulu (ROH), Ordinance 18-1, for projects with an affordable housing agreement with the Department of Planning and Permitting, as set forth in ROH Ordinance 18-10.

on spending by new residents of the State, and income taxes on the development and operational earnings that the Project supports. Altogether, these sources are expected to generate some $0.9 million per year in net additional State taxes, after considering the carrying costs of new residents during development, but only nominal changes thereafter.

- **Revenue to expenditure ratio** - Considering the ratio of additional State operating revenues to expenditures, development of the Halewai'olu Senior Residences could generate some 27.8 times more revenues that expenses for the State. Owing to its much smaller employment impact during operations as compared to development, however, the ratio could fall to about 1.4 to 1.5 once construction is complete. The total (including direct, indirect and induced) fiscal impacts of the Halewai'olu Senior Residences redevelopment are summarized as follows:

Table 9: Estimated Net Total Fiscal Impacts (2019 dollars)

	FY2020 to FY2022 (development)	FY2023 (full operations)	FY2024+ (stabilized)
Net additional revenues (average annual)			
To the County	$0.0 million	$0.0 million	$0.0 million
To the State	$0.9 million	$0.0 million	$0.0 million
Net revenue/expenditure ratio			
For the County	0.4	0.3	0.4
For the State	27.8	1.4	0.5

Source: PBR HAWAII, 2019. See also Exhibit 5-7.

3 – STUDY CONDITIONS AND TERMINOLOGY

Special considerations and terminology for the analyses on which the preceding results rely are presented in this chapter. For a more complete understanding of the study analyses, the reader may refer to the exhibits in the next section of this report, and the notes that accompany each exhibit.

ANALYTICAL CONSIDERATIONS

Commercial Impacts

The Project's commercial facilities are expected to attract spending, but it is likely that Honolulu residents and visitors would have spent an equivalent amount on dining out and/or personal services whether or not the Project's commercial facilities were developed. Given a competitive market, the planned facilities could lead to a geographic reallocation of some spending among areas. Therefore, new spending attributable to the Halewai'olu Senior Residences redevelopment is seen as a function of those new residents that the Project is assumed to attract to the County and/or State, and not to its commercial facilities per se.

In other words, on-site facilities will employ workers, pay taxes and generate other economic and fiscal benefits. These are valid impacts and most associated employment would be located on-site. However, the net benefits of the Halewai'olu Senior Residences redevelopment are best measured in terms of the spending by new residents and visitors that the Halewai'olu Senior Residences attracts to the island, and the taxes and other benefits these persons will generate throughout the County and State. Many of these spending impacts are likely to be felt off-site, likely benefitting enterprises and establishments elsewhere in the County and State.

Government Expenditures

County and State expenditures as estimated herein are based on the structure of tax collections and services for the fiscal year ending June 30, 2018. Cost information is obtained from the Comprehensive Annual Financial Reports of the respective jurisdictions. The impacts estimated herein would differ if County and/or State governmental taxing and spending policies were to be materially altered.

Government Revenues

Government revenues are largely derived from the same sources noted for expenditures. However, County real property tax revenues are based on rates that were in effect during the fiscal year ending June 30, 2018. State income tax revenues are based on 2018 rates[9], as applicable to married taxpayers filing jointly, in income brackets relevant to the employment opportunities created.

Tax structures related to the State's transient accommodations tax (TAT) and GET that were altered by the summer 2017 State Legislature's Special Session have been incorporated into the analyses.

[9] The State's 2019 tax tables were not available as of time of drafting this report, therefore 2018 rates were used as a provisional estimate.

DEFINITION OF KEY TERMINOLOGY

Consistent with established input-output economic theory, the following definitions apply to types of impacts:

- **Direct impacts** – Direct impacts are those economic, population or other impacts attributable to persons or activities that are a direct result of the proposed activity or investment. For instance, direct employment impacts are expected to include those involved in building the proposed facilities, such as construction workers, and those who would later work at them in their operations.

  Many, but not all direct impacts can be expected to occur on-site. For instance, a portion of the construction budget is for architects and engineers. While such persons' employment might be temporarily dependent on contracts related to the Halewai'olu Senior Residences, most such professionals would be expected to work from offices located off-site, elsewhere in Honolulu. Likewise, administrative and managerial staff located off-site would support construction professionals working on-site.

- **Indirect impacts** - Indirect impacts occur when the businesses or persons who are directly affected make expenditures for additional supplies or services. For instance, some of the additional retail spending by visitors or residents attracted to the County or State by the Halewai'olu Senior Residences could be spent on eating out. These elevated dining expenditures could indirectly increase demand for produce, seafood and meats from Hawai'i farms, fishermen and/or ranching enterprises. The Halewai'olu Senior Residences would have thus indirectly supported new business opportunities for area providers of such goods and services.

- **Induced impacts** - Induced impacts occur throughout the community when those persons or companies that have benefited from the direct or indirect impacts of the Halewai'olu Senior Residences spend their associated earnings on consumer goods and services. For instance, a construction worker may spend some of her earned wages to buy a new pair of shoes, or to pay for her child's day care. The farmer who sells produce to a food service facility at the Project may use some of his profit to take his family out to the movies. The businesses and individuals impacted by such re-spending are said to enjoy induced economic impacts from the Halewai'olu Senior Residences redevelopment.

- **Total impacts** - Total impacts are defined as the sum of direct, indirect and induced impacts for any given variable.

- **Resident population -** Resident population refers to all those persons who habitually reside in a given area, whether or not they are temporarily away.

- **De facto population –** De facto population includes all those present in the County or State on any given day. It differs from resident population by excluding those residents who are temporarily away while adding those visitors who are temporarily present.

- **Full-time equivalent** - This study measures employment opportunities in full- time equivalent (FTE) units. One full-time equivalent position is defined herein as 2,080

hours of employment per year, including paid vacation and sick leave. This is equivalent to 40 hours per week and may also be referred to as a "person-year" of employment. Two half-time jobs are considered to together represent one FTE job.

- **Earnings –** This study employs the definition of earnings that corresponds to the DBEDT 2016 models, which includes wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance. Earnings as so defined exclude gratuities and bonuses that may also apply to certain types of work.

REPORT CONDITIONS

Assumptions regarding the scale, nature and timing of the Halewai'olu Senior Residences are made to assess its economic and fiscal impacts. This study relies on physical parameters, layouts, timelines, budgets, development and operating plans and other inputs provided by HSD and other sources as noted.

This assessment also incorporates information provided by government agencies, developers, brokers, landowners, and other sources as cited in the exhibits. While attempts have been made to verify such information via multiple sources, it is not always possible to do so. PBR HAWAII cannot guarantee the accuracy of all information upon which its assessments may be based.

This report has been prepared for the planning purposes of HSD and its consultant teams, as well as for public disclosure of the nature of the Halewai'olu Senior Residences. It is not intended to be used for any solicitation of investment.

Note: Earnings defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance.

1 Based on industry coefficients as shown in Exhibit 3-2 and estimated construction cost.

2 Weighted average of estimated direct earnings by industry as shown above, and direct effect industry multipliers.

Exhibit 3-5
Personal Earnings from Development: Average Annual
2019 dollars, in millions except average earnings

	Basis/reference		FY2020-FY2022	FY2023
Average annual in period:	*Exhibit 3-4*			
Direct earnings	*Incl. professional services, construction and other*		$10.0	$0.0
Indirect & induced earnings			$7.9	$0.0
Total earnings			**$17.9**	**$0.0**
Average per new FTE job:	*Exhibits 3-3 and 3-4, rounded*			
Direct jobs	*Incl. professional services, construction and other*		$81,000	n/a
Indirect and induced jobs			$58,000	n/a
Average per job			**$69,000**	n/a
Estimated average family income:	$44,000	Additional family income[1]		
For direct job-holders			$125,000	n/a
For indirect and induced job-holders			$102,000	n/a
All Project-related job-holders			**$113,000**	n/a
Percent of median family income:	*$99,000*	*median family income, 2019, Honolulu County*[2]		
For direct job-holders			126%	n/a
For indirect and induced job-holders			103%	n/a
All Project-related job-holders			**114%**	n/a

Note: Earnings defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance.

1 Additional family income based on average 1.8 FTE jobs per family with the additional 0.8 FTE income based on 2018 average earnings in Honolulu MSA, all occupations, as provided by State of Hawaii, Department of Labor & Industrial Relations. Reflects multiple job-holders within each family as well as multiple job-holding by individuals.

2 U.S. Department of Housing & Urban Development, as presented by Hawaii Housing Finance and Development Corporation , "Honolulu County Income Schedule by Family Size: 2019."

Exhibit 3-6
On-Site Operational Employment: Direct FTE Jobs

	Basis/reference	FY2022	FY2023	Total/ FY2024+ stabilized
Source of employment -				
Rental housing[1]	*4 FTE persons (Michaels Organization)*	0	4	4
Commercial retail:				
New development - other	*460 Square feet GLA per FTE*	0	1	1
Total on-site jobs		**0**	**5**	**5**
Existing job(s) expected to be displaced	*No existing operations on-site*	0	0	0.0
Net new jobs on-site		**0**	**5**	**5**

Note: FTE = Full time equivalent, defined as 40 hours per week or 2,080 hours per year. Excludes leasing agents marketing personnel that may locate on-site, as well as private household maintenance and related services.

1 Includes anticipated salaried positions as well as contracted employment.

Exhibit 3-7
Net Additional Operational Employment: Annual FTE Jobs
2019 dollars, in millions, except as noted

	Basis/reference	FY2020-FY2022	FY2023	Total/ FY2024+ stabilized
Bases for projection:				
Av. annual spending by residents new to State	*Direct, indirect & induced (new to Island): Exhibit 3-1*	*$0.00*	*$0.27*	*$0.28*
Av. annual commercial & residential leasing fees -				
Initial lease-up (2022)	*$77,500 total budget; shown as average annual in each period*	*$0.03*	*$0.00*	*$0.00*
Releasing in 2023+	*5.0% Turnover per year*	*$0.00*	*$0.00*	*$0.00*
Projected net additional jobs:				
Direct -				
Attributable to new State residents[1]	*7.9 /$mil output, selected industries*	-	2	2
Real estate leasing & rentals	*Michaels Development Company*	0.4	-	-
Rental housing	*Exhibit 3-6*	-	4	4
Commercial retail	*Exhibit 3-6*	-	1	1
Displaced jobs	*Exhibit 3-6*	-	-	-
Subtotal, direct jobs		**0.4**	**7**	**7**
Indirect and induced -	*Multiplier and industry category applied[2]:*			
Attributable to new State residents	*0.88 Selected industries*	-	2	2
Real estate leasing & sales	*1.06 Real estate & rentals industries*	0.4	-	-
Rental housing	*0.64 Other services industry*	-	3	3
Commercial retail	*0.47 Retail industry*	-	1	1
Subtotal, indirect & induced jobs		**0.4**	**5**	**5**
Total net additional jobs, rounded		**1**	**12**	**12**

Note: FTE = Full time equivalent, defined as 40 hours per week or 2,080 hours per year.

1 Coefficient calculated based on total (wage, salary and proprietors') jobs per million output in representative industries as shown in DBEDT 2012 detailed industry input-output transactions table, adjusted to reflect estimate of future inflation and productivity. See DBEDT, ibid.

2 For indirect and induced impacts of respective direct impacts. Multipliers derived from Type II direct effect total job/total job multipliers as shown in DBEDT, ibid; published multipliers reduced by 1.0 to eliminate direct jobs previously calculated.

Exhibit 3-8
Personal Earnings from Net New Operational Activity: Average Annual
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)		FY2020-FY2022	FY2023	Total/ FY2024+ stabilized
Direct earnings -	*Estimated average FTE salary or other basis:*				
Attributable to new Hawaii residents	*$32,300*	*Estimated average salary per person for income-restricted tenants*	$0.00	$0.07	$0.07
Marketing/leasing -	*Residential & commercial properties, Ex. 3-7*				
Initial lease-up	*Actual impact will concentrate in 2021-2022*		$0.03	$0.00	$0.00
Releasing after 2024			$0.00	$0.00	$0.00
Rental housing	*$78,200*	*Michaels Development Company, 2019*	$0.00	$0.31	$0.31
Commercial retail	*$39,700*	*Average sales related occupations* [1]	$0.00	$0.04	$0.04
Subtotal, direct earnings			**$0.03**	**$0.43**	**$0.4**
Indirect and induced earnings -	*Multiplier and industry category* [2] *:*				
Attributable to new Hawaii residents	*0.94*	*Weighted average, selected industries*	$0.00	$0.06	$0.07
Marketing/leasing -	*1.17*	*Real estate & rentals industries*	$0.03	$0.00	$0.00
Rental housing	*1.17*	*Real estate & rentals industries*	$0.00	$0.37	$0.37
Commercial retail	*0.69*	*Retail trade*	$0.00	$0.03	$0.03
Subtotal, indirect & induced			$0.03	$0.46	$0.5
Total earnings, rounded			**$0.1**	**$0.9**	**$0.9**

Note: Earnings defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance. They exclude tips.

1 Annual wage estimate based on average 2018 average wage for the Honolulu MSA all occupations, adjusted to 2019 dollars. Data provided by State of Hawaii, Hawaii Workforce Infonet, "Occupational Employment & Wages, State, MSA, County, 2018." (Latest survey data available as of August 1, 2019.)

2 For indirect and induced impacts of respective direct impacts. Multipliers derived from Type II direct effect total job/total job multipliers from DBEDT, ibid; published multipliers reduced by 1.0 to eliminate direct jobs previously calculated.

Exhibit 3-9
Personal Earnings from Net New Operational Activity: Average Per Job and Family
2019 dollars, in millions, except as noted

		Basis/reference	FY2020-FY2022	FY2023	Total/ FY2024+ stabilized
Average earnings per new FTE job:		*Not in millions*			
Direct jobs			$65,000	$59,000	$59,000
Indirect and induced jobs			$71,000	$94,000	$92,000
Weighted average per job			**$68,000**	**$74,000**	**$75,000**
Estimated average family income[1]:	$44,000	Estimated additional family income			
For direct job-holders			$109,000	$103,000	$103,000
For indirect and induced job-holders			$115,000	$138,000	$136,000
All Project-related job-holders			**$112,000**	**$118,000**	**$119,000**
Percent of median income[2]:	*$99,000*	*median family income, 2019, Honolulu County[2]*			
For direct job-holders			110%	104%	104%
For indirect and induced job-holders			116%	139%	137%
All Project-related job-holders			**113%**	**119%**	**120%**

Note: Earnings defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance. They exclude tips.

1 Additional family income based on average 1.8 FTE jobs per family with the additional 0.8 FTE income based on 2018 average earnings in Honolulu MSA, all occupations, as provided by State of Hawaii, Department of Labor & Industrial Relations. Reflects multiple job-holders within each family as well as multiple job-holding by individuals.

2 U.S. Department of Housing & Urban Development, as presented by Hawaii Housing Finance and Development Corporation, "Honolulu County Income Schedule by Family Size: 2019."

Exhibit 4-1
Average Daily In-Migrant Population

	Basis/reference	FY2020-FY2022	FY2023	Total/ FY2024+ stabilized
Residents of Project:				
Average FTE persons in residence	*Exhibit 2-2, all occupants*	0	198	209
In-migrants to State (rounded)	*Exhibit 2-2, those new to State*	0	6	6
In-migrants to County (rounded)[1]		0	10	10
Employees:				
In-migrants to the State[1] -	*Subset of in-migrants to County*			
Development employees	*4% of direct average annual jobs, Exhibit 3-3*	5	0	0
Operational employees	*2% of net additional annual jobs, Exhibit 3-7*	0	0	0
Dependents[2]	*Ratio of in-migrant employees*	0	0	0
In-migrants to State[3]		5	0	0
In-migrants to County[3] -	*Includes in-migrants to State*			
Development employees	*4% of direct average annual jobs, Exhibit 3-3*	5	0	0
Operational employees	*3% of net additional annual jobs, Exhibit 3-7*	0	0	0
Dependents[2]	*Ratio of in-migrant employees*	0	0	0
In-migrants to County[3]		5	0	0
Total in-migrants:	*Total of those attracted by new residences and by net new employment (rounded)*			
To State		**5**	**6**	**6**
To County		**5**	**10**	**10**

1 Subset of County in-migrants. See footnote 3, below. Share of employees moving from out-of-State because of job opportunity will vary depending on specific Honolulu and other U.S. labor market conditions at the time. Figures applied reflect long-term observations of Hawaii labor market experience.

2 In-migrant dependents estimated to average 0.1 per in-migrant development employee, and 1.0 per in-migrant operational employee.

3 In-migrants to the County include all those moving to the State plus any that may move between islands due to job opportunities at the Project.

Exhibit 5-1
Real Property Taxes Carried by Project
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)	FY2022	FY2023	2024+
Estimated taxable assessed values:	*Estimated unit values, incorporating land and amenities, but net of furnishings*			
Residential apartments:[1]				
Affordable rentals	*$300 per year minimum rate*	n/a	n/a	n/a[1]
New commercial in tower	*Michaels Development Company, 2019*	n/a	n/a	n/a[1]
Total		**$0.0**	**$0.0**	**$0.0**
Real property tax revenues:				
Ongoing and new revenues -	*FYE 2018 rates per $1,000 net taxable value*[2]			
Rental housing	*$0.00 Per ROH 8-10.20 and 8-10.21*	$0.0	$0.0	$0.0
New commercial in tower	*$12.40 Commercial*	$0.0	$0.0	$0.0
Subtotal, potential tax revenues		$0.0	$0.0	$0.0
Discontinued payments due to demolitions and exemption -				
Current payments[3]	*$0 No current RPT collections*	$0.0	$0.0	$0.0
Estimated RPT		**$0.0**	**$0.0**	**$0.0**

Notes: FYE - fiscal year ending.

1 Tax assessed values for Project not estimated because they are assumed to be exempt. Real property tax payments could be higher after 2036, should County exemption expire thereafter.

2 For fiscal year ending June 30, 2020.

3 Existing tax payments on properties expected to be superseded by new tax payments as shown.

Exhibit 5-2
Annual County Government Revenues
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)		FY2022	FY2023	2024+[1]
Bases for projection:					
FTE in-migrants to County -	*Exhibit 4-1*				
Project non-primary residents			*0*	*10*	*10*
Employees and their dependents			*5*	*0*	*0*
Estimated tax and other revenues:					
Net new property tax revenues	*Exhibit 5-1*		$0.0	$0.0	$0.0
Miscellaneous taxes from in-migrant residents[1]	*Other than real property taxes* *$366 per person (residents + employees)*		$0.0	$0.0	$0.0
General excise taxes, on -	*Honolulu County GET surcharges only*[2]				
Development	*0.0%*	*assumed exempt*	$0.0	$0.0	$0.0
Real estate rentals & marketing	*0.5%*	*of commissions*	$0.0	$0.0	$0.0
Operating revenues	*0.5%*	*of residential & commercial space rents, ground lease & related income (Ex. 5-3)*	$0.0	$0.0	$0.0
Spending by Project's new Hawaii residents	*0.5%*	*of spending*	$0.0	$0.0	$0.0
Spending by employee in-migrants to State	*0.5%*	*of employee & dependent spending*	$0.0	$0.0	$0.0
Less State administrative charge	*1.0%*	*of above GET surcharges (as of 1/1/2018)*	($0.0)	($0.0)	($0.0)
Additional County revenues (rounded)			**$0.0**	**$0.0**	**$0.0**

Note: Excludes GET on affordable housing rentals and commercial leasing; also excludes revenues from fuel taxes, licenses and permits and charges for

1 Includes licences and permits, charges for services, fines and forfeits and other miscellaneous taxes and revenues collected by the County.

2 The counties are authorized to levy a surcharge on the State's GET and use taxes per Chapter 46, HRS, until December 31, 2030, given extension granted in the 2017 Special Legislative Session. Honolulu County's 0.5% surcharge must be used for operating and capital costs related to mass transit. From this amount, the State deducts a 1% handling charge beginning on January 1, 2018 (the 2017 Special Legislative Session reduced this administrative charge from 10%), which amounts become a general fund realization for the State. This nominal additional source of County revenue could be eliminated in 2031 and beyond.
However, the project's development costs are assumed to be exempt from GET.

Exhibit 5-3
Bases for Projecting Annual State Government Revenues
2019 dollars, in millions, except as noted

	Basis/reference	FY2022	FY2023	Total/ FY2024+ stabilized
For GET calculations:				
Project development costs -	*Exhibit 3-2*			
Professional services		$1.1	$0.0	$0.0
Construction and other		$25.1	$0.0	$0.0
Taxable expenditures	*Development costs assumed GET-exempt*	$0.0	$0.0	$0.0
Real estate leasing & marketing -	*Initial and ongoing fees: Exhibit 3-7*			
Commercial and residential	*Leasing expenditures*	$0.03	$0.00	$0.0
Spending by Project's new Hawaii residents	*In-State spending: Exhibit 3-7*	$0.0	$0.3	$0.3
Spending by in-migrant employees to the State -				
In-migrant employees	*Exhibit 4-1, net of dependents*	5	0	0
In-State spending	*70% of average earnings per FTE job*	$0.2	$0.0	$0.0
Handling fee on County GET surcharge[2] -	*1% fee*	$0.0	$0.0	$0.0
For individual income taxes:	*Total of direct, indirect and induced*			
Net new personal income earned -	*Average annual in preceding period*			
Development	*Exhibit 3-5*	$17.9	$0.0	$0.0
Operational	*Exhibit 3-8*	$0.1	$0.9	$0.9
Average personal earnings/FTE job -				
Development	*Exhibit 3-5 , not in millions >>*	$69,000	$0	$0
Operational	*Exhibit 3-8 , not in millions >>*	$68,000	$74,000	$75,000
For other State taxes:				
FTE in-migrants to State	*Residents, employees and dependents who are new to State*	5	6	6

1 The counties are authorized to levy a surcharge on the State's GET and use taxes per Chapter 46, HRS. See note at Exhibit 5-2.

Exhibit 5-4
Annual State Government Revenues
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)	FY2022	FY2023	Total/ FY2024+ stabilized
General excise taxes, on:				
Development[1]	*0.0% Development assumed exempt*	$0.00	$0.00	$0.00
Operating revenues and expenses	*4.0% of residential and commercial space rents, related income, and net ground lease payments*	$0.00	$0.00	$0.00
Spending by Project's new Hawaii residents	*4.0% of spending*	$0.00	$0.01	$0.01
Spending by in-migrant employees	*4.0% of share of employee earnings*	$0.01	$0.00	$0.00
Handling fee on County GET surcharge -	*1% fee*	$0.00	$0.00	$0.00
Less: lost taxable income	*4.0% of taxable income to be lost*	$0.00	$0.00	$0.00
Individual income taxes[2]:				
Development employees	*6.5% effective tax rate on av. family AGI estimated at $85,000 Exhibit 3-5*	$0.88	$0.00	$0.00
Operational employees	*6.6% effective tax rate on av. family AGI estimated at $89,000 Exhibit 3-9*	$0.00	$0.04	$0.04
Additional State revenues (rounded)		**$0.9**	**$0.1**	**$0.1**

Note: Projections exclude corporate income tax, GET on commercial spending, and miscellaneous State tax revenues including tobacco and liquor taxes, liquid fuel tax, motor vehicle weight & registration tax, fines & forfeitures, licenses, franchise tax, rental motor vehicle surcharge tax, public service companies tax, tax on premiums of insurance companies and other fees and taxes.

1 As applicable, based on 4% on 100% of professional services and 60% of construction costs, plus a wholesale construction materials tax of 0.5% against 40% of construction costs.

2 Based on average or long-term family incomes for all Project-related job holders as shown in referenced exhibits, and on 2018 Tax Tables and Tax Rate Schedule II, for married taxpayers filing joint returns. Adjusted Gross Incomes (AGI) assumed to be 25% less than total average family earnings, considering potential deductions. Projections will differ should tax policies and rates change, and depending on individual family circumstances.

Exhibit 5-5
County Government Expenditures
Attributable to In-migration
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)	FY2022	FY2023	Total/ FY2024+ stabilized
Bases for County projection -				
FTE in-migrants to County	*New Project residents, employees and dependents, Exhibit 4-1*	*5*	*10*	*10*
Annual expenditures -				
FTE in-migrants to County	*$1,490 per person, ref: Appendix 2*	$0.01	$0.01	$0.01
Visitors from off-Island	*$1,460 per person, ref: Appendix 2*	$0.00	$0.00	$0.00
Additional County expenditures		**$0.01**	**$0.01**	**$0.01**

Exhibit 5-6
Annual State Government Expenditures Attributable to In-migration
2019 dollars, in millions, except as noted

	Basis/reference (not in millions)	FY2022	FY2023	Total/ FY2024+ stabilized
Bases for State projection -

Visitors from out-of-State	*No visitor impact anticipated*	*-*	*-*	*-*
Annual expenditures -				
FTE in-migrants to State	*$6,390 per FTE person, ref: Appendix 3*	$0.03	$0.04	$0.04
Visitors from out-of-State	*$1,650 per FTE person, ref: Appendix 3*	$0.00	$0.00	$0.00
Additional State expenditures		**$0.03**	**$0.04**	**$0.04**

Exhibit 5-7
County & State Government Cost and Benefit Assessments
2019 dollars, in millions, except as noted

	Basis/reference	FY2022	FY2023	2024+[1]
City and County of Honolulu:	*Tax and other fiscal impacts*			
Additional revenues	*Exhibit 5-2*	$0.00	$0.01	$0.01
Additional expenditures	*Exhibit 5-5*	$0.01	$0.01	$0.01
Net additional revenues		**($0.00)**	**($0.01)**	**($0.01)**
Revenue to expenditure ratio[2]		**0.4**	**0.3**	**0.4**
State of Hawaii:	*Tax and other fiscal impacts*			
Additional revenues[3]	*Exhibit 5-4*	$0.89	$0.06	$0.06
Additional expenditures	*Exhibit 5-6*	$0.03	$0.04	$0.04
Net additional revenues		**$0.86**	**$0.02**	**$0.02**
Revenue to expenditure ratio[2]		**27.8**	**1.4**	**1.5**

1 Real property tax payments could be higher after 2036, should the County exemption expire thereafter. Additionally, the currently authorized County surcharge on the State GET, a nominal additional source of County revenue, could expire in 2031 and beyond.

2 Net revenues divided by net expenditures.

3 Excludes potential income taxes from any operating entities.

(This page intentionally left blank.)

APPENDICES

(This page intentionally left blank.)

Appendix 1
Input-Output Multipliers Applied to Development Activities

DIRECT REQUIREMENT COEFFICIENTS

	DBEDT industrial categories applied	Direct requirement coefficients per $1 million (2012$) project cost			
		Jobs[1]	FTE factor[2]	Productivity factor[3]	$ Earnings[4]
Professional services	*#46-Architectural and engineering services*	6.04	0.84	0.73	0.50
Construction:					
On-site	*#14-Construction of other buildings*	5.33	0.90	0.73	0.36
Off-site (community benefits)	*#15-Heavy & civil engineering*	5.33	0.90	0.73	0.36
Other costs	*#41-Other finance & insurance, #43-Real estate, #45-Legal services, #49-Other professional services, #52-Administrative & support services*	17.85	0.89	0.75	0.47

DIRECT EFFECT INDUSTRY MULTIPLIERS[5]

	DBEDT industrial categories applied	Indirect & induced multiplier per direct:	
		FTE job	$ Earnings
Professional services	*Same as above*	1.41	0.68
Construction:			
On-site	*Same as above*	1.41	0.84
Off-site (community benefits)	*Same as above*	1.41	0.84
Other	*Same as above*	0.60	0.61

1 Coefficients calculated from total (wage, salaried and proprietary) jobs per $1 million total output, as shown in Hawai'i State Department of Business, Economic Development and Tourism (DBEDT), "The Hawaii State Input-Output Study: 2012 Benchmark Report," March 2016. Figures derived from 68-industry detailed tables.

2 Adjustment factor applied to the jobs coefficients to estimate full-time equivalent jobs at 40 hours per week, since DBEDT input data reflects all jobs, including full- and part-time. Factor derived from Honolulu MSA data for January 2015 to April 2016 on average weekly hours reported worked in all private sector, mining and construction and financial sectors, as reported by State of Hawai'i, Hawai'i Workforce Infonet

3 Adjustment factor applied to the jobs coefficients to reflect inflation and anticipated gains in labor productivity. Factors derived from 2012 vs. projected 2021 Type I final demand multipliers for total jobs by detailed industry, DBEDT, ibid.

4 Earnings defined to include wage, salary and proprietary incomes, plus directors' fees and employer contributions to health insurance, less employee contributions to social insurance. Calculated from total earnings reported per $1 million total output, DBEDT, ibid.

5 For indirect and induced impacts of respective direct impacts. Multipliers derived from Type II direct effect total job/total job and earnings/earnings multipliers as shown in DBEDT, ibid; published multipliers reduced by 1.0 to eliminate direct jobs previously calculated.

Appendix 2
Government Expenditures - City and County of Honolulu
Per Capita in Fiscal Year July 1, 2017 to June 30, 2018

	Net expense[1] ($thousands)	Service population[2]	Net expenditures (not in thousands) per: Resident	Visitor
Primary government				
Governmental activities:				
General Government	$543,228	1,049,300	$518	$518
Public Safety	$435,543	1,049,300	$415	$415
Highways and Streets	$76,613	1,049,300	$73	$73
Sanitation	$254	1,049,300	$0	$0
Human services	$28,379	987,100	$29	$0
Culture and recreation	$94,514	1,049,300	$90	$90
Utilities or other enterprises	$0	1,049,300	$0	$0
Interest	$86,956	1,049,300	$83	$83
Subtotal	$1,265,487		$1,208	$1,179
Business-type activities:[3]				
Housing	$836	987,100	$1	$0
Sewer	$0	1,049,300	$0	$0
Solid Waste	$74,127	1,049,300	$71	$71
Public Transportation	$191,049	1,049,300	$182	$182
Subtotal	$266,012		$253	$253
Total, primary government	*$1,531,499*		*$1,460*	*$1,432*
Component units, net expense:[3,4]	$0	1,049,300	$0	$0
Total, in FY2017 dollars	**$1,531,499**		**$1,460**	**$1,432**
Estimated in 2019 dollars, based on	1.7%		**$1,490**	**$1,460**

1 Expenses less operating and capital grants and contributions, which are primarily intergovernmental transfers and other grants to the County government, most from State and Federal governments. Business-type activities and component unit net expenses also exclude charges for services, since such programs are intended to recover all or a significant portion of their costs through fees or charges. Set to zero where charges and contributions exceed expenses. Source: Department of Budget & Fiscal Services, City and County of Honolulu, "Comprehensive Annual Financial Report: Fiscal Year Ended June 30, 201," Statement of Activities, pp. 36-37.

2 Resident population and de facto population estimates based on U.S. Census estimates through July 1, 2017 and information provided by State of Hawai'i, Department of Business, Economic Development & Tourism (DBEDT).

3 Net expense shows only those activities requiring government or other subsidy after service charges, grants and contributions but before debt service where applicable, line entry is set to "0" where the unit or activity showed net positive revenues for the year.

4 Semi-autonomous entities including the Board of Water Supply, the Honolulu Authority for Rapid Transportation and Oahu Transit Services, Inc.

5 Based on State of Hawai'i, DBEDT forecast of 2019 vs. 2018 change in Honolulu Consumer Price Index - Urban (CPI-U). Figures from U.S. Department of Labor, Bureau of Labor Statistics not available as of August 2, 2019.

Management Summary

Reference	Archaeological Inventory Survey Report for the Halewai‘olu Senior Residences Project, Honolulu Ahupua‘a, Honolulu (Kona) District, O‘ahu, TMK: [1] 1-7-006:012 (Farley et al. 2019)
Date	December 2019
Project Number(s)	Cultural Surveys Hawai‘i, Inc. (CSH) Job Code: HONOLULU 87
Investigation Permit Number	CSH completed the archaeological inventory survey (AIS) fieldwork under archaeological fieldwork permit number 19-07, issued by the Hawai‘i State Historic Preservation Division (SHPD) per Hawai‘i Administrative Rules (HAR) §13-13-282.
Agencies	SHPD; Federal Housing and Urban Development (HUD); City and County of Honolulu Office of Strategic Development, Department of Land Management (DLM), and Department of Planning and Permitting (DPP)
Land Jurisdiction	City and County of Honolulu
Project Proponent	City and County of Honolulu Office of Strategic Development
Project Funding	Federal; HUD Community Development Block Grants (CDBG)
Project Location	The Halewai‘olu Senior Residences project is at 1331–1347 River Street, between Vineyard Boulevard and North Kukui Street. The AIS study area is depicted on a portion of the 1998 Honolulu U.S. Geological Survey (USGS) 7.5-minute topographic quadrangle.
Project Description	The John R. Gilliland Sr. Building and its surrounding parking lot are planned for demolition, to be replaced by proposed affordable senior housing. The proposed project will redevelop land acquired by the City and County of Honolulu in 1992 with funds received from HUD-CDBG. The 17-story housing facility will consist of 155 units (plus one resident manager unit), a community room with warming kitchen, restrooms and storage, a computer room, social services activity rooms, a social services office, property management offices, mail and package boxes, and an elevator lobby on the ground level. A courtyard, retail space and parking access, trash compactor room, and loading area will also be on the ground level. Ground disturbance associated with project construction will include demolition and removal of the existing building, borings related to foundation pile installation, and excavations for structural footings, utility installation, roadway and parking area installation, and landscaping.
Project Area, Area of Potential Effect (APE), and AIS Study Area	The area of potential effect (APE) is bounded by Beretania Street on the southwest, ‘A‘ala Street on the northwest, the H-1 freeway on the northeast, and portions of Maunakea Street and Nu‘uanu Avenue on the southeast side (forming an “L” shape). The project area is identical to

	the APE, in accordance with HAR §13-275-2. The AIS study area within the APE/project area is restricted to the proposed project's footprint at 1331–1347 River Street.
Project Acreage	The APE/project area is approximately 45 acres (18.2 hectares). The AIS study area is approximately 0.6 acre (0.24 hectare).
Historic Preservation Regulatory Context	As a City and County of Honolulu project on City and County lands, the project is subject to historic preservation review under Hawai‘i Revised Statutes (HRS) §6E-8 and HAR §13-275. Additionally, the proposed project is a federal undertaking as defined by Section 106 of the National Historic Preservation Act (NHPA) of 1966, as amended (2006), due to the use of HUD-CDBG funding for acquisition and/or improvement of the project. Project construction is to be funded with federal equity through the Low Income Housing Tax Credit program and Hawai‘i State funds. With the use of federal funding for initial land purchase, the project is subject to HUD's environmental/historic preservation review regulations (24 CFR [Code of Federal Regulations] Part 58), which includes compliance with the National Environmental Policy Act (NEPA) and Section 106 of the NHPA. Following 24 CFR Part 58, the City is the responsible entity to carry out this federal environmental and historic preservation review in compliance with HUD. The City and County of Honolulu DLM initiated project-related HRS §6E-8 consultation with the SHPD at a meeting with the Architecture and Archaeology branches on 12 April 2017. The City DLM subsequently initiated project-related Section 106 consultation with the SHPD in a letter dated 10 June 2019, which was received by the SHPD on 14 June 2019 (Log No.: 2019.01347). Fung Associates, Inc., completed a *Reconnaissance Level Architectural Inventory Survey Form for the John R. Gilliland Sr. Building* (Hibbard and Chiu 2016; see Appendix A), which assessed the building as eligible for listing on the National Register of Historic Places (National Register) under Criterion C. The SHPD concurred with this assessment in a letter dated 27 February 2017 (Log No.: 2017.02503; Doc. No.: 1702JLP04). Because the project includes demolition of this determined National Register-eligible historic property, a project effect determination of "adverse effect" is likely, leading to a Memorandum of Agreement (MOA) under Section 106. The purpose of the MOA is to codify the mitigation measures for National Register-eligible historic properties that will be adversely affected by the project. CSH prepared a cultural impact assessment (CIA) (Spencer and Hammatt 2019) to support the project's NEPA environmental assessment. This AIS investigation was designed to fulfill both federal and Hawai‘i State historic preservation review requirements for the identification of

	archaeological historic properties. In consultation with the SHPD, this AIS investigation fulfills the requirements of HAR §13-276 and the *Secretary of the Interior's Standards for Archaeology and Historic Preservation*. It was conducted to identify, document, and evaluate archaeological historic properties' eligibility for listing on the National Register and to assess archaeological historic property significance under Hawai‘i State significance criteria pursuant to HAR §13-275-6. Archaeological historic property eligibility for listing on the Hawai‘i Register of Historic Places (Hawai‘i Register) was evaluated following the criteria outlined in HAR §13-198-8. This report is intended to support any project-related historic preservation consultation with consulting parties such as State and County agencies, interested Native Hawaiian Organizations (NHOs), and community groups. The identification and treatment of human skeletal remains discovered during this AIS investigation complied with Hawai‘i State burial law (HRS §6E-43 and HAR §13-300).
Architectural Historic Properties	In 2016, Fung Associates, Inc., prepared a reconnaissance level survey (RLS) of architectural historic properties within the project area (Hibbard and Chiu 2016; see Appendix A). The survey assessed the age, integrity, and significance of the AIS study area's only building, the John R. Gilliland Sr. Building. It also identified potential adverse effects and mitigation alternatives relating to the building's demolition. Staff who conducted the survey meet the Secretary of the Interior's Professional Qualifications Standards as architectural historians, per 36 CFR Part 61. The RLS was accepted by the SHPD Architecture Branch in a letter dated 27 February 2017 (Log No.: 2017.02503; Doc. No.: 1702JLP04). The RLS includes a brief historical context pertaining to the John R. Gilliland Sr. Building. The building was constructed in 1958 and was designed by architect Kenneth Sato. It retains much of its historic character in terms of design, materials, workmanship, and construction methods. The RLS assessed the John R. Gilliland Sr. Building as eligible for listing on the State and National Registers under Criterion C as a very good example of a small retail/office building constructed in Hawai‘i in a modern style in the 1950s. Additionally, Fung Associates, Inc., completed a pedestrian survey in 2019 of all architectural properties within the APE built prior to 1972, in accordance with HAR §13-275 and 36 CFR Part 800.4. This study meets both state and federal requirements for the identification of historic properties. Twenty potentially historic resources comprising buildings, sculptures, or objects were identified and evaluated for eligibility based on the project's anticipated completion date of 2022. On behalf of the project proponents, Fung and Associates has submitted these results to

	the SHPD/State Historic Preservation Officer (SHPO) in support of the project’s historic preservation review compliance.
Consultation	Consultation regarding the Halewai‘olu Senior Residences Project has been ongoing since the project’s inception. Consultation efforts among the project proponents, the SHPD, consulting parties, and the River Street community are summarized below. On 12 April 2017, Liz Char of Halewai‘olu Senior Development, LLC, Alison Chiu and Tonia Moy of Fung Associates, Inc., and Matt McDermott of CSH met with Dr. Susan Lebo (archaeology branch chief), Kimi Matsushima and Stephanie Hacker (O‘ahu archaeologists), and Tanya Gumpac-Maguire (architectural historian) of the SHPD. This meeting initiated HRS §6E-8 consultation with the SHPD. Ms. Char introduced the project and provided a background of the property ownership, agency of record, proposed development, and known consulting parties. Because the demolition of the John R. Gilliland Sr. Building would likely result in an adverse effect, the SHPD staff recommended drafting an MOA in parallel with the project consultation and development and suggested additional parties for consultation. Mr. McDermott noted there was no data about subsurface archaeology in the project area, but that archaeological testing would likely yield findings. The SHPD staff recommended consultation with the O‘ahu Island Burial Council (OIBC) and proposed to meet at a later date to discuss a testing strategy for an AIS. On 8 May 2019, Matt McDermott of CSH gave a presentation at the OIBC monthly meeting to introduce the project, the AIS, and the consultation process. Mr. McDermott discussed the need for federal historic preservation review of the project triggered by federal funding and discussed previous land use within the archaeological study area as indicated by background research. Finally, he presented the proposed subsurface testing strategy for the AIS and explained that as a part of the consultation process, letters would be sent to the OIBC, Chinatown community groups, Nu‘uanu Stream groups, architecture groups, and NHOs. On 10 June 2019, invitations to the 25 June public meeting (see below) were sent via email or U.S. mail to the SHPD and consulting parties; this letter formally initiated NHPA Section 106 consultation with the SHPD. On 25 June 2019, a public informational meeting was held at the Blaisdell Center. Sandra Pfund (City and County DLM [Department of Land Management]) introduced the project and described the purpose of the meeting. Sharon Har (Halewai‘olu Senior Development) provided a project overview. Alison Chiu and Bethany Zedalis (Fung Associates) provided an architectural background. On 9 July 2019, a Section 106 consultation meeting was attended by Alison Chiu and Bethany Zedalis of Fung Associates; Tanya Gumpac-

	Maguire of the SHPD Architecture Branch; Sharon Har and Questor Lau of Halewai‘olu Senior Development, LLC; Keith Kurahashi of R.M. Towill; Sandra Pfund from the City and County of Honolulu DLM; and Matt McDermott of CSH. Sharon Har provided an overview of the project and comments from consulting parties. Mr. McDermott provided an update of the ongoing AIS, including the burial find of 8 July 2019 (State Inventory of Historic Places [SIHP] # 50-80-14-8840 Component 2, Feature 6). Ms. Chiu and Ms. Zedalis proposed the APE for the project to consist of an archaeological APE and an additional architectural APE. Ms. Gumpac-Maguire concurred with the two APEs. On 22 July 2019, Ena Sroat and Matt McDermott of CSH met with Susan Lebo of the SHPD (Archaeology Branch) to discuss the results of the AIS testing up to that point and additional testing based on the identification of an in situ burial (SIHP # -8840 Component 2, Feature 6) in Test Excavation 2 (T-2). Based on this discussion, it was agreed that the AIS testing strategy would be increased by three test excavations—two in the vicinity of T-2 and one in the vicinity of Test Excavation 9 (T-9), where a potential agricultural berm had been identified. On 14 August 2019, Matt McDermott of CSH presented the results of the AIS investigation at the OIBC meeting. Mr. McDermott discussed the burial find of 8 July 2019 (SIHP # -8840 Component 2, Feature 6), and how excavation of two additional trenches—one on either side of the initial trench—failed to identify any additional human remains. He explained that the forthcoming burial treatment plan (BTP) will be part of the MOA and that the Native American Grave Protection and Repatriation Act (NAGPRA) does not apply, as the project does not involve tribal or federal land. He stated that Board Member Mana Caceres had been involved in the early stages of consultation regarding the burial find, and that Mr. Caceres would be applying as a cultural descendant for the remains. On 19 September 2019, a second public informational meeting was held at the Blaisdell Center. Sandra Pfund of the City and County of Honolulu DLM explained that the purpose of the meeting was to update the community regarding the AIS and CIA studies and how they relate to the project’s historic preservation review process. Sharon Har (Halewai‘olu Senior Development) provided a project overview. Bethany Zedalis (Fung Associates) provided an architectural background. Matt McDermott of CSH presented the preliminary results of the project’s AIS and proposed mitigation commitments, including burial treatment for the burial find of 8 July 2019 (SIHP # -8840 Component 2, Feature 6). There were no questions from the audience members.

	On 6, 8, and 9 October 2019, a notice regarding the identification of human remains on 8 July 2019 (SIHP # -8840 Component 2, Feature 6) was published in the *Honolulu Star-Advertiser*. At the 9 October 2019 OIBC meeting, Brandy Caceres and ‘Ohana (family) were recognized as cultural descendants of the *‘iwi kupuna* (ancestral human remains) identified on 8 July 2019 (SIHP # -8840 Component 2, Feature 6). On 19 November 2019, a Section 106 Consultation meeting regarding the project’s MOA was attended by Susan Lebo (archaeology branch) and Tanya Gumpac-McGuire (architecture branch [via phone]) of the SHPD; Randy Chiu of the City and County DLM; Howard and Kehaulani Lum of Lum Sai Ho Ton; Liana Benn of the Chinatown Community Center Association; cultural descendants Mana and Kalehua Caceres; Daron Makaiwi of the Marin ‘Ohana; Sharon Har, Questor Lau, and Benjamin Edger of Halewai‘olu Senior Development, LLC; Matt McDermott of CSH; Tonia Moy and Alison Chiu of Fung Associates; Jay Morford of Hawaiian Memorial Life Plan; Mel Kalahiki of Borthwick Mortuary; Kiersten Faulkner of the Historic Hawai‘i Foundation; and Sylvia Young of HawaiiUSA Federal Credit Union. Ms. Har explained that the purpose of the meeting was to discuss mitigation. Mr. McDermott explained the MOA is being developed to alleviate the adverse effect of the project’s construction on the John R. Gilliland Sr. Building and the archaeological historic property identified during the AIS. SHPD staff proposed that mitigation should focus on things to benefit the community. Ms. Faulkner suggested this could be achieved through a display, a video, an oral history, a traveling exhibit, or by putting funds into an adjacent building. She further emphasized that the MOA needs to be enforceable, with a timeline and specific stipulations as to who does what and to what standard. Discussion also included the proposed activity center within the senior residence, and that it will not just be for residents but also for the community at large. On 21 November 2019, Matt McDermott and Ena Sroat of CSH met with Susan Lebo, Samantha Cragen, and Andrew McCallister of the SHPD Archaeology Branch. Discussion topics included the outstanding SIHP number for the historic property identified during the AIS and possible mitigation measures.
Fieldwork Effort	The AIS fieldwork was conducted between 1 and 30 July 2019, under the general supervision of Matt McDermott, M.A. (Principal Investigator), and Ena Sroat, B.A. (Project Director). CSH archaeologists included Sara Blahut, M.A. (osteologist), Alison Welser, M.A. (osteologist), Gina Farley, M.A., Lisa Manirath, M.A., Brittany Enanoria, B.A., Jessica Burden, B.A., Tanyja Roberson, B.A., Jonathan Alperstein, B.A., Ryan Harismendy, B.A., and Phoenix Pu‘u, B.A. This work required approximately 38 person-days to complete.

	Fieldwork consisted of a pedestrian inspection and the excavation and documentation of 15 test excavations.
Archaeological Historic Properties Identified and Historic Property Significance	One archaeological historic property was newly identified during the Halewai‘olu Senior Residences AIS: SIHP # 50-80-14-8840, subsurface cultural deposits. SIHP # -8840 comprises three components, designated as Components 1–3. SIHP # -8840 Component 1 consists of multiple, buried agricultural deposits associated with use of the Nu‘uanu Stream floodplain. SIHP # -8840 Component 2 consists of possibly pre- to post-Contact habitation layers, including associated pit features and a human burial site, which developed within the uppermost natural alluvium deposits alongside Nu‘uanu Stream. SIHP # -8840 Component 3 consists of historical infrastructure remnants associated with the residential and commercial development of Honolulu. SIHP # -8840 is assessed as significant under Hawai‘i State historic property significance Criterion d (has yielded information important for research on prehistory or history) and Criterion e (has an important value to the native Hawaiian people or another ethnic group of the state), pursuant to HAR §13-275-6. Additionally, it is recommended eligible for inclusion on the Hawai‘i and National Registers under Criterion D. This assessment is based on the historic property’s association with the extensive traditional Hawaiian agricultural system and habitation along Nu‘uanu Stream and the urban development of Honolulu. This historic property has provided and can potentially provide additional information on traditional Hawaiian agricultural practices and chronology; on the residential and commercial growth and ethnic distribution of Honolulu Town from the nineteenth through mid-twentieth centuries; and on late pre- to post-Contact burial practices.
Project Effect	Based on the AIS investigation, the project effect determination per HAR §13-275-7 is “effect, with proposed mitigation commitments.” In addition, under Section 106 of the NHPA, the proposed project will have an “adverse effect” on the identified archaeological historic property.
Mitigation Commitments	Based on the AIS results, the agreed upon mitigation commitments consist of a BTP addressing the previously identified burial site (SIHP # -8840 Component 2, Feature 6) and data recovery in the form of archaeological monitoring for SIHP # -8840 Components 1–3. Mitigation measures will be detailed in the MOA that is currently being prepared pursuant to 36 CFR Part 800.6.

Table of Contents

Management Summary ..... **i**

Section 1 Introduction **1**

1.1 Project Background 1
1.2 Historic Preservation Regulatory Context and Document Purpose 1
1.3 Architectural Historic Properties 6
1.4 Environmental Setting 7
1.4.1 Natural Environment 7
1.4.2 Built Environment 7

Section 2 AIS Methods **9**

2.1 Field Methods 9
2.1.1 Subsurface Testing 9
2.2 Laboratory Methods 14

Section 1 Introduction

1.1 Project Background

At the request of Halewai‘olu Senior Development, LLC, Cultural Surveys Hawai‘i, Inc. (CSH), has prepared this archaeological inventory survey (AIS) report for the Halewai‘olu Senior Residences Project, Honolulu Ahupua‘a, Honolulu (Kona) District, O‘ahu, TMK: [1] 1-7-006:012. The Halewai‘olu Senior Residences project is at 1331–1347 River Street, between Vineyard Boulevard and North Kukui Street. The area of potential effect (APE) is bounded by Beretania Street on the southwest, ‘A‘ala Street on the northwest, the H-1 freeway on the northeast, and portions of Maunakea Street and Nu‘uanu Avenue on the southeast (forming an “L” shape). In accordance with Hawai‘i Administrative Rules (HAR) §13-13-275-2, the project area is identical to the APE, which comprises approximately 45 acres (18.2 hectares). The AIS study area within the APE/project area is restricted to the proposed project’s footprint at 1331–1347 River Street and comprises approximately 0.6 acre (0.24 hectare). The APE/project area is depicted on a 2013 aerial photograph (Figure 1). The AIS study area is depicted on a portion of the 1998 Honolulu U.S. Geological Survey (USGS) 7.5-minute topographic quadrangle (Figure 2), a tax map plat (Figure 3), and a 2013 aerial photograph (Figure 4).

The John R. Gilliland Sr. Building (the only building within the AIS study area) and its surrounding parking lot (see Figure 4) are planned for demolition, to be replaced by proposed affordable senior housing. The proposed project will redevelop land acquired by the City and County of Honolulu in 1992 with funds received from Federal Housing and Urban Development (HUD) Community Development Block Grants (CDBG). The 17-story housing facility will consist of 155 units (plus one resident manager unit), a community room with warming kitchen, restrooms and storage, a computer room, social services activity rooms, a social services office, property management offices, mail and package boxes, and an elevator lobby on the ground level. A courtyard, retail space and parking access, trash compactor room, and loading area will also be on the ground level. Ground disturbance associated with project construction will include demolition and removal of the existing building, borings related to foundation pile installation, and excavations for structural footings, utility installation, roadway and parking area installation, and landscaping.

1.2 Historic Preservation Regulatory Context and Document Purpose

As a City and County of Honolulu project on City and County lands, the project is subject to historic preservation review under Hawai‘i Revised Statutes (HRS) §6E-8 and HAR §13-275. Additionally, the proposed project is a federal undertaking as defined by Section 106 of the National Historic Preservation Act (NHPA) of 1966, as amended (2006), due to the use of HUD-CDBG funding for acquisition and/or improvement of the project. Project construction is to be funded with federal equity through the Low Income Housing Tax Credit program and Hawai‘i State funds. With the use of federal funding for initial land purchase, the project is subject to HUD’s environmental/historic preservation review regulations (24 CFR [Code of Federal Regulations] Part 58), which includes compliance with the National Environmental Policy Act (NEPA) and Section 106 of the NHPA. Following 24 CFR Part 58, the City is the responsible

Figure 1. Aerial photograph showing the AIS study area within the APE (note APE is identical to the project area) (Google Earth 2013)

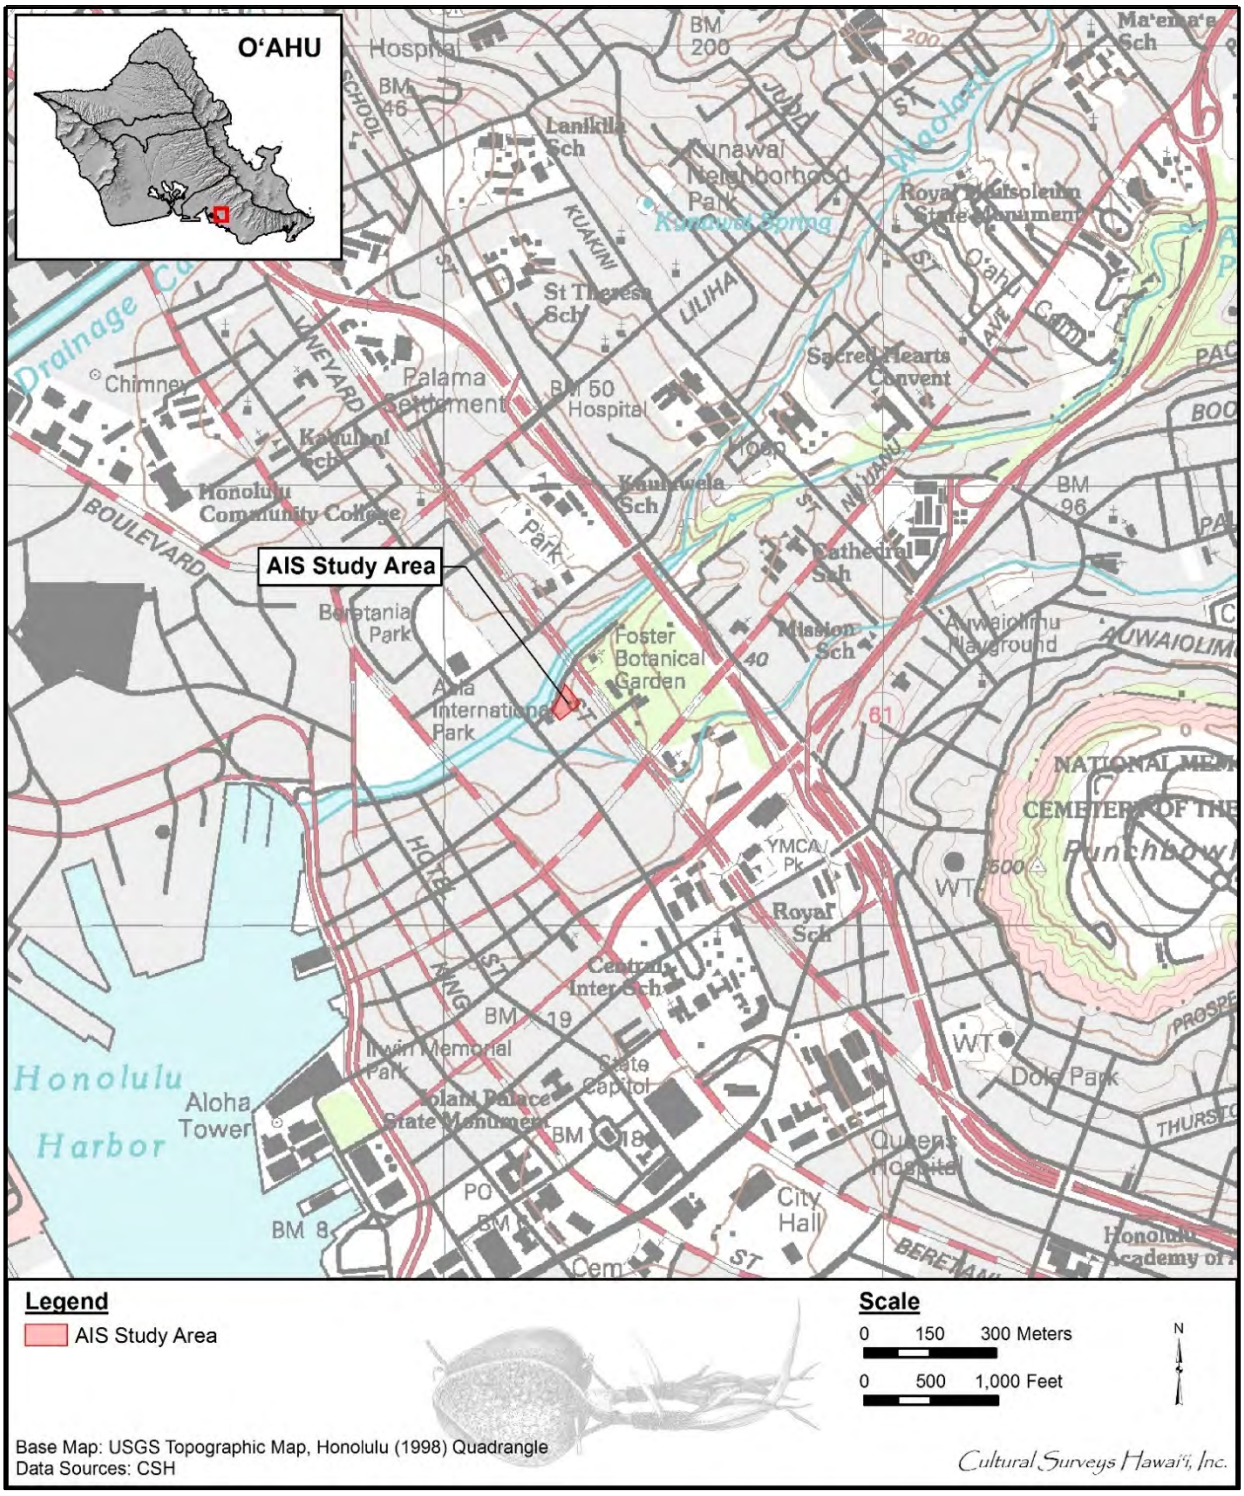

Figure 2. Portion of the 1998 Honolulu USGS 7.5-minute topographic quadrangle, showing the AIS study area

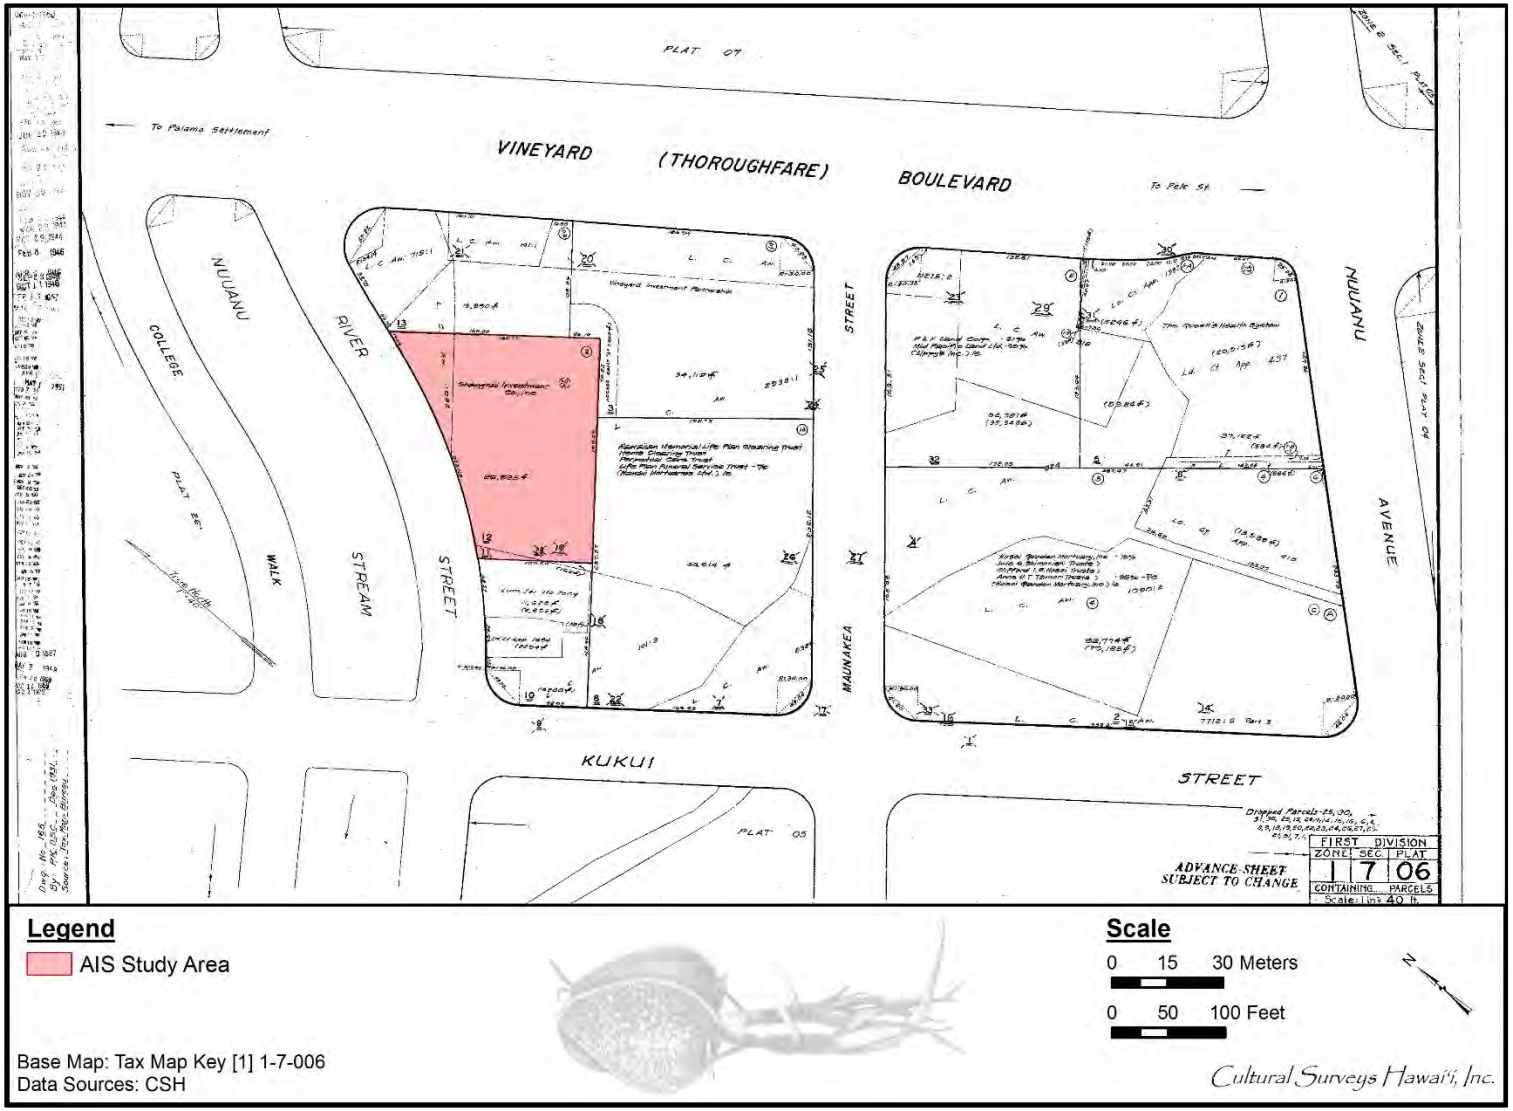

Figure 3. Tax Map Key (TMK) [1] 1-7-006, showing the AIS study area (Hawai‘i TMK Service 2014)

Figure 4. Aerial photograph of the AIS study area (Google Earth 2013)

entity to carry out this federal environmental and historic preservation review in compliance with HUD.

The City and County of Honolulu Department of Land Management (DLM) initiated project-related HRS §6E-8 consultation with the Hawai‘i State Historic Preservation Division (SHPD) at a meeting with the Architecture and Archaeology branches on 12 April 2017. The City DLM subsequently initiated project-related Section 106 consultation with the SHPD in a letter dated 10 June 2019, which was received by the SHPD on 14 June 2019 (Log No.: 2019.01347).

Fung Associates, Inc., completed a *Reconnaissance Level Architectural Inventory Survey Form for the John R. Gilliland Sr. Building* (Hibbard and Chiu 2016; see Appendix A), which assessed the building as eligible for listing on the National Register of Historic Places (National Register) under Criterion C (embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction). The SHPD concurred with this assessment in a letter dated 27 February 2017 (Log No.: 2017.02503; Doc. No.: 1702JLP04). As a result, a Memorandum of Agreement (MOA) is required for the project under Section 106. The purpose of the MOA is to codify the mitigation measures for National Register-eligible historic properties that will be adversely affected by the project.

CSH prepared a cultural impact assessment (CIA) (Spencer and Hammatt 2019) to support the project's NEPA environmental assessment.

This AIS investigation was designed to fulfill both federal and Hawai‘i State historic preservation review requirements for the identification of archaeological historic properties. In consultation with the SHPD, this AIS investigation fulfills the requirements of HAR §13-276 and the *Secretary of the Interior's Standards for Archaeology and Historic Preservation*. It was conducted to identify, document, and evaluate archaeological historic properties' eligibility for listing on the National Register and to assess archaeological historic property significance under Hawai‘i State significance criteria pursuant to HAR §13-275-6. Archaeological historic property eligibility for listing on the Hawai‘i Register of Historic Places (Hawai‘i Register) was evaluated following the criteria outlined in HAR §13-198-8. This report is intended to support any project-related historic preservation consultation with consulting parties, such as State and County agencies, interested Native Hawaiian Organizations (NHOs), and community groups.

The identification and treatment of human skeletal remains discovered during this AIS investigation complied with Hawai‘i State burial law (HRS §6E-43 and HAR §13-300).

1.3 Architectural Historic Properties

In 2016, Fung Associates, Inc., prepared a reconnaissance level survey (RLS) of architectural historic properties within the project area (Hibbard and Chiu 2016; see Appendix A). The survey assessed the age, integrity, and significance of the AIS study area's only building, the John R. Gilliland Sr. Building. It also identified potential adverse effects and mitigation alternatives related to the building's demolition. Staff who conducted the survey meet the Secretary of the Interior's Professional Qualifications Standards as architectural historians, per 36 CFR Part 61. The RLS was accepted by the SHPD Architecture Branch in a letter dated 27 February 2017 (Log No.: 2017.02503; Doc. No.: 1702JLP04).

The RLS included a brief historical context pertaining to the John R. Gilliland Sr. Building. The building was constructed in 1958 and was designed by architect Kenneth Sato. It retains much of its historic character in terms of design, materials, workmanship, and construction methods. The RLS assessed the John R. Gilliland Sr. Building as eligible for listing on the State and National Registers under Criterion C as a very good example of a small retail/office building constructed in Hawai‘i in a modern style in the 1950s.

Additionally, Fung Associates, Inc., completed a pedestrian survey in 2019 of all architectural properties within the APE built prior to 1972, in accordance with HAR §13-275 and 36 CFR Part 800.4. This study meets both state and federal requirements for the identification of historic properties. Twenty potentially historic resources comprising buildings, sculptures, or objects were identified and evaluated for eligibility based on the project's anticipated completion date of 2022. On behalf of the project proponents, Fung and Associates has submitted these results to the SHPD/State Historic Preservation Officer (SHPO) in support of the project's historic preservation review compliance.

1.4 Environmental Setting

1.4.1 Natural Environment

The Halewai‘olu Senior Residences project is on the southern leeward coastal plain of Honolulu, approximately 0.7 km (0.4 mile) inland from Honolulu Harbor. It is relatively flat and is 2.7 m (8.9 ft) above sea level. Rainfall in the AIS study area averages 833.5 mm (32.8 inches) annually (Giambelluca et al. 2013), and the average temperature is 23.7° C (74.6° F) (Giambelluca et al. 2014). There is no vegetation within the AIS study area, which is paved with asphalt and concrete.

The AIS study area is on the margins of Nu‘uanu Stream, within the stream's floodplain as it enters Honolulu Harbor. According to the U.S. Department of Agriculture (USDA) Soil Survey Geographic (SSURGO) database (2001) and soil survey data gathered by Foote et al. (1972), the project area's soils consist of Ewa silty clay loam, moderately shallow, 0 to 2% slopes (EmA) (Figure 5). The Ewa Series is described as follows:

> This series consists of well-drained soils in basins and on alluvial fans on the islands of Maui and Oahu. These soils developed in alluvium derived from basic igneous rock. […]
>
> These soils are used for sugarcane, truck crops, and pasture. The natural vegetation consists of fingergrass, kiawe, koa haole, klu, and uhaloa. [Foote et al. 1972:29]

1.4.2 Built Environment

The Halewai‘olu Senior Residences project is within central Honolulu, surrounded by modern urban development including commercial buildings, paved streets, sidewalks, utility infrastructure, and landscaped margins. The AIS study area consists of a two-story commercial building, the John R. Gilliland Sr. Building, and surrounding asphalt-paved parking lot (see Figure 4). The channelized Nu‘uanu Stream is northwest of the project area, across River Street.

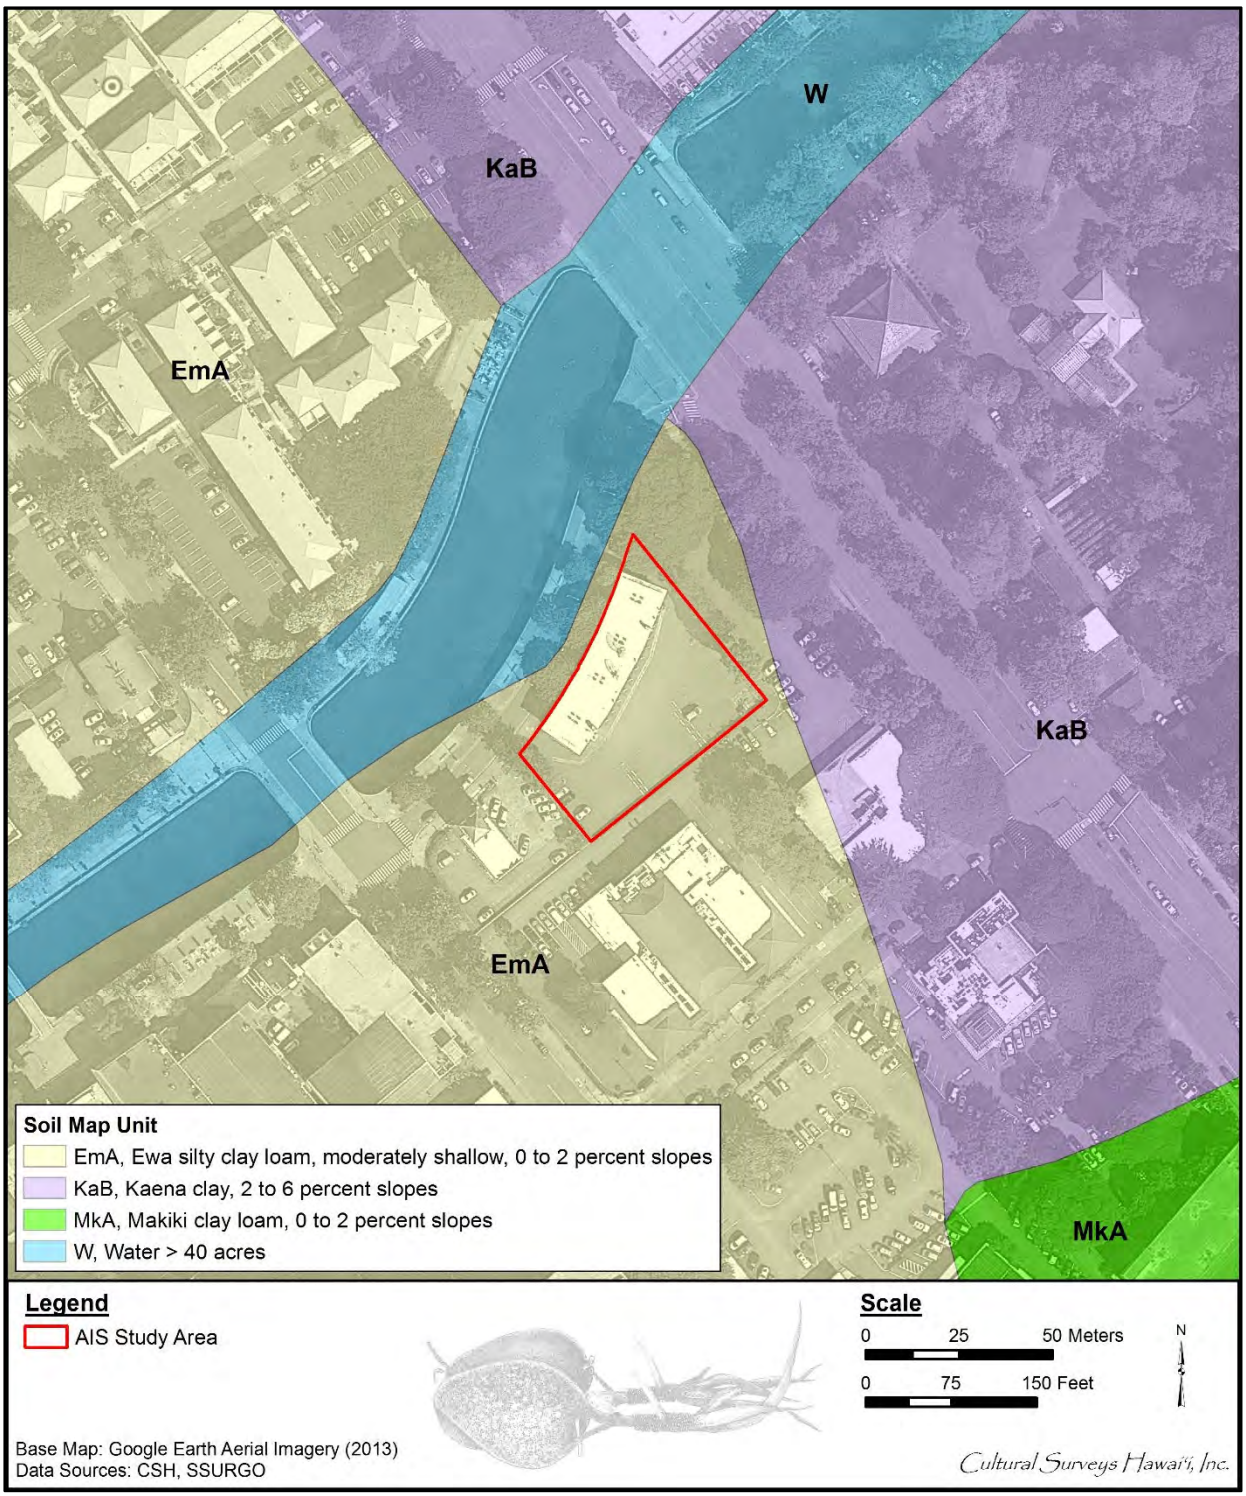

Figure 5. Overlay of *Soil Survey of the State of Hawaii* (Foote et al. 1972), indicating soil types within and surrounding the AIS study area (USDA SSURGO 2001)

Section 2 AIS Methods

2.1 Field Methods

CSH completed the fieldwork component of this AIS under archaeological fieldwork permit number 19-07, issued by the SHPD pursuant to HAR §13-282. Fieldwork was conducted between 1 and 30 July 2019 under the general supervision of Matt McDermott, M.A. (Principal Investigator), and Ena Sroat, B.A. (Project Director). CSH archaeologists included Sara Blahut, M.A. (osteologist), Alison Welser, M.A. (osteologist), Gina Farley, M.A., Lisa Manirath, M.A., Brittany Enanoria, B.A., Jessica Burden, B.A., Tanyja Roberson, B.A., Jonathan Alperstein, B.A., Ryan Harismendy, B.A., and Phoenix Pu‘u, B.A. This work required approximately 38 person-days to complete.

As the Halewai‘olu Senior Residences AIS study area consists of a two-story commercial building (the John R. Gilliland Sr. Building) and associated asphalt parking lot, no surface archaeological historic properties were anticipated. Although fieldwork included a 100% pedestrian survey of the AIS study area, investigations focused on a program of test excavations to identify subsurface archaeological historic properties.

2.1.1 Subsurface Testing

The proposed subsurface testing strategy consisted of 12 test excavations (T-1 through T-12) distributed throughout the AIS study area, each measuring 0.6 by 6.1 m (2 by 20 feet [ft]) (Figure 6). The distribution was based on general coverage of the AIS study area; the planned locations of deep project-related ground disturbance such as elevator shafts (Figure 7); the accessibility of interior building space; and a review of cultural and historical background research, including historical maps and aerial photographs (see Section 3: Background Research). Based on the results of utility toning, several of the exterior test excavations were adjusted slightly (Figure 8). Based on spatial limitations and the results of utility toning, the dimensions of the two planned interior test excavations were adjusted to 0.9 by 3 m (3 by 10 ft) (T-10) and 0.6 by 3 m (2 by 10 ft) (T-11).

Following completion of AIS test excavations T-1 through T-12, CSH consulted with the SHPD regarding the testing results and the sufficiency of the testing strategy. Based on the documentation of a human burial site (State Inventory of Historic Places [SIHP] # 50-80-14-8840 Component 2, Feature 6) within T-2, CSH proposed two additional test excavations (T-2B and T-2C) on either side of T-2 to investigate the presence of a potential burial cluster and to delineate the burial site boundaries. The SHPD agreed with this strategy and additionally requested a third test excavation in the vicinity of T-9 in order to investigate further a potential agricultural berm feature (T-9B) (see Figure 8).

Initial excavation methods consisted of saw-cutting the asphalt parking lot surface (exterior excavations) or concrete building foundation (interior excavations). Excavation then proceeded via backhoe scrapes to approximately 1.5 m (5 ft) below surface (i.e., the maximum depth to safely enter the excavation without a shoring device). The excavation sidewalls were then cleaned, inspected, and documented, and soil samples were collected if appropriate. Excavation then continued to just below the water table and/or a culturally sterile, buried streambed (Stratum III). In general, this final excavation to the water table and/or streambed proceeded in two phases. The

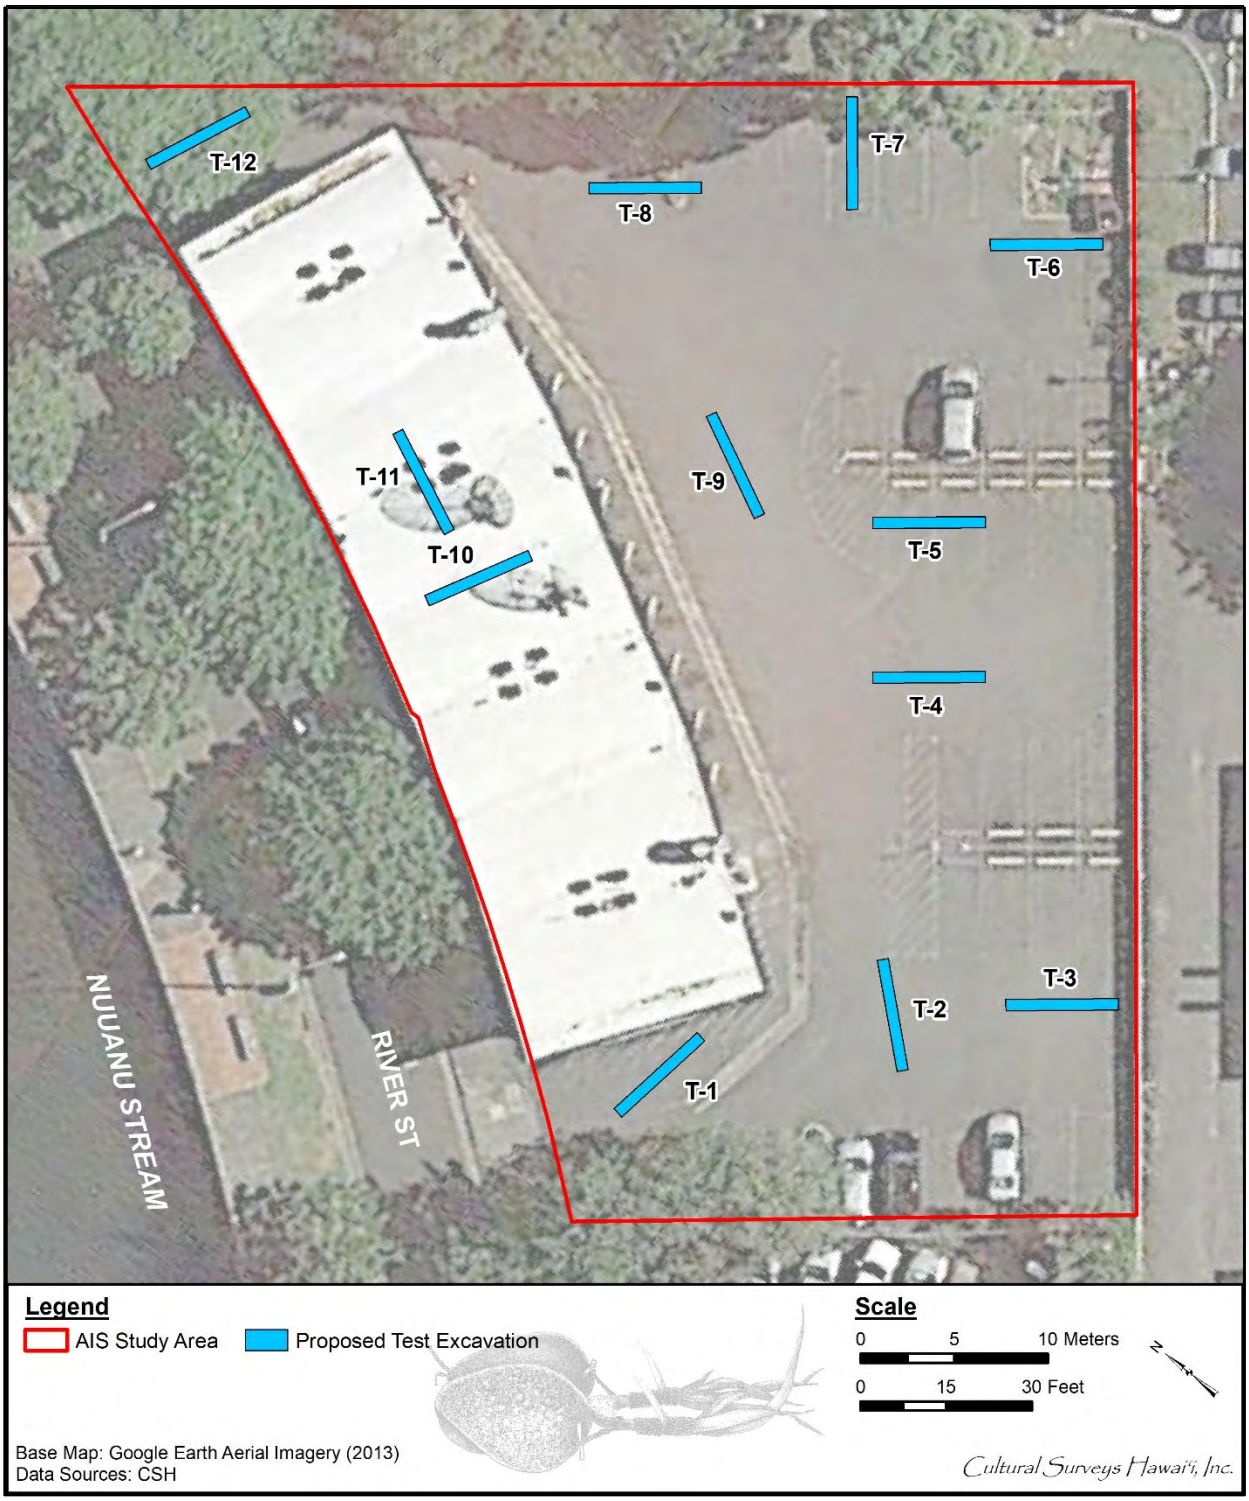

Figure 6. Aerial photograph showing 12 proposed AIS test excavations within the AIS study area (Google Earth 2013)

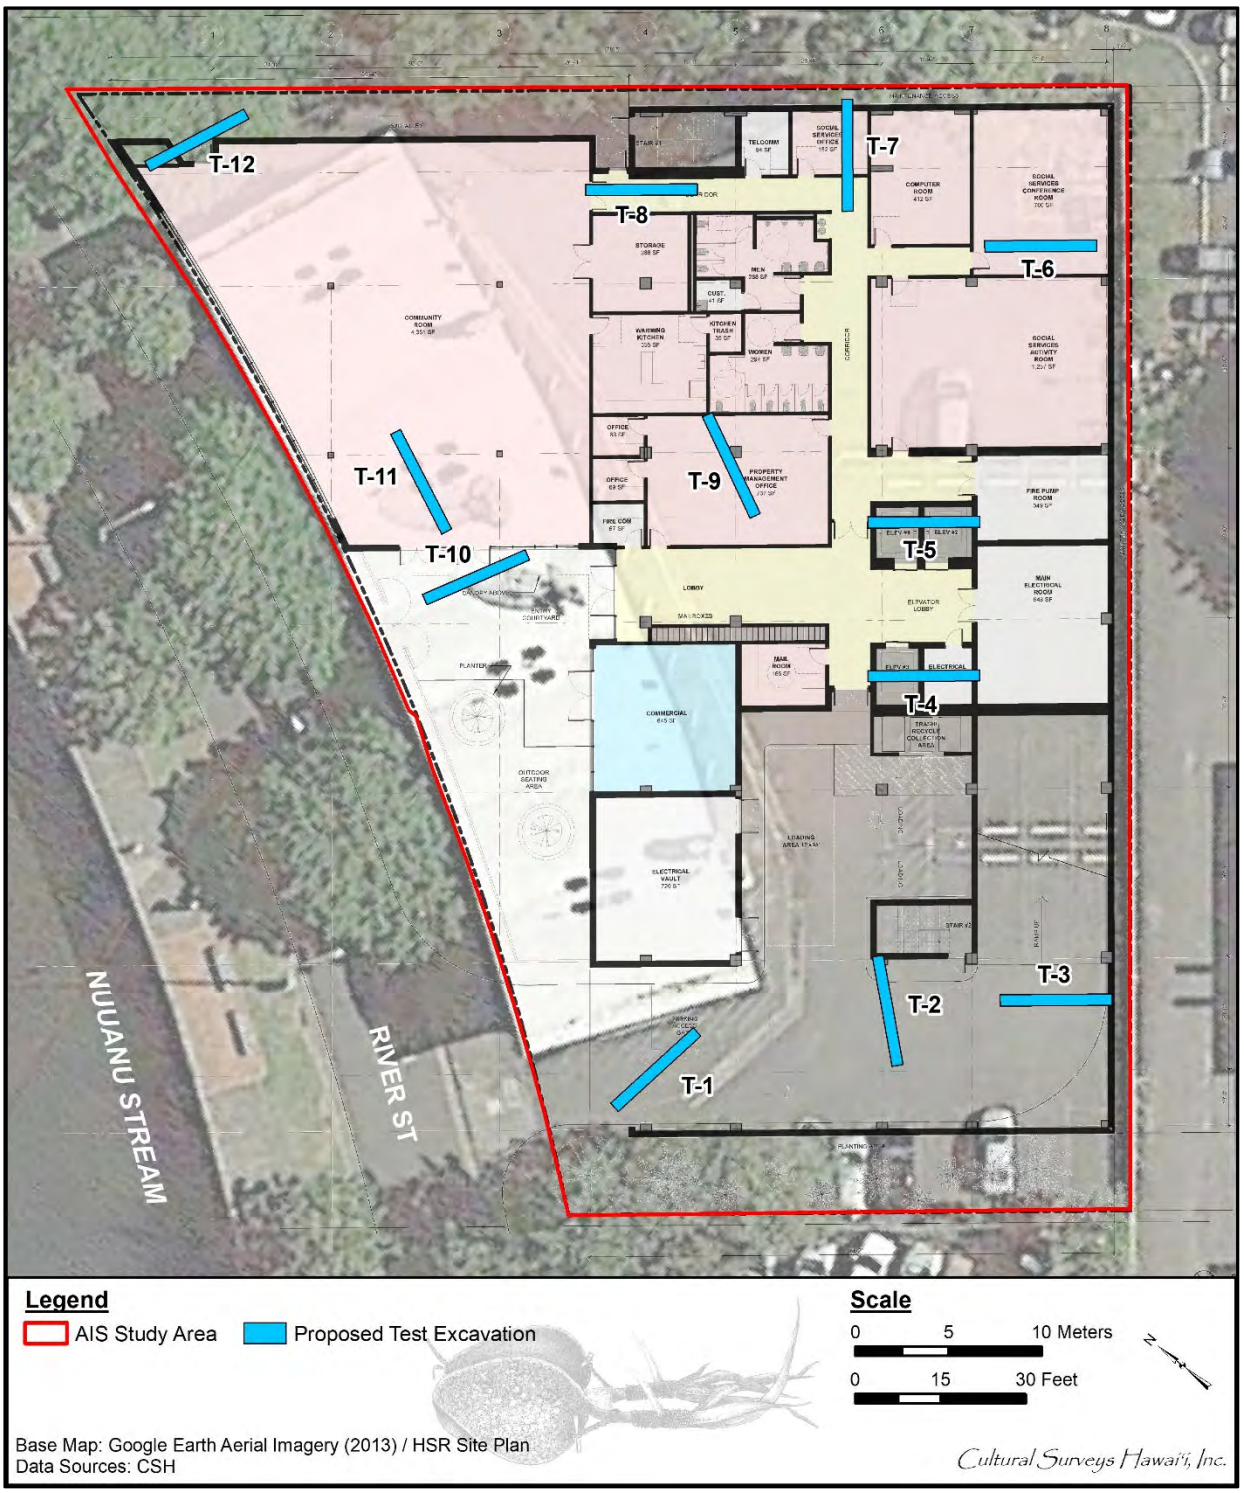

Figure 7. Aerial photograph of the AIS study area, with overlay of the project design; note T-4 and T-5 target planned deep elevator pit ground disturbance (Google Earth 2013)

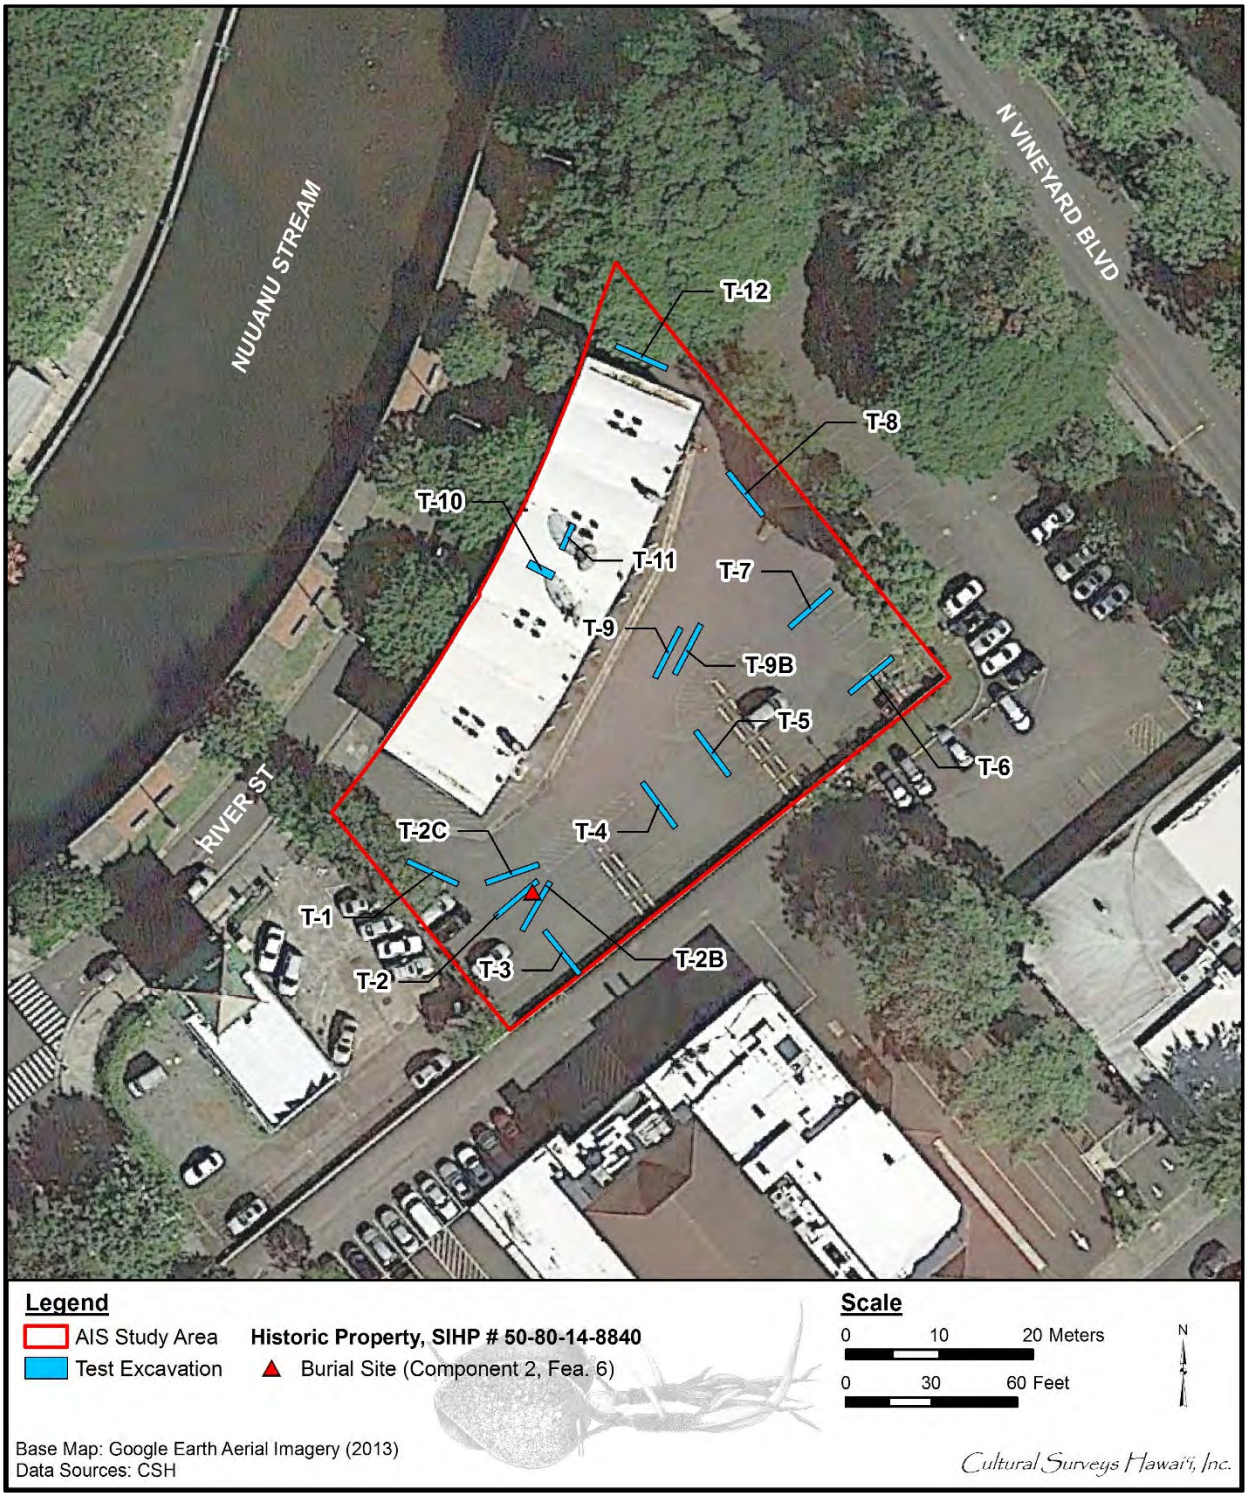

Figure 8. Aerial photograph of the AIS study area, showing the 15 completed AIS test excavations and the SIHP # -8840 Component 2, Feature 6, human burial (Google Earth 2013)

first phase consisted of completion of one half of the trench (e.g., the *makai* half), with the uncompleted portion (e.g., the *mauka* half) serving as a pedestal from which to safely inspect, document, and sample the deepest stratigraphy. The second phase consisted of excavation of the remaining portion of the trench, with close inspection of the extracted sediments to correlate with the previously collected data. Exceptions to this methodology included T-8, which was excavated to the water table in one phase, with shoring installed prior to inspection of the deepest stratigraphy; this was done to compare the efficacy of different methodologies. In a few instances, a portion of the test excavation could not be excavated to the water table and/or streambed due to safety concerns or subsurface obstacles. Safety issues included petroleum contamination within shallow fill deposits (T-4 and T-5) and unstable sidewalls due to demolition rubble (T-3). Subsurface obstacles included a large boulder within T-6 and a utility pipe within T-10. In addition, the immediate area of the human burial site identified within T-2 was not excavated in order to ensure the integrity and safety of the burial.

A stratigraphic profile of each test excavation was drawn and photographed. The observed soils/sediments were described using standard USDA soil description observations/terminology. Descriptions included Munsell color, texture, consistence, structure, plasticity, cementation, origin, descriptions of any inclusions, such as cultural material and/or roots, lower boundary distinctiveness and topography, and other general observations. Where stratigraphic anomalies or potential cultural deposits were exposed, these were carefully represented on test excavation profile maps. Photographs were also taken of the general AIS study area and in-progress work, recording on-the-job procedures, personnel, work conditions, and the area’s natural and built environment. A photographic scale and north arrow were included in each photograph.

Cultural material observed within modern and historical fill deposits such a demolition layers was generally recorded (e.g., photographed, described) but not collected. Cultural material associated with potential historic properties such as historical trash pits was photographed and grab samples were collected, with care given to including representative artifact types as well as those with the most diagnostic characteristics.

Representative soil/sediment samples were collected from the natural strata underlying modern and historical fill deposits, including potential cultural deposits (i.e., habitation layers, agricultural deposits), for further characterization within the CSH laboratory and for outsourced sample analysis as described in Section 2.2 below. Samples were collected as bulk or column samples, and all samples were collected as single stratum samples without crossing stratigraphic boundaries. Care was taken during the collection of column samples to clean/sterilize the extraction implement so as not to cross-contaminate samples.

The locations of the exterior test excavations were recorded using a Trimble GPS Pathfinder ProXH mapping-grade GPS unit with a TSCI Datalogger using real-time differential correction. This unit provides sub-meter horizontal accuracy in the field. GPS field data was then post-processed. GPS location information was converted into GIS shape files using Trimble’s Pathfinder Office software, version 5.6, and graphically displayed using ESRI’s ArcGIS, version 10.2.1. The approximate locations of the two interior test excavations were extrapolated based on triangulation of architectural components of the John R. Gilliland Sr. Building.

2.2 **Laboratory Methods**

Materials collected during AIS fieldwork were identified and catalogued at CSH's laboratory facilities on O‘ahu. Analysis of collected materials was undertaken using standard archaeological laboratory techniques. Materials were washed, screened, sorted, measured, weighed, described, and/or photographed.

2.2.1 Bulk and Column Sample Analysis

Sediment samples collected from a vertical series of natural alluvium deposits (Stratum II), including interpreted agricultural deposits (SIHP # -8840 Component 1), were examined within the CSH laboratory to aid in characterizing these deposits. Samples were collected as bulk or column samples. All samples were labeled with provenience information, and the volume of each sample was recorded so that comparisons could be made among samples. In the lab, bulk and column samples were first visually inspected. Many of the samples were additionally photo-documented, generating a visual record of the potential agricultural deposits. Select column samples were submitted for palynological analysis (see Section 2.2.4.1 below).

Wet screening of samples was performed on selected representative samples (n=7) to document material content. Scaled, close-up photographs of the selected samples were taken prior to wet screening for comparison with post-wet screening results. The samples, ranging from 0.5 to 2 liters, were placed in large (approximately 7-liter) 4-mm sealable (Ziploc-type) plastic bags. The bags were filled with tap water and allowed to soak for an hour with periodic agitation and massaging to break up sediment peds/masses in preparation for wet screening. Soaked and agitated samples were poured onto large, 1/16-inch mesh screens and sprayed with a water hose to work the finer-grained sediment through the mesh. Commonly, gravel-sized peds/masses of soil adhering to itself resulted; the largest of these peds/masses were broken apart by hand as wet screening continued. Smaller peds/masses were not broken down by hand. Sediment that did not pass through the 1/16-inch mesh was spread out on the screen and air-dried. Dried samples were inspected (without magnification) for artifacts, plant remains, charcoal, and limonite root casts and nodules. Post-wet screening, scaled, close-up photographs were taken for comparison. Results of this analysis are presented in Section 5.1: Bulk Sample Analysis.

2.2.2 Artifact Analysis

In general, artifact analysis focused on establishing, to the greatest extent possible, material type, function, cultural affiliation, and age of manufacture. As applicable, artifacts were washed, sorted, measured, weighed, described, photographed, and catalogued. Diagnostic (dateable or identifiable) attributes of artifacts were researched.

No traditional Hawaiian artifactual material was collected. Historical artifacts were analyzed using standard reference materials, as well as resources available on the internet; these included Elliott and Gould (1988), Munsey (1970), Bureau of Land Management/Society for Historical Archaeology (BLM/SHA) (2019), and Florida Museum of Natural History (2018), among others. Analyzed materials were tabulated and are presented in Section 5.2: Artifact Analysis.

2.2.3 Faunal Analysis

Faunal analysis focused on species identification and evidence of food consumption. Collected non-human vertebrate skeletal material was identified to the lowest possible taxa and analyzed

using an in-house comparative collection and reference texts (Adams and Crabtree 2008; France 2009). Identified faunal remains are discussed in Section 5.3: Faunal Analysis.

2.2.4 Floral Analysis

2.2.4.1 Palynological Analysis

Palynology is the branch of science concerned with the study of pollen, spores, phytoliths, and other palynomorphs. Palynomorphs are often preserved in soil/sediment samples and, following physical and chemical extraction, can be identified with a microscope. This information leads to the types of plants that made up the local environment, or the local watershed, at the time the sediment was deposited. A large amount of palynological research has been conducted on O‘ahu to examine human impacts on native vegetation.

Ten samples from two test excavations (T-7 and T-9) were submitted to BGP Consulting, LLC, in Flagstaff, Arizona for pollen analysis. The samples targeted a vertical series of natural alluvium deposits, including interpreted agricultural deposits (SIHP # -8840 Component 1). The results of the palynological analysis are presented in Appendix C and are discussed in Section 5.4.1: Pollen Analysis.

2.2.4.2 Wood Taxa Identification

Charcoal samples from two fire-related features (SIHP # -8840 Component 2, Features 2 and 4) were analyzed for species identification. Samples were sent to the Wood Identification Laboratory at International Archaeological Research Institute, Inc. (IARII), for taxa identification. The samples were viewed under magnification of a dissecting microscope and compared with anatomical characteristics of known woods in the Pacific Islands Wood Collection at the Department of Botany, University of Hawai‘i at Mānoa, as well as in published descriptions. Taxa identification of wood samples provides useful information for interpreting the environmental and cultural history of the area and helps to determine a general time frame of land use. Analysis by IARII also identifies short-lived plant species and/or plant parts that may be used for radiocarbon dating. Following analysis, samples were returned to the CSH laboratory. The results are presented in Appendix D and are discussed in Section 5.4.2: Wood Taxa Identification.

2.2.4.3 Radiocarbon Dating Analysis

Charcoal from SIHP # -8840 Component 2, Feature 4, fire-related feature, was submitted to Beta Analytic, Inc., of Miami, Florida, for radiocarbon dating analysis. Parenchyma charcoal was selected because it is not likely to have much inbuilt age, as soft storage tissues are not long-lived; hence, it provides a tighter timeframe for possible radiocarbon dates. The sample was analyzed using the accelerator mass spectrometry (AMS) method. The conventional radiocarbon age determined by Beta Analytic, Inc., was then calibrated to calendar ages using the IntCal 13 calibration program. The results are presented in Appendix E and are discussed in Section 5.4.3: Radiocarbon Dating Analysis.

2.2.5 Disposition of Materials

The Hawai‘i State rules governing AIS investigations (HAR §13-276) state the following regarding AIS collections from private lands:

> Arrangements shall be made with private landowners on the disposition of collections from their lands. If private landowners request archiving of material, then the archive shall be determined in consultation with the SHPD. [HAR §13-276-6]

All materials collected during the current AIS, including samples and artifacts, are the property of the landowner. Upon conclusion of the AIS investigation, all collected materials were temporarily stored at the CSH office in Waimānalo, O‘ahu. Disposition of the collection will be determined in consultation with the landowner. All data generated during the course of the AIS is stored at the CSH offices.

2.3 Research Methods

Background research included a review of previous archaeological studies on file at the SHPD; review of documents at Hamilton Library of the University of Hawai‘i, the Hawai‘i State Archives, the Mission Houses Museum Library, the Hawai‘i Public Library, and the Bishop Museum Archives; study of historical photographs at the Hawai‘i State Archives and the Bishop Museum Archives; and study of historical maps at the Survey Office of the Department of Land and Natural Resources. Historical maps and photographs from the CSH library were also consulted. In addition, Māhele records were examined from the Waihona ‘Aina database (Waihona ‘Aina 2019). This research provided the environmental, cultural, historical, and archaeological background discussed in the following section.

Section 3 Background Research

3.1 Traditional Background

The area that today comprises the portion of downtown Honolulu surrounding the mouth of Nu‘uanu Stream was known to Hawaiians as “Kou.” This area was a center of population and activity similar to Waikīkī, its preeminent neighbor to the southeast. Kou possessed shoreward fishponds and irrigated fields fed by streams descending from Nu‘uanu and Pauoa valleys (McAllister 1933:80). The land surrounding Nu‘uanu Stream was densely populated, with a concentration of *lo‘i* (irrigated taro patches) and *‘auwai* (irrigation ditches) that brought water to the agricultural fields (Figure 9 and Figure 10). There were several large fishponds, including Kawa and Kūwili, *makai* (seaward) of the current project, where Hawaiians raised fish. Additionally, nearby Honolulu Harbor was brimming with marine resources such as fish, crabs, shells, and seaweed. In addition, Kou/Honolulu had a long tradition as a royal center, where the *ali‘i* (chiefly class) would meet and entertain. Pukui (1983) recounts the poetical saying, *“Hui aka nā maka i Kou”* (“the faces will meet at Kou”), in reference to such gatherings (Pukui 1983:1128).

3.1.1 Place Names and Legends

Pukui et al. (1974:49–50) translate Honolulu as “protected bay,” referring to the protection of Honolulu Harbor. According to Westervelt (1915), Honolulu is a name made by the union of the two words “*Hono*” and “*lulu*”:

> Some say it means ‘Sheltered Hollow.’ The old Hawaiians say that ‘Hono’ means ‘abundance’ and ‘lulu’ means ‘calm,’ or ‘peace,’ or ‘abundance of peace.’ The navigator who gave the definition ‘Fair Haven’ was out of the way, inasmuch as the name does not belong to a harbor, but to a district having ‘abundant calm,’ or ‘a pleasant slope of restful land.’
>
> ‘Honolulu’ was probably a name given to a very rich district of farm land near what is now known as the junction of Liliha and School Streets, because its chief was Honolulu, one of the high chiefs of the time of Kakuhihewa, according to the legends. [Westervelt 1915:14]

Older names for the harbor are Kou and Māmala. Kākuhihewa was a *mō‘ī* (king, sovereign) of O‘ahu prior to the time of Kamehameha I. Kākuhihewa divided the island amongst his favorite chiefs and officers, who gave their names to the places they received; hence, the place now known as Honolulu was, until the time of Kamehameha I, called Kou after a chief who was an *ilāmuku* (marshal) under Kākuhihewa (Westervelt 1915:14). According to Westervelt (1915:14), “Ke-kai-o-Mamala was the name of the surf which came in the outer entrance of the harbor of Kou. It was named after Mamala, a chiefess who loved to play konane (Hawaiian checkers), drink awa [*kawa*; *Piper methysticum*], and ride the surf.”

The *ahupua‘a* (traditional land division) of Kou/Honolulu was subdivided into several smaller land divisions known as *‘ili*. The area between Maunakea Street and Nu‘uanu Stream, *makai* of King Street was known as Kapu‘ukolo. The area between Maunakea Street and Nu‘uanu Stream, *mauka* (inland, toward the mountains) of King Street to Beretania Street was called Kīkīhale. Pukui

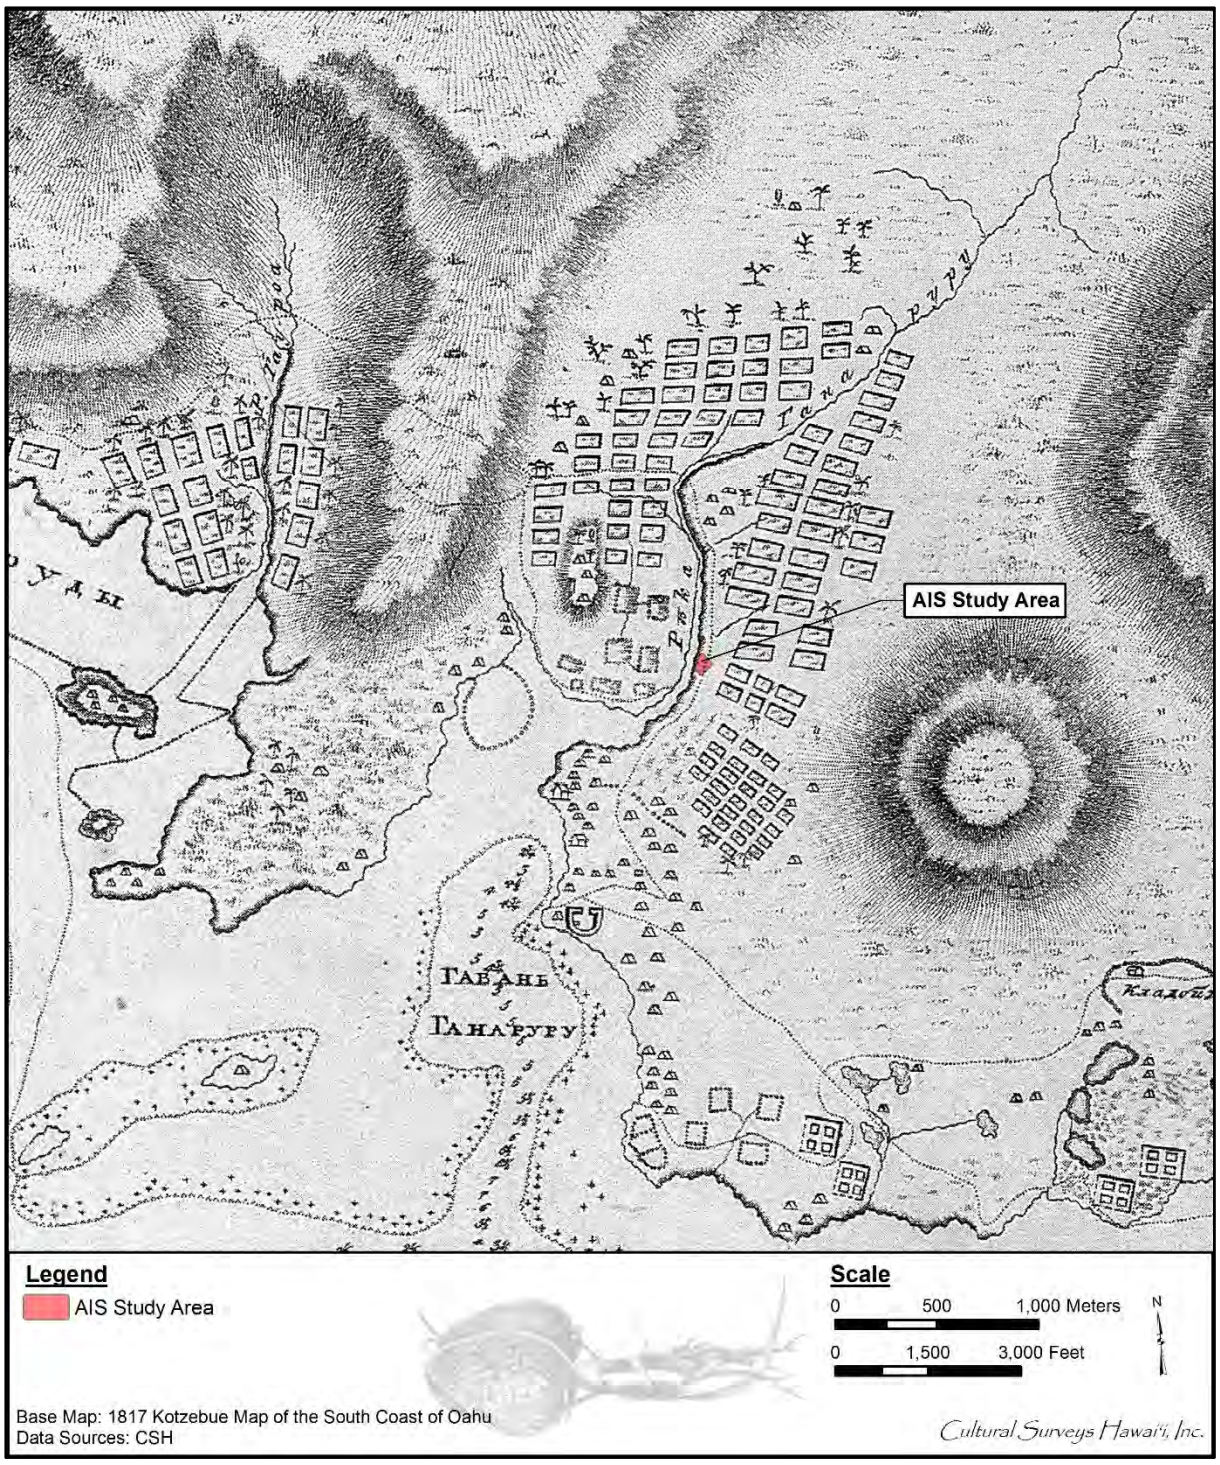

Figure 9. Portion of the 1817 map of the south coast of O‘ahu by Otto von Kotzebue, lieutenant of the Russian naval vessel, the *Rurick*, showing a concentration of taro fields (rectangles) around the banks of Nu‘uanu Stream and grass huts along the coast and the inland trails

Figure 10. Portion of the 1855 LaPasse map of the South Coast of Oahu, showing the AIS study area within a concentration of taro fields (rectangles) around the banks of Nu‘uanu Stream

et al. (1974:110) state that Kīkīhale was named for the daughter of the chief, Kou, for whom the area was named. The current project is within the *‘ili* of Kalāwahine (Figure 11), which Pukui et al. (1974) indicate as being named for a deity who guarded water sources. The literal translation is “the day [of] women” (Pukui et al. 1974:76). Some of these place names are mentioned in the legend of ‘Ai‘ai, described below (Thrum 1998:230–254).

Kū‘ula, the god presiding over the fish of the sea, had a son named ‘Ai‘ai. ‘Ai‘ai was the first to teach the Hawaiians how to make various fishing lines and nets and was the first to set up a *ko‘a kū‘ula*, a rock shrine, on which the fishermen would place their first catch as an offering to Kū‘ula. He was also the first to set up *ko‘a i‘a*, fishing stations, where certain fish were known to gather (Thrum 1998:231). Leaving his birthplace in Maui, ‘Ai‘ai traveled around the islands establishing *ko‘a kū‘ula* and *ko‘a i‘a*. He landed first at Ka‘ena Point, then traveled around the island of O‘ahu, stopping in Kaka‘ako (an *‘ili* now covered by One Waterfront Plaza) to visit his friend, Apua. Here, he met the famed O‘ahu chief, Kou, a skilled fisherman who caught the large *aku* (bonito; *Katsuwonus pelamis*) in the bay of Māmala (Honolulu Harbor). ‘Ai‘ai soon met a young woman named Puiwa. They married and had a son named Puniaiki.

One day, the family went to a dam on Nu‘uanu Stream to catch *‘o‘opu* (gobies) and *‘ōpae* (shrimp). When Puiwa left the newborn, Puniaiki, on the bank of the stream, the baby started to cry. ‘Ai‘ai told his wife to tend to the child, but she answered him back saucily. ‘Ai‘ai called on his ancestors, and a storm came up, flooding the dam and sweeping the child into the stream. Leaving his wife, ‘Ai‘ai went downstream to the *‘ili* of Kaumakapili. Here, he saw the chiefess Kīkīhale gather a large *‘o‘opu* from the stream. Kīkīhale’s guardian advised her to put it in a calabash with water and keep it as a pet. ‘Ai‘ai realized that the *‘o‘opu* was Puniaiki, his transformed child who had been swept downstream to Kīkīhale (referring to both the person and the *‘ili* named Kīkīhale). The next day, the chiefess’ guardian saw that the *‘o‘opu* had turned back into a child, and Kīkīhale instructed her to raise the child until it was an adult, so that she could take the young man for a husband. This came to pass, but the chiefess was not satisfied with her husband Puniaiki, since he did not bring fish home as the other men in the islands. Puniaiki was annoyed with her complaints and took the pearl fishhook, Kahuai, given to him by his father, ‘Ai‘ai, and went out with the men of Kou to fish for the *aku*. When Puniaiki held the pearl fishhook in his hand, “the akus, unprecedented in number, fairly leaped into the canoes. They became so filled with the fish, without labor, that they sank in the water as they reached Kapuukolo, and the men jumped overboard to float them to the beach” (Thrum 1998:247–248). This suggests Kapu‘ukolo was not only an *‘ili* name but also a canoe landing, a place to come ashore after *aku* fishing.

Kou is also mentioned in the legend of Hi‘iaka, beloved sister of the Hawaiian volcano goddess, Pele. Hi‘iaka and her companions had been traveling around O‘ahu on the land trails but decided to travel from Pu‘uloa (Pearl Harbor in ‘Ewa) to Waikīkī by canoe. At Pu‘uloa, Hi‘iaka met a party who was planning on traveling to the house of the chiefess Pele‘ula in Waikīkī. Hi‘iaka recited a chant, telling the people that although they were going by land, and she was going by sea, they would meet again in Kou:

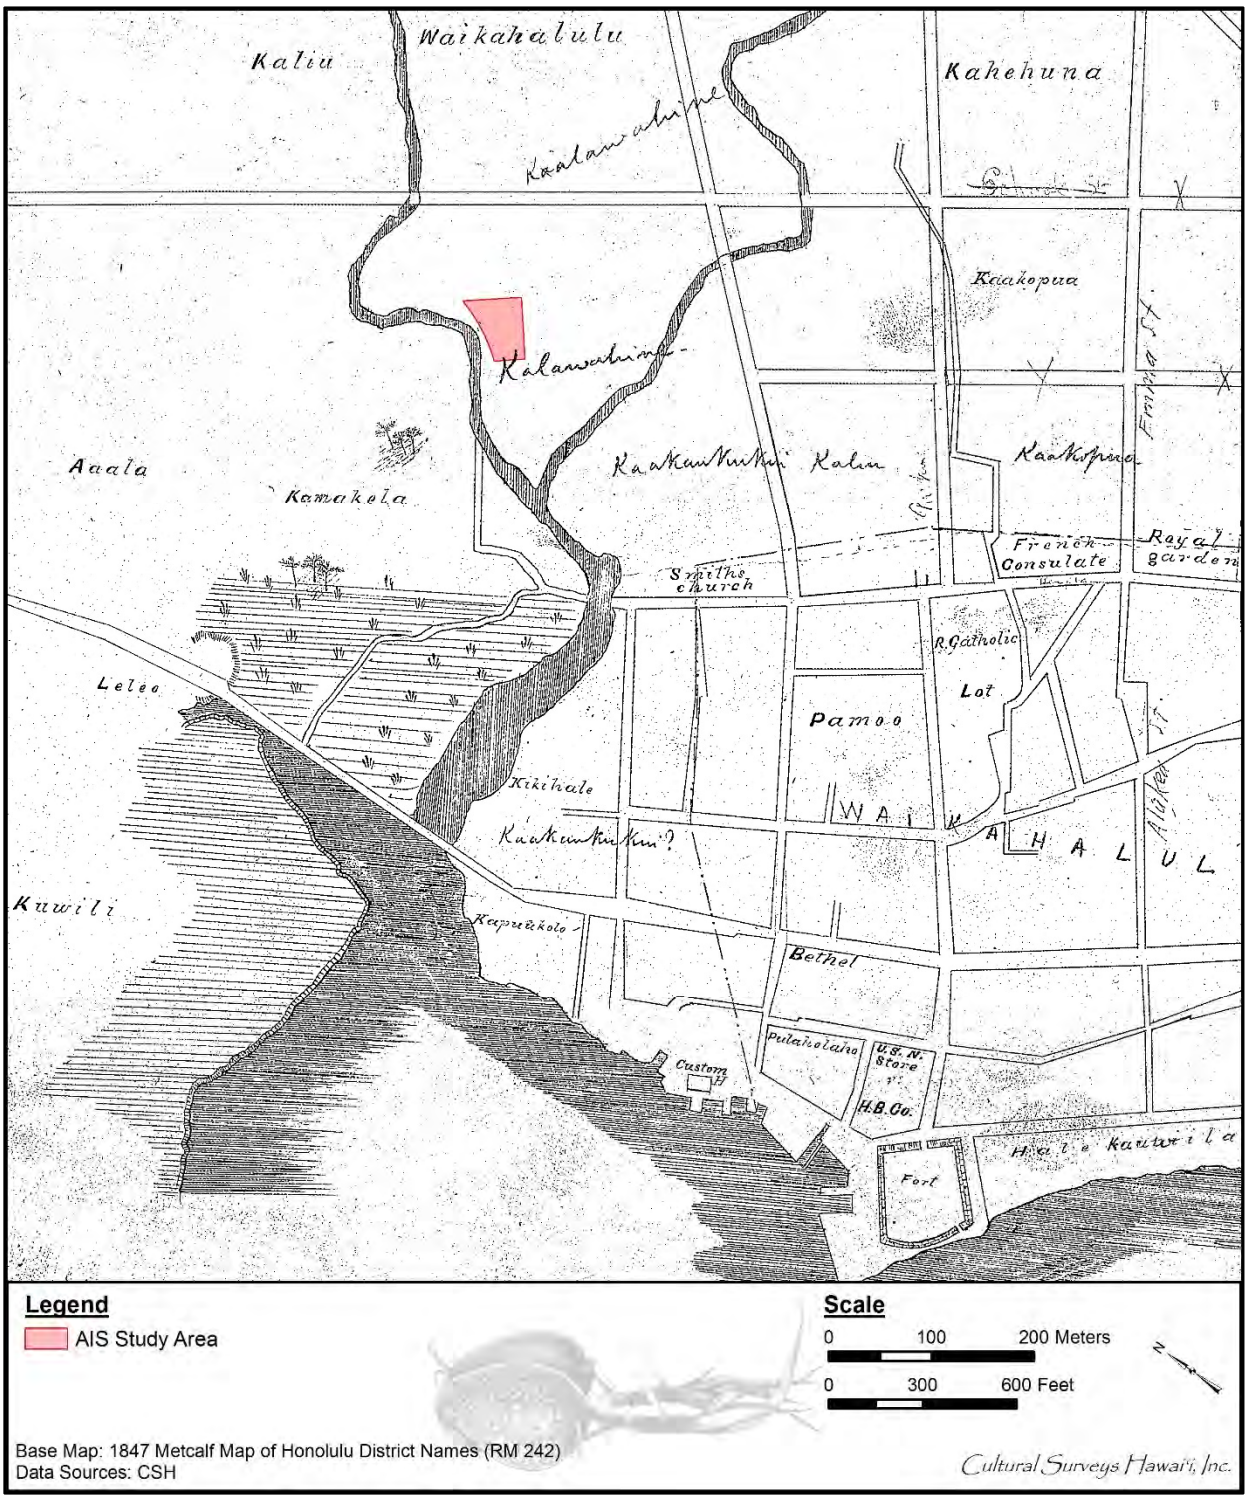

Figure 11. Portion of the 1847 Metcalf map of Honolulu District names (RM 242), showing the AIS study area within the *‘ili* of Kalāwahine

Kou is the coral flat	*‘O Kou ka papa*
Ka‘ākaukukui is the pool	*‘O Ka‘ākaukukui ka loko*
Some ‘alamihi [a black crab], indeed	*‘O ka ‘alamihi a‘e nō*
Wait all day until night	*‘O ka lā a pō iho*
Friends shall meet in Kou.	*Hui aku i Kou nā maka*.

[Ho‘oulumāhiehie 2008a:277; Ho‘oulumāhiehie 2008b:297]

3.1.2 *Ali‘i* and Battles

Nu‘uanu Valley, *mauka* of the current project, was the site of several battles during the pre-Contact period, usually between leeward Kona chiefs and windward Ko‘olau chiefs who moved along the Pali trail and pass to conduct raids into each other’s territories:

> Between Kahapa‘akai clear to the mouth of the valley were situated many celebrated *heiaus* (*luakini waihau*) where people went to worship. [These had been] erected in ancient days as war *heiaus* or *heiaus* for purifying the land; for Nu‘uanu had been a magnificent battleground in those old times. Here Pele-io-holani fought against Alapa‘i-nui, ruling chief of Hawaii, and so fought chiefs before and after his day. [Kamakau 1991:291]

Through a series of such battles, Kū‘ali‘i unified the island of O‘ahu around AD 1720-1740. In the Legend of Kalelealuaka, Kū‘ali‘i fought to overcome the district chief, Kākuihiwewa. An account from Thrum (1907:102) reported, “In a few days again came a report that Kualii had an army at a place called Kahapaakai, in Nuuanu. Maliuhaaino [the war chief of Kākuihiwewa] immediately marshaled his forces and started for the scene of battle the same evening.”

The hero Kalelealuaka had the ability to fly from one point to another in the blink of an eye. He became a warrior for the O‘ahu chief, Kākuhihewa, during a series of battles with the O‘ahu chief Kūali‘i. “Kalelealuaka flew to the battlefield, slaying many of the warriors, including the captain of Kūali‘i’s forces. Kūali‘i sued for peace and agreed to live as a subject under the dominion of Kākuihiwewa” (Thrum 1907:102).

However, in a second story of the battles in Nu‘uanu, it is Kūali‘i who is the victor:

> In the valley of Waolani, a side valley from the great Nuuanu, stood one of the sacred Heiaus called Kawaluna, which only the highest chief of the island was entitled to consecrate at the annual sacrifice. As Moi of Oahu the undoubted right to perform the ceremony was with *Kualii*, and he resolved to assert his prerogative and try conclusions with the Kona chiefs, who were preparing to resist what they considered an assumption of authority by the Koolaupoko chief. Crossing the mountain by the Nuuanu and Kalihi passes, *Kualii* assembled his men on the ridge of Keanakamano, overlooking the Waolani valley, descended to the Heiau, performed the customary ceremony on such occasions, and at the conclusion fought and routed the Kona forces that had ascended the valley to resist and prevent him. The Kona chiefs submitted themselves, and *Kualii* returned to Kailua. [Fornander 1996:280]

In 1783, the Maui chief Kahekili invaded O‘ahu, landing at Waikīkī. The chief of O‘ahu, Kahahana, resided at Kawānanakoa in upland Nu‘uanu at the time (Kamakau 1992:135). In

Fornander’s (1996) legendary account, Kahekili marched through several places in the vicinity of the current project:

> In the beginning of 1783—some say it was in the month of January—Kahekili, dividing his forces in three columns, marched from Waikiki by Puowaina, Pauoa, and Kapena [in Nu‘uanu], and gave battle to Kahahana near the small stream of Kaheiki. Kahahana’s army was thoroughly routed, and he and his wife Kekua-poi-ula fled to the mountains. [Fornander 1996:224–225]

Kahekili’s forces first moved toward Nu‘uanu Valley and reached Kulaokahu‘a, the arid coastal plain between Honolulu and Waikīkī. The great warrior Pe‘ape‘a, a follower of Kahekili who lived in Mānoa, heard of the Maui’s chief’s movements and ran toward the battle:

> *A lohe o Peapea, haalele iho la ia i ka wahine a holo mai la ma uka mai o Ualakaa, a Makiki, Pauoa, Kaheiki, e pili la me Maemae. Ilaila loaa iaia ka maka mua o na kanaka o Kahekili. A o ko Kahahana aoao hoi, i Waolani ka poe, i Maemae ka maka mua e iho mai ana.*
>
> When Peapea heard this he left his wife and ran above Ualakaa [Roundtop], Makiki, Pauoa, and Kaheiki, which is adjacent to Maemae. There he met the van of the army of Kahekili. As to the forces of Kahahana, the main army was at Waolani, while the front was descending from Maemae. [Fornander 1919:458–459]

At Ma‘ema‘e, which Fornander (1919) places around Wyllie Street (approximately 2 km *mauka* of the current project), Pe‘ape‘a came between the two forces and began to single handedly destroy Kahahana’s army:

> *Pela no kona hele luku ana a hiki i Luakaha, a Nuuanu. Hee o Kahahana ame kona mau alii a holo aku la, o ka nui ua pau i ka make ia Peapea. A puni ae la o Oahu nei ia Kahekili, lawe ae la o Peapea ia Kekuapoi, wahine a Kahahana i wahine nana, mamuli o kona koa ame ka ikaika, a noho iho la.*
>
> Thus he went slaughtering until reaching Luakaha [most *mauka ‘ili*] in Nuuanu. Kahahana and his chiefs were defeated and fled, the majority having been all slain by Peapea. Oahu being conquered by Kahekili, Peapea took Kekuapoi, Kahahana’s wife, as his own, on account of his courage and strength, and [they] lived together. [Fornander 1919:460–461]

3.1 Historical Background

3.1.1 Early Post-Contact Period

In the early post-Contact period, Kou was not a major destination for foreigners visiting the island. A discouraging factor for early trade on O‘ahu was political instability. The ruling chief Peleiōhōlani died around 1779, and his heir, Kumuhana, was almost immediately deposed in a *coup d’etat*. A period of political unrest followed. This included the successful invasion by Kahekili of Maui in 1783; the bloody crushing of the O‘ahu rebellion in 1786; the invasion by the Kaua‘i ruler, Ka‘eokūlani, in 1791; the passing of the rule to Kalanikūpule after Kahekili’s death in 1794; and finally, Kalanikūpule’s defeat by Kamehameha I at the Battle of Nu‘uanu in 1795 (Cordy 2002:42–44).

These events contributed to political and economic instability, which in turn delayed the development of Honolulu as a major port. Other events that diminished O‘ahu’s reputation as a port of call include the *Daedalus* killings in 1792; the mysterious death of Captain Kendrick in 1794; the seizure of the *Jackal* and *Prince Lee Boo* ships, which led to the deaths of Captains Brown and Gordon in 1795; and the wreck of the *Arthur* under Captain Henry Barber in 1796 (Beechert 1991:12–14). The earliest accounts of the south shore of O‘ahu recount the fear of attack; the difficulty of getting water and food, particularly yams (Portlock 1789); and, in one instance, the efforts of natives to seize a whaleboat (Dixon 1789:161).

3.1.1.1 Battle of Nu‘uanu

The Battle of Nu‘uanu, the most significant post-Contact battle, took place when Kamehameha, Hawai‘i Island chief, landed at Waikīkī to fight the forces of O‘ahu. This was Kamehameha’s final battle in his conquest of the island of O‘ahu, which took place in the valley *mauka* of the current project:

> Kamehameha landed his fleet and disembarked his army on Oahu, extending from Waialae to Waikiki. Consuming but a few days in arranging and organizing, he marched up the Nuuanu valley, where Kalanikupule had posted his forces, from Puiwa upwards, occupying Kaumuohena, Kapaeli, Kaukahoku, Kawananakoa, Luakaha, Kahapaakai, Kamoniakapueo, and Nuuanu. At Puiwa the hostile forces met, and for a while the victory was hotly contested; but the superiority of Kamehameha’s artillery, the number of his guns, and the better practice of his soldiers, soon turned the day in his favour, and the defeat of the Oahu forces became an accelerated rout and a promiscuous slaughter. Of those who were not killed, some escaped up the sides of the mountains that enclose the valley on either side, while a large number were driven over the pali of Nuuanu, a precipice of several hundred feet in height, and perished miserably. [Fornander 1996:347–348]

Thomas Thrum (1897) provides additional details regarding how the battle raged at Nu‘uanu:

> […] the position of the Oahu army was on the steep side of the hill, about three miles in the rear of the town of Honolulu. A stone wall protected them in front, and the steepness of the ground availed them against an assault. Believing themselves secure, they defied their enemies with insulting gestures and bravados. A field piece, which Young had brought to bear upon them, knocking the stones about their heads, disordered their ranks and they broke and fled. Its most fatal result was the death of Kaiana, who was killed by this ball. His loss spread consternation among his troops and rendered the victory comparatively easy. The forces of Kamehameha charged; in the onslaught many of the Oahuans were slain, and the rest pursued with great slaughter until they were driven to the end of the valley, which terminates in a precipice of six hundred feet, nearly perpendicular height, forming a bold and narrow gorge between the two forest-clad mountains. A few made their escape; some were driven headlong over its brink, and tumbled, mangled and lifeless corpses, on the rocks and trees beneath; others fought with desperation and met a warrior’s death […] [Thrum 1897:111]

3.1.1.2 Honolulu Harbor

Another factor for the delay in the development of Kou as a major port was the relatively late discovery of Honolulu Harbor, attributed to Captain William Brown in early 1793. Furthermore, Honolulu's prominence had to wait until Kamehameha I established peace and encouraged trade. Kamehameha defeated Kalanikūpule at the battle of Nu‘uanu in 1795 and in 1809, moved his court, government, and residence from Waikīkī to Honolulu. Hence, it was not until the first decade of the nineteenth century that newly arrived foreigners considered Honolulu a place of commercial importance. According to Kuykendall (1938:27), Honolulu was situated in a "rich and productive island and its protected harbor, the only accessible one in the entire group, [which] caused foreign ships to go there in preference to other places." However, into the 1820s, Honolulu remained more notable for its native culture than for Western urbanization. A visitor to Honolulu in 1819 wrote the following:

> The port of Onorourou [Honolulu], generally frequented today by all the European vessels that come to the islands, is without doubt the most favorable location with respect to shelter, commerce, and resources for the supply of ships. The town of Onorourou is located on a large, flat plain. It is on the shores of a bay of the same name. The houses, similar to the most part to those of Owhyhi [Hawai‘i] and of Mowi [Maui], are however interspersed with a certain number of houses built of stone that belong for the most part to Europeans or to Anglo-Americans. [de Freycinet 1978:42]

The 1830s marked a shift in the character of Honolulu as perceived by its inhabitants. By this time, Western commercial and missionary interests had supplanted the Native Hawaiian traditions that had once shaped the environment, and Western and urban ideals propelled Honolulu's growth. Such ideals found expression in events like the formal naming of streets, which commenced in September 1836. At that time, the *Sandwich Island Gazette* began soliciting suggestions for street names from its readers. Among those accepted were King Street, Beretania Street, and Garden Lane (Thrum 1884).

3.1.1.3 Francisco de Paula Marín

The history of the Gillilands in Hawai‘i (after whom the John R. Gilliland Sr. Building in the current AIS study area is named) begins first with Francisco de Paula Marín. Marín was a horticultural experimenter who acquired his knowledge as a youth working in the Andalusian vineyards of Spain. In 1793 or 1794, he traveled to Hawai‘i, where he was befriended by Kamehameha I. Marín served as Kamehameha's interpreter and assumed many government duties. Kamehameha, in turn, gave land to Marín for his agricultural experiments, and Marín introduced numerous plant species to the Islands (Gast and Conrad 1973). Marín had at least three wives of Hawaiian blood and many children. He was known for his flourishing gardens and vineyards, as well as for his reluctance to share those crops with friends and acquaintances; hence, the Hawaiian corruption of his name "Manini" has become a slang word for miserly (Encyclopaedia Britannica 2019).

Most of the current AIS study area is within land formerly owned by Marín, known as "The Vineyard" (see Figure 12 and discussion below of LCA 2938). Around 1813 or 1814, Marín travelled to California to obtain grape cuttings and other plants, which he brought back to O‘ahu. The site of the first planting of the grape cuttings was likely at his land on the harbor front (the

foot of present-day Fort Street); however, the following year (1815), he began a larger planting at his “new vineyard,” described as follows:

> The site of this planting was in the area known as Kalawahine, which had been allotted to Jonathan Winship [pioneer of the sandalwood trade, which Marín had encouraged to Kamehameha to enter] by the king. It was located at the confluence of Nuuanu and Pauoa streams, close to what is now Kukui and River streets […]. Marin had asked Kalanimoku [high chief, similar to a prime minister] for land in which to plant his vines, and Kalanimoku arranged with Winship for the use of part of the Kalawahine holding. [Gast and Conrad 1973:50]

From that time onward, wine-making was almost a year-round activity for Marín. Years later, when a new street adjacent to its *mauka* boundary was constructed, it was called Vineyard Street.

Jacques Arago visited the vineyard in 1819 and described it as follows:

> Yesterday, I made a very interesting excursion, and visited the vineyard of Marin […]. It is situated on the slope of a beautiful hill. The foot of which is watered by a small river bordered by palma christi [castorbean; *Ricinus communis*], banana and superb cocoa-nut trees. I gathered some of the grapes from the vine and found them excellent. [Hee 1955 in Gast and Conrad 1973:52]

Ten years later (1829), C.S. Stewart visited the vineyard and described it as follows:

> We had scarcely passed a hundred rods from the village before we found something new to admire in the yard of Mr. Marini. After crossing a small stream which bounds it on one side, our path led us the whole length of another. It is well planted and cultivated, and yields grapes sufficient to make considerable quantities of wine. Along the fences in some parts are bushes of the damask rose in full bloom, which appeared to fine advantage, in contrast with the pale yellow blossom of the cotton tree, with which they are interspersed. The vineyard is also skirted with pineapples, in different stages of maturity […] [Stewart n.d. in Gast and Conrad 1973:52]

3.1.2 Mid-1800s

3.1.2.1 The Māhele

The Organic Acts of 1845 and 1846 initiated the process of the Māhele, the division of Hawaiian lands, which introduced private property into Hawaiian society. In 1848, the crown and the *ali‘i* received their land titles. *Kuleana* (commoner) awards for individual parcels within the *ahupua‘a* were subsequently granted in 1850. These awards were presented to tenants, Native Hawaiians, naturalized foreigners, non-Hawaiians born in the Islands, or long-term resident foreigners who could prove occupancy on the parcels prior to 1845 (Chinen 1958).

Land Commission Award (LCA) documentation provides information on land use within the AIS study area. Historical maps show the majority of the AIS study area as within LCA 2938 to Huanu, for the heirs of Lahilahi (Gilliland ‘Ohana [Family]) (Figure 12 and Figure 13). Huanu is the “grandson of Marin” (see above discussion of Francisco de Paula Marín), and this claim is for “farm land in the vineyard” (Waihona ‘Aina 2019). According to LCA documentation, “P. Manini [another name for Marín] formerly held this land from Kamehameha I, having received it from

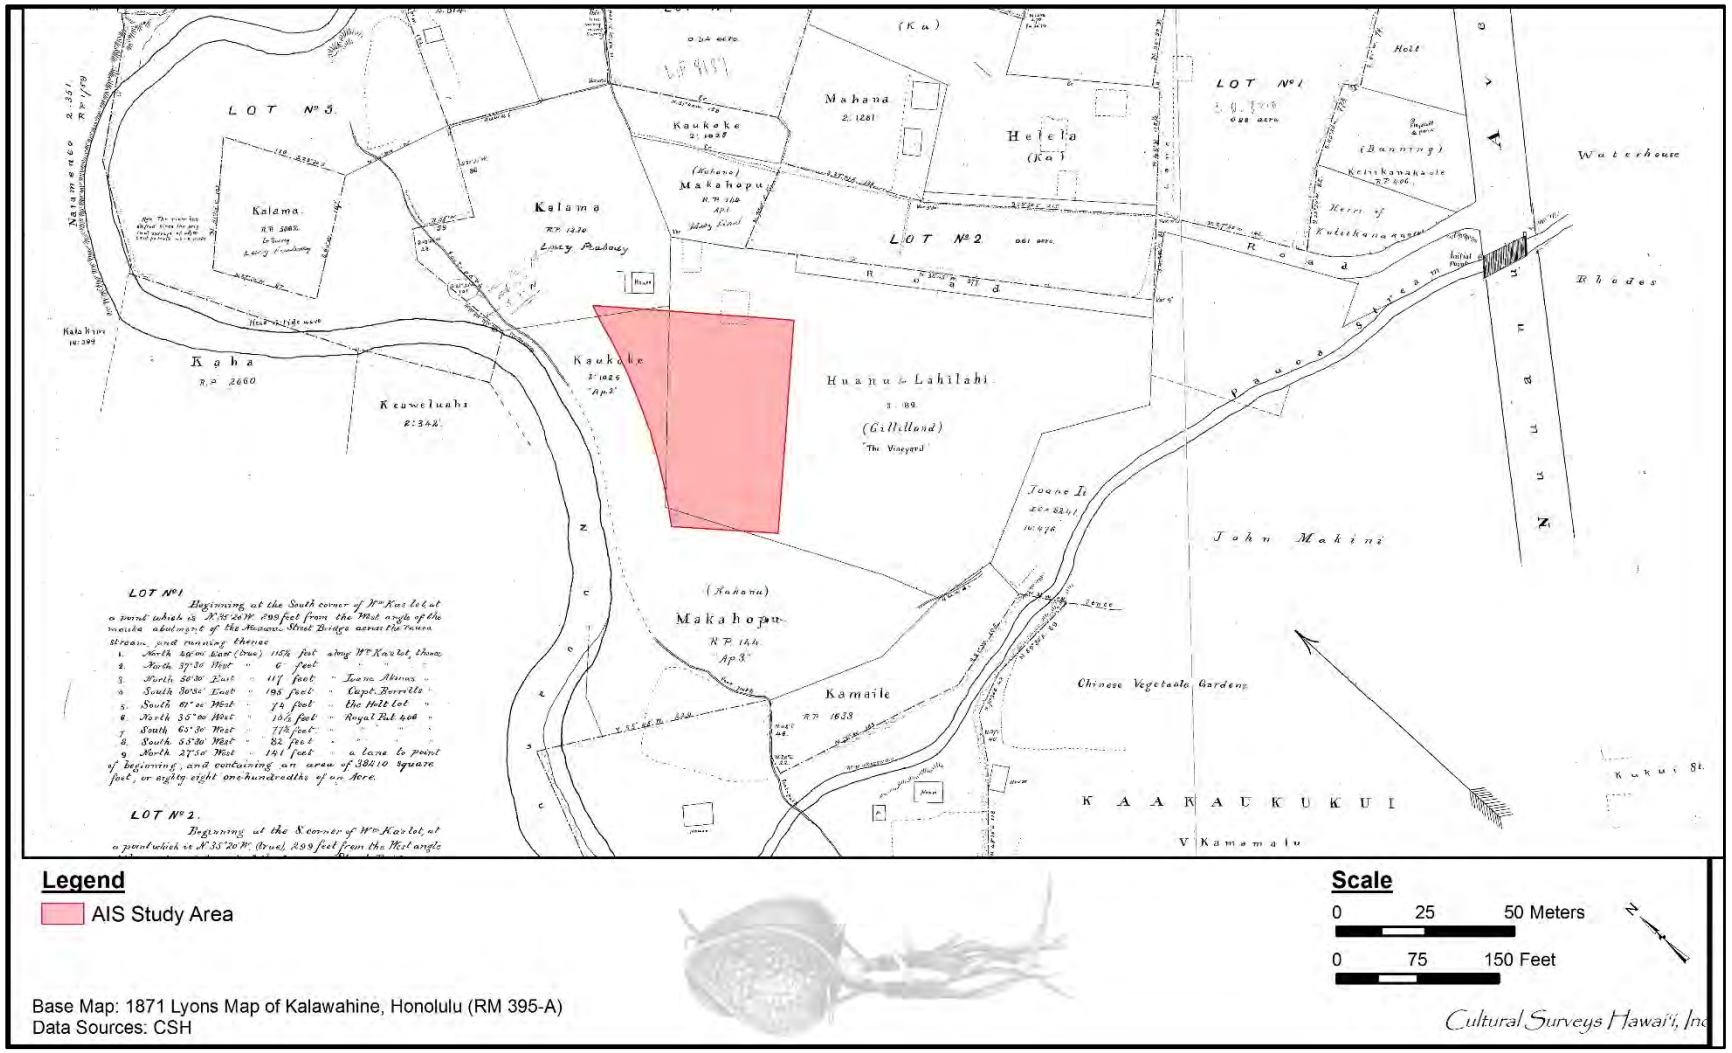

Figure 12. 1871 Lyons map of Kalawahine, Honolulu (RM 395-A), showing LCAs in the vicinity of the AIS study area

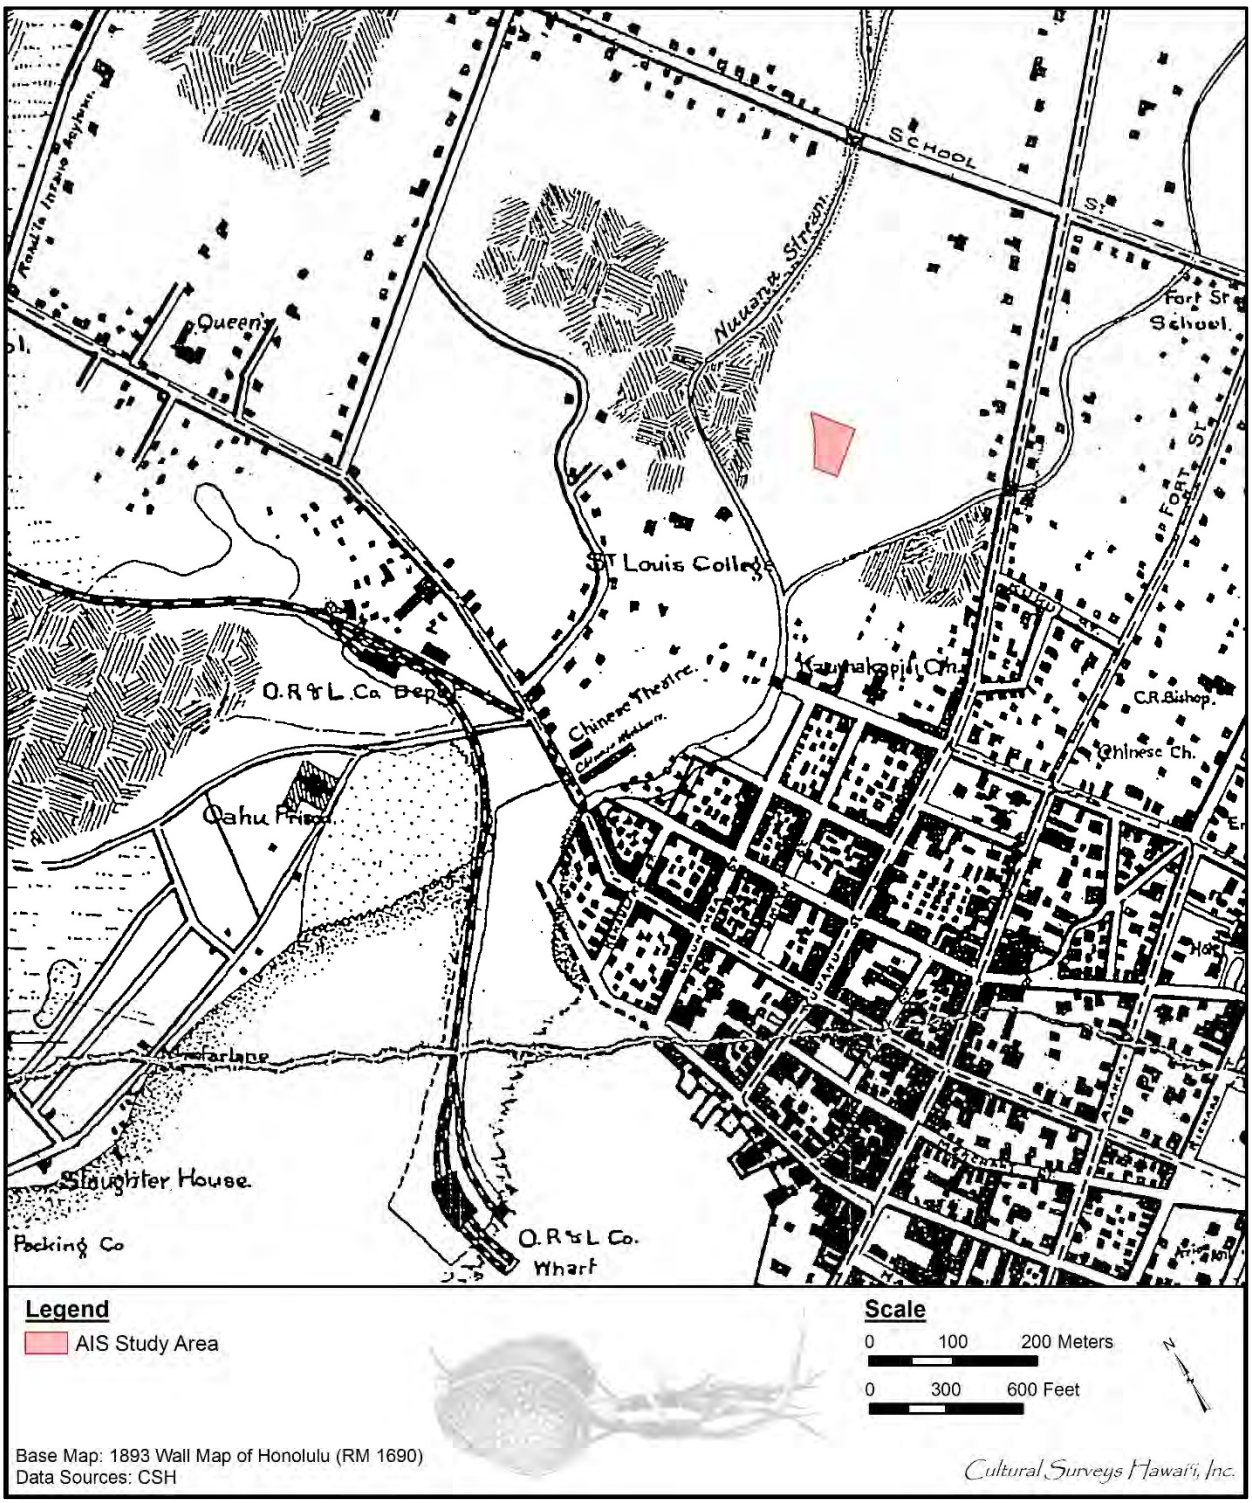

Figure 13. 1893 Dodge and Wall map of Kamanuwai Block and a Part of Kamakakela (RM 1651), showing LCAs in the vicinity of the AIS study area

him. On death of Manini, it came to his daughter, Lahilahi, and on her death to her children […]. The lot is fenced round and has been cultivated and never disputed" (Waihona ‘Aina 2019). The parcel comprises 2.311 acres.

Most of the ‘Ewa (northwest) portion of the AIS study area is within LCA 11082:3 to Kaukoke. The parcel is 330.8 *anana* (Hawaiian unit of measurement equivalent to the distance between the fingertips of the outstretched arms, approximately 2 yards [Mattimoe and Nagao 1967]). In addition, small sections in the west corner of the AIS study area appear to overlap with LCA 141:2 and 3 to Makahopu (also called Makahoku). According to LCA documentation, Makahopu "made the fence and a house and planted food […]. There are some lahala [*Pandanus tectorius*] trees planted on the land by Kaahumanu's orders" (Waihona ‘Aina 2019). ‘Āpana (lot) 2 is 105.9 *anana*, while ‘Āpana 3 is 1,133.7 *anana*. Additionally, the far north corner of the AIS study area may be within LCA 715:1 to Kalama. This claim for four taro patches and a house site comprises 1.03 acres. LCA documentation is included in Appendix B.

Landscape features (solid and dashed lines) depicted within the AIS study area on the 1871 Lyons map and the 1893 Dodge and Wall map (see Figure 12 and Figure 13) may represent the boundaries between LCAs and/or agricultural or house plots within LCAs. A structure is also indicated as partially within the northeast portion of the AIS study area.

3.1.2.2 Mentions of Kalāwahine in Hawaiian Language Newspapers

Two notices published in *Ka Hae Hawaii* in 1861 describe the prohibition of people and animals, including horses, cows, mules, and donkeys, from trespassing upon the fields of Kalāwahine (*Ka Hae Hawaii* 10 and 31 July 1861). The second notice additionally describes a prohibition on the collection of firewood at the mountain in Kalāwahine, without permission from the *konohiki* (land supervisor) P. Naone. These prohibitions were placed by "L. Haalelea," presumably referring to Liwai (Levi) Ha‘alelea, the son of Ha‘alou, governor of Moloka‘i under Kalaimoku. Ha‘alelea was a Hulumanu (court favorite) of Kamehameha III and was elevated to chief upon his marriage to Kekauonohi, daughter of Kamehameha I, around 1848 (Barrere 1994).

A 31 October 1861 notice in *Ka Hoku o Ka Pakipika* announces the auction of the estate of Po, which included five *lo‘i* at Kalāwahine.

In addition, two birth and death announcements for residents of Kalāwahine appeared in *Ka Nupepa Kuokoa*. Nawahinelua was born on 22 April 1862 (*Ka Nupepa Kuokoa* 10 May 1862), while Kaili passed away on 25 June 1865 (*Ka Nupepa Kuokoa* 6 July 1865).

3.1.3 Late 1800s

3.1.3.1 Increased Urbanization

The first efforts to deepen Honolulu Harbor were made in the 1840s. The idea of using the dredged material composed of sand and crushed coral to fill in low-lying lands was quickly adopted. From 1857 to 1870, the "Esplanade" between Fort and Alakea streets was created on 22 acres of former reef and tideland. By 1874, Sand (Quarantine) Island, site of the first immigration station, had been created over "reclaimed" land on reefs.

In 1846, Honolulu was made the capitol of the Hawaiian Kingdom and was well on its way to becoming the commercial and political hub of the Islands. Charles Wilkes, commander of the U.S.

Exploring Expedition, visited Hawai‘i in 1841 and related that Honolulu was “very conspicuous from the sea and has more the appearance of a civilized land, with its churches and spires, than any other island in Polynesia” (Wilkes 1856:373). Honolulu was in a period of rapid change during the latter half of the nineteenth century, and Reverend Sereno Bishop (1916) offered a unique perspective on the changes in the layout of Honolulu and the buildings that lined the streets:

> When I returned to Honolulu in 1853, after an absence of thirteen years, I was struck by the many changes […]. The major portion of the residents of Honolulu still lived in thatched houses [in 1840]. In fact the town was almost entirely composed of this kind of dwellings […]. When I went away there were only Punchbowl Road, Beretania Street, King Street and Merchant Street. This was the condition of the city in 1840. [Bishop 1916:58]

Beginning at the start of the whaling era (ca. 1820) and extending into the 1840s and 1850s, when seamen came ashore for “rest and relaxation,” the downtown area from Nu‘uanu Street west to Nu‘uanu Stream was a district of “dilapidated native huts and tenements, tiny bar-rooms, coffeeshops, and run-down boarding houses, all turning to the harbor for their opportunities and income” (Daws 2006:239). However, there was some movement of wealthy Caucasian residents into the lower section of Nu‘uanu in the mid- to late nineteenth century. Malcolm Brown (1918) noted the following:

> Towards the latter part of the 1800’s, Nuuanu became the fashionable residential district, and there were many beautiful homes lining Nuuanu Ave. and the cross streets in the valley […]. The houses were big because there were many children in most families, and the house lots were large because they needed pasture space for their horses. [Brown 1918:28]

By the late 1800s, historical maps show increasingly dense land use and urbanization in the vicinity of the current project, particularly *makai* of the subject parcel (Figure 14 through Figure 17). St. Louis College, approximately 100 m west of the current project, was established in 1883 by Right Reverend Hermann, D.D. (Doctor Divinitatis), Bishop of Olba. Hermann recruited teachers from the United States and intended for the school to be a first-class preparatory, classical, and commercial school. The school initially comprised a single two-story brick building; however, due to the influx of students, additional accommodations were later constructed (Alexander 1896). The gradual expansion of the campus can be seen in Figure 15 through Figure 17.

3.1.3.2 Realignment of Nu‘uanu Stream

Another change in the late nineteenth century was the realignment of Nu‘uanu Stream. In the late nineteenth century, spurred by the deaths during the recent cholera epidemic, the government began to plan and institute public improvements to the roads, bridges, sewer systems, and streams in the western Honolulu area. Thomas Thrum (1896), editor of the *Hawaiian Almanac and Annual*, reported on these improvements in his annual retrospect of the preceding year:

> The new spirit of public improvements […] has been pushed with vigor. The relaying of larger water mains through a number of streets and completion of the new pumping plant, auxiliary to the reservoir system, was effected in time to do valuable service during the cholera period by shutting off the reservoir supply with its possible contamination, and flushing the mains with artesian water […]. The

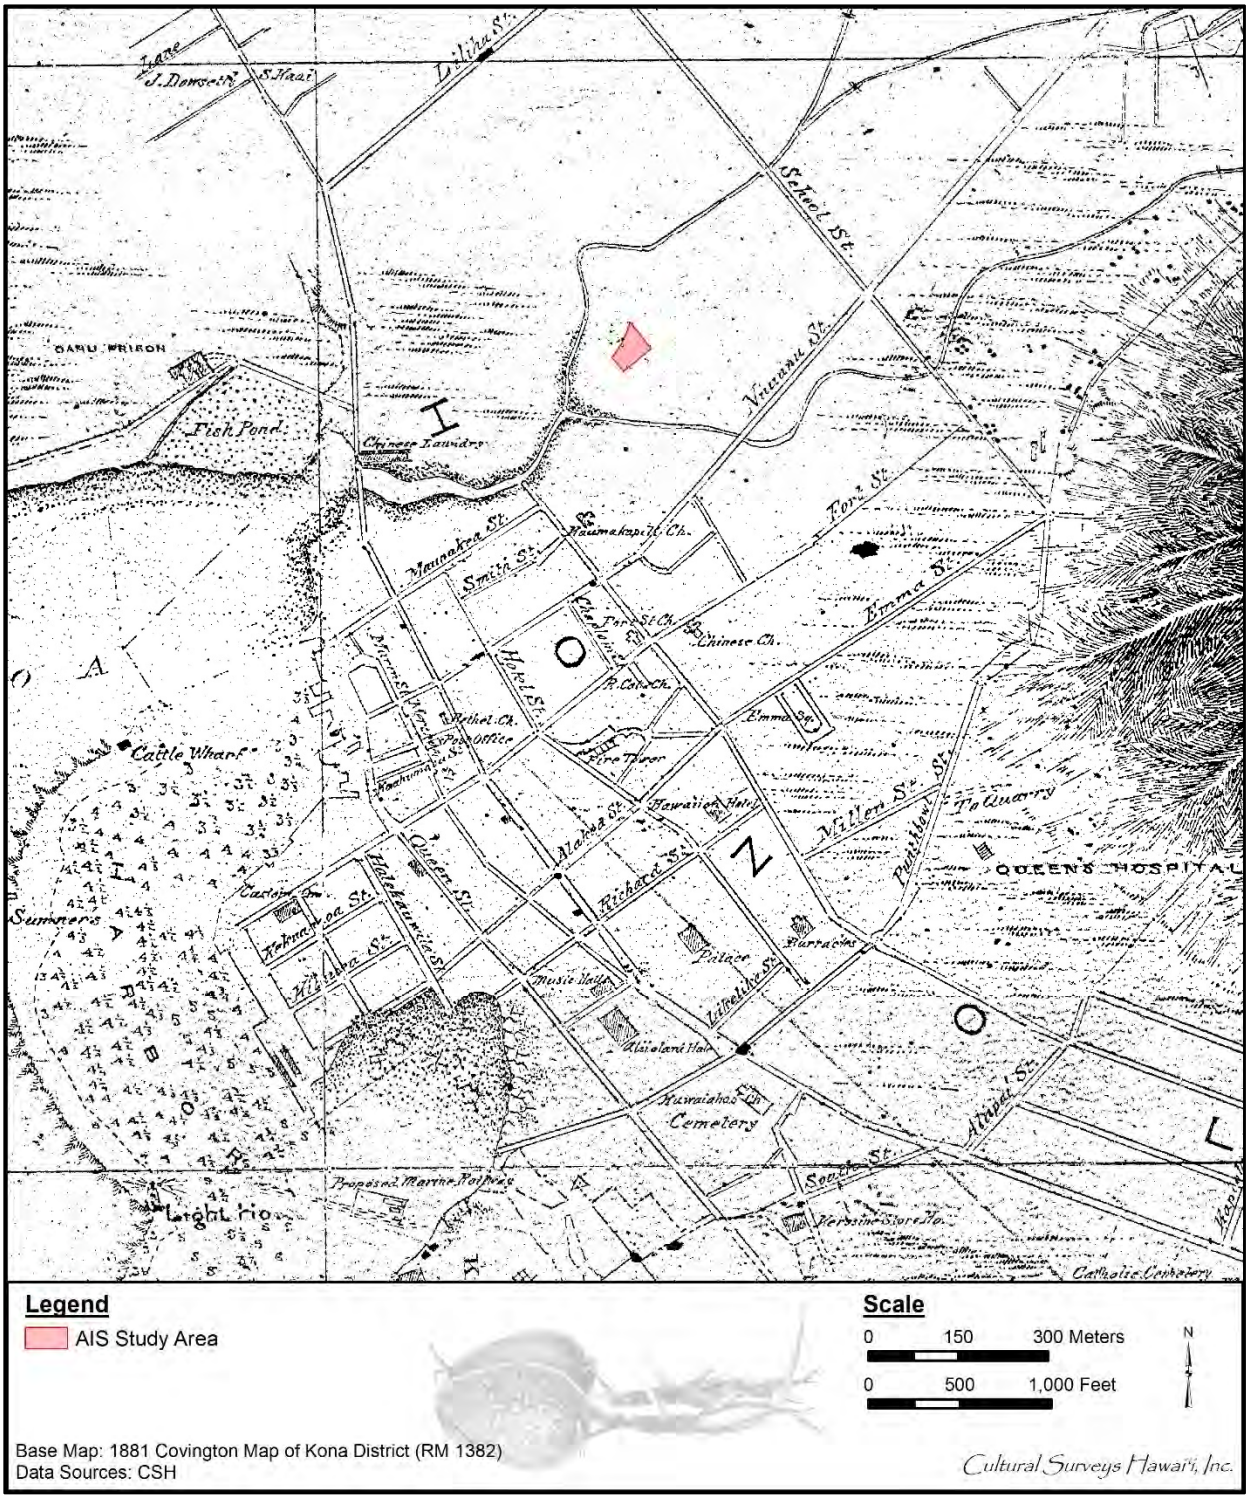

Figure 14. Portion of the 1881 Covington map of Kona District (RM 1382), showing urban development *makai* of the AIS study area

> enlargement of the inner harbor by dredging, with contemplated increased wharfage facilities along the extension of Queen street toward the King street bridge has already been entered upon. The dredging serves the further beneficial purpose of filling in the low land partly occupied, till recently, by the old wash houses, on the northern side of Nuuanu stream which is to be assigned to park [Aala Park] purposes for the benefit of the residents in that part of the city and the improvement of its sanitary condition. This, with the change of the wash houses to Iwilei, and the hurried occupancy of the new market, and destruction of the old one, were imperative health measures adopted during the cholera visitation. [Thrum 1896:144]

Beginning in 1896, Nu‘uanu Stream was dredged, and the water course was changed. The stream was diverted from approximately 100 m west of the current AIS study area to nearly adjacent to it (see Figure 11 through Figure 17). A stone wall was built on both sides of the stream, and dredged material was used to create River Street, adjacent to the current AIS study area (Hurst 1992). Due to the infilling and stabilization of the Nu‘uanu stream banks, more substantial wood structures could be built, replacing the adobe cottages and dilapidated shacks of the early years.

3.1.4 1900s to Present

Honolulu in the late nineteenth century consisted of many unpaved streets and several small lanes (that no longer exist) between major roads. Bishop Street, the main road now between Fort and Alakea streets, did not exist. However, by 1919, Honolulu had wide paved streets with blocks of contiguous brick and stone stores along all major downtown roads. The first section of Bishop Street, between Fort and King streets, was built in 1900. This street quickly became the financial sector of the city, and many of the “Big Five” companies (Castle & Cooke, Alexander & Baldwin, C. Brewer & Company, American Factors [now Amfac], and Theo H. Davies & Company) built their headquarters and their banks on this street (Ames 1996:27). By 1918, the section from the harbor to King Street had been completed and paved (Ames 1996:119). In 1919, the *mauka* extension of Bishop Street from Hotel to Beretania streets began. The city condemned all the property in the way of this new thoroughfare and, in 1927, razed all of the buildings (Ames 1996:120).

3.1.4.1 Chinatown

In 1852, there were only about 71 Chinese living around Honolulu, most of whom had come to the Islands as merchants and continued to carry out this trade. That year, sugar planters began to import large numbers of Chinese “coolies” to work on their sugar plantations. Once their contracts were fulfilled, some of the workers moved to Honolulu to open their own businesses in the area that came to be known as Chinatown. The unsanitary and over-populated area alarmed the white business class, who noted that “[m]ost Chinese businesses were housed in decaying buildings on the depressed lower blocks of Nu‘uanu and Maunakea Street, and in Chinatown the womanless coolies congregated to gamble, smoke opium or simply pass the time” (Daws 2006:300). By the 1870s, a sizeable population of Chinese immigrants had settled in Honolulu, concentrated in the blocks between Nu‘uanu and Maunakea streets (see Figure 16). An 1878 census recorded 1,299 Chinese in Honolulu; the total city population numbered 14,114.

In 1899, the first case of bubonic plague was identified in Hawai‘i, in a Chinese bookkeeper named You Chong. After an examination by Dr. G.H. Herbert, who noted a high temperature and

swelling in the groin, the patient died the next night. After an autopsy, the diagnosis of bubonic plague was determined. Since the disease had broken out in the immigrants' area of Honolulu, all Chinese and Japanese were barred from leaving Honolulu for other ports. Two other cases were reported the same day, and the Board of Health laid down a strict quarantine for Chinatown (area bound by Nu‘uanu, Kukui, River, and Queen streets; just *makai* of the current project). Approximately 7,000 people, primarily Chinese and Japanese immigrants, lived and worked in this area (Iwamoto 1967:122–124). A third ethnic group who inhabited this area were Hawaiians, numbering approximately 1,000, on land their families had occupied for generations (Mohr 2005:63).

From 12 December 1899 to 31 March 1900, 71 cases of bubonic plague were reported; 61 people died, 41 of whom lived within the established Chinatown quarantine area. The Board of Health concluded they could not contain the plague and decided the best remedy was to set "sanitary fires" to infected wooden buildings. Forty-one controlled fires were set between 31 December 1899 and 13 August 1900 as follows:

> Therefore, on December 30, after careful deliberation, the Board of Health chose fire as the 'surest, most thorough, and most expeditious' method. Fire would destroy the plague germs, kill rats, cleanse the soil and open it up to the purifying influence of sun and air, and would prevent any occupancy of the premises until a safe period of time had elapsed. [Iwamoto 1967:124]

Infected patients were moved to a quarantine camp at Kaka‘ako. Some people, not necessarily patients, whose houses were burned were housed at the barracks of the Kaka‘ako Rifle Range. Their belongings were stored in the cellars of Kaumakapili Church, approximately 200 m south of the current project (see Figure 14 through Figure 17).

On 20 January 1900, a fire set between Kaumakapili Church and Nu‘uanu Avenue quickly got out of control. Rising winds swept burning embers to the roof of the church; the fire then jumped to several other blocks and then to the wharfs:

> By 1:30 p.m. the fire began making its way from Beretania Street along Achi Lane toward Kukui Street. People feared that the *mauka* section of the city would be destroyed. Chinatown refugees rushed back to save belongings, but were driven back by fire and smoke; they formed a seething mob near the bridge and Kukui Street […]. The Chinese consul and vice consul also circulated among the people and tried to pacify them, since at this time the Chinese believed that the Board of Heath had purposely burned their homes. [Iwamoto 1967:130–131]

No one was killed in the fire, but Chinatown was destroyed. Many people were homeless and bereft of all belongings, which were lost when Kaumakapili Church burned to the ground. No additional patients were identified with the disease in April 1900, and the Hawaiian Islands were declared free of the plague (Iwamoto 1967:125, 129).

The Chinatown Historic District (SIHP # -9986) is approximately 200 m *makai* (southwest) of the current project. The buildings are typically two or three stories, with older buildings made of brick, wood, or cut stone, and newer buildings made of concrete or steel. Despite the relatively small population of Chinese currently living in Chinatown, this area still serves as the principle

center for the business and social life of the Chinese community of the island (Historic Hawai‘i Foundation 2015-2016).

3.1.4.2 Foster Botanical Garden

Foster Botanical Garden comprises 21.02 acres of land adjoining Nu‘uanu Stream in downtown Honolulu. The garden can be divided into two sections. The southern section, called Foster Garden, is 13.55 acres. The northern section, called Lili‘uokalani Garden, is 7.475 acres. Although there are no major architectural features within the garden, the historic landscaping, which includes a large number of historic trees, makes this area significant to the history of Hawai‘i (Follmer 1988).

In 1855, William Hillebrand, a German physician and botanist, settled on approximately 6 acres of purchased and leased land west of Nu‘uanu Avenue and east of Nu‘uanu Stream. Hillebrand propagated trees and cultivated a botanical garden there until he returned to Germany some 20 years later. In 1880, ship owner Thomas Foster and his part-Hawaiian wife, Mary, purchased the property. Mary Foster expanded the existing garden by increasing the acreage of the property and planting additional trees. In 1919, she leased 2 acres to the Hawaiian Sugar Planters' Association for an experiment station (Follmer 1988).

In 1884, Princess (later Queen) Lili‘uokalani purchased the land that came to be known as Lili‘uokalani Garden from the estate of Queen Kalama, wife of Kamehameha III. During most of her adult life, Lili‘uokalani kept a small house on the property, just above the falls. In 1912, five years before her death, the newly established Lili‘uokalani Trust transferred the Queen's land to the Civic Federation of Honolulu as a park and recreation ground. The Civic Federation then acquired additional lots in the area and, in 1916, transferred 2.75 acres of land to the City of Honolulu. The City subsequently added another 4.75 acres to the garden (Follmer 1988).

In 1930, Mary Foster bequested her home and garden, comprising 5 acres, to the City of Honolulu; an additional 8.5 acres was subsequently added. Foster Botanical Garden (SIHP # -1389) is the core of a botanical garden system that collectively contains the most diverse tropical plant collection in the United States (Follmer 1988). It is approximately 50 m *mauka* (northeast) of the current project, just across Vineyard Boulevard (Figure 28 through Figure 31).

3.1.4.3 Development within the Current AIS Study Area

A review of twentieth century historical maps and aerial photographs (Figure 18 through Figure 31) indicates urban development within the AIS study area by 1906. At that time, a tenement was at the center of the AIS study area, while several dwellings and stores were along the northwestern boundary; a kitchen facility was in between the tenement and the stores (see Figure 18 and Figure 20). The stores included a Plumbing and Tin Shop, a restaurant, and a Mattress Factory (see Figure 20 and Figure 23). By 1950, additional dwellings were within the eastern and southeastern portions of the AIS study area, and a parking area for automobiles was at the south corner (see Figure 27). The stores along the northwestern boundary, although in the same location, were described as having concrete floors by that time; hence, these buildings may have been remodeled or rebuilt between 1927 and 1950.

The John R. Gilliland Sr. Building was constructed within the AIS study area in 1958; it is visible on 1968 and 1982 aerial photographs (see Figure 29 and Figure 31). Fung Associates (Hibbard and Chiu 2016) assessed this two-story commercial building as eligible for listing on the National Register under Criterion C. They assert that the building is architecturally significant as

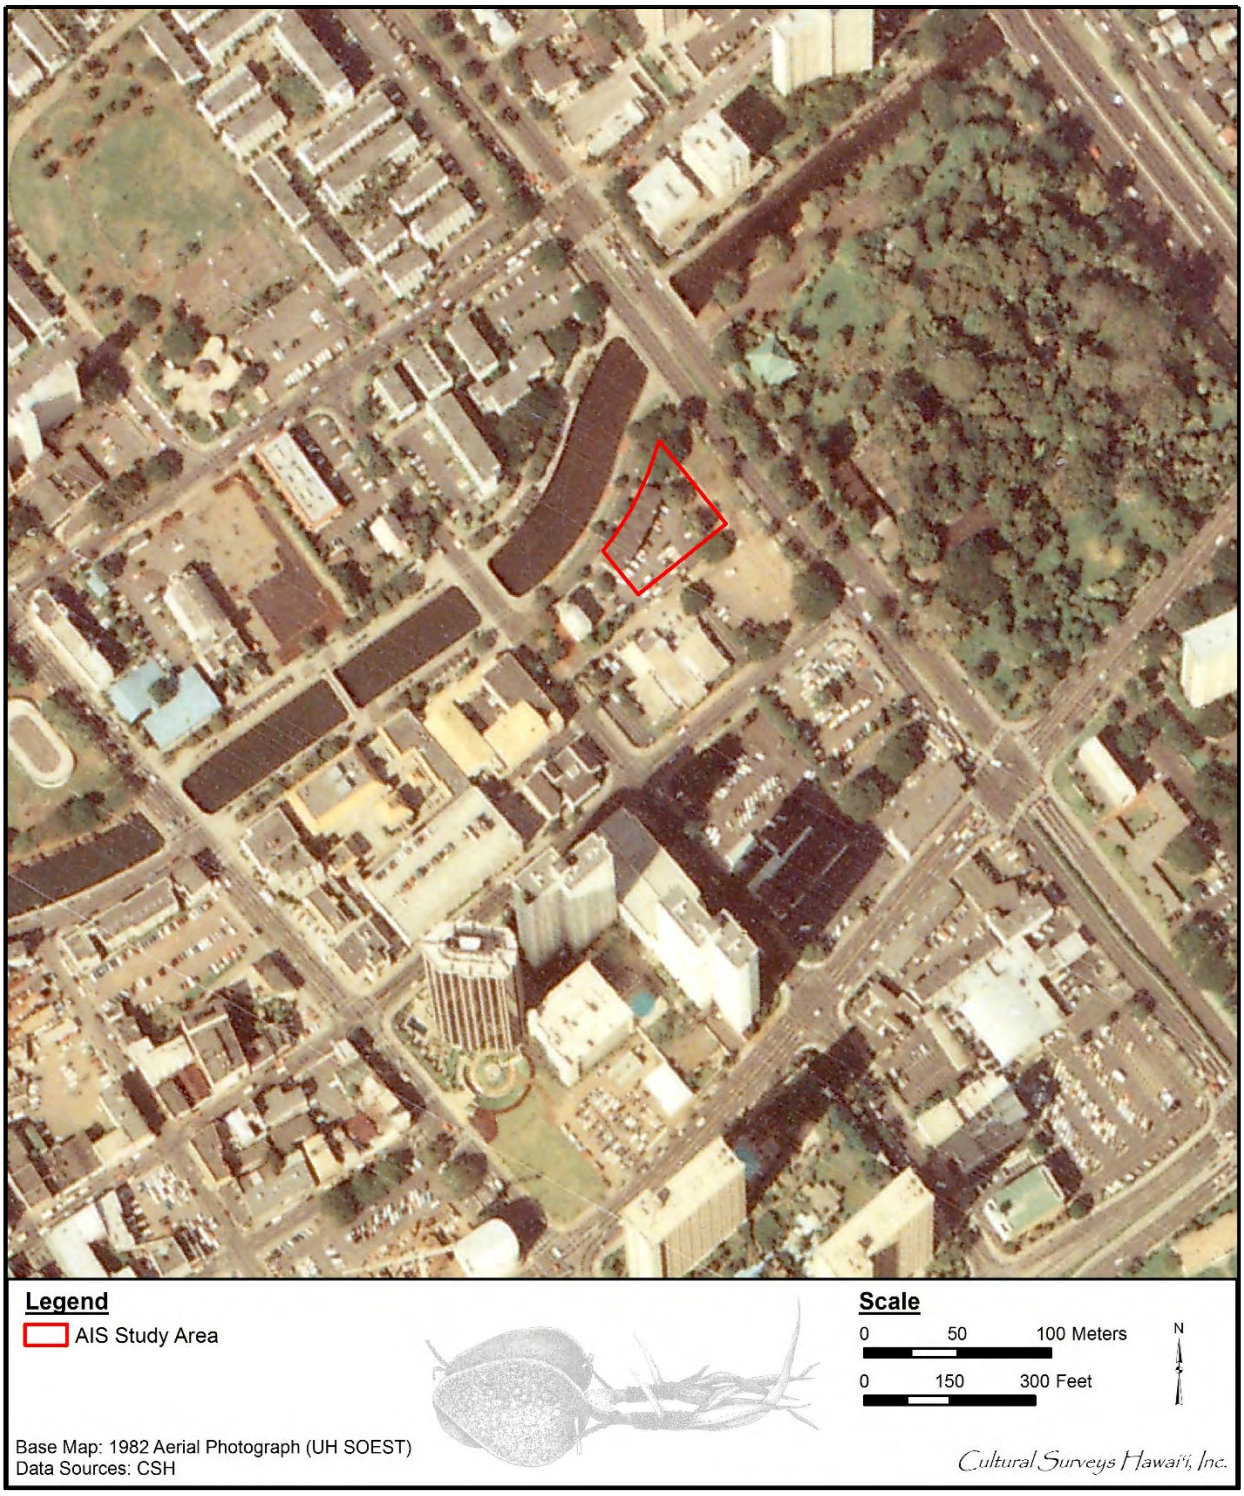

Figure 31. 1982 aerial photograph (UH SOEST), showing the AIS study area

Figure 32. The John R. Gilliland Sr. Building within the AIS study area (from Hibbard and Chiu 2016)

a very good example of a small retail/office building constructed in Hawai‘i in a modern style in the 1950s, and that it is typical of its period in design, materials, workmanship, and construction methods.

The John R. Gilliland Sr. Building is also a good example of the architectural work of Kenneth Sato. Sato was born in Kahuku on O‘ahu and received a civil engineering degree from the University of Hawai‘i. He owned the Kewalo Steel Company and designed a number of churches, apartments, and low-rise commercial buildings. He also worked on a number of public schools and bridges for the Territory of Hawaii. Other works by Sato include the Miyamoto buildings at 1331 Nu‘uanu Avenue and the Door of Faith Church on Young Street in Honolulu (Hibbard and Chiu 2016).

As of the 2016 study by Fung Associates, only two spaces on the ground floor of the building were occupied: Uptown Café and Hanagasa Inn, with both restaurants serving local/Asian food. Chikara Mochi formerly occupied the space south of Hanagasa Inn. Hibbard and Chiu (2016) also noted three Royal Ponciana trees (*Delonix regia*) lining the sidewalk fronting the building (i.e., the River Street southeast sidewalk) (see Figure 32), and the asphalt-paved parking lot occupying the rear portion of the property. According to Hibbard and Chiu (2016), the rear parking lot was improved and enclosed in 1966 by a concrete masonry unit (CMU) retaining wall.

3.2 **Previous Archaeological Research**

No previous archaeological studies have been conducted within or adjacent to the current AIS study area. Below is a discussion of previous studies in the vicinity, which are depicted on Figure 33 and summarized in Table 1. Historic properties previously identified in the vicinity are depicted on Figure 34.

3.2.1 Erkelens et al. 1994; Goodwin 1997; Goodwin and Allen 2005

In 1994, IARII conducted an AIS for the Kekaulike Revitalization project, Diamond Head Block in the Chinatown Historic District (SIHP # 50-80-14-9986) (Goodwin 1997). The survey identified more than 100 features, designated as SIHP # -4875. At least one of the features was assessed as pre-Contact, while others were determined to be from the first approximately 70 years following Western Contact. Other residential and commercial features dated to the first 50 years of Chinese immigration, along with several from the twentieth century.

The survey also identified human skeletal remains, which were part of a secondary burial containing the incomplete remains of three individuals (Erkelens et al. 1994). Represented in these remains were a male aged 24-30, a female aged 15-18, and a female aged 3-4. These individuals were likely moved from their original context during construction of a post-1900 water line; hence, the original internment may have occurred during the nineteenth century. Erkelens et al. (1994) hypothesize that the individuals may have been victims of the 1860 Chinatown fire.

IARII subsequently conducted data recovery from 2 August to 30 September and 7 October 1994 (Goodwin and Allen 2005). Staff archaeologists recovered artifacts and charcoal that indicated the area was in use as early as the thirteenth century, with heavy occupation occurring from the early to mid-nineteenth century. Four compounds and a blacksmith’s shop, dating partly to the early nineteenth century, were excavated. The 8,552 collected artifacts were associated with a variety of ethnic groups (Hawaiian, Euro-American, and Asian). They included porcelains, earthenware, stoneware, lithics, fishhooks, pendants, a *poi* (taro corm paste) pounder, metal, coins, beads, bottles, glass shards, bone, and shell. Identified features included post molds, living floors, firepits, refuse pits, and fence lines. The large amount of faunal bone recovered included species present in the pre-Contact period (pig, dog, turtle, chicken, shark, fish, and Pacific rat), as well as post-Contact introductions (cow, horse, goat, sheep, domestic cat, and the Norway/roof rat).

Human fetal remains were found in a refuse deposit (Feature 338) during data recovery. Osteological analysis determined the fetus was carried into the second or beginning of the third trimester of pregnancy before a premature birth or miscarriage; there was no evidence of deliberate burial (Erkelens et al. 1994). Artifacts within Feature 338 suggest it dates to 1850-1880.

3.2.2 Kennedy et al. 1994; Riley et al. 1995

Kennedy et al. (1994) conducted an AIS for the Kekaulike Revitalization project, ‘Ewa Block, bounded by King, River, Hotel, and Kekaulike streets (Kennedy et al. 1994). Investigations consisted of nine backhoe trenches and three hand-excavated test units. Two historic properties were identified: SIHP # -4587, a small pond, and SIHP # -4588, a multi-component historic property consisting of 53 features of various functions spanning the pre- to post-Contact periods. The features included 20 post holes, three pits of indeterminate function, three fire pits, three cut stone walls, seven crushed coral foundations, a burn layer (possibly from the 1900 or 1902

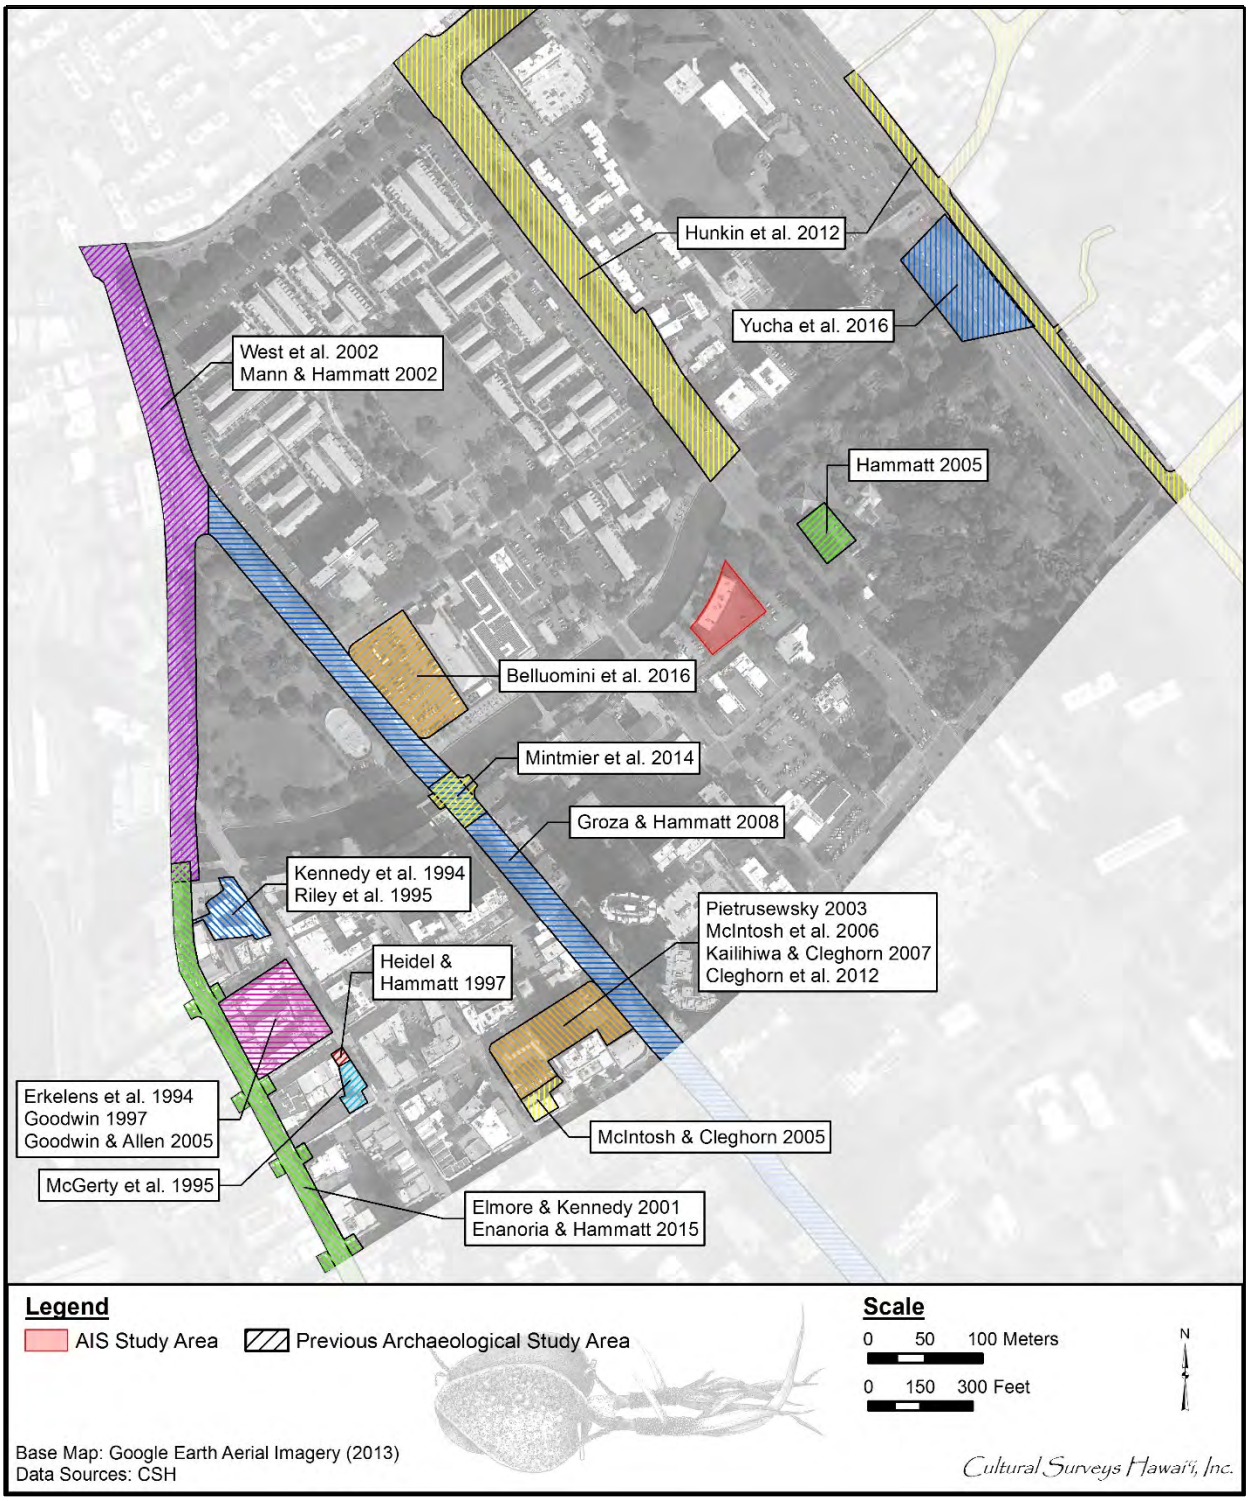

Figure 33. Previous archaeological studies in the vicinity of the AIS study area (Google Earth 2013)

Table 1. Previous archaeological studies in the vicinity of the AIS study area

Reference	Type of Study	Location	Results (SIHP # 50-80-14-****)
Erkelens et al. 1994	Burial report	Kekaulike revitalization, Diamond Head (DH) block	Documented four sets of human skeletal remains associated with SIHP # -4875
Kennedy et al. 1994	Archaeological inventory survey	Kekaulike revitalization, ‘Ewa block	Identified SIHP # -4587, a small fishpond, and SIHP # -4588, a multi-component historic property consisting of 53 features dating from pre-Contact period to twentieth century, including three human burials
McGerty et al. 1995	Archaeological assessment (no finds AIS)	Chinatown Community Service Center	Background research of project area and immediate surroundings indicated pre-Contact agriculture and habitation and urban development associated with Chinatown; AIS recommended
Riley et al. 1995	Data recovery	Kekaulike revitalization, ‘Ewa block	Documented 55 features spanning early pre-Contact period through twentieth century; C14 dating of SIHP # -4587, fishpond, yielded an early tenth century date; dating of SIHP # -4588, coral reef stone platform, yielded an eleventh century date
Goodwin 1997	Archaeological inventory survey	Kekaulike revitalization, DH block	Identified SIHP # -4875, consisting of over 100 features and six culturally enriched strata; majority of features interpreted as Native Hawaiian from early post-Contact period but also included historical and modern features and structural remnants; documented a single burial
Heidel and Hammatt 1997	Archaeological testing	1,700-sq-ft lot in Chinatown	No historic properties identified in four test excavations
Elmore and Kennedy 2001	Archaeological monitoring	King St, between River St and Bethel St	Identified one in situ, flexed human burial (SIHP # -5781) between Maunakea St and Smith St

Reference	Type of Study	Location	Results (SIHP # 50-80-14-****)
Mann and Hammatt 2002	Archaeological monitoring	King St rehabilitation	Identified one incomplete, previously disturbed, human burial (SIHP # -6317) near intersection of King St and Punchbowl St and a pit feature containing non-human skeletal remains at corner of King St and Richards St (no SIHP # assigned)
West et al. 2002	Archaeological monitoring	King St, between Liliha St and River St	Identified Honolulu Rapid Transit & Land Company (HRT&L) trolley (SIHP # -5942) and associated artifacts
Pietrusewsky 2003 (in Kailihiwa and Cleghorn 2007)	Osteological analysis	Smith-Beretania parking lot	Identified remains of two children, five young adults, and 16 adults of Asian, Caucasian, and/or Polynesian descent (SIHP # -6772)
Goodwin and Allen 2005	Data recovery	Kekaulike revitalization, DH block	Excavated four house compounds and a blacksmith’s shop (SIHP # -4875); C14 dating indicated area in use as early as thirteenth century; four human burials documented
Hammatt 2005	Burial report	Foster Botanical Gardens (180 N Vineyard Blvd)	Human bone fragments recovered from backdirt and reinterred on botanical garden grounds (SIHP # -1389)
McIntosh and Cleghorn 2005	Archaeological inventory survey	Pearl St. One Bldg	Identified SIHP # -6691, a four-component historic property composed of two disturbed sets of human remains, two historical trash pits, charred remains of Chinatown structure destroyed in 1900 Chinatown fire, and remnant of historic building that partially collapsed in 2001
McIntosh et al. 2006	Archaeological inventory survey	Smith-Beretania parking lot	Documented SIHP # -6772, which includes trash pits, a cooking feature, building structural foundations, traditional and historic artifacts, and abundant midden deposits
Kailihiwa and Cleghorn 2007	Archaeological monitoring	Smith-Beretania parking lot	Documented SIHP # -6772, including 23 sets of human remains
Groza and Hammatt 2008	Archaeological monitoring	Beretania St between King St and Alapa‘i St	No historic properties identified, likely due to prior disturbance

Reference	Type of Study	Location	Results (SIHP # 50-80-14-****)
Cleghorn et al. 2012	Data recovery	Smith-Beretania parking lot	Documented SIHP # -6772, consisting of pits, privies, and other features with traditional Hawaiian artifacts and two human burials
Hunkin et al. 2012	Archaeological monitoring	Kalihi/Nu‘uanu sewer project	Identified an isolated human bone fragment in fill (no SIHP # assigned)
Mintmier et al. 2014	Archaeological monitoring	Intersection of Beretania St and River St	No historic properties identified
Enanoria and Hammatt 2015	Archaeological monitoring	King St between Bethel St and River St	No historic properties identified
Belluomini et al. 2016	Archaeological inventory survey	American Savings Bank Campus (300 N Beretania St)	Identified SIHP # -7933, human remains and associated features; SIHP # -7934, LCA boundary wall remnants; and SIHP # -7935, building foundation remnants
Yucha et al. 2016	Archaeological monitoring	H-1 from Middle St to Ward Ave	No historic properties identified

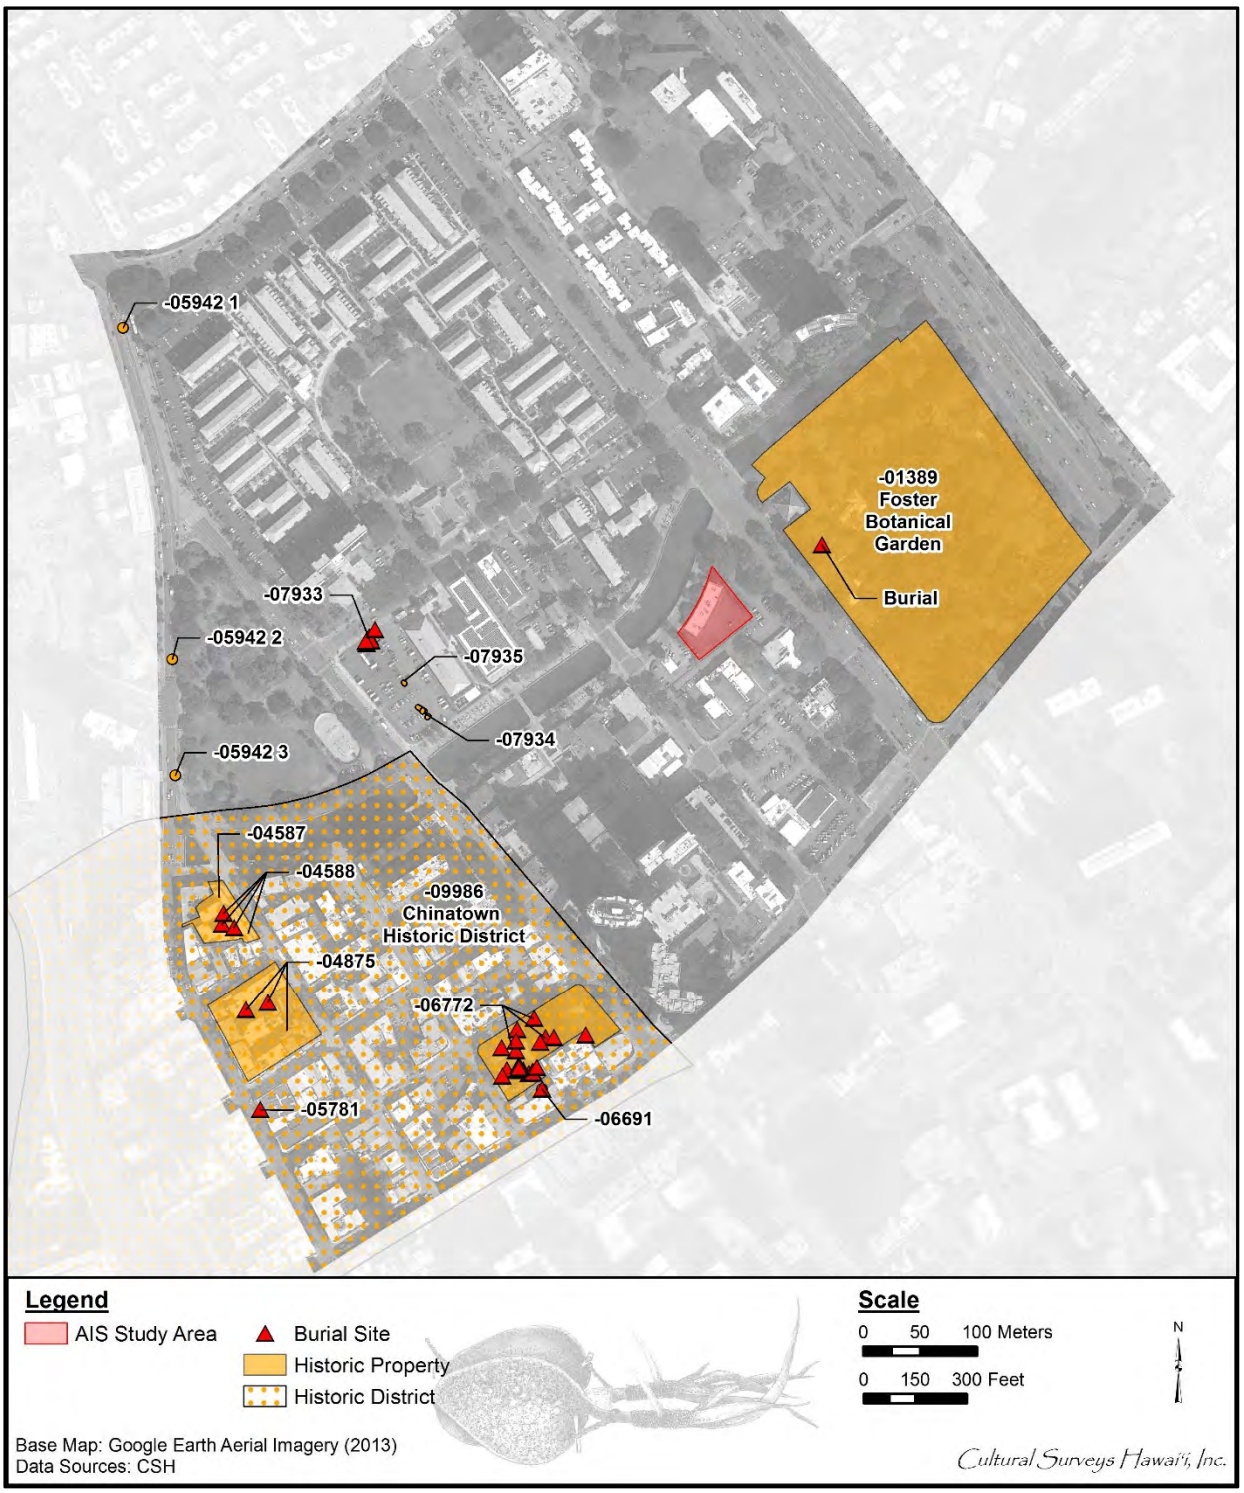

Figure 34. Aerial photograph with overlay of historic properties, historic districts, and human burials in the vicinity of the AIS study area

Chinatown fires), historic trash pits, and three human burials (two likely historical and one likely traditional Hawaiian) (Kennedy et al. 1994).

Subsequently, Riley et al. (1995) conducted data recovery for SIHP #s -4587 and -4588. Sixty-four test units were excavated, and 55 features documented; these inlcuded three additional human burials. Radiocarbon dating of charcoal from SIHP # -4587 yielded a much earlier date than expected, within the tenth century. As the dated charcoal was obtained from behind the pond wall, the radiocarbon date was believed to represent the construction or renovation of the pond. Investigations indicated use of the pond continued up to the 1860s, when it was in-filled.

Analysis of the documented features of SIHP # -4588 indicated an extensive timeline of occupation of the study area. Features ranged from the tenth and eleventh centuries (as evidenced by the pond and a coral reef stone platform with the remnants of a possible human burial), to the seventeenth and eighteenth centuries (as evidenced by a hard-packed living surface with associated traditional Hawaiian artifacts), through the nineteenth century (as evidenced by a latrine pit, a Kaua‘i *poi* pounder, and traditional style fishhooks made from copper), and up to the twentieth century.

Osteological analysis of the three human burials identified during data recovery and the three burials documented during the AIS identified five of the six individuals as being of Chinese descent. The other individual was in a “pre-Western contact” context and was assessed as likely Native Hawaiian.

3.2.3 McGerty et al. 1995

In 1995, McGerty et al. (1995) conducted background research for the Chinatown Community Service Center project. Research included a review of previous archaeological studies in the vicinity, *mo‘olelo* (stories) of the area, archival documents, and historical maps. The study indicated that pre-Contact land use comprised agriculture and habitation. During the historical period, which saw the growth of urban Honolulu Town, the area (known as Kikihale) transformed into a portion of Chinatown and contained a shifting complex of small businesses.

3.2.4 Heidel and Hammatt 1997

In 1997, CSH conducted archeological testing at a 1,700-sq-ft parcel (TMK: [1] 1-7-003:014) in Chinatown (Heidel and Hammatt 1997). Four test trenches yielded no cultural features or materials, with the exception of a historical basement filled with modern debris and sediment. The report does not present a possible association or date of occupation for the basement, and no SIHP number was assigned (Heidel and Hammatt 1997).

3.2.5 Elmore and Kennedy 2001

Elmore and Kennedy (2001) conducted archaeological monitoring for miscellaneous sidewalk improvements on King Street, between River Street and Bethel Street. One in situ human burial, designated as SHIP # -5781, was identified between Maunakea Street and Smith Street, beneath the *mauka* lane of King Street. Based on the burial’s flexed position and lack of post-Contact artifacts, the burial was assessed as likely Native Hawaiian. Artifacts recovered from the backdirt pile included glass and ceramic fragments, a shark tooth, possible drilled shell fragments, a possible shark tooth tool, and one fishhook; however, none could be definitively associated with the burial.

3.2.6 Mann and Hammatt 2002

In 2002, CSH conducted archaeological monitoring for the King Street Rehabilitation project on sections of King Street, between Dillingham Boulevard and South Street (Mann and Hammatt 2002). One human burial, designated as SIHP # -6371, was identified near the intersection of South King Street and Punchbowl Street, *makai* of Honolulu Hale. The skeletal remains were incomplete and poorly preserved due to previous disturbance by construction activities; the SHPD took custody of the remains. In addition, a pit feature containing a substantial quantity of non-human skeletal remains was documented at the corner of South King Street and Richards Street; no SIHP number was assigned.

3.2.7 West et al. 2002

In 2002, Garcia and Associates (GANDA) conducted archaeological monitoring for the installation of water mains along King Street, between Liliha Street and River Street (West et al. 2002). One previously recorded historic property, structural remnants of the Honolulu Rapid Transit & Land Company Trolley (SIHP # -5942), was documented in multiple locations. Documented remnants include railroad ties, metal hardware, and bricks. Small sections of the trolley track (not in situ) were exposed atop fill material, which overlay coral bedrock. Identified cultural material included glass bottles and jars, handmade leather shoes, ceramics, faunal bone (pig, cow, and chicken), shell, wood, charcoal, Belgian Block cobblestones, and metal hardware.

3.2.8 Pietrusewsky 2003; McIntosh et al. 2006; Kailihiwa and Cleghorn 2007; Cleghorn et al. 2012

In 2001, Pacific Legacy conducted an AIS for Block 10, Smith-Beretania Parking Lot, in Chinatown (McIntosh et al. 2006). Six backhoe excavations yielded abundant post-Contact structural materials and artifacts with 68 associated subsurface features, designated as SIHP # -6772. The features included trash pits, cooking features, and building structural foundations with associated European, American, and Asian artifacts; traditional Hawaiian artifacts; and abundant midden deposits. Most of the structural remnants dated between 1850 and 1900 and were likely associated with the buildings destroyed in the 1900 Chinatown fire. Post-Contact artifacts consisted of glass, metal, ceramic, and bone, indicating a wide variety of functions. Fewer Native Hawaiian artifacts were recovered; these included *poi* pounder fragments, an *‘ulu maika* (game stone), cowrie shell lures, a complete stone adze, and a complete conch shell trumpet.

Subsequently in 2001, Pacific Legacy conducted data recovery for Block 10, Smith-Beretania Parking Lot, to mitigate the impacts to SIHP # -6772 (Cleghorn et al. 2012). Data recovery excavations identified numerous pits, privies, and miscellaneous features with traditional Hawaiian and post-Contact artifacts. Two human burials, one adult and one child, were also documented.

In 2002, Pacific Legacy conducted archaeological monitoring for Block 10, Smith-Beretania Parking Lot (Kailihiwa and Cleghorn 2007). Additional features, deposits, and human remains associated with SIHP # -6772 were identified; these consisted of six non-burial features and 22 human burials. In addition, 20 “find spots” (locations where collected artifacts were not associated with a cultural layer or deposit) were documented. The human remains were primarily identified near the south wall of the Smith-Beretania apartment structure.

Dr. Michael Pietrusewsky (2003) analyzed the human remains and determined they could represent individuals of Asian, Caucasian, and/or Polynesian descent. His analysis revealed the remains included two children, five young adults, and 16 adults; hence, he suggests a portion of the study area may have served as a family cemetery. All burials were inventoried, excavated, mapped, and reburied on the property.

3.2.9 Hammatt 2005

In 2004, CSH received a call from Terry Hildebrand of the City and County of Honolulu Department of Design and Construction, reporting a discovery of human remains during trenching activities at Foster Botanical Gardens (SIHP # -1389) (Hammatt 2005). Dr. Sara Collins of the SHPD noted that the remains, which included a maxilla fragment and portion of a long bone, were found in a previously disturbed context. CSH archaeologists screened the backdirt in which the maxilla fragment was found and recovered additional remains, including a long bone, clavicle, fragments of a mandible, loose teeth, and rib fragments. The remains were reinterred on the grounds of the botanical garden near the western side of the Kuan Yin Temple.

3.2.10 McIntosh and Cleghorn 2005

In 2005, Pacific Legacy conducted an AIS at the corner of Nu‘uanu Avenue and Pauahi Street (McIntosh and Cleghorn 2005). A multi-component historic property, SIHP # -6691, was identified. SIHP # -6691 comprises the incomplete remains of two disturbed human burials within two historical trash pits; the charred remains of a structure destroyed in the 1900 Chinatown fire; and structural remnants of a historical building that partially collapsed in 2001. McIntosh and Cleghorn (2005) concluded the burials had been previously disturbed and incorporated into later trash pits, likely during the early 1900s.

3.2.11 Groza and Hammatt 2008

In 2008, CSH conducted archaeological monitoring for the Rehabilitation of Streets project on an approximately 1,800-m (5,900-ft) segment of Beretania Street, between North King Street and Alapa‘i Street (Groza and Hammatt 2008). No historic properties were identified, and extensive fill deposits were encountered. In the eastern portion of the study area, the natural sediment consisted of volcanic cinder from the Sugar Loaf/Tantalus series. In the western portion, the natural sediment was silty clay loam with clay inclusions, likely alluvial deposits from nearby Nu‘uanu Stream.

3.2.12 Hunkin et al. 2012

In 2011, CSH conducted archaeological monitoring for the Kalihi/Nu‘uanu Sewer Rehabilitation project, which extended from Middle Street in Kalihi west toward Pi‘ikoi Street near the eastern boundary of Punchbowl Crater (Hunkin et al. 2012). No historic properties were identified. The study area’s subsurface deposits appeared to have been disturbed by past land use, including extensive earthmoving activity and importation of fill sediments. However, a single isolated human bone fragment was discovered in fill material. The custody of this skeletal fragment was transferred to the SHPD on 4 August 2008, and treatment of the fragment was carried out under the SHPD’s authority. No SIHP number was assigned.

3.2.13 Mintmier et al. 2014

Pacific Consulting Services, Inc. (PCSI), conducted archaeological monitoring for traffic infrastructure improvements at the intersection of Beretania and River streets, partially within the Chinatown Historical District, SIHP # -9986. No contributing features/components of SIHP # -9986, nor any new historic properties, were documented. Eighteen glass and ceramic artifacts were collected and dated to the late nineteenth to mid-twentieth century.

3.2.14 Enanoria and Hammatt 2015

In 2013, CSH conducted archaeological monitoring for rehabilitation and replacement of water, gas, sewer, and drain lines along King Street and at each of the cross-street intersections between River and Bethel streets (Enanoria and Hammatt 2015). In general, the documented stratigraphy consisted of a series of fill sediments associated with the construction of the existing asphalt surface and the construction of subsurface utilities, overlying disturbed natural alluvium, natural volcanic cinder, and the coral shelf. No historic properties were identified.

3.2.15 Belluomini et al. 2016

In 2016, CSH conducted an AIS for the American Savings Bank Campus at 300 North Beretania Street. Subsurface testing identified three historic properties: SIHP #s -7933, -7934, and -7935. SIHP # -7933, identified in the northwest portion of the study area, consists of seven human burials (Burials 1–7) and six associated features (Features 8–13). SIHP # -7934, identified in the southeast portion of the study area, consists of structural remnants interpreted as LCA boundary walls and designated as Features 1–3. SIHP # -7935 consists of the structural remnants of a building foundation, identified in the central portion of the study area.

3.2.16 Yucha et al. 2016

Between 2013 and 2014, CSH conducted archaeological monitoring for the H-1 Resurfacing project from Middle Street to Ward Avenue. As archaeological monitoring was conducted only for excavations conducted deeper than the overlying asphalt/concrete surfaces, monitoring was limited to the area of the Nu‘uanu Stream Bridge widening and lighting replacement activities, identified as Project Area 3. The archaeologists documented a series of highly disturbed fill deposits that averaged more than 100 cm in depth. No historic properties were identified.

3.3 Background Summary and Predictive Model

The current project is within the portion of downtown Honolulu surrounding the mouth of Nu‘uanu Stream, known to Hawaiians as “Kou.” This area was a center of population and activity similar to Waikīkī. Kou had a long tradition as a royal center, where the *ali‘i* would meet and entertain. Kou also possessed shoreward fishponds and irrigated fields, and nearby Honolulu Harbor was brimming with marine resources. The land surrounding Nu‘uanu Stream was particularly densely populated, with a concentration of *lo‘i* and *‘auwai*. Historical maps show the AIS study area as within that dense cluster of *lo‘i*.

In the early post-Contact period, Kou was not a major destination for foreigners visiting the island. However, in 1809, Kamehameha moved his court, government, and residence from Waikīkī to Honolulu, and newly arrived foreigners began to consider Honolulu a place of commercial importance. By the 1830s, Western commercial and missionary interests had supplanted the Native Hawaiian traditions that had once shaped the environment, and Western and urban ideals propelled

Honolulu’s growth. The Organic Acts of 1845 and 1846 initiated the process of the Māhele, the division of Hawaiian lands, which introduced private property into Hawaiian society. Historical maps indicate most of the ‘Ewa (northwest) portion of the AIS study area was within LCA 11082:3 to Kaukoke, while small sections in the western corner appear to overlap with LCA 141:2 and 3 to Makahopu. LCA documentation indicates these parcels included a house, a fence, and agricultural plots. In addition, the far north corner of the AIS study area may have been within LCA 715:1 to Kalama, who claimed four taro patches and a house site. Landscape features (solid and dashed lines) depicted on late nineteenth century maps as within the AIS study area may represent the boundaries between the LCAs and/or agricultural or house plots within the LCAs. A building or structure is also indicated as partially within the northeast portion of the AIS study area.

However, the majority of the AIS study area was within LCA 2938 to Huanu, for the heirs of Lahilahi (Gilliland ‘Ohana). Huanu was the grandson of Francisco de Paula Marín, and the claim was for “farm land in the vineyard” (Waihona ‘Aina 2019). The history of the Gillilands in Hawai‘i (after whom the John R. Gilliland Sr. Building in the current AIS study area is named) begins first with Francisco de Paula Marín, a Spanish horticultural experimenter. In 1793 or 1794, Marín traveled to Hawai‘i, where he was befriended by Kamehameha I. He served as Kamehameha’s interpreter and assumed many government duties. Kamehameha, in turn, gave land to Marín for his agricultural experiments, and Marín introduced numerous plant species to the Islands. Marín’s land within the current AIS study area was known as “The Vineyard,” which he planted with grape cuttings sourced from California in 1815. Visitors to the vineyard also reported seeing damask rose (*Rosa damascena*) bushes, cotton (*Gossypium* sp.) trees, and pineapples (*Ananas comosus*) growing on the parcel.

By the late 1800s, historical maps show increasingly dense land use and urbanization in the vicinity of the current project, particularly *makai* of the parcel in an area that came to be known as Chinatown. By the 1870s, a sizeable population of Chinese immigrants had settled in Honolulu, concentrated in the blocks between Nu‘uanu and Maunakea streets. Today, this area still serves as the principle center for the business and social life of the Chinese community of the island.

Another change in the late nineteenth century was the realignment of Nu‘uanu Stream. Beginning in 1896, Nu‘uanu Stream was dredged, and the water course was changed, with the stream diverted from approximately 100 m west of the current project to nearly adjacent to it. A stone wall was built on both sides of the stream, and dredged material was used to create River Street, adjacent to the current AIS study area.

A review of twentieth century historical maps and aerial photographs indicates development within the AIS study area by 1906. At that time, a tenement was at the center of the AIS study area, while several dwellings and stores were along the northwestern boundary; a kitchen facility was in between the tenement and the stores, which included a Plumbing and Tin Shop, a restaurant, and a Mattress Factory. By 1950, additional dwellings were present in the eastern and southeastern portions of the AIS study area, and a parking area for automobiles was in the south corner. The stores along the northwestern boundary were by that time described as having concrete floors.

The John R. Gilliland Sr. Building was constructed within the AIS study area in 1958. In 2016, Fung Associates assessed this two-story commercial building as eligible for listing on the National Register under Criterion C, as a very good example of a small retail/office building constructed in

Hawai‘i in a modern style in the 1950s. It is also a good example of the architectural work of Kenneth Sato, who designed several notable buildings in the Islands. According to the study, the rear parking lot was improved and enclosed by a CMU retaining wall in 1966.

Mauka (northeast) of the AIS study area, across Vineyard Boulevard (named for Marín's vineyard), is Foster Botanical Garden (SIHP # -1389), which is the closest previously identified historic property to the current AIS study area (approximately 50 m away). In 2004, human remains were encountered during trenching activities in the southern portion of the garden (Hammatt 2005). The remains were found in a previously disturbed context and were reinterred on the grounds; no SIHP number was assigned. No previous archaeological studies have been conducted within or adjacent to the current AIS study area. However, previous studies in the vicinity have documented pre- and post-Contact habitation layers with associated features, including human burials; infrastructure remnants with associated artifacts; historical trash pits; buried fishpond sediment; LCA boundary wall remnants; and disturbed/displaced human remains.

Based on this background research, it was anticipated that the current AIS could identify buried agricultural deposits and features associated with taro and/or grape cultivation; pre- and/or post-Contact habitation layer(s) with associated features, potentially including human remains; landscape features or structural remnants associated with LCA boundaries; and twentieth century structural remnants with associated artifacts and/or historical trash pits.

Section 4 Results of Fieldwork

The fieldwork component of the Halewai‘olu Senior Residences AIS was conducted between 1 and 30 July 2019 under the general supervision of Matt McDermott, M.A. (Principle Investigator), and Ena Sroat, B.A. (Project Director). The subsurface testing program consisted of 15 test excavations (T-1 through T-12, including T-2B, T-2C, and T-9B), comprising 13 exterior excavations and two interior excavations (Figure 35). The maximum depth of the excavations ranged from 160 to 252 cm below surface (cmbs). The water table was encountered in ten of the 15 test excavations, between 193 and 247 cmbs.

4.1 Historic Properties Identified

One archaeological historic property was newly identified during the Halewai‘olu Senior Residences AIS: SIHP # 50-80-14-8840, subsurface cultural deposits (see Figure 35). SIHP # -8840 consists of three components, designated as Components 1–3. SIHP # -8840 Component 1 consists of agricultural deposits, including possible agricultural berms. SIHP # -8840 Component 2 consists of two habitation layers with associated pit features and a human burial site. SIHP # -8840 Component 3 consists of historical infrastructure remnants associated with the residential and commercial growth of Honolulu.

4.2 Stratigraphic Overview

Stratigraphy within the AIS study area was designated using a Roman numeration system (e.g., Stratum I, II, III), with substrata designated using an alphabetic system (e.g., Stratum Ia, Ib, Ic). Although the alphabetic substrata designations within the Roman numeral designations may vary between test excavations, the Roman numeral stratigraphic designations correlate across the study area, so that stratigraphic patterns can be clearly documented and discussed (Table 2 and Table 3).

All current land surfaces and fill deposits, as well as SIHP # -8840 Component 3 infrastructure remnants, are designated as Stratum I; these are associated with the modern development of the area. All SIHP # -8840 Component 3 infrastructure remnants are given feature numbers; former surfaces and fill deposits are also given stratum designations. The underlying vertical series of natural alluvial deposits is designated as Stratum II; this includes interpreted habitation layers (SIHP # -8840 Component 2) and agricultural deposits (SIHP # -8840 Component 1). Like Stratum I, Stratum II was documented in all 15 test excavations. The Stratum II deposits likely represent overflow or flooding episodes of nearby Nu‘uanu Stream. The two uppermost alluvial deposits, Strata IIa and IIb, contain evidence of cultural use in some areas; within those

Table 2. Stratigraphic designations

Stratum	Sediment Description
I	Modern developed land, fills, and infrastructure remnants (SIHP # -8840 Component 3)
II	Naturally deposited alluvium, including habitation layers (SIHP # -8840 Component 2) and agricultural deposits (SIHP # -8840 Component 1)
III	Streambed

excavations, they are designated as part of SIHP # -8840 Component 2, habitation layers. The underlying strata (Strata IIc–IIg) represent at least three periods of agricultural use, likely associated with wetland taro agriculture along the banks of Nu‘uanu Stream. In test excavations where these layers contain evidence of agriculture (e.g., oxidized [red] mottling), they are designated as part of SIHP # -8840 Component 1.

The most recent agricultural deposit (Stratum IIc in T-2, T-2B, T-3 through T-8, T-10, and T-12; Stratum IId in T-9 and T-9B) was identified almost ubiquitously across the AIS study area, within 12 of the 15 test excavations. It contains a dense latticework of oxidized (red) mottling, believed to be the result of chemical interactions between taro roots and the surrounding soil, and in some areas, cinder gravel. The layer generally presents as dark brown silty clay loam. Deeper (i.e., older) agricultural deposits were identified within a discrete zone in the central/*mauka* portion of the AIS study area (within T-4, T-5, and T-7 through T-9B). These strata contain a similar latticework of oxidized (red) mottling, although generally less dense than the overlying stratum.

The basal stratum, Stratum III, is interpreted as a streambed and may represent a former braid delta of Nu‘uanu Stream, pre-dating the deposition of the Stratum II alluvium. Stratum III was documented in nine test excavations (T-1, T-2, T-2B, T-2C, T-9, T-9B, and T-10 through T-12) in the northwestern portion of the AIS study area, closest to Nu‘uanu Stream. Stratum III typically presents as very dark grayish brown sandy clay, sandy clay loam, or silty clay loam. This stratum is distinct from the overlying alluvial series for its inclusion of abundant waterworn basalt gravel and cobbles.

4.3 Subsurface Testing Results

4.3.1 Test Excavation 1 (T-1)

Test Excavation 1 (T-1) is an exterior excavation near the southwestern boundary of the AIS study area. It is oriented northwest-southeast and is 6 m long by 0.85 m wide, with a maximum depth of 230 cmbs. The water table was encountered at 200 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia) and associated extremely gravelly (basalt) loamy sand base course (Stratum Ib), very gravelly sand (crushed coral) base course (Stratum Ic), a second layer of extremely gravelly (basalt) loamy sand base course (Stratum Id), and cobbly (basalt) silty clay fill (Stratum Ie), overlying an oil-rolled crushed coral surface with associated very gravelly (basalt) sandy loam base course (Strata If and Ig; SIHP # -8840 Component 3, Feature 1), atop silty clay (Stratum IIa; SIHP # -8840 Component 2), three layers of silty clay loam (Strata IIb–IId), and very gravelly (basalt) silty clay loam (Stratum III) (Figure 36 through Figure 39 and Table 4).

The oil-rolled, crushed coral surface and associated base course (Strata If and Ig) are designated as SIHP # -8840 Component 3, Feature 1. Strata If and Ig were documented within all four trench walls, although they were absent from the northeast corner of the excavation (see Figure 36 through Figure 40). Each layer is approximately 10 cm thick, and the base course (Stratum Ig) contains pig (*Sus scrofa*) bone, brick, glass, and ceramic fragments. The pig bone and a grab sample of artifacts were collected. Diagnostic artifacts are of primarily Asian origin and date from the mid-nineteenth to twentieth century. One machine-made bottle fragment (Accession [Acc.] # 132) dates to post-1908, indicating the layer was deposited after that time.

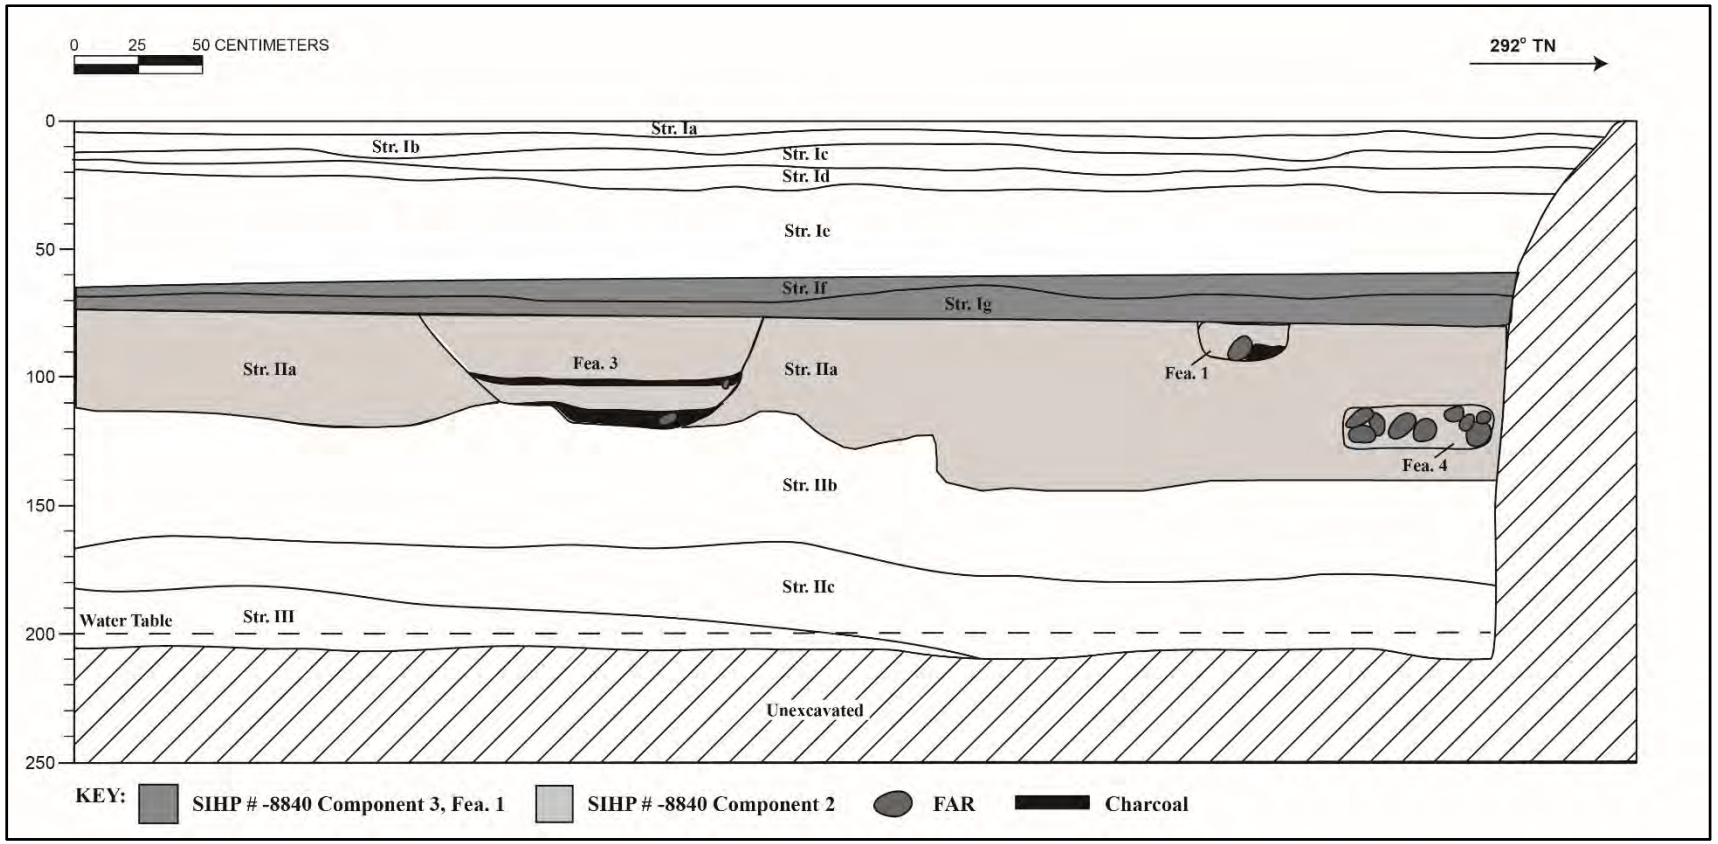

Figure 39. Profile of T-1 southwest wall

Table 4. T-1 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–7	Asphalt; parking lot surface
Ib	5–16	Base course; 10YR 3/1, very dark gray; extremely gravelly loamy sand; weak, very fine, granular structure; moist, friable consistence; no cementation; non-plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; basalt gravel base course
Ic	11–20	Base course; 10YR 6/3, pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Id	16–30	Base course; 5YR 3/3, dark reddish brown; extremely gravelly loamy sand; weak, very fine, granular structure; moist, friable consistence; no cementation; non-plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; basalt gravel base course
Ie	20–71	Fill; 10YR 4/4, dark yellowish brown; cobbly silty clay; moderate, medium, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; fill derived from alluvium, containing basalt cobbles
If	54–71	SIHP # -8840 Component 3, Feature 1; 10YR 8/2, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, discontinuous lower boundary; no roots observed; oil-rolled crushed coral surface
Ig	60–81	SIHP # -8840 Component 3, Feature 1; 10YR 3/4, dark yellowish brown; very gravelly sandy loam; weak, very fine, granular structure; moist, friable consistence; no cementation; slightly plastic; mixed origin; abrupt, discontinuous lower boundary; no roots observed; basalt gravel base course with pig (*S. scrofa*) bone and brick, glass, and ceramic fragments
IIa	70–155	SIHP # -8840 Component 2; 10YR 2/2, very dark brown; silty clay; strong, medium, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, irregular lower boundary; few, fine roots; habitation layer with charcoal flecking and four associated pit features (Features 1–4)
	77–93	SIHP # -8840 Component 2, Feature 1; 10YR 3/2, very dark grayish brown; cobbly silty clay; fire-related feature containing fire-affected rock (FAR) and charcoal
	71–115	SIHP # -8840 Component 2, Feature 2; 10YR 3/2, very dark grayish brown; silty clay; fire-related feature containing charcoal

Stratum	Depth (cmbs)	Description
	76–120	SIHP # -8840 Component 2, Feature 3; 10YR 3/2, very dark grayish brown; cobbly silty clay; fire-related feature containing FAR and charcoal
	111–127	SIHP # -8840 Component 2, Feature 4; 10YR 2/2, very dark brown; cobbly silty clay loam; fire-related feature containing FAR and charcoal
IIb	109–181	Natural; 10YR 3/4, dark yellowish brown; silty clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; very plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; naturally deposited alluvium
IIc	130–205	Natural; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; naturally deposited alluvium
IId	135–205	Natural; 10YR 3/3, dark brown; silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; naturally deposited alluvium
III	140–230 (BOE)	Natural; 10YR 3/2, very dark grayish brown; very gravelly silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; lower boundary not observed; few, fine roots; streambed with waterworn basalt gravel and cobbles

Figure 40. SIHP # -8840 Component 3, Feature 1, oil-rolled crushed coral surface and associated base course (Strata If and Ig), in T-1 southwest wall, view to southwest

Stratum II (a–d) is naturally deposited alluvium, while the underlying Stratum III is interpreted as a streambed, based on the presence of waterworn basalt gravel and cobbles. Because Stratum IIa contains charcoal flecking and four associated pit features, it is designated as part of SIHP # -8840 Component 2, habitation layers. The four features, interpreted as fire-related features, are designated as SIHP # -8840 Component 2, Features 1–4 (Figure 41 through Figure 44). Features 1–3 originate at the upper boundary of the stratum, while Feature 4 is within the lower/middle portion of the stratum. While the upper boundaries of Features 1–3 may have been truncated by the deposition of the overlying fill deposit, based on their matrices, they appear to originate within Stratum IIa; their position at the upper boundary of the layer indicates they are more recent than (i.e., they post-date) Feature 4. The features are described below.

Feature 1 is a basin-shaped pit feature identified in the southwest wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 39 and Figure 41). It was documented between 77 and 93 cmbs and measures 35 cm across. A thin, heat-altered band of reddened sediment, a fire-affected basalt cobble, and a 6-cm thick layer of charcoal were observed at the base of the pit, which is interpreted as a fire-related feature. A charcoal sample was collected.

Feature 2 is a basin-shaped pit feature identified in the northeast wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 36, Figure 37, and Figure 42). It was documented between 71 and 115 cmbs and measures 1 m across. A thin, heat-altered band of reddened sediment and a 4-cm thick layer of charcoal were observed at the base of the pit, which is interpreted as a fire-related feature. Several small, non-diagnostic bottle glass fragments (not collected) and fire-affected basalt cobbles were also observed within the pit. A charcoal sample was collected.

Feature 3 is a basin-shaped pit feature identified in the southwest wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 39 and Figure 43). It was documented between 76 and 120 cmbs and measures 1.5 m across. Multiple heat-altered bands of reddened sediment and layers of charcoal ranging from 5–10 cm thick were observed within the pit, which is interpreted as a fire-related feature. A charcoal sample was collected.

Feature 4 is a pit feature identified in both sidewalls of T-1, within Stratum IIa/SIHP # -8840 Component 2 (see Figure 37 and Figure 44). It was documented between 111 and 127 cmbs and measures 55 cm across; the exposed portion is 85 cm long, spanning the width of the trench. This

Figure 41. SIHP # -8840 Component 2, Feature 1, fire-related feature, in T-1 southwest wall, view to west

Figure 42. SIHP # -8840 Component 2, Feature 2, fire-related feature, in T-1 northeast wall, view to northeast

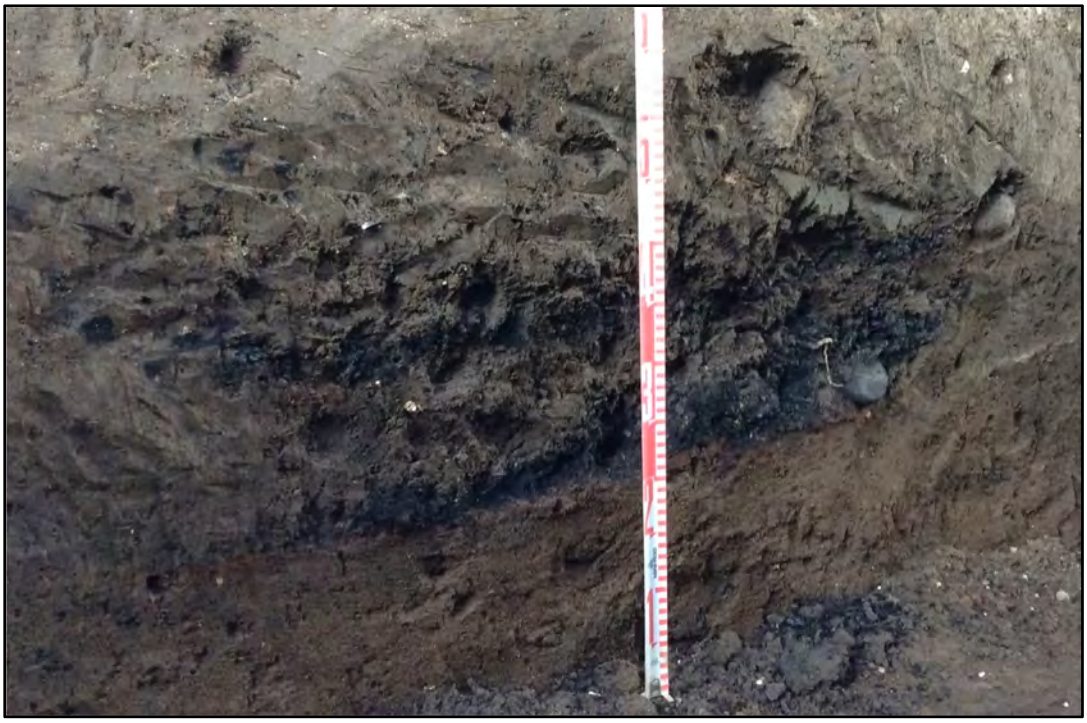

Figure 43. SIHP # -8840 Component 2, Feature 3, fire-related feature, in T-1 southwest wall, view to west

Figure 44. SIHP # -8840 Component 2, Feature 4, fire-related feature, in T-1 southwest wall, view to west

pit is lined with fire-affected basalt cobbles, and charcoal flecking was observed in the matrix surrounding the cobbles; a charcoal sample was collected. This feature is interpreted as a fire-related feature.

Charcoal samples from SIHP # -8840 Component 2, Feature 2 (Sample 1) and Feature 4 (Sample 2), were submitted to the Wood Identification Laboratory at IARII for taxa identification (see Section 5.4.2 for full results). Most of Sample 1 is *kiawe* (*Prosopis pallida*); the rest is indeterminate hardwood. As *kiawe* was likely introduced to Hawai‘i in 1828 (Wagner et al. 1990 in Huebert 2019), the feature was therefore used after that date. In contrast, Sample 2 contains wood from native and endemic species including *‘ōhi‘a lehua* (*Metrosideros polymorpha*), *koa* (*Acacia* cf. *koa*), *kōpiko* (*Psychotria* sp.), and possibly *hau* (*Hibiscus* sp.); no post-Contact introductions were identified within the sample.

The wood identification results are in agreement with the stratigraphic contexts of Features 2 and 4. Although both features were identified within Stratum IIa, Feature 2 originates at the upper boundary of the layer, while Feature 4 is within the middle portion; hence, Feature 2 post-dates Feature 4. The identification of charcoal from a historically introduced species (*kiawe*; *P. pallida*) within Feature 2 securely dates that feature to the post-Contact period, while the apparent lack of historical introductions within the underlying Feature 4 suggests it dates to the pre- or early post-Contact period.

A subsample derived from Sample 2 (Feature 4) was submitted to Beta Analytic, Inc., for radiocarbon dating analysis. The portion of Sample 2 identified as parenchyma charcoal was submitted because it is not likely to have much inbuilt age, as soft storage tissues are not long-lived. The radiocarbon analysis yielded two-sigma calibrated date ranges of AD 1728-1810 (53.5% probability), 1646-1690 (26.0%), and 1925-post 1950 (15.9%). While diagnostic artifacts recovered from overlying fill deposits suggest Stratum IIa functioned as a surface into the 1930s (see Section 5.2.4), the most recent date (1925-post 1950) can likely be discarded. The identification of pit features within different vertical portions of the quite thick stratum suggests the layer was not deposited all at once, but rather over a (potentially extended) period of time. As Feature 4 was identified within the lower portion of Stratum IIa, it would therefore date to the early part of that time period. Furthermore, the cobble-lined fire pit is consistent with traditional Hawaiian fire-related features. Hence, the radiocarbon analysis, like the wood taxa analysis (discussed above), supports a pre- or early post-Contact date for Feature 4.

4.3.2 Test Excavation 2 (T-2)

Test Excavation 2 (T-2) is an exterior excavation near the south corner of the AIS study area. It is oriented northeast-southwest and is 6.1 m long by 0.76 m wide, with a maximum depth of 220 cmbs. The water table was encountered at 214 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly (basalt) loamy sand base course (Stratum Ib), very gravelly loamy sand (mixed crushed coral) base course (Stratum Ic), very cobbly (basalt) sandy clay loam fill (Stratum Id; demolition fill), and a hollow tile wall with concrete base (SIHP # -8840 Component 3, Feature 2), overlying silty clay loam (Stratum IIa; SIHP # -8840 Component 2), sandy loam (Stratum IIb; SIHP # -8840 Component 2), another layer of silty clay loam (Stratum IIc; SIHP # -8840 Component 1), and terrigenous sand (Stratum IId), atop very cobbly (basalt) sandy clay (Stratum III) (Figure 45 through Figure 50 and Table 5).

Stratum Id is a demolition fill layer containing basalt gravel and cobbles, glass and ceramic fragments, and pig (*S. scrofa*) bone; the pig bone and three complete glass bottles were collected. One machine-made beer bottle (Acc. # 44) dates to post-1921, indicating deposition of the layer after 1921. A hollow tile wall with a concrete base, designated as SIHP # -8840 Component 3, Feature 2, was also identified within Stratum Id (see Figure 49 through Figure 52). The wall remnant was documented at the *makai* (southwest) end of T-2, extending roughly east-west from the southwest endwall into the southeast sidewall. It was documented between 37 and 70 cmbs. The exposed portion is 3.1 m long with a maximum width of 20 cm. The hollow tile portion comprises a single course and is approximately 20 cm thick. The underlying concrete base is 15 cm thick. No associated builder’s pit was observed; rather, it appeared the wall was founded on Stratum IIa prior to the deposition of the Stratum Id fill. Other portions of this structural remnant were documented in nearby T-2b (see Section 4.3.3) and possibly also in T-4 (see Section 4.3.6).

A review of historical maps suggests SIHP # -8840 Component 3, Feature 2, may have served as a boundary marker between dwellings in the southeastern portion of the AIS study area and tenements in the central portion of the AIS study area, indicated with a solid line on the 1906 Dakin map (see Figure 18 and Figure 163) and the 1914, 1927, and 1950 Sanborn maps (see Figure 20, Figure 23, Figure 27, and Figure 164 through Figure 166). Although Feature 2 lines up quite well with the boundary as depicted on the 1950 Sanborn map, it appears to be several meters to the east on the earlier maps. It is possible the boundary shifted over time, or that the margin of error is greater for older maps; alternatively, Feature 2, which was likely constructed after 1910 (see T-2B discussion in Section 4.3.3 below), may not be associated with this boundary.

Stratum II (a–d) is naturally deposited alluvium, although the upper portion of Stratum IIa has been disturbed or reworked. Stratum IIa contains charcoal flecking, red brick fragments, and two pit features (Features 5 and 6), one of which contains human skeletal remains (Feature 6); hence, it is designated as part of SIHP # -8840 Component 2, habitation layers. While the upper boundary of Feature 5 may have been truncated, based on its matrix, it appears to originate within Stratum IIa; its position at the upper boundary of the layer indicates it is more recent than (i.e., post-dates) Feature 6, which extends from the lower boundary of the stratum. In addition, a concentration of metal, basalt, and charcoal was noted within Stratum IIa/SIHP # -8840 Component 2 in the northwest wall but was not designated as a feature (Figure 53). Features 5 and 6 are described below.

Table 5. T-2 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–7	Asphalt; parking lot surface
Ib	7–20	Base course; 10YR 3/1, very dark gray; extremely gravelly loamy sand; weak, very fine, granular structure; moist, friable consistence; no cementation; non-plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; basalt gravel base course
Ic	14–27	Base course; 10YR 6/4, light yellowish brown; very gravelly loamy sand; weak, very fine, granular structure; moist, friable consistence; no cementation; non-plastic; mixed origin; abrupt, smooth lower boundary; no roots observed; mixed crushed coral base course
Id	19–70	Fill; 10YR 2/2, very dark brown; very cobbly sandy clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; non-plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; demolition fill containing basalt cobbles, glass and ceramic fragments, and pig bone
SIHP # -8840 Comp. 3, Fea. 2	37–70	SIHP # -8840 Component 3, Feature 2; hollow tile wall with concrete base; possibly a boundary wall
IIa	55–127	SIHP # -8840 Component 2; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; habitation layer with charcoal flecking and pit features (Features 5 and 6)
	60–103	SIHP # -8840 Component 2, Feature 5; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; pit feature containing red brick, glass, metal, charcoal, FAR, and coral gravel
	120–127	SIHP # -8840 Component 2, Feature 6; 10YR 3/2, very dark grayish brown; silty clay loam; small pit feature containing human skeletal remains
IIb	115–160	SIHP # -8840 Component 2; 10YR 3/4, dark yellowish brown; sandy loam; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; mixed origin; clear, smooth lower boundary; no roots observed; habitation layer containing sparse basalt and coral gravel, and small marine shell fragments, and a stacked basalt feature (Feature 7)
	124–160	SIHP # -8840 Component 2, Feature 7; stacked basalt cobbles of an unknown function

Stratum	Depth (cmbs)	Description
IIc	140–164	SIHP # -8840 Component 1; 7.5YR 3/2, dark brown; silty clay loam; weak, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; agricultural layer containing cinder and oxidized (red) mottling
IId	160–182	Natural; 7.5YR 3/4, dark brown; sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited sand
III	175–220 (BOE)	Natural; 7.5YR 2.5/2, very dark brown; very cobbly sandy clay; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; lower boundary not observed; no roots observed; streambed with waterworn basalt cobbles and gravel

Figure 51. Plan view of SIHP # -8840 Component 3, Feature 2, hollow tile wall remnant with concrete base, in T-2

Figure 53. Concentration of metal, basalt, and charcoal within Stratum IIa/SIHP # -8840 Component 2 in T-2 northwest wall

Feature 5 is a basin-shaped pit feature identified at/near the upper boundary of Stratum IIa/SIHP # -8840 Component 2 within both sidewalls of T-2 (see Figure 47, Figure 48, and Figure 54). It was documented between 60 and 103 cmbs and measures 85 cm across. The exposed portion is 76 cm wide, spanning the width of the trench. The feature contains red brick, glass, metal, charcoal, FAR, and coral gravel (not collected). Its function is indeterminate.

Feature 6 is a small pit feature containing human skeletal remains (see Figure 45, Figure 46, Figure 55, and Figure 56). It was documented between 120 and 127 cmbs within the southwest wall of T-2, near the southeast end of the excavation. It originates at the base of Stratum IIa/SIHP # -8840 Component 2 and terminates in the underlying Stratum IIb/SIHP # -8840 Component 2. The pit measures 26 cm across and contains the remains of a single fetal individual (at or near birth). Observed skeletal elements comprise the lower limbs; the upper body likely remains in situ within the southwest sidewall (see Figure 56). The remains are in good condition, and the individual is approximately 85% complete.

The human remains were identified during cleaning of the sidewall, when the trench was excavated to approximately 150 cmbs; this portion of the trench was benched and was not excavated further (see Figure 46). The archaeologists troweled through the loose sediment within the trench and recovered several displaced fragments; these were wrapped in muslin. Troweling through portions of the backdirt pile did not yield any additional remains.

A sheet of muslin was nailed over the exposed portion of the burial (see Figure 45 and Figure 55). A small pit measuring 10 cm high by 12 cm across was dug into the sidewall approximately 15 cm northeast of Feature 6, and the muslin-wrapped, displaced remains were placed into the pit. A second sheet of muslin was then nailed over the pit (Figure 57). Afterwards, a plywood board measuring 2.5 by 2.5 ft was placed over the wall, covering both Feature 6 and the pit with the displaced remains. Following documentation of the excavation, the trench was backfilled to a depth of 90 cmbs. Four plywood boards, each approximately 1 by 2.5 ft, were placed on the excavation floor above the burial find location. The remainder of the trench was then backfilled.

The underlying Stratum IIb contains sparse basalt and coral gravel and small marine shell fragments, as well as a stacked basalt feature. Hence, Stratum IIb is also designated as part of SIHP # -8840 Component 2. The feature, designated as Feature 7, is described below.

Feature 7 comprises three stacked basalt cobbles identified within Stratum IIb/SIHP # -8840 Component 2 in the northwest wall of T-2 (see Figure 47, Figure 48, and Figure 54). It was documented between 124 and 160 cmbs and measures 25 cm across. Its function is indeterminate.

Beneath the SIHP # -8840 Component 2 (Strata IIa and IIb) habitation layers is Stratum IIc, interpreted as an agricultural deposit. Stratum IIc contains cinder gravel and oxidized (red) mottling and is designated as part of SIHP # -8840 Component 1. The underlying Stratum III contains abundant waterworn basalt cobbles and gravel and is interpreted as a streambed.

Figure 57. Two pieces of cloth covering SIHP # -8840 Component 2, Feature 6 (right) and reinterred displaced remains (left)

4.3.3 Test Excavation 2B (T-2B)

Test Excavation 2B (T-2B) is an exterior excavation, just east of T-2, excavated to investigate the presence of a potential burial cluster and to delineate the burial site boundaries for SIHP # -8840 Component 2, Feature 6 (see Section 4.3.2 above); however, no human remains were identified in T-2B. T-2B is oriented northeast-southwest and measures 6.1 m long by 0.73 m wide, with a maximum depth of 225 cmbs. The water table was encountered at 222 cmbs.

The observed stratigraphy includes three layers of asphalt comprising the parking lot surface (Strata Ia–Ic) and associated very gravelly sand (crushed coral) base course (Stratum Id), gravelly (basalt) silty clay loam fill (Stratum Ie), very gravelly (basalt) sandy clay loam fill (Stratum If; demolition fill), and a hollow tile wall with concrete base (SIHP # -8840 Component 3, Feature 2), overlying two layers of silty clay loam (Strata IIa and IIb; SIHP # -8840 Component 2), gravelly (cinder) loam (Stratum IIc; SIHP # -8840 Component 1), and extremely gravelly (basalt) sand (Stratum III) (Figure 58 through Figure 60 and Table 6). A saw-cut cow (*Bos taurus*) bone recovered from the spoils pile was collected; its exact provenience is unknown.

The Stratum Ib and Ic asphalt layers were highly degraded/crumbly. The Stratum Ie fill contains historical trash, including a small lens of burnt trash; a grab sample of metal, glass, and ceramics as well as a bone artifact were collected. The bone artifact (Acc. # 26), likely part of a folding personal hygiene tool, dates to post-1926, indicating deposition of Stratum Ie after that time. Stratum If is a demolition fill containing basalt gravel and metal and glass debris.

At the lateral interface of Strata Ie and If, resting atop Stratum IIa, is a hollow tile wall with a concrete base (see Figure 58 through Figure 61 and Figure 62). This structural remnant, designated as SIHP # -8840 Component 3, Feature 2, was documented between 22 and 73 cmbs, extending roughly east-west from near the east corner of the trench into the northwest sidewall. The exposed portion is approximately 2.5 m long with a maximum width of 35 cm. No associated builder's pit was observed; rather, it appeared the wall was founded on Stratum IIa prior to the deposition of the Strata Ie and If fills. As the wall overlies and therefore post-dates SIHP # -8840 Component 2, Feature 8 (historical trash pit, discussed below), it was constructed no earlier than 1910. Other portions of this structural remnant were documented in nearby T-2 (see Section 4.3.2) and possibly also in T-4 (see Section 4.3.6).

The underlying Stratum II (a–c) is natural alluvium. Because Strata IIa and IIb contain pit features, they are designated as part of SIHP # -8840 Component 2, habitation layers. The features, designated as Features 8–10, are described below.

Feature 8 is a large pit feature identified at the *mauka* (northeast) end of T-2B in the southeast sidewall (see Figure 58, Figure 59, and Figure 62). It was documented between 70 and 145 cmbs at the upper boundary of Stratum IIa/SIHP # -8840 Component 2. Glass, metal, ceramic, and bone artifacts were collected from this feature, which is interpreted as a historical trash pit; a grab sample was collected. Diagnostic artifacts are Euro-American and Asian in origin. A machine-made glass marble (Acc. # 37), a bottle glass fragment (Acc. # 41), and a Dutch gin bottle date to post-1910, 1910-1919, and ca. 1910, respectively, indicating use of the feature after that date. Feature 8 overlies and therefore post-dates Feature 9, discussed below. Feature 8 underlies and therefore pre-dates SIHP # -8841 Component 3, Feature 2 (hollow tile wall), discussed above.

Table 6. T-2B stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–5	Asphalt; parking lot surface
Ib	5–10	Second layer of asphalt
Ic	10–19	Third layer of asphalt
Id	12–22	Base course; 10YR 8/2, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ie	21–70	Fill; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; fill derived from alluvium, containing basalt gravel
SIHP # -8840 Comp. 3, Fea. 2	22–73	SIHP # -8840 Component 3, Feature 2; hollow tile wall with concrete base; possibly a boundary wall
If	16–79	Fill; 10YR 5/6, yellowish brown; very gravelly sandy clay loam; moderate, medium, blocky structure; moist, friable consistence; no cementation; slightly plastic; mixed origin; clear, discontinuous lower boundary; no roots observed; demolition fill containing basalt gravel and metal and glass debris
IIa	70–191	SIHP # -8840 Component 2; 10YR 3/1, very dark gray; silty clay loam; moderate, fine, blocky structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, irregular lower boundary; no roots observed; habitation layer containing pit features (Features 8 and 9)
	70–145	SIHP # -8840 Component 2, Feature 8; 10YR 3/1, very dark gray; silty clay loam; historical trash pit containing glass, metal, ceramic, and bone artifacts
	115–191	SIHP # -8840 Component 2, Feature 9; 10YR 3/1, very dark gray; silty clay loam; pit feature of indeterminate function
IIb	112–176	SIHP # -8840 Component 2; 10YR 3/6, dark yellowish brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; habitation layer containing a pit feature (Feature 10)
	117–171	SIHP # -8840 Component 2, Feature 10; 10YR 3/6, dark yellowish brown; silty clay loam; pit feature of indeterminate function

Stratum	Depth (cmbs)	Description
IIc	175–216	SIHP # -8840 Component 1; 10YR 2/2, very dark brown; gravelly loam; weak, very fine, granular structure; moist, friable consistence; no cementation; non-plastic; terrigenous origin; clear, wavy lower boundary; no roots observed; agricultural deposit containing cinder gravel, oxidized (red) mottling, reddish-orange concretions and nodules, and several tubular root casts
III	197–225 (BOE)	Natural; GLEY 10Y 2.5/1, greenish black; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; terrigenous origin; lower boundary not observed; no roots observed; streambed with waterworn basalt gravel and cobbles

Figure 61. Plan view of SIHP # -8840 Component 3, Feature 2, hollow tile wall with concrete base, in T-2B

Figure 62. Northeast end of T-2B southeast wall, showing SIHP # -8840 Component 3, Feature 2 (hollow tile wall remnant) overlying SIHP # -8840 Component 2 Features 8 and 9, pit features, view to east

Feature 9 is a large pit feature identified at the *mauka* (northeast) end of T-2B in the southeast sidewall (see Figure 58, Figure 59, and Figure 62). It was documented between 115 and 191 cmbs, extending from the lower boundary of Stratum IIa/SIHP # -8840 Component 2, intrusive through Stratum IIb, and terminating in Stratum IIc. It underlies Feature 8 (described above), which it therefore pre-dates. The exposed portion of the feature is approximately 2 m long. No cultural materials were identified wihtin the feature; its function is indeterminate.

Feature 10 is an oblong pit feature identified in the southeast wall of T-2B (see Figure 58, Figure 59, and Figure 63). It was documented at the upper boundary of Stratum IIb/SIHP # -8840 Component 2, between 117 and 171 cmbs and measures 25 cm across. No cultural materials were identified within the feature; its function is indeterminate.

Stratum IIc contains basalt gravel and oxidized (red) mottling and is interpreted as an agricultural deposit; hence, it is designated as part of SIHP # -8840 Component 1. A bulk sample of Stratum IIc was collected from the excavator bucket. Wet screening of the sample yielded reddish-orange concretions and nodules and several tubular root casts; based on previous archaeological studies (see Section 5.1.1), these are interpreted as evidence of agricultural use. The underlying Stratum III contains abundant waterworn basalt gravel and cobbles and is interpreted as a streambed.

Figure 63. SIHP # -8840 Component 2 Feature 10, pit feature, in T-2B southeast wall, view to south

4.3.4 Test Excavation 2C (T-2C)

Test Excavation 2C (T-2C) is an exterior excavation, just north of T-2, excavated to investigate the presence of a potential burial cluster and to delineate the burial site boundaries of SIHP # -8840 Component 2, Feature 6 (see Section 4.3.2 above); however, no human remains were identified in T-2C. T-2C is oriented northeast-southwest and measures 6.1 m long by 0.76 m wide, with a maximum depth of 225 cmbs. The water table was not encountered.

The observed stratigraphy includes three layers of asphalt (Strata Ia–Ic) and associated very gravelly sand (crushed coral) base course (Stratum Id), very gravelly (basalt) sandy clay loam base course (Stratum Ie), and gravelly silty clay loam fill (Stratum If; demolition fill), overlying two layers of silty clay loam (Strata IIa/SIHP # -8840 Component 2 and IIb) and very gravelly (basalt) sandy clay (Stratum III) (Figure 64, Figure 65, and Table 7).

The Strata Ib and Ic asphalt layers were highly degraded/crumbly. Stratum If is a demolition fill containing medium mammal bone (inconsistent with human) and ceramic, metal, and glass artifacts. The mammal bone and a grab sample of artifacts were collected. Diagnostic artifacts are Hawaiian, Euro-American, and Japanese in origin. One machine-made bottle (Acc. # 161) dates to 1935, indicating the fill was deposited after that date.

Stratum II (a and b) is naturally deposited alluvium, while the underlying Stratum III contains abundant waterworn basalt gravel and cobbles and is interpreted as a streambed. Because Stratum IIa contains charcoal flecking and a pit feature, it is designated as part of SIHP # -8840 Component 2, habitation layers. The feature, designated as Feature 11, is described below.

Feature 11 is a small pit feature identified in the southeast sidewall of T-2C (see Figure 65 and Figure 66). It was documented between 137 and 152 cmbs, extending from the lower boundary of Stratum IIa/SIHP # -8840 Component 2 and terminating in Stratum IIb. It measures 30 cm across. No cultural materials were observed within the feature; its function is indeterminate.

Figure 64. T-2C southeast wall, view to south

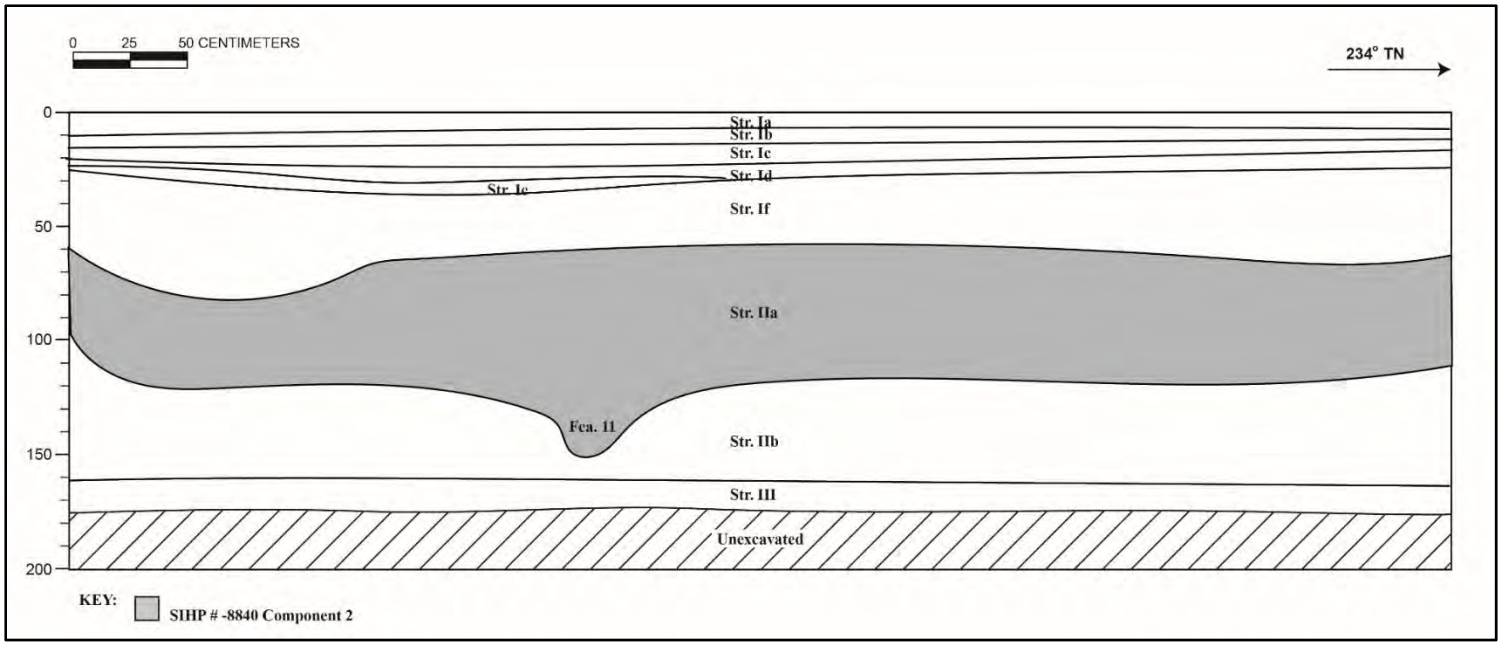

Figure 65. Profile of T-2C southeast wall

Figure 66. SIHP # -8840 Component 2, Feature 11, pit feature of indeterminate function, in T-2C southeast sidewall, view to southeast

Table 7. T-2C stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–8	Asphalt; parking lot surface
Ib	6–16	Second layer of asphalt
Ic	12–26	Third layer of asphalt
Id	25–29	Base course; 10YR 7/3, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ie	29–37	Base course; 10YR 3/1, very dark gray; very gravelly sandy clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; abrupt, discontinuous lower boundary; no roots observed; basalt gravel base course
If	27–64	Fill; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; moderate, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, wavy lower boundary; no roots observed; demolition fill, containing basalt gravel and cobbles, medium mammal bone, and glass, metal, and ceramic artifacts
IIa	55–152	SIHP # -8840 Component 2; 10YR 2/2, very dark brown; silty clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, irregular lower boundary; no roots observed; habitation layer containing charcoal flecking and a pit feature (Feature 11)
	137–152	SIHP # -8840 Component 2, Feature 11; 10YR 2/2, very dark brown; silty clay loam; pit feature of indeterminate function
IIb	100–161	Natural; 10YR 3/3, dark brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium
III	161–174 (BOE)	Natural; 10YR 3/2, very dark grayish brown; very gravelly sandy clay; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; lower boundary not observed; no roots observed; streambed containing abundant waterworn basalt gravel and cobbles

4.3.5 Test Excavation 3 (T-3)

Test Excavation 3 (T-3) is an exterior excavation near the south corner of the AIS study area. It is oriented northwest-southeast and is 6.15 m long by 0.8 m wide, with a maximum depth of 160 cmbs. The water table was not encountered.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia) and associated extremely gravelly (basalt) sandy clay loam base course (Stratum Ib), very gravelly sand (crushed coral) base course (Stratum Ic), very gravelly (basalt) sandy clay loam fill (Stratum Id), and gravelly (basalt) sandy clay loam fill (Stratum Ie; demolition fill), overlying gravelly (basalt) silty clay loam (Stratum IIa; SIHP # -8840 Component 2) and two layers of silty clay loam (Strata IIb and IIc/SIHP # -8840 Component 1) (Figure 67 through Figure 69, and Table 8).

Stratum Ie is a demolition fill containing concrete and metal debris. Large pieces of concrete at either end of the excavation within Stratum Ie threatened to destabilize the sidewalls if removed; hence, only the central portion of the trench was excavated fully (see Figure 69).

The underlying Stratum II (a–c) is naturally deposited alluvium. The upper portion of Stratum IIa has been disturbed or reworked and contains charcoal flecking and red brick fragments (not collected); hence, it is designated as part of SIHP # -8840 Component 2, habitation layers. Stratum IIc contains oxidized (red) mottling and is interpreted as an agricultural deposit; it is designated as part of SIHP # -8840 Component 1.

Figure 67. Southeast end of T-3 southwest wall, showing concrete debris within Stratum Ie, demolition fill, which prevented full excavation, view to south

Figure 68. T-3 southwest wall, central portion, view to southwest

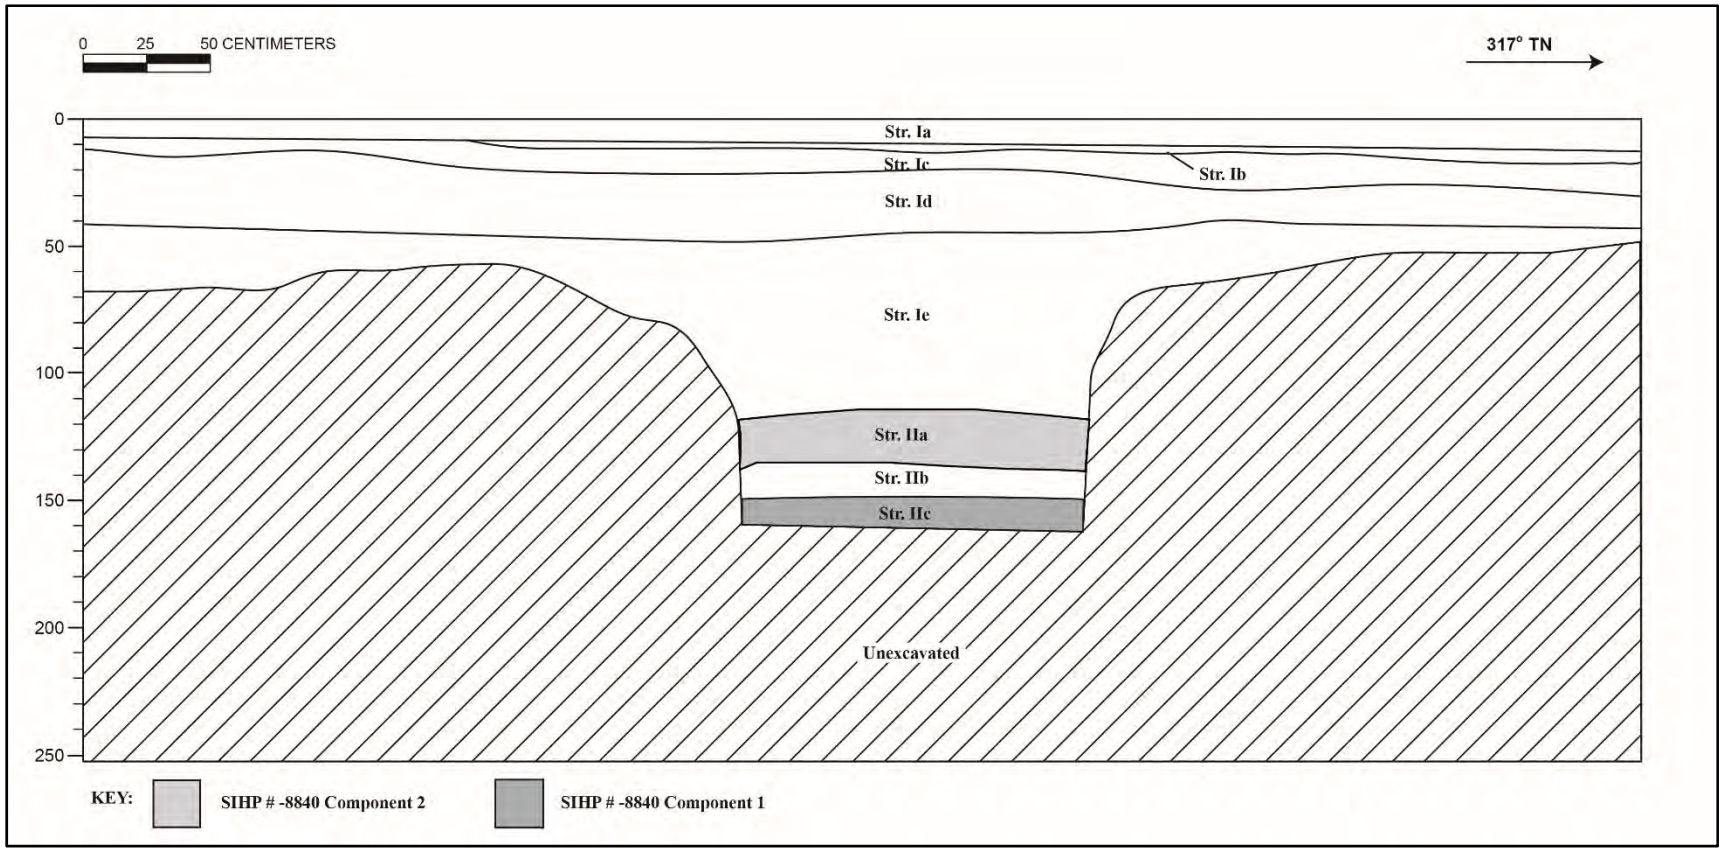

Figure 69. Profile of T-3 southwest wall

Table 8. T-3 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–7	Asphalt; parking lot surface
Ib	7–12	Base course; 10YR 4/2, dark grayish brown; extremely gravelly sandy clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; abrupt, discontinuous lower boundary; no roots observed; basalt gravel base course
Ic	7–35	Base course; 10YR 7/3, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Id	12–45	Fill; 2.5YR 3/2, dusky red; very gravelly sandy clay loam; terrigenous origin; moderate, medium, granular structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; contains basalt gravel
Ie	35–110	Fill; 10YR 3/3, dark brown; gravelly sandy clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; demolition fill containing basalt gravel and metal and concrete debris
IIa	110–133	SIHP # -8840 Component 2; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; habitation layer with basalt gravel, charcoal, and red brick in its upper portion
IIb	136–148	Natural; 10YR 3/3, dark brown; silty clay loam; weak, very fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; naturally deposited alluvium
IIc	146–160 (BOE)	SIHP # -8840 Component 1; 10YR 3/2, very dark grayish brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; lower boundary not observed; no roots observed; agricultural deposit with oxidized (red) mottling

4.3.6 Test Excavation 4 (T-4)

Test Excavation 4 (T-4) is an exterior excavation in the southeastern portion of the AIS study area. It is oriented northwest-southeast and is 6.1 m long by 0.8 m wide, with a maximum depth of 229 cmbs. The water table was encountered at 223 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly sand (crushed coral) base course (Stratum Ib), very gravelly (basalt) sandy clay loam fill (Stratum Ic; demolition fill), and a concrete footing (SIHP # -8840 Component 3, Feature 3), overlying gravelly (basalt) silty clay loam (Stratum IIa; SIHP # -8840 Component 2), three layers of silty clay loam (Strata IIb, IIc/SIHP # -8840 Component 1, and IId), and a second layer of gravelly (basalt) silty clay loam (Stratum IIe; SIHP # -8840 Component 1) (Figure 70 through Figure 75 and Table 9). A saw-cut cow (*Bos taurus*) bone and a small mammal bone fragment were collected from the spoils pile; their exact provenience is unknown.

Stratum Ic is a demolition fill containing concrete, brick, hollow tile, and metal debris, as well as a concrete footing (see Figure 72 through Figure 75). A strong odor of petroleum indicated Stratum Ic was contaminated in the ‘Ewa (northwest) portion of the trench; hence, that portion was not fully excavated (see Figure 73). The concrete footing is designated as SIHP # -8840 Component 3, Feature 3. The exposed portion is 85 cm long by 45 cm wide and 15 cm thick, documented between 43 and 58 cmbs within the trench floor and both sidewalls. It may represent the concrete base of the hollow tile wall (SIHP # -8840 Component 3, Feature 2) identified in T-2 and T-2B (see Sections 4.3.2 and 4.3.3 above), as it is of approximately the same thickness, width, and orientation (roughly east-west). Furthermore, the presence of hollow tile debris in the surrounding Stratum Ic fill material supports this hypothesis, suggesting the upper hollow tile portion was once present but has been demolished. Like Feature 2, Feature 3 appeared to be founded upon Stratum IIa and to pre-date the deposition of the surrounding fill layer.

Stratum II (a–e) is natural alluvium. The upper portion of Stratum IIa has been disturbed or reworked and contains charcoal flecking and red brick fragments; hence, it is designated as part of SIHP # -8840 Component 2, habitation layers. Strata IIc and IIe contain oxidized (red) mottling and are interpreted as agricultural deposits; they are designated as part of SIHP # -8840 Component 1 (Figure 76). A bulk sample of Stratum IIe was collected from the spoils pile.

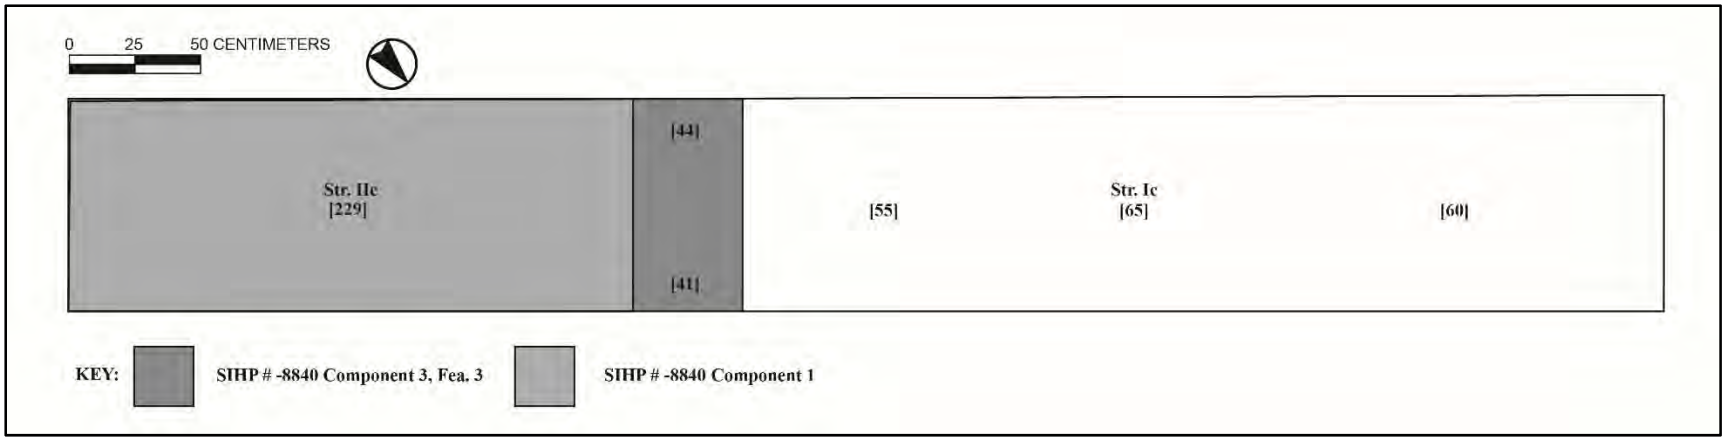

Figure 75. Plan map of T-4

Table 9. T-4 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–6	Asphalt; parking lot surface
Ib	6–20	Base course; 10YR 6/3, pale brown; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ic	14–74	Fill; 2.5YR 3/2, dusky red; very gravelly sandy clay loam; terrigenous origin; moderate, medium, granular structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; demolition fill containing basalt gravel and concrete, hollow tile, brick, and metal debris
SIHP # -8840 Comp. 3, Feature 3	43–58	SIHP # -8840 Component 3, Feature 3; concrete footing; possibly the base of a former hollow tile wall
IIa	71–115	SIHP # -8840 Component 2; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; weak, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium with basalt gravel, charcoal flecking, and red brick fragments in its upper portion
IIb	105–148	Natural; 10YR 4/3, brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium
IIc	145–165	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; agricultural deposit with oxidized (red) mottling
IId	158–200	Natural; 10YR 4/3, brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; naturally deposited alluvium
IIe	196–229 (BOE)	SIHP # -8840 Component 1; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; lower boundary not observed; no roots observed; agricultural deposit with abundant oxidized (red) mottling

Figure 76. Stratum IIe/SIHP # -8840 Component 1 sediment, showing abundant oxidized (red) mottling

4.3.7 Test Excavation 5 (T-5)

Test Excavation 5 (T-5) is an exterior excavation in the southeastern portion of the AIS study area. It is oriented northwest-southeast and is 6.1 m long by 0.75 m wide, with a maximum depth of 224 cmbs. The water table was encountered at 220 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia) and associated extremely gravelly sand (crushed coral) base course (Stratum Ib), very gravelly (basalt) sandy clay loam fill (Stratum Ic), and very gravelly (basalt) silty clay loam fill (Stratum Id), overlying gravelly (basalt) silty clay loam (Stratum IIa; SIHP # -8840 Component 2) and five layers of silty clay loam (Strata IIb, IIc/SIHP # -8840 Component 1, IId, IIe, and IIf/SIHP # -8840 Component 1) (Figure 77 through Figure 79 and Table 10). Due to petroleum contamination within Stratum Id, minimal cleaning of the sidewalls was conducted, and a 1-m profile drawing was documented at the center of the trench to minimize the archaeologists' exposure to the contaminated sediment.

A corroded metal spike or nail and a small, non-diagnostic ceramic fragment were identified in Stratum Id; these were photographed but not collected (Figure 80). The underlying Stratum II (a–f) is natural alluvium. The upper portion of Stratum IIa has been disturbed or reworked and contains an abandoned utility pipe as well as glass, metal, and ceramic fragments; hence, Stratum IIa is designated as part of SIHP # -8840 Component 2, habitation layers. Artifacts associated with Stratum IIa were photographed but not collected (Figure 81). Strata IIc and IIf contain oxidized (red) mottling and are interpreted as agricultural deposits; they are designated as part of SIHP # -8840 Component 1. A bulk sample of Stratum IIf was collected from the spoils pile.

Table 10. T-5 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–10	Asphalt; parking lot surface
Ib	10–18	Base course; 10YR 6/3, pale brown; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ic	17–24	Fill; 2.5YR 3/2, dusky red; very gravelly sandy clay loam; terrigenous origin; moderate, medium, granular structure; moist, firm consistence; no cementation; slightly plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed contains basalt gravel
Id	23–55	Fill; 10YR 3/2, very dark grayish brown; very gravelly silty clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; contaminated with petroleum, mottled with 10YR 2/1, black, containing a corroded metal spike or nail and a small, non-diagnostic ceramic fragment
IIa	48–80	SIHP # -8840 Component 2; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; weak, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium with basalt gravel, an abandoned utility pipe, and glass, metal, and ceramic fragments in its upper portion
IIb	80–118	Natural; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium
IIc	118–130	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; agricultural deposit with oxidized (red) mottling
IId	130–150	Natural; 10YR 4/3, brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium
IIe	150–187	Natural; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium

Stratum	Depth (cmbs)	Description
IIf	187–224 (BOE)	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; lower boundary not observed; no roots observed; agricultural deposit with oxidized (red) mottling

Figure 80. A metal spike or nail (too corroded to analyze) and a non-diagnostic ceramic fragment from T-5 Stratum Id, fill (not collected)

Figure 81. Post-Contact artifacts and utility pipe fragments identified in the upper portion of T-5 Stratum IIa/SIHP # -8840 Component 2 (not collected; no diagnostic elements could be discerned from the photograph)

4.3.8 Test Excavation 6 (T-6)

Test Excavation 6 (T-6) is an exterior excavation in the east corner of the AIS study area. It is oriented northeast-southwest and is 6 m long by 0.7 m wide, with a maximum depth of 213 cmbs. The water table was encountered at 210 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia) and associated extremely gravelly sand (crushed coral) base course (Stratum Ib), gravelly (basalt) sandy clay loam fill (Stratum Ic; demolition fill), and two layers of silty clay loam fill (Strata Id and Ie), overlying three layers of silty clay loam (Strata IIa, IIb, and IIc/SIHP # -8840 Component 1) and clay loam (Stratum IId) (Figure 82 through Figure 84 and Table 11).

Stratum Ic is a demolition fill layer containing basalt gravel, fish (Osteichthyes) bone, brick, hollow tiles, and concrete (Figure 85); two brick fragments were collected. Both are Euro-American in origin, and one (Acc. # 158) post-dates 1916, indicating the layer was deposited after that date. A large piece of concrete within Stratum Ic near the *mauka* (northeast) end of the trench prevented full excavation in that area (see Figure 84 and Figure 86).

Strata Id and Ie are fills derived from alluvium. Stratum Ie contains red brick, a coral construction block, glass, ceramic, metal, *Sphyraenidae* sp. (barracuda) dentary, slate, and concrete, as well as a carbon graphite rod for a dry-cell battery; a grab sample was collected. Diagnostic artifacts are mainly Japanese and Euro-American in origin. The carbon graphite rod (Acc. # 77) post-dates 1912, indicating the layer was deposited after that date.

The underlying Stratum II (a–d) is naturally deposited alluvium. Stratum IIa contains sparse charcoal flecking but no other potentially cultural materials; hence, it is not designated as part of SIHP # -8840 Component 2, habitation layers. Stratum IIc contains oxidized (red) mottling and is interpreted as an agricultural deposit; it is designated as part of SIHP # -8840 Component 1. Bulk samples were collected from Strata IIa–IId from the northwest wall (see Figure 84).

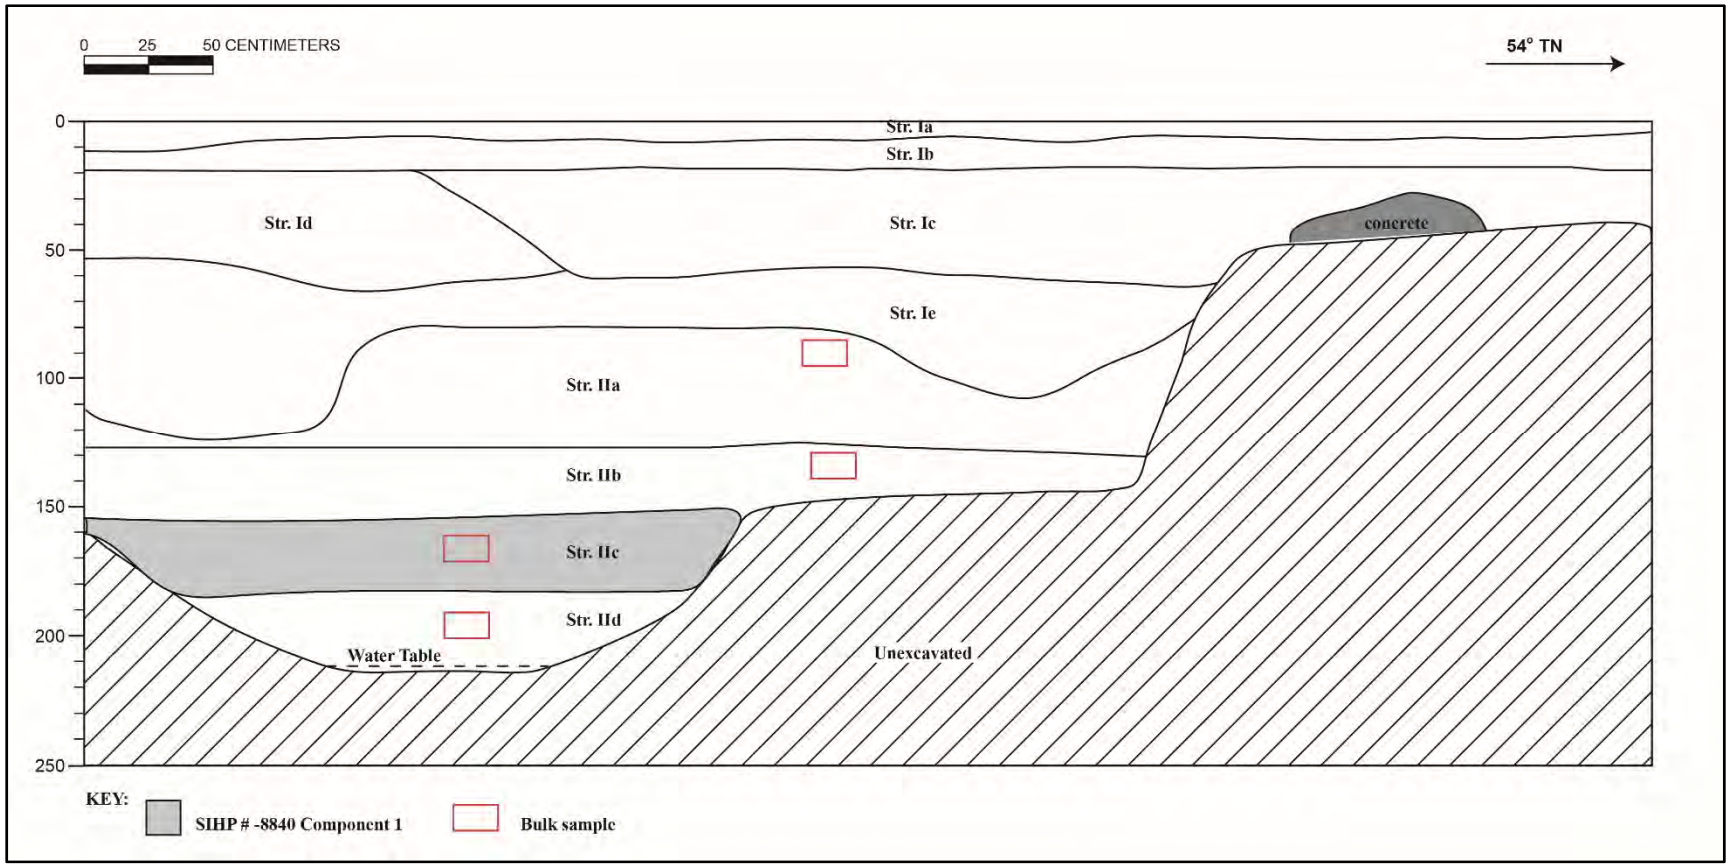

Figure 84. Profile of T-6 northwest wall

Table 11. T-6 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–10	Asphalt; parking lot surface
Ib	7–19	Base course; 10YR 6/3, pale brown; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ic	17–60	Fill; 10YR 4/2, dark grayish brown; gravelly sandy clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; mixed origin; abrupt, discontinuous lower boundary; no roots observed; demolition fill containing basalt gravel, fish bone, brick, hollow tiles, and concrete
Id	17–65	Fill; 10YR 4/3, brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; abrupt, discontinuous lower boundary; no roots observed; fill derived from alluvium
Ie	51–125	Fill; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; abrupt, irregular lower boundary; no roots observed; contains yellow and red brick, glass, ceramic, metal, marine shell, *Sphyraenidae* sp. (barracuda) dentary, and concrete
IIa	79–130	Natural; 10YR 3/2, very dark grayish brown; silty clay loam; weak, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium with charcoal flecking
IIb	125–155	Natural; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium
IIc	150–182	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, medium granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; agricultural deposit with oxidized (red) mottling
IId	180–213 (BOE)	Natural; 10YR 4/2, dark grayish brown; clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; very plastic; terrigenous origin; lower boundary not observed; few, fine roots; naturally deposited alluvium

Figure 85. Concrete debris from T-6 Stratum Ic, demolition fill (not collected)

Figure 86. North corner of T-6, showing large piece of concrete within Stratum Ic, demolition fill, which prevented further excavation in that area

4.3.9 Test Excavation 7 (T-7)

Test Excavation 7 (T-7) is an exterior excavation in the northeastern portion of the AIS study area. It is oriented northeast-southwest and is 6 m long by 0.7 m wide, with a maximum depth of 218 cmbs. The water table was encountered at 204 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly sand (crushed coral) base course (Stratum Ib), and very gravelly (basalt) silty clay loam fill (Stratum Ic), overlying gravelly (coral and basalt) silty clay loam (Stratum IIa), silty clay loam (Stratum IIb), gravelly (cinder) silty clay loam (Stratum IIc; SIHP # -8840 Component 1), and three additional layers of silty clay loam (Strata IId/SIHP # -8840 Component 1, IIe, and IIf) (Figure 87, Figure 88, and Table 12).

Stratum Ic is fill derived from alluvium, containing coral and basalt gravel and a utility pipe. Stratum II (a–f) is natural alluvium. Strata IIc and IId contain charcoal flecking and oxidized (red) mottling and are interpreted as agricultural deposits; they are designated as part of SIHP # -8840 Component 1. A column sample collected from Stratum II (a–f) was submitted to BGP Consulting (Phillips 2019) for pollen analysis (see Figure 88 and Section 5.4.1).

The Strata IIa, IIb, and IIf samples contain no pollen and therefore could not be assessed. Asteraceae and Cheno-Ams dominate the Stratum IIe sample, suggesting a shrubland environment. Grass pollen gradually increases over time (i.e., increases up the sample column), becoming dominant in Stratum IIc. A single large grass grain identified in Stratum IIc may represent rice (*laiki*; *Oryza sativa*) or sugarcane (*kō*; *Saccharum* sp.) cultivation in the vicinity or the collection of *pili* (*Heteropogon contortus*) grass. In addition, a high proportion of fern spores in Stratum IIc might reflect increased input from upslope and/or overbank flooding.

Taken at face value, the pollen data from T-7 suggests a change over time from shrubland to grassland; sedge family pollen, representing wetlands (including *loʻi*), is present but found in relatively low percentages. However, as the percentages of degraded grains within the samples are very high, and the total pollen concentrations are very low, Phillips (2019) cautions that the data is likely not an accurate reflection of the original pollen assemblage. Hence, the lack of evidence for past agriculture is very likely a product of taphonomy (i.e., the very poor pollen preservation).

Figure 87. T-7 southeast wall, view to south

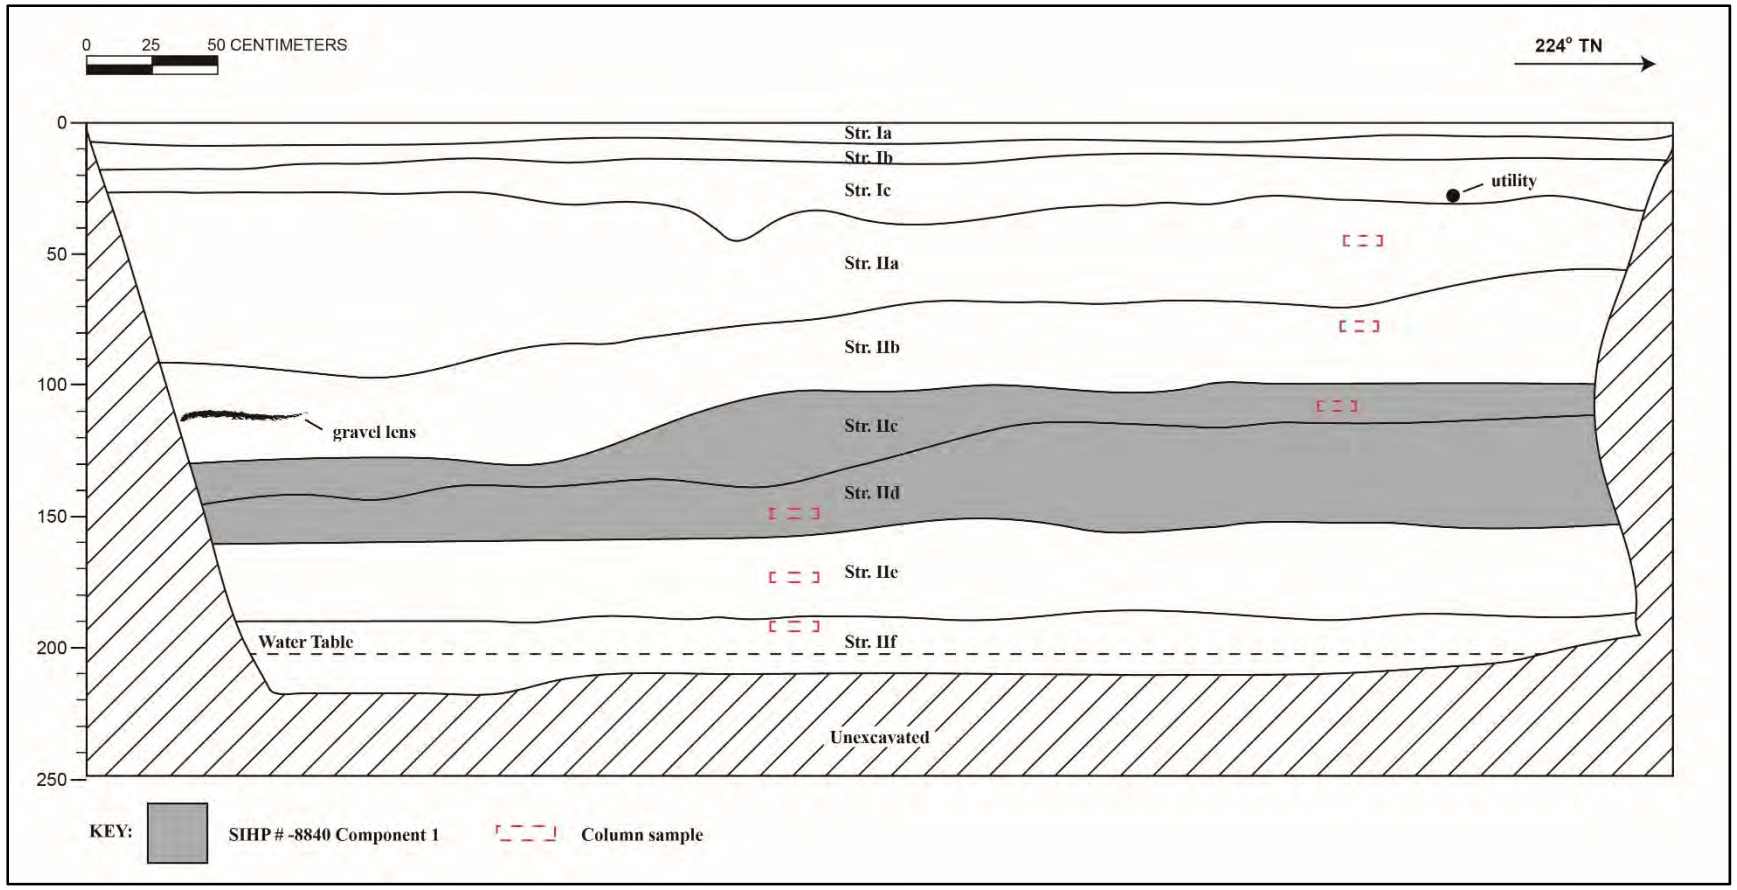

Figure 88. Profile of T-7 southeast wall

Table 12. T-7 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–7	Asphalt; parking lot surface
Ib	5–17	Base course; 10YR 6/3, pale brown; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ic	15–45	Fill; 10YR 4/3, brown; very gravelly silty clay loam; moderate, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; few, fine to medium roots; derived from alluvium and contains coral and basalt gravel and a utility pipe
IIa	28–100	Natural; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; common, fine roots; naturally deposited alluvium with sparse charcoal flecking
IIb	56–130	Natural; 10YR 3/4, dark yellowish brown; silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; common, fine roots; naturally deposited alluvium
IIc	99–148	SIHP # -8840 Component 1; 5YR 3/2, dark reddish brown; gravelly silty clay loam; moderate, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, smooth lower boundary; agricultural layer with cinder gravel, charcoal flecking, and oxidized (red) mottling
IId	112–160	SIHP # -8840 Component 1; 10YR 3/4, dark yellowish brown; silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; agricultural layer with charcoal flecking and oxidized (red) mottling
IIe	151–188	Natural; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, medium, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; naturally deposited alluvium
IIf	188–218 (BOE)	Natural; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, fine, granular structure; moist, firm consistence; no cementation; plastic; terrigenous origin; lower boundary not observed; no roots observed; naturally deposited alluvium

4.3.10 Test Excavation 8 (T-8)

Test Excavation 8 (T-8) is an exterior excavation in the northeastern portion of the AIS study area. It is oriented northwest-southeast and is 6.1 m long by 0.72 m wide, with a maximum depth of 225 cmbs. The water table was encountered at 198 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly (basalt) loamy sand base course (Stratum Ib), and extremely gravelly sand (crushed coral) base course (Stratum Ic), overlying gravelly (cinder, basalt) silty clay loam (Stratum IIa; SIHP # -8840 Component 2), four layers of silty clay loam (Strata IIb, IIc/SIHP # -8840 Component 1, IId/SIHP # -8840 Component 1, and IIe), sandy clay loam (Stratum IIf) and sandy clay (Stratum IIg; SIHP # -8840 Component 1) (Figure 89, Figure 90, and Table 13).

Stratum II (a–g) is natural alluvium (Figure 91). The upper portion of Stratum IIa is disturbed or reworked and contains charcoal, red brick fragments, and fish bone; hence, it is designated as part of SIHP # -8840 Component 2, habitation layers. Strata IIc, IId, and IIg contain charcoal flecking and oxidized (red) mottling and are interpreted as agricultural deposits; they are designated as part of SIHP # -8840 Component 1. Stratum IIg was documented below the water table via excavation of a pot hole (see Figure 90).

4.3.11 Test Excavation 9 (T-9)

Test Excavation 9 (T-9) is an exterior excavation in the central portion of the AIS study area. It is oriented northeast-southwest and is 6 m long by 0.8 m wide, with a maximum depth of 196 cmbs. The water table was encountered at 193 cmbs.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly (basalt) silt loam base course (Stratum Ib), and very gravelly loamy sand (crushed coral) base course (Stratum Ic), overlying five deposits of silty clay loam (Strata IIa/SIHP # -8840 Component 2, IIb, and IIc–IIe/SIHP # -8840 Component 1), gravelly (basalt) silty clay (Stratum IIf; SIHP # -8840 Component 1), and very gravelly (basalt) sandy loam (Stratum III) (Figure 92 through Figure 95 and Table 14).

Stratum II (a–e) is natural alluvium. Stratum IIa contains three pit features, interpreted as historical trash pits, and is designated as part of SIHP # -8840 Component 2, habitation layers. Although the upper boundary of Feature 14 is truncated, and the upper boundaries of Features 12 and 13 may also be truncated, based on their matrices, they appear to originate in Stratum IIa. Features 12–14 and are described below.

Feature 12 is a historical trash pit identified in both sidewalls of T-9, originating at the upper boundary of Stratum IIa/SIHP # -8840 Component 2, intruding through Strata IIb–III, and continuing beyond the base of excavation (see Figure 92 through Figure 96). It was documented between 45 and 196 cmbs and ranges between 65 and 100 cm across (*mauka-makai*). The exposed portion of the feature is 80 cm wide, spanning the width of the trench. Feature 12 contains abundant bottle glass and ceramics, as well as marine shell midden (*Periglypta reticulata*), bird (Aves) and saw-cut mammal (inconsistent with human) bone, charcoal, and fire-affected basalt cobbles. The faunal bone and a grab sample of glass, ceramics, and shell midden were collected. Diagnostic artifacts are mainly of European and Euro-American origin and date from the late nineteenth to possibly early twentieth century. One item, a Dutch glass gin bottle (Acc. # 55), dates between 1890 and 1910, indicating use of the feature post-1890. Similarly, the completeness, lack of damage, and consistent size of the collected shells indicate the midden is likely historical (i.e., post-Contact).

Feature 13 is a historical trash pit identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 in the northwest sidewall of T-9 (see Figure 93, Figure 95, and Figure 97). It was documented between 45 and 67 cmbs and measures 1.7 m across. It truncates and therefore post-dates the underlying Feature 14 (see description below). Feature 13 contains metal, glass, ceramic, bird (Aves) and cow (*Bos taurus*) bone, and charcoal. The faunal bone was collected.

Feature 14 is a historical trash pit identified in the northwest sidewall of T-9, originating at the upper boundary of Stratum IIa/SIHP # -8840 Component 2, intruding through Strata IIb–IId, and terminating in Stratum IIe (see Figure 93, Figure 95, and Figure 97). It was documented between 44 and 137 cmbs and measures 1.8 m across. It is truncated by the overlying Feature 13 (see description above), which it therefore pre-dates. Feature 14 contains metal, ceramic, glass, goat (*Capra hircus*) bone, charcoal, and fire-affected basalt cobbles. The faunal bone and a grab sample of metal, glass, and ceramics were collected. Diagnostic artifacts are Euro-American in origin, dating from the late nineteenth to possibly the early twentieth century. One glass bottle fragment (Acc. # 159) dates between 1880 and 1920, indicating use of the feature post-1880.

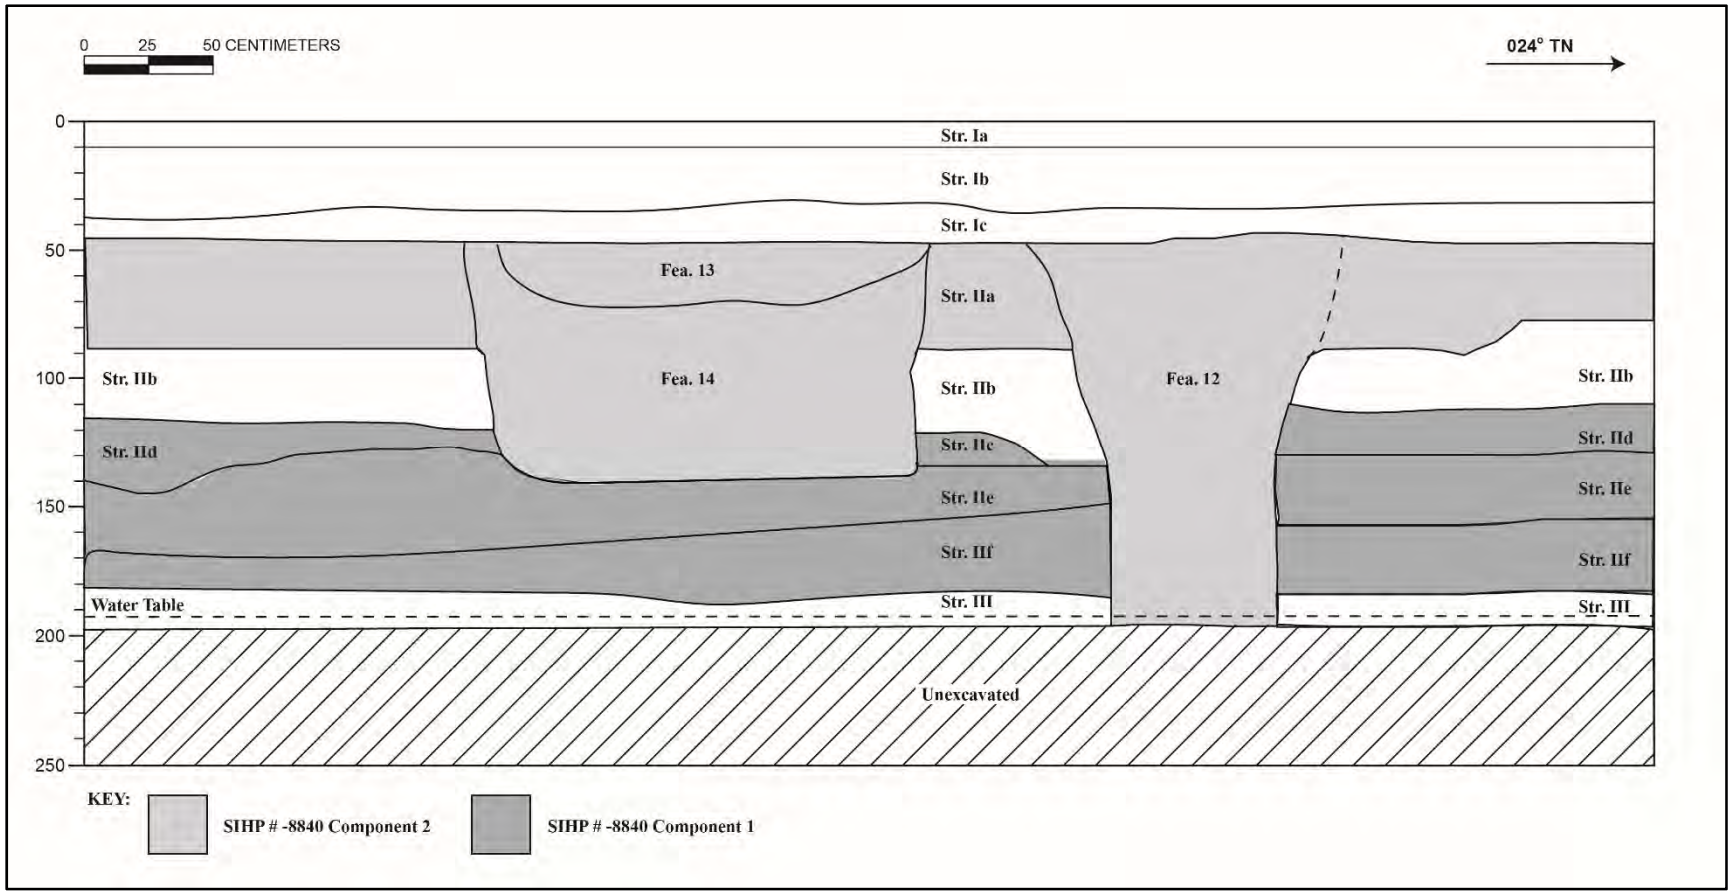

Figure 95. Profile of T-9 northwest wall

Table 14. T-9 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–10	Asphalt; parking lot surface
Ib	10–30	Base course; 10YR 2/1, black; extremely gravelly silt loam; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; basalt gravel base course
Ic	30–40	Base course; 10YR 7/3, very pale brown; very gravelly loamy sand; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
IIa	45–90	SIHP # -8840 Component 2; 10YR 3/2, very dark grayish brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; habitation layer with pit features (Features 12–14)
	45–196 (BOE)	SIHP # -8840 Component 2, Feature 12; 10YR 3/2, very dark grayish brown; silty clay loam; historical trash pit containing bottle glass, ceramic, shell midden, bird and saw-cut mammal bone, charcoal, and FAR
	45–67	SIHP # -8840 Component 2, Feature 13; 2.5Y 3/3, dark olive brown; silty clay loam; historical trash pit containing metal, ceramic, bird and cow bone, and charcoal
	44–137	SIHP # -8840 Component 2, Feature 14; 10YR 3/3, dark brown; silty clay loam; historical trash pit containing metal, ceramic, goat bone, charcoal, and FAR
IIb	72–122	Natural; 10YR 3/3, dark brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; naturally deposited alluvium
IIc	100–138	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; possible agricultural berm
IId	115–145	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; agricultural deposit with abundant oxidized (red) mottling

Stratum	Depth (cmbs)	Description
IIe	115–160	SIHP # -8840 Component 1; 10YR 4/3, brown; silty clay loam; moderate, fine, blocky structure; moist, firm consistence; no cementation; very plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; agricultural deposit with abundant oxidized (red) mottling
IIf	125–185	SIHP # -8840 Component 1; 10YR 3/2, very dark grayish brown; gravelly silty clay; strong, fine, blocky structure; moist, extremely firm consistence; no cementation; very plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; agricultural deposit with abundant oxidized (red) mottling and basalt gravel
III	181–196 (BOE)	Natural; 10YR 3/2, very dark grayish brown; very gravelly sandy loam; weak, fine, granular structure; west, slightly sticky consistence; no cementation; non-plastic; terrigenous origin; lower boundary not observed; no roots observed; streambed with waterworn basalt gravel and cobbles

Figure 96. SIHP # -8840 Component 2, Feature 12, historical trash pit, in T-9 southeast wall, view to south

Figure 97 SIHP # -8840 Component 2, Features 13 (above) and 14 (below), historical trash pits, in T-9 northwest wall, view to northwest

Strata IIc–IIf are interpreted as agricultural deposits and are designated as part of SIHP # -8840 Component 1. Strata IId–IIf contain abundant oxidized (red) mottling. Stratum IIc does not contain mottling but, based on morphology, is interpreted as a possible berm. Stratum IIc measures approximately 2 m across and 25 cm tall in the southeast sidewall. In the northwest sidewall, it measures only 50 cm across, as it appears to be truncated by SIHP # -8840 Component 2, Feature 14. (Note: it is very difficult to distinguish the T-9 berm in photographs; see Figure 102 for a photograph of a berm in nearby T-9B). The underlying Stratum III contains waterworn basalt gravel and cobbles and is interpreted as a streambed (Figure 98).

Column and bulk samples were collected from Strata IIb and IId–IIf from the southeast wall (see Figure 94; note the Stratum IIf bulk sample was collected from the trench floor and is therefore not depicted on the profile drawing). The column sample was submitted to BGP Consulting (Phillips 2019) for pollen analysis (see Section 5.4.1 for full results). The Stratum IIe sample contained no pollen and therefore could not be assessed.

The T-9 assemblage is more diverse than the T-7 assemblage, with a greater number of types identified in all productive samples. No distinct temporal trends are apparent; rather, the assemblage is characterized by less common types, particularly the spurge and madder families. Normally, this data would be interpreted as reflecting local stands of shrubs and herbs. However, as the percentages of degraded grains within the samples are very high, and the total pollen concentrations are very low, Phillips (2019) cautions that the data is likely not an accurate reflection of the original pollen assemblage. The fact that sedge pollen, indicative of a wetland environment such as a *lo‘i*, is unexpectedly scarce is likely also a product of the very poor pollen preservation within the samples.

Wet screening of the bulk samples yielded reddish nodules within Strata IId and IIe, as well as reddish-orange concretions and nodules and several tubular root casts within Stratum IIf; based on previous archaeological studies (see Section 5.1.1), these are interpreted as evidence of agricultural use.

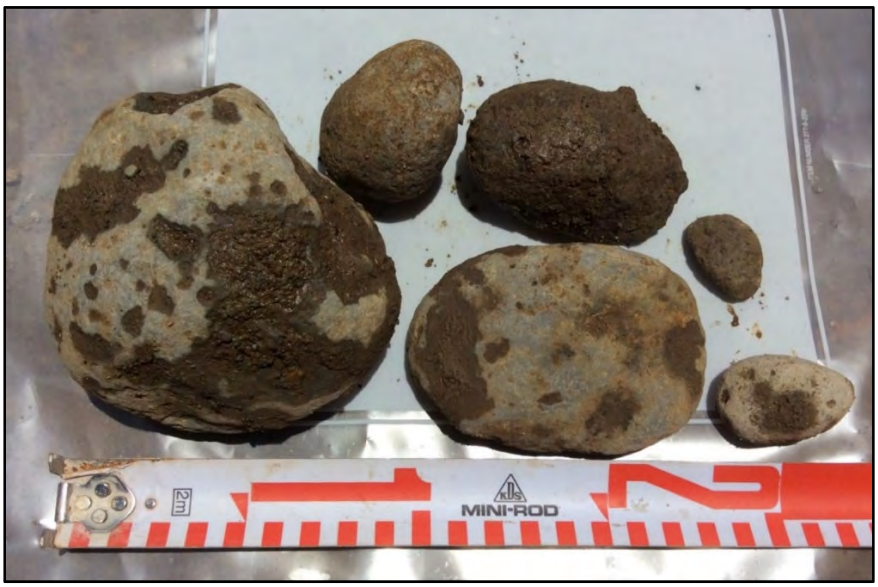

Figure 98. Waterworn basalt cobbles from Stratum III, streambed

4.3.12 Test Excavation 9B (T-9B)

Test Excavation 9B (T-9B) is an exterior excavation, just east of T-9, excavated to investigate a potential agricultural berm feature identified in T-9 (see Section 4.3.11 above). It is oriented northeast-southwest and is 6.1 m long by 0.73 m wide, with a maximum depth of 212 cmbs. The water table was not encountered.

The observed stratigraphy includes the asphalt parking lot surface (Stratum Ia), associated extremely gravelly (basalt) silt loam base course (Stratum Ib), and very gravelly loamy sand (crushed coral) base course (Stratum Ic), overlying gravelly (basalt) loam (Stratum IIa; SIHP # -8840 Component 2), loam (Stratum IIb), three layers of silty clay loam (Strata IIc–IIe; SIHP # -8840 Component 1), and very gravelly (basalt) sandy loam (Stratum III) (Figure 99, Figure 100, and Table 15). A large pocket of modern disturbance truncates Stratum II (a–e) at the *makai* (southwest) end of the excavation (see Figure 100).

Stratum II (a–e) is natural alluvium. Because Stratum IIa contains a pit feature, it is designated as part of SIHP # -8840 Component 2, habitation layers. The pit feature, designated as Feature 15, is described below.

Feature 15 is an oblong pit feature identified in the southeast wall of T-9B. It originates in Stratum IIa/SIHP # -8840 Component 2, intrudes through Strata IIb and IIc, and terminates in Stratum IIe (see Figure 100 and Figure 101). It was documented between 65 and 150 cmbs and measures 35–45 cm across. No cultural materials were identified within the feature; its function is indeterminate.

Strata IIc through IIe are interpreted as agricultural deposits and are designated as part of SIHP # -8840 Component 1. Strata IId and IIe contain abundant oxidized (red) mottling. Stratum IIc, which does not contain mottling, represents possible agricultural berms identified at both ends of the excavation. The berm at the *mauka* (northeast) end measures approximately 1.7 m across by 35 cm tall (Figure 102). The berm at the *makai* (southwest) end measures approximately 1.5 m across by 30 cm tall, although it is bisected by SIHP # -8840 Component 2, Feature 15. As these berms do not align with the potential berm identified in T-9, this area may represent the convergence of multiple agricultural plots.

Bulk samples were collected from Strata IIc–IIe, and a column sample was collected from Strata IIc and IIe from the southeast wall (see Figure 100). The underlying Stratum III contains abundant waterworn basalt gravel and cobbles and is interpreted as a streambed.

Figure 99. T-9B southeast wall, view to east

4.3.13 Test Excavation 10 (T-10)

Test Excavation 10 (T-10) is an interior excavation inside the central portion of the John R. Gilliland Sr. Building. It is oriented northwest-southeast and is 3.05 m long by 0.89 m wide, with a maximum depth of 180 cmbs. The water table was not encountered.

The observed stratigraphy includes the concrete floor (Stratum Ia), gravelly (basalt) sandy clay loam fill (Stratum Ib), an etched concrete surface (Stratum Ic; SIHP # -8840 Component 3, Feature 4), very gravelly sand (crushed coral) fill (Stratum Id), gravelly (basalt) clay loam construction fill (Stratum Ie), and a mortared brick structural remnant with a concrete foundation (SIHP # -8840 Component 3, Feature 5), overlying three layers of gravelly (basalt or cinder) silty clay loam (Strata IIa/SIHP # -8840 Component 2, IIb, and IIc/SIHP # -8840 Component 1) and cobbly (basalt) silty clay loam (Stratum III) (Figure 103 through Figure 105 and Table 16). Small mammal and saw-cut cow (*Bos taurus*) bone was collected from the spoils pile; the exact provenience is unknown.

Stratum Ib contains concrete debris. The underlying etched concrete surface (Stratum Ic) is designated as SIHP # -8840 Component 3, Feature 4 (see Figure 103 through Figure 106). It is 10–15 cm thick, documented between 28 and 43 cmbs, and extended across the entire excavation prior to be being removed. It overlies crushed coral fill (Stratum Id) and construction fill (Stratum Ie), which contain utility pipes that prevented full excavation in the southeast portion of the trench (see Figure 105). A review of historical maps suggests SIHP # -8840 Component 3, Feature 4, is associated with a former unspecified store fronting River Street, indicated on the 1950 Sanborn map as having a “CONC FL” (concrete floor) (see Figure 27 and Figure 166).

A second infrastructure remnant, designated as SIHP # -8840 Component 3, Feature 5, was identified below the Stratum Id crushed coral fill in the southern corner of the excavation, between 60 and 110 cmbs. It is composed of mortared brick atop a concrete foundation (see Figure 104, Figure 105, and Figure 107). Each brick is 13 cm long by 10 cm wide and 6 cm tall; no maker’s mark was observed. The concrete base is approximately 10 cm thick. A maximum of seven courses was observed within the exposed portion of the feature (adjacent to the southwest sidewall, not depicted in the stratigraphic profile), which comprises two walls at right angles, representing the northern corner of a former building/structure. The exposed portion of the feature is 50 cm long (northeast-southwest) by 45 cm wide (northwest-southeast) and 50 cm tall. It was not possible to extend the excavation in order to expose the feature further, due to the presence of an active subsurface electrical line.

SIHP # -8840 Component 3, Feature 5, appeared to be founded on Stratum IIb, natural alluvium, as no builder’s pit was identified within the surrounding Stratum IIa (SIHP # -8840 Component 2, habitation layer), suggesting Feature 5 pre-dates Stratum IIa. However, according to Lebo (1997:106–107), the first brick structure was built in Honolulu in 1847. As radiocarbon dating (see Section 5.4.3) indicates use of Stratum IIa by 1810, Feature 5 therefore post-dates at least the older portions of Stratum IIa (the Stratum IIa sediment likely accumulated over a relatively long period of time, with multiple episodes of deposition). A review of historical maps dating from 1906 to 1950 (see Figure 163 through Figure 166) depict no brick structure or building in this location, suggesting Feature 5 pre-dates 1906. In addition, glass, metal, and ceramic fragments collected from the spoils pile likely originate from the Stratum Ie fill, which overlies and therefore

Table 16. T-10 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–14	Concrete; John R. Gilliland Sr. Building floor
Ib	11–29	Fill; 10YR 4/4, dark yellowish brown; gravelly sandy clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; abrupt, smooth lower boundary; no roots observed; contains basalt gravel and concrete debris
Ic	28–43	SIHP # -8840 Component 3, Feature 4; etched concrete surface, likely associated with a former unspecified store on River Street
Id	37–49	Fill; 10YR 7/4, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; marine origin; abrupt, discontinuous lower boundary; no roots observed; crushed coral fill containing two utility pipes
Ie	37–100	Construction fill; 10YR 3/2, very dark grayish brown; gravelly clay loam; moderate, medium, blocky structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; utility pit composed of fill derived from alluvium and containing two utility pipes
IIa	45–170	SIHP # -8840 Component 2; 10YR 3/4, dark yellowish brown; gravelly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; habitation layer containing basalt gravel and pit features
	46–99	SIHP # -8840 Component 2, Feature 16; 10YR 3/4, dark yellowish brown; gravelly silty clay loam; pit feature of indeterminate function
	90–170	SIHP # -8840 Component 2, Feature 17; 10YR 3/4, dark yellowish brown; gravelly silty clay loam; pit feature of indeterminate function containing sparse bottle glass and FAR
SIHP # -8840 Comp. 3, Feature 5	60–110	SIHP # -8840 Component 3, Feature 5; mortared brick structural remnant with concrete foundation
IIb	74–127	Natural; 10YR 2/2, very dark brown; gravelly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; naturally deposited alluvium with root voids

Stratum	Depth (cmbs)	Description
IIc	143–160	SIHP # -8840 Component 1; 10YR 3/2, very dark grayish brown; gravelly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; agricultural deposit containing cinder gravel and oxidized (red) mottling
III	160–180 (BOE)	Natural; 10YR 3/1, very dark gray; cobbly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; streambed containing waterworn basalt gravel and cobbles

Figure 106. Plan view of SIHP # -8840 Component 3, Feature 4, etched concrete surface

Figure 107. SIHP # -8840 Component 3, Feature 5, mortared brick structural remnant with concrete foundation, in T-10 southern corner, view to south

post-dates Feature 5. These include items of U.S., Euro-American, and Asian (primarily Chinese) origin, dating from the mid-nineteenth to early twentieth century. One glass medicine bottle (Acc. # 110) dates to 1924-1940, indicating Stratum Ie was deposited after 1924. This is consistent with a late nineteenth or early twentieth century date for construction of Feature 5.

Stratum II (a–d) is natural alluvium. Because Stratum IIa contains two pit features, it is designated as part of SIHP # -8840 Component 2, habitation layers. Although the upper boundary of Feature 16 may be truncated, based on its matrix, it appears to originate in Stratum IIa. Its position at the upper boundary of the layer indicates it is more recent than (i.e., post-dates) the underlying Feature 17. Features 16 and 17 are described below.

Feature 16 is a basin-shaped pit feature identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 in the northeast wall of T-10 (see Figure 105 and Figure 108). It was documented between 46 and 99 cmbs and measures approximately 65 cm across. It overlies and

therefore post-dates Feature 17 (described below). No cultural materials were observed within the feature; its function is indeterminate.

Feature 17 is a large pit feature identified in the northeast wall of T-10, below Feature 16 (described above), which it therefore pre-dates (see Figure 105 and Figure 108). It extends from the lower boundary of Stratum IIa/SIHP # -8840 Component 2, intrudes through Strata IIb and IIc, and terminates in Stratum III. It was documented between 60 and 110 cmbs and measures 95 cm across. Several pieces of bottle glass and FAR were identified at the base of the feature. The bottle glass was collected; two diagnostic fragments (Acc. #s 74 and 76) date to 1800-1910, indicating use of the feature post-1800. The function of this feature is indeterminate.

Stratum IIc contains oxidized (red) mottling and is interpreted as an agricultural layer; it is designated as part of SIHP # -8840 Component 1. The underlying Stratum III contains waterworn basalt gravel and cobbles and is interpreted as a streambed.

Figure 108. Northwest end of T-10 northeast wall, showing remnant of SIHP # -8840 Component 3, Feature 4, etched concrete surface, above SIHP # -8840 Component 2, Features 16 and 17, pit features, view to north

4.3.14 Test Excavation 11 (T-11)

Test Excavation 11 (T-11) is an interior excavation, northeast of T-10 (discussed in Section 4.3.13 above). It is oriented northeast-southwest and is 2.96 m long by 0.71 m wide, with a maximum depth of 195 cmbs. The water table was not encountered.

The observed stratigraphy includes the concrete floor of the John R. Gilliland Sr. Building (Stratum Ia) and associated extremely gravelly (basalt) sand base course (Stratum Ib), an etched concrete surface (Stratum Ic; SIHP # -8840 Component 3, Feature 4), very gravelly (basalt) sandy loam construction fill (Stratum Id), very gravelly sand (crushed coral) fill (Stratum Ie), gravelly silty clay loam burnt trash fill (Stratum If; SIHP # -8840 Component 3, Feature 6), gravelly sandy loam fill (Stratum Ig), and very gravelly clay loam fill (Stratum Ih), overlying two layers of silty clay loam (Strata IIa/SIHP # -8840 Component 2 and IIb) and a layer of cobbly (basalt) silty clay loam (Stratum III) (Figure 109, Figure 110, and Table 17).

Beneath the current concrete floor and associated basalt gravel base course (Strata Ia and Ib) is an etched concrete surface (Stratum Ic), documented between 18 and 41 cmbs (see Figure 109 through Figure 111). Designated as SIHP # -8840 Component 3, Feature 4, it is 15–20 cm thick and extended across the entire excavation prior to being removed. The same concrete surface was documented in nearby T-10. As in T-10, it overlies construction fill (Stratum Id) and crushed coral fill (Stratum Ie). A review of historical maps suggests Feature 4 is associated with a former unspecified store fronting River Street, indicated on the 1950 Sanborn map as having a “CONC FL” (concrete floor) (see Figure 27 and Figure 166).

Below Stratum Ie is a thin burnt trash layer (Stratum If), approximately 5–10 cm thick, documented between 45 and 56 cmbs (see Figure 109, Figure 110, and Figure 112). Designated as SIHP # -8840 Component 3, Feature 6, it contains bottle glass, charcoal, and ceramics; a grab sample of glass and ceramics was collected. A saw-cut small mammal bone recovered from the backdirt pile may also be associated with the layer; however, its provenience is uncertain. Feature 6 underlies and therefore pre-dates the Feature 4 etched concrete surface (discussed above), which was likely in place by 1950. As the underlying Stratum IIa/SIHP # -8840 Component 2 habitation layer likely functioned as a surface until at least 1935 (see Section 5.2.4 discussion), Feature 6 was likely deposited sometime between 1935 and 1950. This timeline is supported by the associated artifacts. Although none of the collected artifacts were sufficiently diagnostic to be dated to a particular year or even decade, the date ranges for the items fall between the 1840s and 1930s (see Section 5.2 Artifact Analysis).

The underlying Strata Ig and Ih contain sparse red brick fragments. No maker’s mark was observed, and the fragments were not collected.

Stratum II (a and b) is naturally deposited alluvium. Stratum IIa contains charcoal flecking and pit features and is therefore designated as part of SIHP # -8840 Component 2. The two pit features, designated as Features 18 and 19, are described below.

Feature 18 is a basin-shaped pit feature identified in the western corner of T-11 (see Figure 109, Figure 110, and Figure 112). It was documented between 61 and 105 cmbs within the northwest sidewall and southwest endwall, originating in Stratum IIa/SIHP # -8840 Component 2, intruding through Stratum IIb, and terminating in Stratum III. The feature is 70 cm long

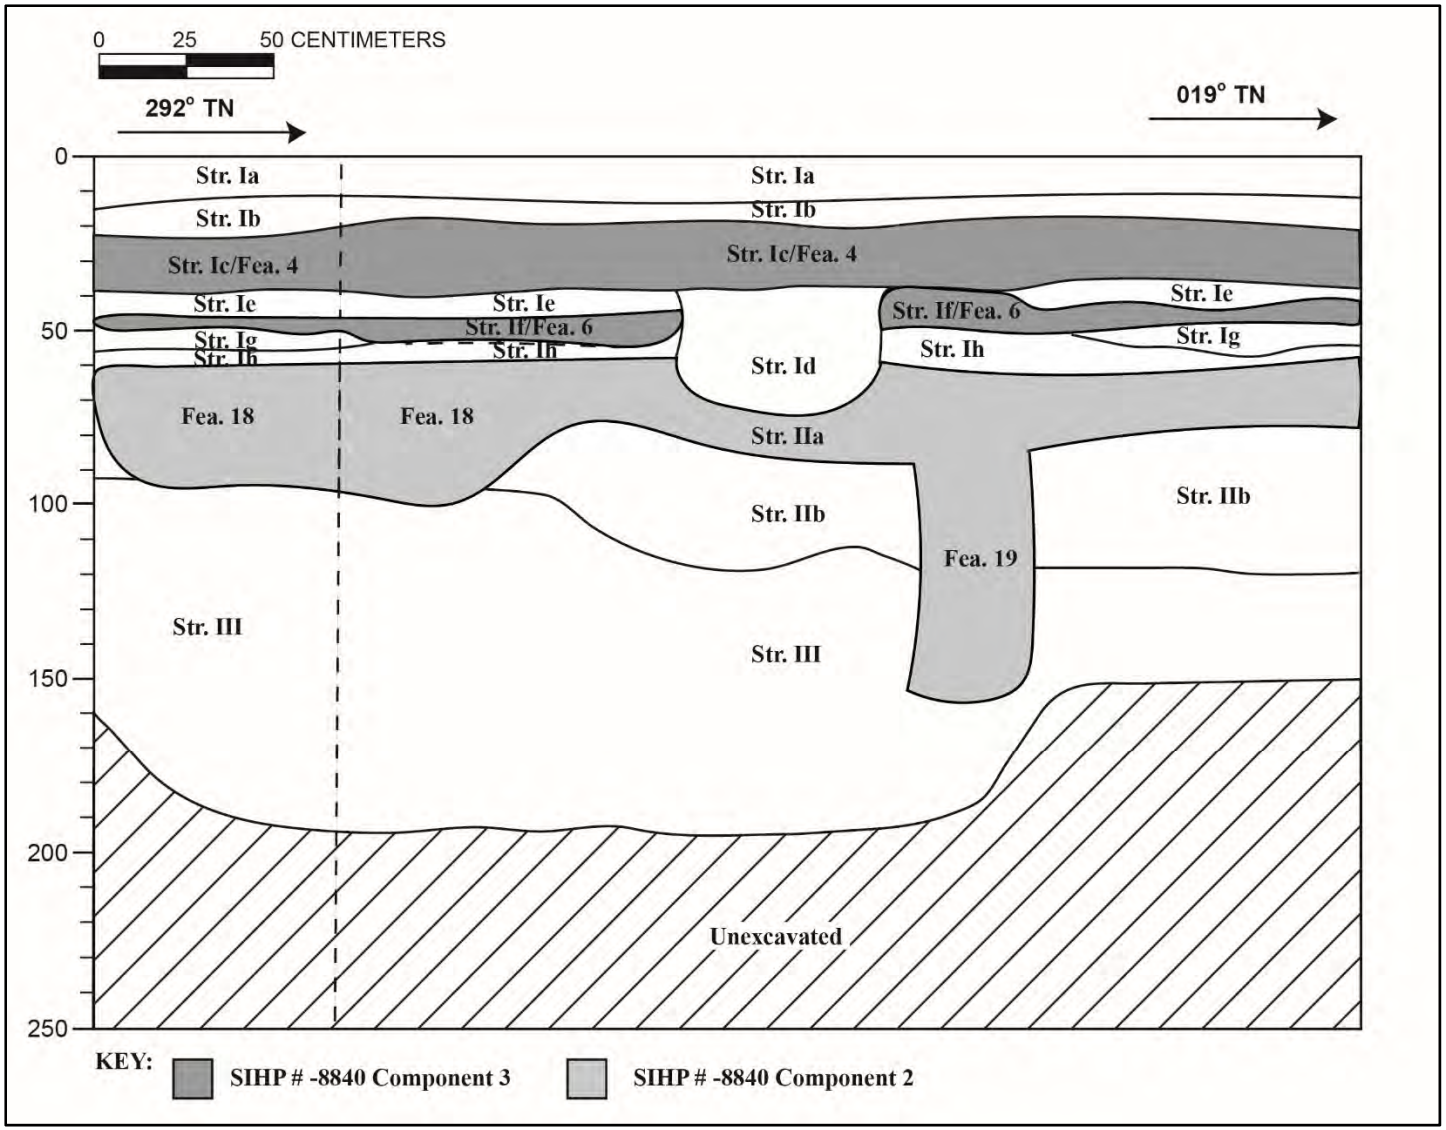

Figure 110. Profile of T-11 southwest (left) and northwest (right) walls

Table 17. T-11 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–13	Concrete; John R. Gilliland Sr. Building floor
Ib	13–19	Base course; 10YR 6/2, light brownish gray; extremely gravelly sand; structureless (single-grain); moist, loose consistence; no cementation; non-plastic; terrigenous origin; abrupt, discontinuous lower boundary; no roots observed; basalt gravel base course
Ic	18–41	SIHP # -8840 Component 3, Feature 4; etched concrete surface, likely associated with a former unspecified store on River Street
Id	38–74	Fill; 10YR 2/2, very dark brown; very gravelly sandy loam; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; mixed origin; abrupt, discontinuous lower boundary; no roots observed; contains basalt gravel
Ie	35–46	Fill; 10YR 7/4, very pale brown; very gravelly sand; structureless (single-grain); moist, loose consistence; marine origin; abrupt, discontinuous lower boundary; no roots observed; crushed coral fill
If	45–56	SIHP # -8840 Component 3, Feature 6; 10YR 2/2, very dark brown; gravelly silty clay loam; moderate, fine, granular structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; burnt trash fill containing charcoal, bottle glass, and ceramics
Ig	47–58	Fill; 10YR 6/2, light brownish gray; gravelly sandy loam; weak, fine, granular structure; moist, friable consistence; no cementation; non-plastic; mixed origin; abrupt, discontinuous lower boundary; no roots observed; contains basalt gravel, a utility pipe, and red brick fragments
Ih	50-62	Fill; 5YR 4/4, reddish brown; very gravelly clay loam; moderate, medium, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; abrupt, discontinuous lower boundary; no roots observed; contains basalt gravel and red brick fragments
IIa	54–156	SIHP # -8840 Component 2; 10YR 2/2, very dark brown; silty clay loam; weak, fine, blocky structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, irregular lower boundary; no roots observed; habitation layer containing charcoal flecking and pit features (Features 18 and 19)
	61–105	SIHP # -8840 Component 2, Feature 18; 10YR 2/2, very dark brown; sandy clay loam; pit feature of indeterminate function, containing charcoal flecking
	85–156	SIHP # -8840 Component 2, Feature 19; 10YR 2/2, very dark brown; sandy clay loam; pit feature interpreted as a post hole

Stratum	Depth (cmbs)	Description
IIb	74–118	Natural; 10YR 3/4, dark yellowish brown; silty clay loam; weak, fine, blocky structure; moist, friable consistence; no cementation; slightly plastic; terrigenous origin; clear, discontinuous lower boundary; no roots observed; naturally deposited alluvium
III	95–195 (BOE)	Natural; 10YR 4/4, dark yellowish brown; cobbly silty clay loam; very moist, friable consistence; no cementation; non-plastic; weak, medium, granular structure; lower boundary not observed; no roots observed; streambed containing waterworn basalt gravel and cobbles

Figure 111. SIHP # -8840 Component 3, Feature 4, etched concrete surface

Figure 112. Close-up of the western corner of T-11, upper portion, showing SIHP # -8840 Component 3, Feature 4 (etched concrete surface [after removal]) and Feature 6 (burnt trash layer), and Component 2, Feature 18 (pit feature of indeterminate function), view to southwest

(northwest-southeast) by 60 cm wide (northeast-southwest) and contains sparse charcoal; its function is indeterminate.

Feature 19 is a long, rectangular pit feature identified in the northwest wall of T-11 (see Figure 109, Figure 110, and Figure 113). It was documented between 85 and 156 cmbs, extending from the lower boundary of Stratum IIa/SIHP # -8840 Component 2, intruding through Stratum IIb, and terminating in Stratum III. Based on morphology, this feature is interpreted as a posthole. The darker, organic-stained portion at the center of the feature represents the location of the former post, while the surrounding pit matrix is lighter in color (see Figure 113). A small amount of charcoal was observed near the base of the feature.

The underlying Stratum III contains waterworn basalt gravel and cobbles (see Figure 114) and is interpreted as a streambed.

Figure 113. SIHP # -8840 Component 2, Feature 19, posthole, in T-11 northwest wall, view to north

Figure 114. Waterworn basalt gravel and cobbles from T-11 Stratum III, streambed

Test Excavation 12 (T-12)

Test Excavation 12 (T-12) is an exterior excavation in the northern corner of the AIS study area. It is oriented northwest-southeast and is 6.15 m long by 0.74 m wide, with a maximum depth of 252 cmbs. The water table was encountered at 247 cmbs.

The observed stratigraphy consists of the asphalt parking lot surface (Stratum Ia) and associated extremely gravelly sand (crushed coral) base course, gravelly (basalt) sandy clay fill (Stratum Ic), and cobbly (basalt) silty clay loam fill (Stratum Id), overlying silty clay (Stratum IIa; SIHP # -8840 Component 2), gravelly (basalt) silty clay loam (Stratum IIb), and silty clay loam (Stratum IIc; SIHP # -8840 Component 2), atop very gravelly (basalt) sandy clay (Stratum IIIa) and cobbly (basalt) sandy clay (Stratum IIIb) (Figure 115, Figure 116, and Table 18).

Stratum Id is a demolition fill layer containing cut basalt blocks, concrete, asphalt, bottle glass, ceramics, and brick; two glass bottles and a ceramic spoon fragment were collected. The bottles (Acc. #s 125 and 126) date to post-1921 and 1923-1956, respectively, indicating deposition of the layer post-1923. A pyramidal dressed basalt pillar with a square base was removed from Stratum Id within the southwest sidewall, near the southeast end of the trench. The pillar was photographed (Figure 117) but not collected, and the resulting void in the sidewall was documented in the profile drawing (see Figure 116). In addition, a large piece of concrete was removed from the southwest sidewall at the opposite end of the trench, from the Stratum Id/IIa interface; the resulting void was documented in the profile drawing (see Figure 116). Another large piece of concrete, approximately 5 cm thick, could not be removed from the southeast end of the trench without destabilizing the sidewalls; hence, this portion of the excavation was benched (see Figure 116).

Stratum II (a–c) is natural alluvium, although the upper portion of Stratum IIa has been disturbed or reworked and contains charcoal flecking and faunal material; hence, Stratum IIa is designated as part of SIHP # -8840 Component 2, habitation layers. The faunal material, identified as fish (Osteichthyes) bone, saw-cut cow (*Bos taurus*) bone, and possible baleen whale (*Mysteceti*), was collected.

Stratum IIc exhibited quite a bit of variation within this trench. In some places, the clay content was higher, and the sediment appeared mottled with oxidized (red) mottling; in other places, the silt content was higher, and the sediment appeared less mottled. Based on the presence of oxidized (red) mottling, Stratum IIc is interpreted as an agricultural deposit and is designated as part of SIHP # -8840 Component 1. Bulk samples were collected from Stratum IIc within the trench floor and from the spoils pile (an intact block, removed from a localized deposit indicated on the profile drawing with a dashed line). Wet screening of the sample from the trench floor yielded reddish nodules. Wet screening of the sample from the localized deposit revealed a pronounced tubule structure still intact, with reddish coloration on the interior of the broken open tubules. Based on previous archaeological studies (see Section 5.1.1), these are interpreted as evidence of agricultural use.

The underlying Stratum III (a and b) contains waterworn basalt gravel and cobbles and is interpreted as a streambed. A bulk sample of Stratum IIIa was collected from the excavator bucket.

Figure 115. T-12 southwest wall, view to west

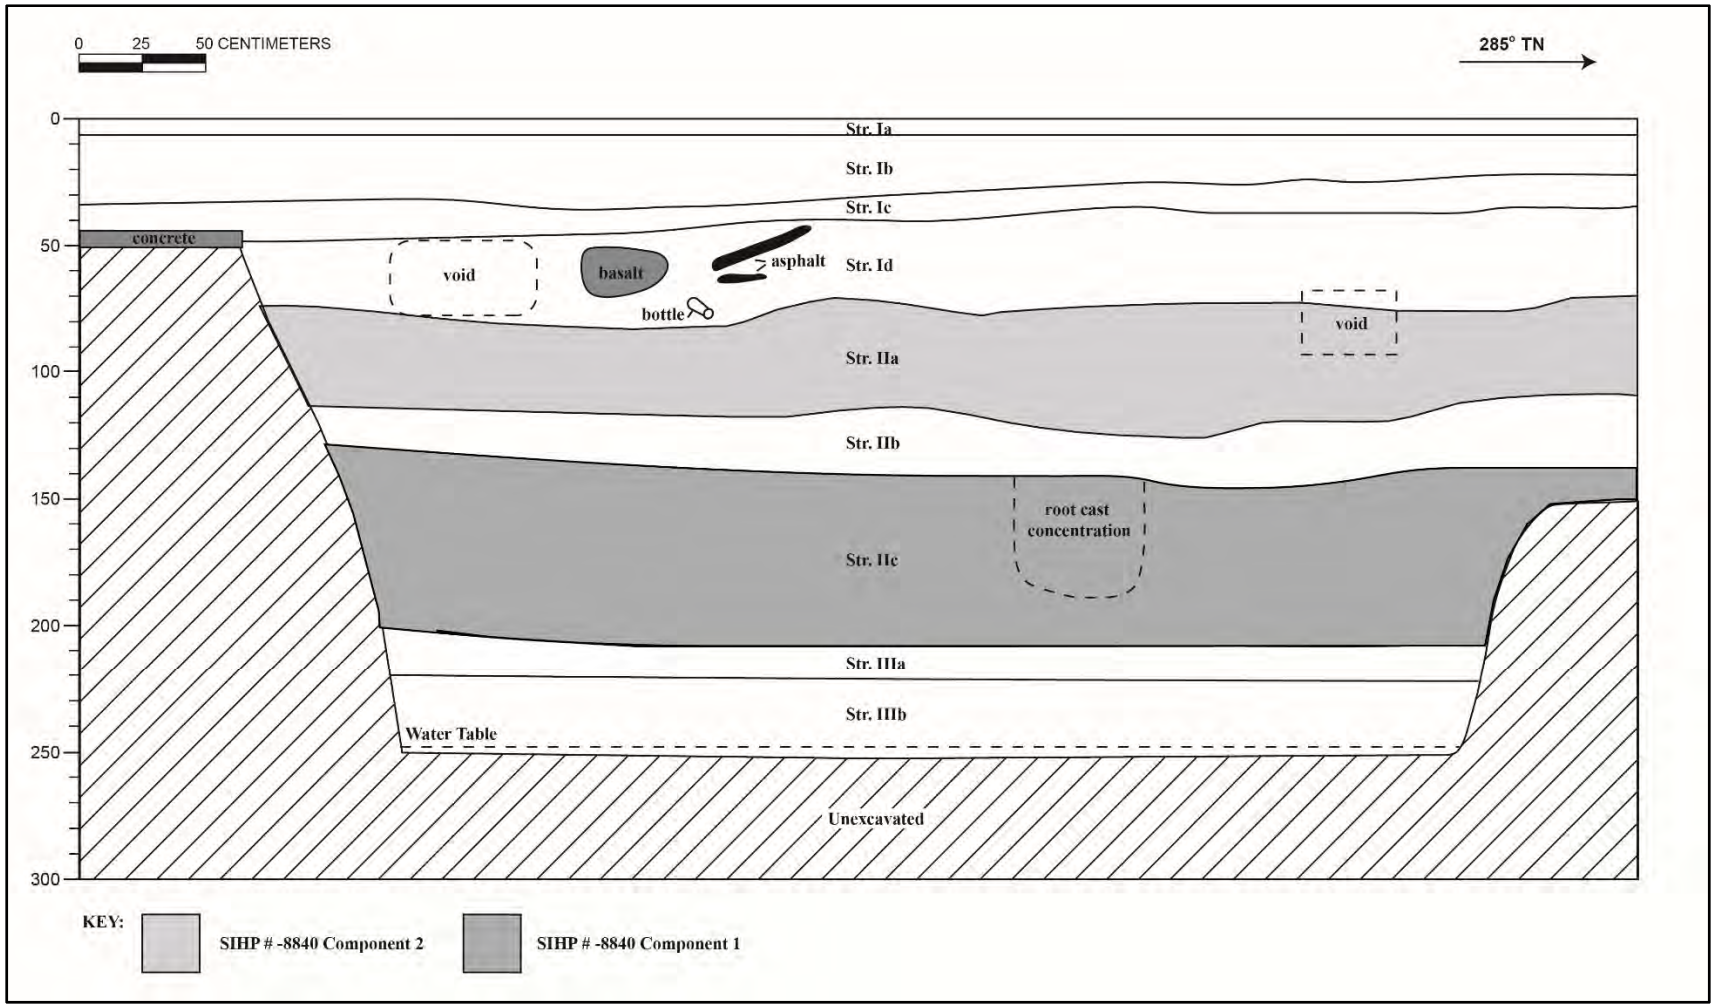

Figure 116. Profile of T-12 southwest wall

Table 18. T-12 stratigraphic description

Stratum	Depth (cmbs)	Description
Ia	0–7	Asphalt; parking lot surface
Ib	5–35	Base course; 10YR 7/3, very pale brown; extremely gravelly sand; structureless (single-grain); moist, loose consistence; marine origin; abrupt, smooth lower boundary; no roots observed; crushed coral base course
Ic	21–46	Fill; 5YR 3/3, dark reddish brown; gravelly sandy clay; moderate, medium, blocky structure; moist, firm consistence; no cementation; plastic; mixed origin; clear, smooth lower boundary; no roots observed; contains basalt gravel
Id	34–82	10YR 3/3, dark brown; cobbly silty clay loam; weak, medium, granular structure; moist, friable consistence; no cementation; slightly plastic; clear, smooth lower boundary; no roots observed; demolition fill containing basalt cobbles, concrete, asphalt, bottle glass, ceramic, and brick
IIa	70–125	SIHP # -8840 Component 2; 10YR 2/2, very dark brown; silty clay; weak, medium, blocky structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; naturally deposited alluvium with charcoal flecking, fish and saw-cut cow bone, and possible baleen whale
IIb	108–140	Natural; 10YR 3/4, dark yellowish brown; gravelly silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, fine roots; naturally deposited alluvium with basalt gravel
IIc	127–207	SIHP # -8840 Component 1; 10YR 3/3, dark brown; silty clay loam; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; few, medium roots; naturally deposited alluvium with oxidized (red) mottling
IIIa	200–222	Natural; 10YR 3/2, very dark grayish brown; very gravelly sandy clay; weak, fine, granular structure; moist, friable consistence; no cementation; plastic; terrigenous origin; clear, smooth lower boundary; no roots observed; streambed with waterworn basalt gravel
IIIb	218–252 (BOE)	Natural; 10YR 3/1, very dark gray; cobbly sandy clay; weak, fine, granular structure; wet, slightly sticky consistence; no cementation; plastic; lower boundary not observed; no roots observed; streambed with waterworn basalt gravel and cobbles

Figure 117. Cut, pyramid-shaped basalt stone removed from T-12 Stratum Id, demolition fill (not collected)

Section 5 Results of Laboratory Analysis

5.1 Bulk Sample Analysis

A total of 17 bulk samples were collected from seven test excavations during the current AIS (Table 19). Samples were collected from the Stratum II alluvium series, primarily from strata interpreted as possible agricultural deposits (i.e., SIHP # -8840 Component 1), which are likely associated with *lo‘i kalo*. Seven were wet screened to further characterize the targeted deposits. These include one sample from T-2B (Stratum IIc, interpreted agricultural deposit), near the southern corner of the AIS study area; two samples from T-12 (Stratum IIc [one general sample and one from a localized deposit], interpreted agricultural deposit), near the northern corner of the study area; and a series of four samples from T-9 (Stratum IIb, natural alluvium, and Strata IId–IIf, interpreted agricultural deposits), in the central portion of the study area.

5.1.1 Previous Archaeological Investigations of Taro *Lo‘i* Deposits

Previous archaeological investigations of former taro *lo‘i* have characterized the associated agricultural deposits as gleyed and predominantly clay, with ferruginous mottling, limonite root casts, and abundant dispersed charcoal. Maury Morgenstein's (1978) study of abandoned taro *lo‘i* within Kaiwainui Marsh, Kailua, O‘ahu documented two subsurface agricultural deposits associated with a terrace wall, both of which contained abundant diffused charcoal particles and limonite root casts:

> The presence of charcoal and ferruginous impregnated root tubes associated with the terrace wall strongly supports an agricultural hypothesis for soils layers III and IV. The root tubes are wider than the present grass vegetation root tubes and were formed by a heavier rooted plant such as Taro. [Morgenstein 1978:37]

The presence of ferruginous mottling, limonite casts, and dispersed charcoal within former *lo‘i* was also noted by Jane Allen and colleagues (1987) during extensive investigations of the Luluku field system within Kāne‘ohe, O‘ahu:

> In ponded soils, aeration along roots also oxidizes small areas in the subsoil, resulting in bright mottling within a dark, gleyed soil matrix; precipates of iron and manganese as limonite casts and manganese nodules, respectively, often occur. […] Charcoal in pondfields is typically churned and dispersed throughout the soil through subsequent cultivation and ponding activities. [Allen et al. 1987:36]

A. Rose Schilt (1980) made similar observations of *lo‘i* deposits in Hanalei Valley, Kaua‘i, and provided the following summary of her findings in relation to earlier *lo‘i* studies:

> Previous archaeological projects in Mākaha Valley, O‘ahu, and Hālawa Valley, Molokai have documented the appearance of pondfield soils in which irrigated taro has been cultivated (Morgenstein and Burnett 1972; Riley 1975). These soils are characterized by hydrated iron-oxide (limonite) tubes which appear as prominent reddish mottles. These ferruginous tubes are known to develop around the roots of taro plants, although the mechanism of concentration is not well understood. […] These tubes or mottles were quite prominent in the soil core we took in a recently cultivated lo‘i in Hanalei Valley. [Schilt 1980:29]

Table 19. Bulk samples collected during the AIS

Test Excavation	Stratum (location)	SIHP # -8840 Component 1	Depth (cmbs)	Size (L)	Screened? (Y/N)	Observations

More recently, Sroat et al. (2016) analyzed suspected buried taro *lo‘i* deposits from Waikele, O‘ahu, as part of archaeological data recovery carried out in the footprint of the Waipahu Transit Station for the Honolulu Authority for Rapid Transit’s Honolulu Rail Transit Project. As with the investigations cited above, these analyses documented varying amounts of dispersed charcoal particles, oxidized reddish (ferruginous) mottling, and tubular root casts and concretions consistent with the limonite casts and nodules described above, thought to be associated with buried taro *lo‘i* deposits (Figure 118 through Figure 120).

5.1.2 Results of Wet Screening for the Current AIS

Background research indicated the possibility for remnants of former agricultural activity within the current AIS study area, potentially including buried pre-Contact or post-Contact taro *lo‘i* deposits and/or deposits associated with Don Marín’s Vineyard. However, based on the results of radiocarbon dating of a feature associated with the Stratum IIa habitation layer (see Section 5.4.3), the interpreted agricultural deposits (Strata IIc–IIg) likely pre-date Marín’s Vineyard. During the AIS fieldwork, these interpreted agricultural deposits were observed to have sparse charcoal flecking and readily discernable reddish mottles, similar to those described in the earlier investigations (discussed above). These mottles are indicative of the type of oxidation that appears to result from chemical interactions between taro roots and the surrounding soil. Additionally, potential structural remains, interpreted as remnant pond-field berms consistent with taro *lo‘i*, were documented in T-9 and T-9B.

Photographs of each sample before and after wet screening are presented in Figure 121 through Figure 136. The results of the wet screening generally support a modest correlation between the field observation of reddish oxidized mottling and the presence of limonite nodules and root casts within the samples. For instance, the bulk sample from T-9 Stratum IIb (see Figure 124 and Figure 125) did not contain oxidized nodules or root casts, which is consistent with the lack of mottling observed during fieldwork and the interpretation of the layer as natural alluvium (i.e., not agricultural). Similarly, the T-2B Stratum IIc (see Figure 121 through Figure 123) and T-9 Stratum IIf (see Figure 130 through Figure 132) bulk samples yielded distinctive oxidized nodules and root casts, which is consistent with the strong reddish oxidized mottles observed in the field. In contrast, bulk samples from T-9 Strata IId (see Figure 126 and Figure 127) and IIe (see Figure 128 and Figure 129) and T-12 Stratum IIc (general sample; see Figure 133 and Figure 134), which were observed in the field to have reddish oxidized mottles, yielded only limited evidence of reddish limonite nodules and no evidence of root casts. These results indicate significant variability in the formation of these nodules and root casts, possibly related to minor differences in soil chemistry and/or the duration of use of the deposit for agriculture.

A second bulk sample from T-12 Stratum IIc (intact block) was markedly different from the other samples. In the southwest sidewall of T-12, within Stratum IIc (see Figure 116), a localized (approximately 70-cm by 70-cm area in the profile) and pronounced concentration of dense, clayey sediment with what appeared to be abundant root casts was observed. The bulk sample from this localized deposit was collected as a single, large, intact block (Figure 135). This bulk sample was distinctive during the wet screening process, as it did not break down with water soaking and agitation, nor during spraying with the water hose. The pronounced adherence of the matrix remained even after days of soaking and agitation, approaching cementation that was only eventually broken down into fragments by hand. Figure 136 shows some of the remnant after wet screening, with the pronounced tubule structure still intact and some reddish coloration on the

interior of the broken open tubules. This localized area of T-12 Stratum IIc appears to be distinct from the other bulk samples and likely represents different formation processes, potentially interactions with the soil and/or a different plant species.

No charcoal flecks, artifacts, or plant remains were observed in any of the samples. The lack of observable charcoal flecks in the wet screened samples may be a result of the wet screening method or the relatively modest size of the samples (0.5 to 2 liters).

Figure 118. Portion of a bulk sample collected from suspected taro *lo‘i* deposits from the Waipahu Transit Station, showing ferruginous (red) mottling, dispersed charcoal particles, and remnant root casts (from Sroat et al. 2016:73)

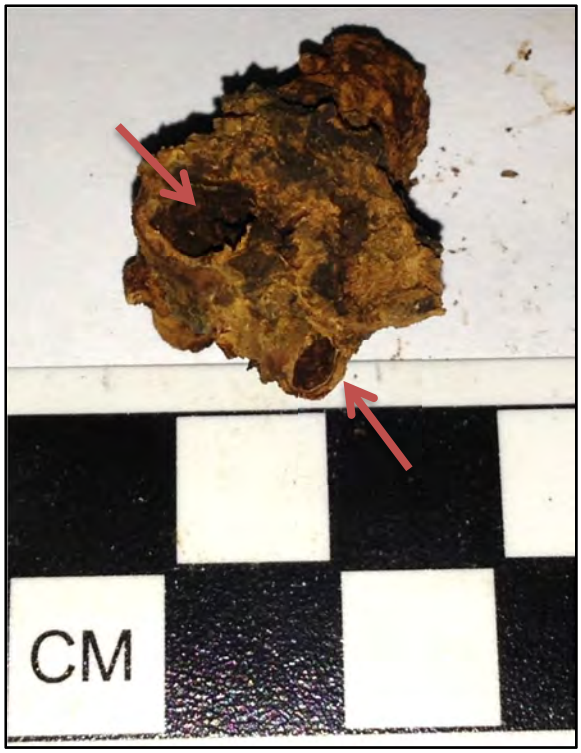

Figure 119. Dried portion of a bulk sample from suspected taro *lo‘i* deposits from the Waipahu Transit Station, showing ferruginous (red) mottling and an intact root cast (orange arrows) (from Sroat et al. 2016:77)

Figure 120. Root nodules (left) and root casts (right), identified through wet screening of bulk samples from suspected taro *lo‘i* deposits from the Waipahu Transit Station (from Sroat et al. 2016:81)

Figure 121. T-2B Stratum IIc bulk sample before wet screening; the red oxidized mottling observed in the field was less apparent in the collected bulk sample, likely as a result of drying and potentially abrasion or polishing of the large sediment masses/peds during transport within the plastic sample bag

Figure 122. T-2B Stratum IIc bulk sample after wet screening; note distinct reddish-orange concretions and nodules and several tubular root casts on right side of photo (see Figure 123 below for close-up)

Figure 123. Close-up of limonite root casts and nodules (and one natural, water-rounded basalt pebble) in the T-2B Stratum IIc bulk sample, believed to be the result of oxidation at the interface between surrounding soil and former taro roots; orange arrows indicate remnant tubules believed to have formed around taro roots and rootlets

Figure 124. T-9 Stratum IIb bulk sample before wet screening; no red oxidized mottling

Figure 125. T-9 Stratum IIb bulk sample after wet screening; no evidence of tubular root casts or nodules were observed

Figure 126. T-9 Stratum IId bulk sample before wet screening; note easily discernable reddish mottling

Figure 127. T-9 Stratum IId bulk sample after wet screening; note the reddish nodules

Figure 128. T-9 Stratum IIe bulk sample before wet screening; some reddish mottling discernable

Figure 129. T-9 Stratum IIe bulk sample after wet screening; note the small, faint, reddish nodules and the smaller volume compared to other samples of similar size

Figure 130. T-9 Stratum IIf bulk sample before wet screening; some reddish mottling discernable

Figure 131. T-9 Stratum IIf bulk sample after wet screening; note the reddish-orange concretions and nodules, several tubular root casts (right side of photo; close-up in Figure 132 below), and one limestone pebble (top right corner)

Figure 132. Close-up of limonite root casts and nodules T-9 Stratum IIf bulk sample, believed to be the result of oxidation at the interface between surrounding soils and former taro roots; orange arrows indicate remnant tubules believed to have formed around taro roots and rootlets; the reddish coloration of the interior of the root tubules can be seen in portions of tubules that have been broken open

Figure 133. T-12 Stratum IIc general bulk sample before wet screening; the red oxidized mottling observed in the field was less apparent in the collected bulk sample, likely as a result of drying and potentially abrasion or polishing of the large sediment masses/peds during transport within the plastic sample bag

Figure 135. T-12 Stratum IIc bulk sample (localized deposit) after wet screening

Figure 136. A portion of the T-12 Stratum IIc bulk sample (localized deposit) after wet screening

5.2 Artifact Analysis

Artifacts collected during the AIS were curated and analyzed by CSH personnel as described in Section 2.2.2 above. One hundred sixty-one historic artifacts were collected during the AIS; no traditional Hawaiian artifacts were identified or collected. The collected artifacts do not represent 100% collection from the study area; rather, grab samples were collected with an emphasis on representative artifact types, complete artifacts, and those with diagnostic traits. The collected artifacts are presented in Table 20 and discussed below.

The current assemblage includes 74 glass bottles or bottle fragments, one glass jar, four pressed glass artifacts, three window glass fragments, one glass marble, one unidentified milk glass object, three unidentified glass fragments, one glass insulator, 36 ceramic hollowwares, four ceramic flatwares, three ceramic tablewares, one ceramic spoon, one ceramic doorknob, two stoneware storage vessels, two stoneware bottles, one unidentified stoneware vessel fragment, four common pottery vessels, one bone grooming tool, one bone toothbrush, four nails, two metal utility pipes, four unidentified metal fragments, one carbon battery rod, one slate fragment, one brick, one coral block, one concrete brick, and one concrete masonry unit.

Artifacts were assessed for type, material, origin, and date. Artifacts were identified to country of origin where possible. Some artifacts lacked the diagnostic characteristics necessary to identify the country of origin and were identified only as Euro-American, indicating origin from a country in either North America or Europe (most likely the United States or England). Origin was only identified more specifically than country when the artifact could be identified as having been made in Hawai‘i or for a Hawaiian company.

Artifacts were assessed to determine date of manufacture first and foremost. Where applicable, manufacture date ranges were modified by available information regarding dates of import of certain materials and immigration of ethnic groups to Hawai‘i. Notable dates frequently used in this capacity are 1850, the date of increased import of goods to support the influx of missionaries; 1852, the date of the first immigration of Chinese workers; and 1868, the date of the first immigration of Japanese workers. Some date ranges are quite wide, due to a lack of diagnostic characteristics needed to narrow the range. Additionally, it is not expected that artifacts were always consumed and discarded immediately; many types of artifacts would have had long periods of use between manufacture and deposition. The below discussion includes *terminus ante quem* (latest possible date) and *terminus post quem* (earliest possible date) limits for dates of deposition of artifacts, features, and stratigraphic layers based on a combination of artifact manufacture/ import dates and available land use information.

5.2.1 Glass Artifacts

The glass artifacts include 74 glass bottles or bottle fragments, one glass jar, three pressed glass tumblers, one unidentified pressed glass fragment, three window glass fragments, one glass insulator, one glass marble, one unidentified milk glass fragment, and three unidentified glass fragments. The country of origin for 18 of the bottles could be determined; these items are from the mainland United States (n=7), Hawai‘i (n=3), the Netherlands (n=2), Scotland (n=2), Japan (n=2), and China (n=2).

Table 20. Artifacts collected during the Halewai‘olu Senior Residences AIS

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-1, Str. Ig SIHP # -8840 Component 3 Base course	Ceramic	Bottle	127	Stoneware cylindrical mineral water/gin bottle, base to body fragment, ferruginous salt glaze, unglazed interior; helical marks in interior and cut-off scars on base indicate a wheel-thrown bottle	Germany	1850-1879
	Glass	Jar	128	Cobalt blue glass jar or bottle, lip fragment, continuous external thread finish without ground rim, unidentified method of manufacture	–	Post-1900
	Ceramic	Hollowware	129	Porcelain “*tz‘u*” rice bowl, body to rim fragment (1) and base to body fragment (1), cobalt underglaze, hand-painted Double Happiness motif on exterior	China	1850-1870
			130	Porcelain hollowware, body to rim fragment, deep green glaze on exterior	Asia	Post-1852
			131	Porcelain hollowware, *kozara* dish (shallow dish for side dishes), base to rim fragment, underglaze blue floral katagami stencil decoration	Japan	1870s-1912
	Glass	Bottle	132	Colorless glass beverage bottle, base to heel fragment, cylindrical shape, slight recessed base, machine-made; embossing: “[REGI] (STERED)” on heel, partial propriety mark on base	–	Post-1908
	Ceramic	Other	133	Porcelain door knob fragment	–	Post-1850
T-2, Str. Id Demolition fill	Glass	Bottle	42	Blue aqua glass bottle, complete, cylindrical shape, slight kick-up base, mold-blown, two-piece cup-bottom mold, tooled oil finish, dimples in finish for “Swingtop” lightning-type closure (not present)	–	1897-1920
			43	Blue aqua glass bottle, complete, cylindrical shape, slight kick-up base, machine-made, club sauce or similar finish; embossing: “8” on base	–	Post-1908

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2, Str. Id Demolition fill	Glass	Bottle	44	Amber glass beer bottle, complete, cylindrical shape, flat base, machine-made, crown finish	Japan	Post-1921
T-2B, Str. Ie, Fill	Metal	Unknown	1	Rusted ferrous metal ring, unknown function	–	–
	Glass	Bottle	2	Colorless glass bottle, heel to body fragment (1), body fragments (3), and shoulder fragments (2), side seam visible on one fragment, cylindrical shape, unidentified method of manufacture	–	Post-1870
			3	Colorless glass bottle, shoulder to finish fragment, cylindrical shape, machine-made, crown finish	–	Post-1908
			4	Colorless glass bottle, base to body fragment, cylindrical body, flat base, one side mold seam and horizontal seam on heel visible, unidentified method of manufacture	–	Post-1870
			5	Colorless glass bottle, body fragment, cylindrical body, side seam evident, unidentified method manufacture	–	Post-1870
			6	Aqua glass bottle, body fragment, cylindrical shape, no seam evident, unidentified method of manufacture	–	–
			7	Blue-aqua glass bottle, base to body fragment, cylindrical shape, machine-made (press-and-blow), valve mark on base	–	Early 1910s
			8	Aqua glass beer bottle, base to body fragment, cylindrical shape, flat base, mold-blown, two-piece post-bottom mold; embossing: “[HONOLULU] B.& M.Co., LTD./ [HONO]LULU, T.H.” vertically on body, “I.P.G.CO/3004” on base (double stamped with same info); mark for Illinois-Pacific Glass Co.; would have had tooled crown finish; bottle for Honolulu Brewing & Malting Co., Ltd.	Hawai‘i	1911-1917

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2B, Str. Ie, Fill	Glass	Bottle	9	Aqua glass bottle, heel to body fragment, cylindrical shape, horizontal seam on heel, unidentified method of manufacture	–	–
			10	Gray tinted colorless glass bottle, body fragment, square body, no seams evident, unidentified method of manufacture	–	1915-1925
			11	Amber glass bottle, body fragment, cylindrical body, mold-blown, turn mold	–	1870-1920
	Ceramic	Hollowware	12	Porcelain rice bowl, base to body fragment (1), body fragment (1), and body to rim fragment (1), hand-painted blue and pink underglaze striped decoration on exterior, unglazed footring, hand-painted blue ring on base	Japan	Post-1868
			13	Porcelain "*tz'u*" rice bowl, base to body fragment (1) and body to rim fragment (1), cobalt underglaze hand-painted Double Happiness motif on exterior, unglazed footring	China	1850-1870
	Glass	Bottle	14	Amber glass bottle, body fragment, cylindrical shape, unidentified method of manufacture	–	–
			15	Olive-amber glass bottle, body fragment, cylindrical body, unidentified method of manufacture	–	–
			16	Amber glass bottle, body fragment, cylindrical shape, unidentified method of manufacture	–	–
	Ceramic	Hollowware	17	Porcelain straight-sided cup, body fragment (1), underglaze blue landscape transfer-print decoration on exterior	Japan	Post-1888

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2B, Str. Ie, Fill	Ceramic	Hollowware	18	Porcelain hollowware, base to body fragment, underglaze blue floral transfer-print decoration on interior	Japan	Post-1888
			19	Porcelain hollowware, body to rim fragment, underglaze winter green on exterior	Asia	Post-1852
			20	Porcelain hollowware, body to rim fragment, remnant of overglaze decoration (possible floral pattern) on exterior and interior	China	Post-1852
			21	Porcelain hollowware, body fragment, wintergreen with green, white, and brown floral hand-painted decoration underglaze on exterior, unglazed interior	Japan	Post-1868
		Common pottery	22	Porcelain planter, body fragment (1) and shoulder to rim fragment (1), cobalt underglaze on exterior, on flat rim, and top part of interior, applique white and green floral design on exterior	China	Post-1852
		Hollowware	23	Whiteware hollowware, body to rim fragment, underglaze polychrome green and black hand-painted decoration	–	Post-1850
		Tableware	24	Ironstone tableware, body to rim fragment, wavy rim, undecorated	Euro-America	1850-20th century
		Hollowware	25	Porcelain flatware, body fragment, undecorated	–	Post-1850

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2B, Str. Ie, Fill	Bone	Toiletries	26	Polished bone object, long thin straight-sided fragment with parallel sides and rounded end, decorative incised lines along edges of object, 11 alternating decorative square holes at rounded end, metal pin and washer through hole at rounded end; incised text: “MADE IN JAPAN” on one side; likely part of a folding personal hygiene tool	Japan	Post-1926
T-2B, Str. IIa SIHP # -8840 Component 2, Fea. 8, Historical trash pit	Glass	Bottle	27	Amber glass bottle, base to heel fragments (2), cylindrical shape, kick-up base, mold-blown, unidentified mold type	–	1800-1920
			28	Amber glass bottle, body fragment, unidentified method of manufacture	–	–
		Bottle	29	Amber glass bottle, body fragment, cylindrical shape, unidentified method of manufacture	–	–
		Window	30	Aqua flat glass fragment, one straight intact edge indicates likely part of square or rectangular pane, smooth surface	–	1838–1889
		Unknown	31	Aqua flat glass fragment, unknown function; possibly window glass but outside the thickness range of most dating methods for historic window glass	–	–
			32	Colorless glass fragment, slightly curved	–	Post-1870
		Bottle	33	Aqua glass bottle, neck to lip fragment, machine-made, small mouth external thread finish	–	Post-1908
	Ceramic	Tableware	34	Whiteware tableware fragment, undecorated	Euro-America	Post-1850
		Hollowware	35	Ironstone hollowware fragment, handle fragment, remnant of copper or gold luster	Euro-America	1850s-ca. 1900

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2B, Str. IIa SIHP # -8840 Component 2, Fea. 8, Historical trash pit	Metal	Nail	36	Wire nail, rusted, complete, round shank, pointed tip, round head	–	Post-1894
	Glass	Marble	37	Glass machine-made marble, “opaque” type, light brown	–	Post-1910
	Metal	Nail	38	Wire nail, complete, white corrosion and ferrous rust, likely nickel-plated, round head, round shaft, pointed nail end	–	Post-1894
	Metal	Nail	39	Wire nail, complete, white corrosion, round head, round shaft, pointed nail end, bent profile from being pulled	–	Post-1894
	Glass	Pressed	40	Colorless pressed glass fragment, embossed ridges on edges of fragment and convex circle on center, function unknown	–	–
		Bottle	41	Colorless glass fragment, base to body fragment, cylindrical shape, flat base, machine-made, Owens machine mark on base; embossing: “986” horizontally on heel, “B/10” on base; marks for Charles Boldt Glass Co.	U.S.	1910-1919
			45	Olive glass beverage bottle, cylindrical shape, flat base, mold-blown, turn-mold, tooled mineral finish	–	1880–1920
			46	Aqua glass bottle, base to heel fragment, cylindrical shape, slight recessed base, machine-made, suction scar on base; embossing: “15 IG” on heel, possibly mark for Imperial Glass Co.	–	Post-1908

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-2B, Str. IIa SIHP # -8840 Component 2, Fea. 8, Historical trash pit	Glass	Bottle	47	Colorless glass Dutch case gin bottle, body to lip fragment, square paneled body, tooled oil finish, applied blob seal' embossing: palm tree image surrounded by text "PALMBOOM C MEYER & Co / SCHIEDAM PALMBOOM" in seal	Netherlands	ca. 1910
	Bone	Toiletries	48	Bone toothbrush, handle fragment	–	Pre-1884
	Ceramic	Hollowware	49	Porcelain hollowware sauce dish, complete except for chips in rim, flower relief mold on interior	Japan	Post-1852
T-2C, Str. If Demolition fill	Glass	Bottle	121	Blue-green beverage bottle, neck to lip fragment, machine-made, variation of crown finish	–	Post-1908
	Ceramic	Hollowware	134	Porcelain hollowware, *kozara* dish (shallow dish for side dishes), base to rim fragment, underglaze blue transfer-print on interior	Japan	Post-1888
	Glass	Bottle	135	Aqua glass bottle, complete, cylindrical shape, flat base, mold-blown, two-piece post bottom mold, tooled crown finish; embossing: "0/81/3" on base	–	1870-1890
		Pressed	136	Colorless pressed glass tumbler, base to body fragment (1) and body fragment (1), cylindrical fluted body	–	Post-1870
	Ceramic	Unknown	139	Stoneware knob fragment, possibly lid knob, for unknown vessel, dark brown metallic glaze, possibly salt or alkaline glaze	Euro-America	–
	Glass	Bottle	161	Colorless glass bottle, complete except for thin chip from base to shoulder, cylindrical shape, flat base, vertical embossed ribs on heel and shoulder, machine-made, crown finish; embossing: "Pacific//Pacific (script)" at upward angled diagonal on shoulder, "NET CONTENTS 6 1/2 FLU[ID OZ]" on body just below shoulder, "P/ 21 (Owens-Illinois mark) 5"	Hawai‘i	1935

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-6, Str. Ic Demolition fill	Other	Brick	157	Concrete dark gray block, faced on all sides but not ground to a smooth finish	Euro-America	Post-1871
			158	Concrete hollow block, half fragment, faced on all sides, light gray; length unknown, width unknown	Euro-America	Post-1916
T-6, Str. Ie, Fill	Carbon	Other	77	Carbon graphite rod for a dry-cell battery	–	Post-1912
	Stone	Slate	78	Slate fragment, one straight edge indicating it was part of a square or rectangular panel, uniform thickness, smooth sides, painted black on both sides; possibly an early chalkboard, but slate pencils do not mark it, hence, it is not a slate board	–	–
	Glass	Bottle	79	Amber glass bottle, base to body fragment, cylindrical shape, unidentified method of manufacture	–	–
	Metal	Other	80	Ferrous metal handle, semi-circular shape	–	–
		Nail	81	Rusted wire nail	–	Post-1894
	Ceramic	Hollowware	82	Porcelain hollowware, body fragment, transparent glaze, underglaze blue *fukizumi* decoration on interior	Japan	1870s–ca. 1920
			83	Porcelain hollowware, base to body fragment, relief molded scallop decoration on exterior, scalloped base/footring	Euro-America	Post-1850
			84	Japanese ceramic rice bowl lid (futa), complete with base to rim fragment (1) and body to rim fragment (1), underglaze criss-crossing line design on exterior of hand-painted blue and light green lines and transfer-printed dark green lines	Japan	Post-1888

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-6, Str. Ie, Fill	Ceramic	Hollowware	85	Porcelain bowl, base to rim fragment high unglazed footring with one blue circle around interior and two around exterior; underglaze hand-painted blue design on exterior, slightly everted rim has blue hand-painted motif of plum blossoms on exterior side of rim	Japan	Post-1868
	Glass	Bottle	86	Amber glass liquor bottle, base to lip, cylindrical shape, slight kick-up base, mold-blown, two-piece cup-bottom mold, tooled brandy finish; embossing: “W.C. PEACOCK & CO/ (company monogram logo)/ HONOLULU, H.I./ WINE & LIQUOR MERCHANTS” vertically on body	Hawai‘i	Early 1900s
	Coral	Other	137	Coral construction block, light yellow red (orange); complete, rectangular; eroded on one side but originally faced on all sides; no trace of mortar on any side	–	–
	Other	Brick	138	Dark red brick fragment, portion of one face remaining only, no measurements possible; some mortar on one side	–	–
T-9, Str. IIa SIHP # -8840 Component 2, Fea. 12, Historical trash pit	Glass	Bottle	50	Dark amber olive (black) glass bottle, base to shoulder fragment, cylindrical shape, kick-up base, mold-blown, turn mold	–	1870-1920
			51	Dark olive (black) glass bottle, base to lip fragment, cylindrical shape, kick-up base, mold-blown, two-piece cup-bottom mold, applied mineral or brandy finish	–	1850-1885
			52	Dark olive (black) glass whiskey bottle, base to body fragment, cylindrical shape, kick-up base, Ricketts’ style plate on base, three-piece dip-mold; embossing: “R. COOPER (arch) & CO/PORTOBELLO (inverted arch)” on base	Scotland	1866-1885

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-9, Str. IIa SIHP # -8840	Glass	Pressed	53	Colorless glass tumbler, base to body fragment, cylindrical body, flat base	–	Post-1870
Component 2, Fea. 12,			54	Colorless glass tumbler, base to body fragment, fluted cylindrical shape, flat base	–	Post-1870
Historical trash pit		Bottle	55	Olive glass Dutch case gin bottle, body fragments (3), square shape, corrugated marking on body fragment typical of European case gin bottles, mold-blown, unidentified mold type, applied mineral finish; embossing: “[COSMOPO]LIET” on body above remnant of embossed male figure known as the “Standing Man”; would have been embossed with further proprietary information for J.J. Melchers Wz distillery	Netherlands	1890-1910
			56	Olive glass bottle, shoulder fragment, horizontal seam on shoulder, mold-blown, mold type unidentified	–	1870-1920
			57	Aqua glass household bottle, body to lip fragment, round body, flat base, blowpipe pontil mark on base, mold-blown, two-piece mold, “tooled” folded finish; embossing: “SPALDING'S//GLUE” vertically on body	U.S.	1850-1870
			58	Aqua glass bottle, base to body fragment, round shape, slight kick-up base, manufacturing technique unidentified, embossed ring of dots around shoulder; embossing: “393//M”; maker’s mark unidentified	–	–
			59	Olive glass champagne bottle, complete, round body, kick-up base, turn mold, applied champagne finish with beveled top, remnant of paper label on neck	–	1880s-1920
			60	Dark olive (black) glass bottle, base to body fragment, cylindrical shape, kick-up base, mold-blown, dip mold	–	1800-1910

Provenience	Material	Type	Acc. #	Description	Origin	Age
T-9, Str. IIa SIHP # -8840 Component 2, Fea. 12, Historical trash pit	Glass	Bottle	61	Aqua glass bottle, shoulder to lip fragment, mold-blown, mold type unknown, applied double ring finish	–	1800-1885
			62	Dark olive (black) glass bottle, base to body fragment, cylindrical shape, kick-up base, mold-blown, turn mold	–	1870-1920
			63	Dark olive (black) glass export beer bottle, body to lip fragment, mold-blown, dip mold, applied mineral finish	–	1878-1885
		Insulator	64	Blue-aqua glass threaded pin-type insulator, upper wire groove ridge to crown fragment	–	Post-1865
		Bottle	65	Dark olive (black) case gin bottle, base to body fragment, square shape, kick-up base, mold-blown, dip mold, faint embossed radial lines from center on base	–	1800-1870
			66	Green-aqua glass bottle, body to shoulder fragment, cylindrical shape, mold-blown, unidentified mold type	–	1800-1920
			67	Green-aqua glass bottle, body fragment, unidentified method of manufacture	–	–
			68	Aqua glass bottle, base to heel fragment, round body, slight kick-up base, blowpipe pontil scar on base, no mold seams, free-blown or dip mold	–	1850-1870
		Window glass	69	Aqua flat glass, two intact straight edges indicating it was part of a square or rectangular pane	–	1845-1889
		Bottle	70	Green-aqua glass bottle, neck to lip fragment, applied double ring finish	–	1840-1885
			71	Olive glass bottle, neck to lip fragment, mold-blown, unidentified mold type, applied grooved ring finish	–	1860-1885
			72	Olive glass bottle, neck to lip fragment, mold-blown, unidentified mold type, applied grooved ring finish	–	1860-1885

Provenience	Material	Type	Acc. #	Description	Origin	Age

5.2.1.1 Bottles

The terminology used to describe bottle traits and dating information is based on information from the U.S. Department of the Interior, Bureau of Land Management (BLM) Society of Historic Archaeology (SHA) “Historic Glass Bottle Identification and Information Website” (BLM/SHA 2018), unless otherwise noted. Bottle research focused on function and date of manufacture, using reference texts and online resources to identify maker’s marks and company histories.

5.2.1.2 Bottle Manufacturing Methods

The evolution of bottle manufacturing breaks down into three stages. Since antiquity, bottles have been free-blown with a blow pipe. Free-blown bottles are usually asymmetrical, crudely made, and have a pontil mark where a rod was used to hold the bottle during the last steps of manufacture. The lip of the bottle was finished by hand. In the United States, these types of bottles usually pre-date ca. 1865 (BLM/SHA 2018). The current assemblage contains no free-blown bottles.

Around ca. 1800, glass workers began to blow bottles in molds. The current assemblage includes 37 mold-blown bottles (Acc. #s 8, 11, 27, 42, 45, 47, 50–52, 55–57, 59–63, 65, 66, 70–74, 76, 86, 93–95, 98, 99, 107, 111, 116, 119, 135, and 159). One of the first types of molds was the one-piece dip mold, which dates from 1800 to 1870. Bottles made with this type of mold do not have seams or embossing. Beginning in 1830, the one-piece dip mold was gradually replaced by the three-piece dip mold, which dates from 1830 to 1870. A bottom mold was used to form the body of the bottle, and a hinged top mold was used to form the shoulder, neck, and finish of the bottle. This resulted in a seam wrapping horizontally around the shoulder, and two vertical side seams extending from the shoulder seam up the neck. There are no vertical side seams on the lower body. The current assemblage contains six dip-molded bottles (Acc. #s 52, 60, 65, 73, 74, and 116).

The most common type of mold is the two-piece mold, which dates from 1850 to 1920. There are four variations of the two-piece mold: hinge, key, post-bottom, and cup-bottom. The two-piece post-bottom mold was used between 1850 and 1890. This type of mold leaves two vertical side seams extending up the heel, body, and neck of the bottle from a circle seam on the center of the base. The two-piece cup-bottom mold dates to post-1850, with peak use from 1880 through the 1910s. This mold leaves a horizontal seam around the heel of the bottle, and two side seams extending from the heel seam up the bottle body and neck. In the current assemblage, three bottles were made with a two-piece post-bottom mold (Acc. #s 8, 93, and 135), and four bottles were made with a two-piece cup-bottom mold (Acc. #s 42, 51, 86, and 107). The variation of one two-piece mold bottle (Acc. # 57) could not be determined.

Turn-mold bottles date from 1870 to 1920. They were made by turning the bottles inside the mold, which left the body of the bottles seamless and shiny. Unlike free-blown bottles, turn-mold bottles are symmetrical and evenly proportioned. They can be identified by faint concentric rings around the heel and body of the bottle. Most do not have marking or embossing. Turn-molded bottles are often used for wine or liquor. There are seven turn-mold bottles in the current assemblage (Acc. #s 11, 45, 50, 59, 62, and 119). In addition, 19 bottles in the current assemblage were identified as mold-blown, but the type of mold could not be determined (Acc. #s 27, 47, 55, 56, 61, 63, 66, 70–72, 76, 89, 90, 94, 95, 98, 99, 111, and 117).

Semi-automatic machines were introduced in the 1890s and were mostly used to make wide-mouth bottles/jars. The glass had to be manually fed into the machines by glass workers. In 1903, Michael Owens invented a machine that took the place of the skilled glass workers. The machine could blow wide-mouth bottles as early as 1905 and narrow-necked bottles (e.g., beverage bottles) as early as 1908. The Automatic Bottle Machine (ABM) blew a bottle from base to lip, usually with a two-piece cup-bottom mold. The two side seams extend to and over the lip of the bottle or to a horizontal seam at the bottom of the bottle finish. The base of a bottle made in the early Owens ABM machines often had a round scar with feathered edges. There are few ways aside from the presence of the Owens suction scar on the base to distinguish a bottle made by a semi- versus fully-automatic machine; hence, both types of bottles are described in this report as "machine-made" (BLM/SHA 2019). There are 16 machine-made bottles in the current assemblage (Acc. #s 3, 7, 33, 41, 43, 44, 46, 106, 108–110, 121, 125, 126, 132, and 161).

Additionally, the manufacturing techniques for 22 bottles in the current assemblage are unknown (Acc. #s 2, 4–6, 9, 10, 14–16, 28, 29, 58, 67, 68, 72, 75, 79, 89, 90, 92, 117, and 120). These bottle fragments do not have the diagnostic physical features (e.g., pontil marks, mold seams, suctions scars, valve marks) necessary to determine the method of manufacture.

5.2.1.3 Bottle Finishing Methods

Methods for adding the bottle finish are also useful in artifact dating. In conjunction with the method of bottle manufacturing (discussed above), bottle finishing methods were used to narrow the date range of the collected artifacts. During the mold-blown era, from 1800 to ca. 1920, the lip of the bottle continued to be done by hand. Early mouth-blown bottles were removed from the blowpipe by cracking off, bursting off, or shearing the neck. The post-manipulation of the bottle to create the lip was known as "finishing." One method, known as an "applied finish," was used from 1840 to 1885. In this method, glass was applied to the bottle neck, and the finish was shaped with a specialized lipping tool. Diagnostic features of an applied finish include side mold seams that end abruptly on the neck at the bottom of the finish; excess glass slopping over the upper neck below the finish; and a horizontal ridge inside the neck of the bottle that can be felt by inserting a finger into the bottle bore (BLM/SHA 2019). Eight bottles in the current assemblage have an applied finish (Acc. #s 51, 55, 59, 63, 70, 71, 99, and 111).

The standard tooled finish was used as early as the 1860s on smaller bottles, but it did not become the dominant finishing method until 1890. The date range for a tooled finish is generally 1870 to 1920. The upper part of the bottle was refired, and some of the glass from the neck was formed into the finish with a lipping tool. Diagnostic features of a tooled finish include side mold seams that fade out on the neck of the bottle below the finish; concentric horizontal tooling marks present on the finish and upper neck; an absence of glass flopping over the upper neck; and an absence of the interior ride in the bore (BLM/SHA 2019). Seven bottles in the current assemblage have a tooled finish (Acc. #s 42, 45, 47, 86, 95, 98, and 135).

5.2.1.4 Bottle Embossing

Several other bottle characteristics can also provide dating information. These include maker's marks, proprietary embossing, bottle type, closure type, and color. A combination of characteristics is often used to assess the most likely date range for manufacture.

Accession # 8 is an aqua glass beer bottle made by the Illinois-Pacific Glass Company for the Honolulu Brewing and Malting Company. The Illinois-Pacific Glass Company was founded in 1902 as a consolidation of the Abramason-Heunisch Company, the U.S. Bottlers' Supply Company, and the Illinois Glass Company's Pacific Coast Division (Lockhart et al. 2016:417; Moody 1926:2111). The three main manufacturer's marks used were IPGCo, IPGCo with the letters formed in a diamond shape, and IPGCo surrounded by a diamond; all three can be dated generally to 1910-1925 (Lockhart et al. 2016:443). Accession # 8 features the first listed maker's mark (IPGCO) and can be more narrowly dated by its proprietary embossing to 1911-1917 (Elliot and Gould:189).

The Owens-Illinois Glass Company was created through the merger of the Owens Glass Company and the Illinois Glass Company in 1929. The company was formally incorporated as the Owens-Illinois Glass Company, Ltd., in 1931 (Lockhart and Hoenig 2018:297; Paquett 1994). It was one of the largest glass bottle manufacturers in the world, with plants across the U.S. Since the company's incorporation, three maker's marks have been used. The first maker's mark combined the logos of both companies. It comprised a diamond around an "O" containing an "I," called the Diamond-OI logo. It was used from 1929 to 1954. Number codes were also introduced in 1929. The number on the left of the logo represents the production plant, while the number on the right represents the year of manufacture. The plant and date codes on Acc. # 161 indicate this bottle was manufactured in San Francisco, California, in 1935 (Lockhart and Hoenig 2018:303).

Accession #s 52 and 73 (Figure 137) are olive glass whiskey bottles with base embossing by Richard Cooper & Company. This company was one of several glass manufacturers that emerged in Portobello, Scotland, in the late nineteenth century. Richard Cooper began manufacturing glass in 1856 alongside William Bailey, until Bailey's death in 1859. At that time, Cooper took on his brother-in-law, Thomas Wood, as a partner (Lockhart et al. 2014:493). The two split after a disagreement in 1866, dividing the company and becoming competitors. This continued until 1928, when Cooper's plant was purchased by Distillers Company, Ltd, which had previously purchased Wood's plant (Lockhart et al. 2014:494). A few different variations of Cooper's proprietary information were used as a mark throughout the years the plant operated. The variation that appears on Acc. #s 52 and 73 was used from ca. 1866-1885 (Lockhart et al. 2014:496).

Accession # 57 is an aqua glass Spalding's glue bottle. Little is known about Henry C. Spalding & Company, the company responsible for manufacturing Spalding's Celebrated Prepared Glue, but advertisements can be found in newspapers dating to the 1860s (Henry C. Spalding & Co. 1860). The current bottle is an early two-piece mold bottle, with a blowpipe pontil scar and a "tooled" rolled finish. This type of finish, though technically created using an implement on the existing glass of the bottle lip, was phased out in the 1870s and predates the implements later used to create what is typically referred to as a tooled finish (BLM/SHA_Bottle Finishes & Closures 2019). A manufacture date of pre-1870s is further supported by the discontinuation of the use of a blowpipe as a pontil ca. 1870 (BLM/ SHA_Bottle Bases 2019).

Accession # 86 (Figure 138) is an amber glass liquor bottle manufactured for W.C. Peacock & Company Ltd., of Honolulu. Walter Chamberlain Peacock was born in England in 1858 and relocated to Hawaii in 1881. He started a liquor business with George Freeth. By 1890, Freeth had left the Islands, and W.C. Peacock & Company, Ltd., was established. After Peacock's death in

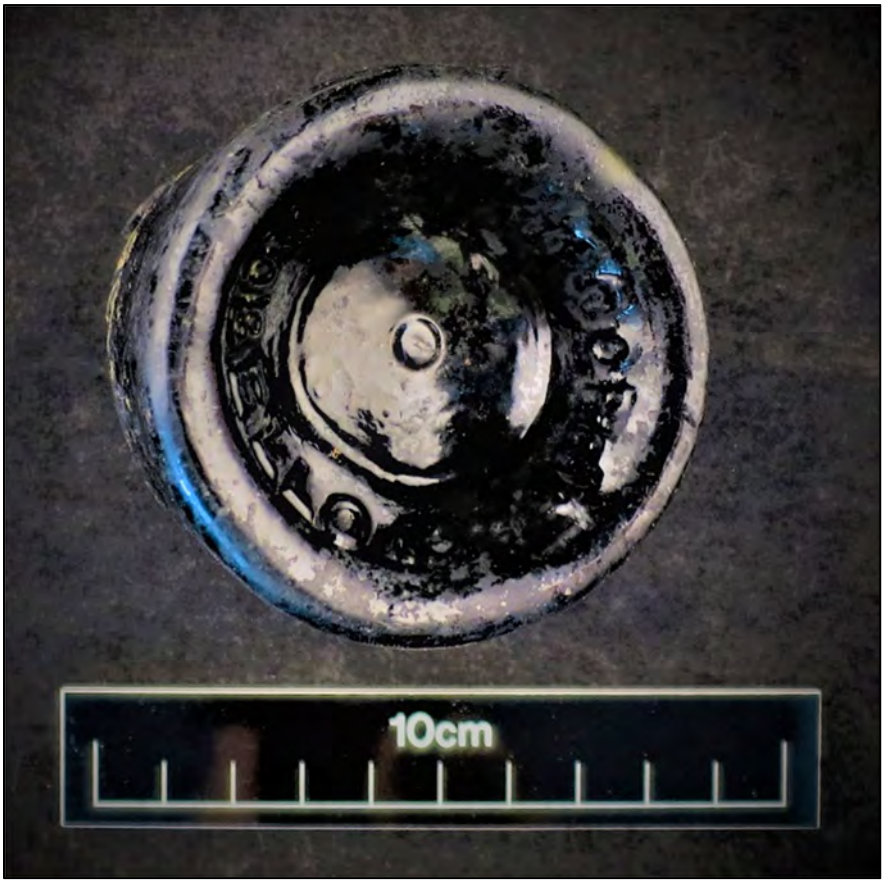

Figure 137. Acc. # 73, olive (black) glass whiskey bottle manufactured by Richard Cooper & Company

Figure 138. Acc. # 86, amber glass liquor bottle manufactured for W.C. Peacock & Company, Ltd.

1909, operation of the company passed to his nephew, before Prohibition forced the company's termination in 1915 (Sullivan 2013). The embossing on Acc. # 86 is consistent with bottles manufactured in the early 1900s (Elliot and Gould 1998:177).

Accession # 110 (Figure 139) is a colorless glass medicine bottle that held Davis brand vegetable painkiller. Created by Perry Davis to treat his own ailments and later marketed to the public, Davis' vegetable painkiller was a popular medicine sold from 1843 through the early 1940s (Davis and Son 2014; Tamburello 2008). The machine-made bottle was manufactured by the Diamond Glass Company of Pennsylvania, which was founded in 1886 when ten partners purchased and renamed the Penn Glass Works facilities. The company successfully operated and expanded to serve eastern Pennsylvania and the surrounding states through several decades, eventually merging with another firm to become Diamond-Bathurst in 1983. In 1987, it became a subsidiary of Anchor Hocking, which closed the plant for good in 1990 (Lockhart et al. 2015:88). A horizontally elongated diamond mark is embossed on the base of Acc. # 110; this logo was used by the Diamond Glass Company from 1924 to 1940 (Lockhart et al. 2015:88).

Three bottles in the current assemblage (Acc. #s 7, 106, and 108) were manufactured with a press-and-blow machine. Accession # 108 is a colorless glass milk bottle with a cap-seat finish. Based on the horizontal seam tapering out below the finish, it was made by a press-and-blow machine, which could be semi-automatic (late 1890s to mid-1910s) or fully automatic (post-1910s). Accession # 106 is a colorless glass bottle also made with a press-and-blow machine, as evidenced by the valve mark on the base. The mark is made as a machine's push-rod valve ejects the partially expanded parison from the blank mold and shifts it to the blow mold. Valve marks are round, about half an inch in diameter, and incised into the surface of the glass. As the same diagnostic features are shared by bottles made from semi-automatic and fully automatic machines, Acc. # 108 dates from the late 1890s to the mid-twentieth century (BLM/SHA 2019). Accession # 7 is a blue-aqua glass bottle with a valve mark on the base. Narrow-mouthed bottles with valve marks are uncommon, but some soda and beer bottles were manufactured on press-and-blow machines in the early 1900s (BLM/SHA 2019).

Accession # 109 (Figure 140) is a colorless glass Heinz pickle bottle. H.J. Heinz founded the company in 1869 and sold it to his brother, John, and cousin, Frederick, in 1875. They named the company F&J Heinz, which became H.J. Heinz when they sold the company back to H.J in 1888 (BLM/SHA 2019). The number embossed on the bases of Heinz bottles can help to identify bottle use and manufacture date. The "132" on the base of Acc. # 109 indicates the bottle was manufactured to hold pickles between 1918 and 1933 (BLM/SHA 2019).

Accession # 107 is an aqua glass Carter's ink bottle. Carter's Ink Company was founded in Boston in 1858 and eventually became the world's largest ink manufacturer (Faulkner and Faulkner 2003:41; Old Main Artifacts 2015). It produced ink and related products until 1976, when it was purchased by the Dennison Company (Old Main Artifacts 2015). The base embossing on Acc. # 107 indicates it was manufactured in the United States in 1897.

Accession # 55 is an olive glass Cosmopoliet Gin bottle. The gin was made by Dutch distillery Melchers, founded by Petrus Melchers in Scheidam, Netherlands, in 1837. The company made a number of branded gins, which it exported first to the United States and later to South America, Africa, and Australia. The company was operated by several generations of the Melcher family

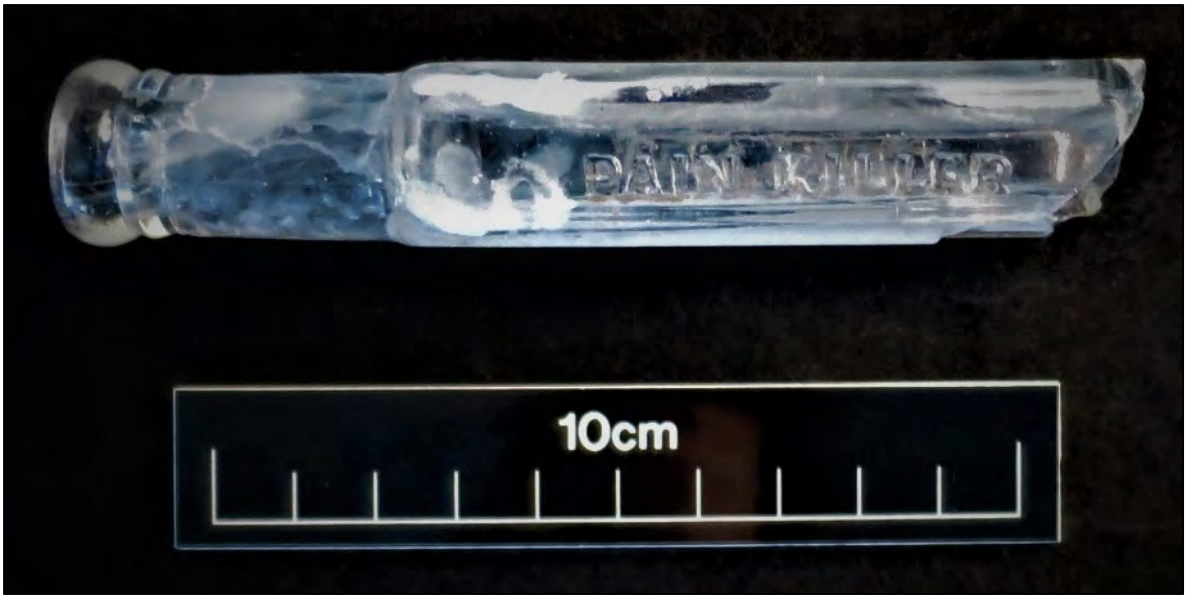

Figure 139. Acc. # 110, machine-made colorless glass medicine bottle manufactured for Davis brand vegetable painkiller

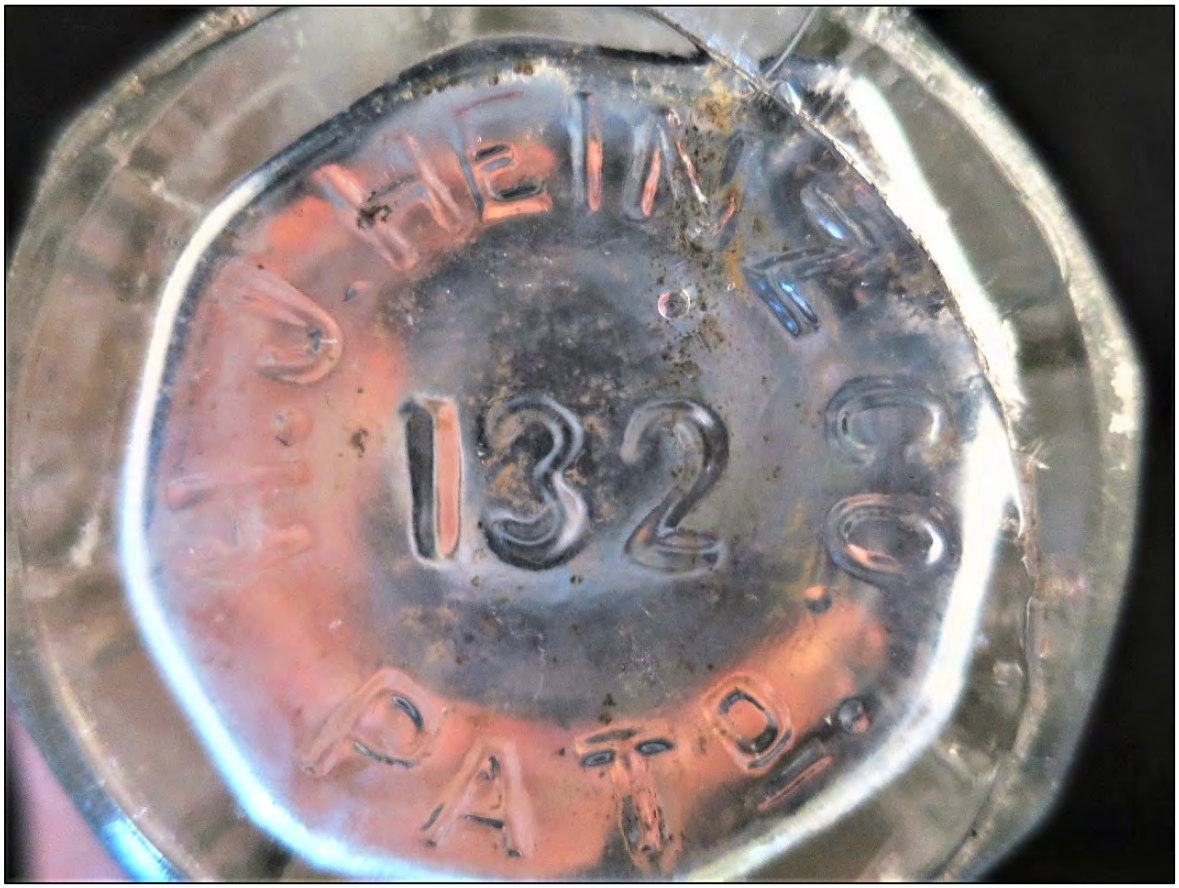

Figure 140. Acc. # 109, colorless glass Heinz pickle bottle base embossing

through both world wars, eventually being sold to the Vonk family in 1970. The company continues to produce a variety of products under the Melcher name to this day (Melchers Group 2019). Accession # 55 is a Cosmopoliet brand case gin bottle embossed with the brand's distinctive "Standing Man" figure. The bottle is incomplete, but available examples of the complete bottle show it would have had an applied mineral finish (Munsey 2009:31). Dutch case gin bottles were made with this type of finish from 1890 to 1910 (BLM/SHA 2019). Accession # 47 (Figure 141) is also a Dutch case gin bottle, colorless, with a mineral finish and a blob seal on the shoulder. This bottle was made by C. Meyer & Company, a gin distiller in Schiedam, Netherlands, about which little information could be found. This bottle, which held Palmboom gin, is common in Hawai‘i and dates to ca. 1910 (Johnston 2015:145).

Accession # 126 is a machine-made colorless glass condiment bottle manufactured by the F.E. Reed Glass Company. The company was founded in the late 1800s, when the Reed family bought into, and eventually took over, Rochester Glass Works in New York. The company produced glass for sale in the eastern United States until closing due to bankruptcy in 1956 (Lockhart et al. 2015:1). The company used the mark featured on Acc. # 126, an R in a triangle, from 1923 to 1956 (BLM/SHA 2019).

Accession # 41 is a colorless glass bottle made by the Charles Boldt Glass Company, which was founded in 1900 when the Muncie Glass Company reorganized. Boldt procured a license to manufacture liquor bottles and flasks using an Owens ABM in 1910 but sold the majority of his company stock to the Owens Bottle Company in 1919 as a result of increasing Prohibition. Owens took control of and diversified production. He acquired the rest of the company stock in 1926, closing the operation's Cincinnati plant (Schulz et al. 2014). The company used the mark that appears on Acc. # 41 from 1910 to 1919 (BLM/SHA 2019).

Accession # 42 (Figure 142) is a blue aqua glass bottle manufactured to be compatible with a "Swingtop" closure. The "Swingtop" closure is a variation of a common closure type, the lightning style closure, which features a rubber stopper held in place by a wire around the neck of the bottle. The "Swingtop" differs from a standard lightning closure in that it utilizes two dimples in the finish to hold the wire and stopper in place rather than wire around the neck of the bottle. The earliest known use of this variation is by Grolsch®, a Dutch alcohol manufacturer, in 1897 (BLM/SHA 2019).

Accession #s 44 and 125 are machine-made amber glass beer bottles with "JAPAN" embossed on the base. The McKinley Tariff Act ratified by the United States in 1891 required imports to be marked with their country of origin. Japan used "Nippon" until the term was declared inadequate by the United States in 1921, and all future imports were required to be labeled with "Japan" (Ross 2012:24).

Accession # 116 is a Chinese medicinal vial, which was made using a special process. First, a hollow glass tube was blown. Then, the tube was dipped in molten glass, and the outer body was shaped into a rectangle with four sides and a base on a hard surface. The free end of the tube was then broken from the blowpipe, creating a "burst off" finish, which was left rough on purpose, so that the rough edges would "grab" the cork seal and keep it in place. These vials contained liquid or oil-based medicine and are often associated with Chinese overseas sites in the American west dating from 1850 to 1930 (BLM/SHA 2019; Montana Historical Society 2010:7).

Figure 141. Acc. # 47, colorless glass Dutch Palmboom case gin bottle with applied blob seal

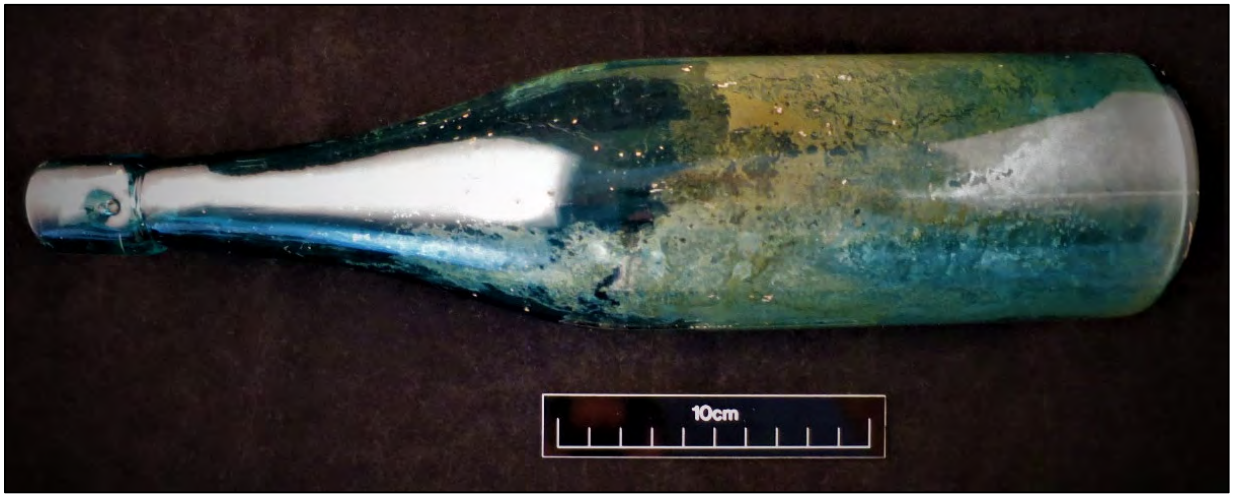

Figure 142. Acc. # 42, aqua glass beverage bottle with “Swingtop” closure

Accession # 94 is a colorless glass bottle fragment with a slight sun-colored amethyst tint. Colorless glass is usually created through the use of a decolorizing agent such as manganese dioxide. Upon exposure to ultraviolet (UV) light, manganese dioxide causes the glass to take on a tint ranging in color from light pink to moderately dark amethyst, commonly referred to as "sun-colored amethyst." Manganese dioxide was commonly used to decolor glass bottles, primarily mold-blown bottles, between 1890 and 1920 (BLM/SHA 2019). Accession # 10 is a colorless glass bottle fragment with a slight gray tint. Gray-tinted colorless glass bottles usually date from 1915 to 1925 (BLM/SHA 2019).

5.2.1.5 Miscellaneous Glass Artifacts

Accession #s 53 (Figure 143), 54, and 136 are colorless pressed glass tumblers. To make pressed glass, molten glass is poured into a mold and "pressed" with a plunger. Pressed glass tableware was produced beginning in 1825. Early pressed glass was ornate to hide manufacturing flaws (Welker and Welker 1985). By 1865, pressed glass technology had advanced, and it became more functional and affordable. True colorless pressed glass dates to post-1870 (BLM/SHA 2019).

There are three window glass fragments in the current assemblage (Acc. #s 30, 91, and 118). Flat window glass can be diagnostic depending on—among other traits—surface texture, uniformity, and thickness. Hand-blown window glass dates to pre-1920, and machine-made window glass dates to post-1905. Cylinder window glass was made when a tube of blown glass was flattened to create a large, smooth, even sheet. Its predecessors, broad and crown glass, produced glass with less even surfaces and variable thicknesses (Weiland 2009:29). Cylinder glass was the most popular type of window glass in the early nineteenth century, and an increasing demand for larger (and therefore thicker) windows resulted in a steady increase in glass thickness. Glass thickness increased from 0.75 mm in the early 1800s to 3.3 mm in the early 1900s, when machine-produced glass replaced cylinder glass (Weiland 2009:29). Accession #s 30 and 91 are both aqua window glass fragments, 2.2 mm and 2.0 mm thick, respectively. Taking into account all of the methods tested by Weiland, Acc. # 30 was likely manufactured between 1838 and 1889, while Acc. # 91 was most likely manufactured between 1840 and 1881 (Weiland 2009:31). Accession # 118 is also a flat glass fragment; however, its thickness of 7 mm is well outside the range for pre-machine-made window glass. Accession # 31 is 3.1 mm thick, which is outside the dating range of most of the methods tested by Weiland. Only one method includes glass of this thickness, indicating a date of post-1845 (Weiland 2009:31).

Accession # 64 is a blue-aqua glass insulator. Glass insulators came into use during the mid-1840s to early 1850s, when they were used on telephone and electrical power lines. They were attached to the wooden utility lines using metal pins, and their peak popularity was between 1875 and 1930. Some of the styles manufactured include toll style, telegraph style, rural and long-distance telephone styles, beehive, hoopskirt, and pony. Accession # 64 is a threaded pin-style insulator, which was invented in 1865 (Berge 1980:155–156).

Accession # 37 (Figure 144) is an opaque brown-swirled glass machine-made marble. Marbles are some of the first toys in history, with use during Roman times and the Middle Ages, and can be made of ceramic, stone, or glass. They were mass produced in Europe, particularly Germany, during the eighteenth and nineteenth centuries (Carskadden and Gartley 1990). Germany was the world leader in marble production throughout the nineteenth century into the 1920s. Marbles were

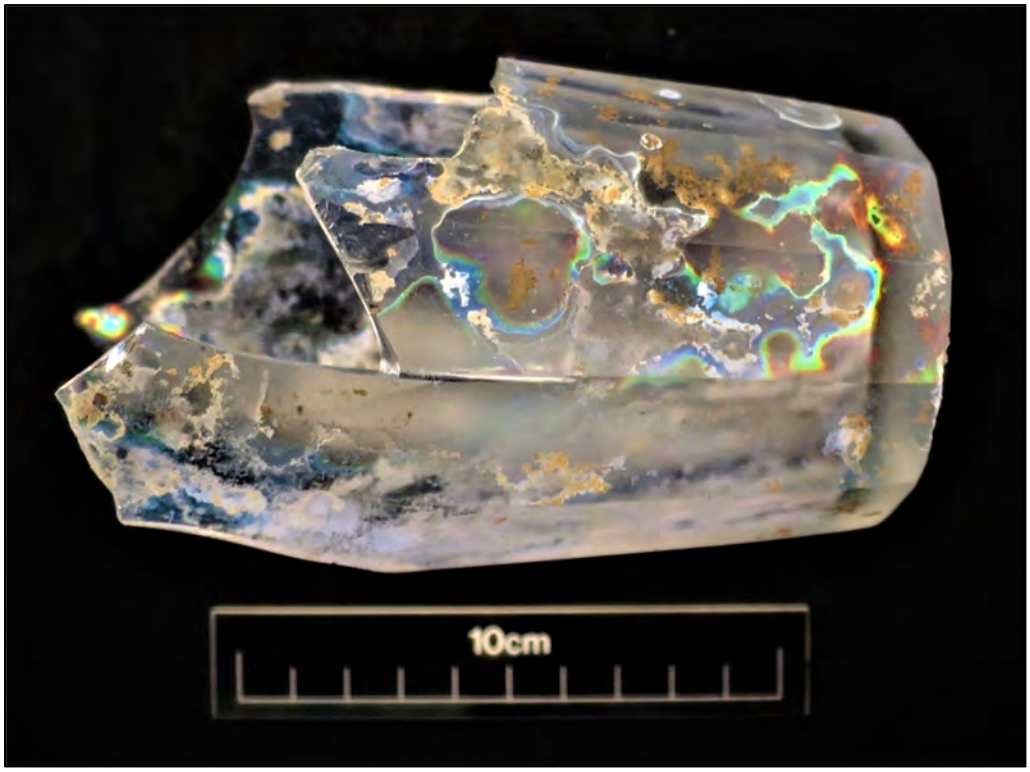

Figure 143. Acc. # 53, colorless pressed glass tumbler

Figure 144. Acc. # 37, machine-made brown glass marble

produced in the United States but not in large quantity until the invention of the automatic marble-making machine in 1901 (Randall 1971). Machine-made marbles most likely date to post-1910, when glass marbles became more common in the United States (Carskadden and Gartley 1990).

Accession # 96 is a fragment of a circular, hollow milk glass object of indeterminate function. Milk glass was first introduced in Venice during the 1500s. Milk glass tableware was popular from ca. 1870s to the mid-twentieth century. It waned in popularity during the Great Depression but experienced a resurgence after World War II. Like pressed glass, milk glass was an economical substitute for more expensive China (BLM/SHA 2019).

5.2.2 Ceramic Artifact Analysis

Ceramic vessels were analyzed for paste, shape, color, decoration, and origin. Paste includes "earthenware," "stoneware," and "porcelain." Shapes are designated as "flatware" (e.g., plates, shallow saucers) or "hollowware" (e.g., bowls, cups). When a fragment was too small to determine general shape, the artifact is listed as "tableware" (Huddleson 2013). The terminology and dates for manufacturing and decoration techniques used in this section are from the Maryland Archaeological Conservation Lab (2002) internet site "Diagnostic Artifacts of Maryland," unless otherwise noted.

Fifty-four ceramic artifacts were collected during the AIS. These include 52 vessel fragments, a spoon, and a doorknob. The 52 vessel fragments include flatware (n=4), hollowware (n=36), tableware (n=3), common pottery vessels (n=4), storage containers (n=2), bottles (n=2), and one unidentified item. Twenty-five of the artifacts originate from Euro-America, two from England, two from Germany, ten from Japan, eight from China, and three from Asia (China or Japan).

5.2.2.1 Euro-American Ceramics

The ceramics discussed in this section were manufactured in the United States or England or were identified only as Euro-American. They fall into three main categories: earthenwares, stonewares, and porcelains.

Whiteware is a type of earthenware made of a semi-porous to porous, compact material fired at 1100–1200º C (Florida Museum of Natural History 2018). Whiteware production began in 1820, with the height of production from 1850-1910 (Lebo 1997). Hand-painted whiteware dates between 1830 and 1870 (Maples 1998:110). One whiteware fragment (Acc. # 149; Figure 145) is decorated with a painted thick-line polychrome floral design, which was most popular on whiteware from 1840 to 1870.

Accession # 100 (see Figure 145) is a whiteware fragment with a transfer-print decoration. This type of decoration was made using tissue paper to transfer designs from inked, engraved plates onto the surfaces of ceramic vessels. Transfer-printing began in Staffordshire in 1783 and was popular in the United States until the mid-nineteenth century, when undecorated or minimally decorated ceramic wares came into style. There was a resurgence in use ca. 1870, and transfer-printed wares remained on the market until they were replaced by decals in the early 1900s. Accession # 100 has a scenic vignette print, which dates from 1850 to 1889 (Maryland Archaeological Conservation Lab 2019).

Figure 145. 1) Acc. # 149, whiteware hollowware fragment with hand-painted floral decoration; 2) Acc. # 100, whiteware plate marly to rim fragment with blue scenic vignette transfer; 3) Acc. # 150, dipped London-shaped whiteware bowl fragments with blue annular banding

Dipped wares are refined earthenwares decorated with clays that had different colors when fired or were dyed with mineral oxides suspended in a liquid solution called slip. Slip could be used as a dip for the entire surface of the vessel or solution to pour, band, drip, or trail decoration. Dipped earthenwares could also be decorated by removing the slip in cut patterns and exposing the ceramic body underneath. Dipped earthenwares were the most affordable hollowware decoration available from ca. 1780s through the nineteenth century. Dating is based on decorative technique and vessel shape. Accession # 150 (see Figure 145) is a London-shaped bowl with blue annular banding. Banded wares date from the 1770s to the early twentieth century, with blue bands being most common after 1840 (Miller 1991:6).

One artifact in the current assemblage, Acc. # 141 (Figure 146), is a Victorian majolica style whiteware planter. Victorian majolica is a ware characterized by intricate relief molding and brightly colored glazes, usually on earthenware (Maryland Archaeological Conservation Lab 2019). It was first produced in Great Britain in 1851 to mimic Italian Renaissance tin-glazed pottery. It then spread through Europe and the Americas, with production beginning in North America by the 1870s (Bergesen 1990:9, 87, 103; Dawes 1990:140). Victorian majolica's popularity in the United States began as a result of its appearance at the 1876 Centennial Exposition in Philadelphia. Its popularity peaked in the 1880s but waned by the turn of the twentieth century, with production discontinued in the United States by World War I (Dawes 1990:151; Maryland Archaeological Conservation Lab 2019). As Victorian majolica is relatively fragile compared to

Figure 146. Acc. # 141, whiteware Victorian majolica planter fragments

other types of wares, special use items such as butter dishes, dessert plates, and cheese plates were more common than everyday tableware (Bergesen 1990:22). Accession # 141 is decorated with a turquoise underglaze on the exterior and a lavender underglaze on the interior. The exterior body has a relief molded repeating a Celtic style pattern along the rim and heel and multicolored embossed lilies on the exterior body. There is no maker's mark on this artifact; however, while colors are not considered diagnostic, it should be noted that this color scheme was favored by popular British potter George Jones.

Accession #s 103 and 144 are yellowware hollowware fragments. Yellowware is a type of earthenware made from yellow clays in England and North America. The paste is coarser than refined earthenwares such as whitewares and porcelains, and yellowwares are fired at higher temperatures. Yellowware production began in the United Kingdom in the late eighteenth century. By 1800, North American potteries were producing yellowware in Ohio, New Jersey, Pennsylvania, and Maryland. Yellowware continued to be produced until the 1930s, but popularity declined around the turn of the century. Five common decorating techniques include slipped decoration, mocha, Rockingham glazes, oxide washes/flint enamels, and relief molding (Maryland Archaeological Conservation Lab 2019). Accession # 144 is a yellowware nappy, a plain deep bowl with flared sides (Liebowitz 1985). Nappies are a common yellowware vessel type, with most produced between 1840 and 1900 (Lebo 1997:83)

Another type of Euro-American ceramic in the current assemblage is ironstone (Acc. #s 24, 35, 143, 145–147, and 151–155; Figure 147). This is a semi-vitreous refined earthenware fired at higher temperatures than whiteware, with an intermediate hardness between whiteware and porcelain (Florida Museum of Natural History 2018). It was produced in England's Staffordshire district and in the United States. White ironstone was most popular from 1840 to 1870 but was sold into the twentieth century. Many patterns and shapes were produced and replicated by

Figure 147. 1) Acc. # 154, paneled ironstone hollowware vessel, base to body fragment; 2) Acc. # 146, ironstone ewer or pitcher fragments with J.W. Pankhurst maker's mark on base; 3) Acc. # 147, ironstone saucer fragment with Henry Alcock & Company maker's mark on base; 4) Acc. # 35, ironstone hollowware handle fragment with remnants of copper or gold luster decoration

different potters, and the rise and fall in popularity of the styles is useful for dating. Before 1860, wares with detailed molding and sharp angles were popular. Examples include foliage, paneled/scalloped, harvest, classical, and ribbed motifs. Post-1860, detailed molding was replaced by wares with simple lines (Maryland Archaeological Conservation Lab 2019; Wetherbee 1985:102). Around the turn of the century, household use declined and white ironstone began to be used commercially in hotels, train depots, and restaurants. Accession #s 145, 151, and 154 are all paneled wares, indicating a manufacture date of pre-1860.

Several ironstone artifacts in the collection have maker's marks. Accession # 146, a pitcher or ewer with relief-molded foliage, was made by J.W. Pankhurst, a British potter who operated in Hanley, Stoke-on-Trent, from 1850 to 1883 (Birks 2016). Accession # 147 is an undecorated saucer made by Henry Alcock & Company, a potter operating in Cobridge, Stoke-on-Trent, between 1861 and 1910 (Birks 2016). Accession # 35 is a hollowware handle fragment with remnants of copper or gold luster, a decoration used on ironwares from the 1850s to ca. 1900 (Wetherbee 1996:150–151). Accession #s 24, 143, 152, 153, 155, and 160 are all incomplete and lack diagnostic characteristics to further narrow the date of manufacture.

Accession # 142 is a common earthenware garden flowerpot. Flowerpots were hand thrown until William Lond made a pottery molding machine in 1861 (Scanland and Redmond 2013:30). Accession # 142 appears to be machine-made, indicating it was made after 1861.

Stoneware is fired at higher temperatures and is more vitrified and durable than earthenwares (Florida Museum of Natural History 2018). Stonewares are often decorated with a salt glaze, which is produced when salt is introduced into the kiln during firing. The salt reacts with the silicates in the clay leaving a shiny, pitted surface; this texture is also called “orange peel.” Color varies between pale beige, dark gray, and red. Accession # 156 is a stoneware vessel fragment, likely from a flowerpot. Accession # 162 is a knob fragment from an unidentified vessel with a shiny brown glaze, possibly a salt-glaze.

Accession #s 127 (Figure 148) and 148 are German “Westerwald” stoneware bottles. These bottles were made in a variety of shapes that evolved over time, but most are tall and cylindrical with a short neck and shoulder handle. They were salt-glazed for decoration. The bottles were typically used to export mineral water from the lower Westerwald region of Germany (Leavitt 2013:324); however, some were sent to Holland, filled with Dutch gin, and exported. The sturdiness of the bottles made them ideal for shipping water and gin overseas. Production range is from the early to mid-nineteenth century until World War I. Until the end of the nineteenth century, the bottles were thrown on a wheel, creating a distinctive pattern of helical ridges on the interior of the jug. In 1879, an extruding press used in the manufacture of sewer pipes was adapted for use in bottle-making, soon replacing wheel manufacture and resulting in fine, near-vertical marks on the interior of the bottles (Leavitt 2013:329). Accession #s 127 and 148 both have helical ridges on the interior, indicating they were produced before 1897.

One Euro-American porcelain fragment was collected (Acc. # 83). Porcelains are very hard, compact, vitreous, and fired at temperatures of 1300–1450º C (Florida Museum of Natural History 2018). The manufacture of Euro-American porcelain began as early as the mid-1700s, but the popularity of porcelain did not take hold until the mid- to late nineteenth century. Most Euro-American porcelain was decorated, with common techniques including overglaze painting and printing, relief molding, gilding, and decal print. Accession # 83 is a relief molded hollowware fragment, while Acc. # 133 is a doorknob. Until the mid-1800s, porcelain doorknobs were imported from France and England. In 1841, porcelain doorknobs with simple cast iron shanks were patented in the United States. They gained popularity and became more widespread by the 1860s (Hall 2009).

5.2.2.2 Asian Ceramics

Twenty-one Asian ceramic artifacts were collected during the AIS. They include 17 hollowware porcelain vessels, one porcelain spoon, one common pottery planter, and two stoneware storage jars. Eight were identified as Chinese, and ten were identified as Japanese. Another three could only be identified as Asian.

5.2.2.2.1 Chinese Ceramics

Of the Chinese ceramics collected during the AIS, three can be categorized as “*tz‘u*” wares or “Kitchen Qing” wares (Acc. #s 13, 104, and 129; Figure 149). These wares were made and exported to America between 1644 and 1911 (Lister and Lister 1989). They are typically found in nineteenth and early twentieth century archaeological contexts for overseas Chinese communities in the western United States and Hawai‘i (Costello and Maniery 1988; Lebo 1997). The immigration of Chinese to work on Hawaiian sugar plantations took place between 1852 and 1892, but several Chinese entrepreneurs had established themselves in the Islands earlier (Nordyke and

Figure 148. Acc. # 127, German stoneware bottle, base to body fragment

Figure 149. Acc. # 129, porcelain *tz‘u* rice bowl with Double Happiness decoration

Lee 1898). In fact, there were three Chinese stores in Honolulu by the 1830s dealing in “dry goods,” with at least one selling “crockery.” In this context, “crockery” probably refers to inexpensive export Chinese porcelain (Char 1974:20). Chinese exports were not only bought by Chinese immigrants but were also purchased by Hawaiians, Caucasians, and other residents. In a study on three early Chinese stores in Hawai‘i, Char (1974:31) stated that “[m]issionary and merchant families of the white population took to China goods, as did the New Englanders at home in America.”

Chinese ceramics were made with a variety of motifs including “Double Happiness,” “Bamboo,” “Four Seasons,” and “Winter Green” (Lebo 1997). The “Double Happiness” motif consists of a blue hand-painted design with two stylized “Happiness” symbols. This can be accompanied by a “Swirl” or “Sweet Pea” motif.

“Winter Green” is a decoration consisting of a light blue to bluish green glaze, usually on the interior and exterior of the vessel. It has been noted in collections containing both Chinese and Japanese ceramics. Some sources say it was a Chinese invention adopted by the Japanese in the seventh century (Lister and Lister 1989; Ross 2012), while others say it was of Japanese origin and adopted by the Chinese (Sando and Felton 2013; Stenger 1986; Wegars 1988). Certain techniques can be linked to Japanese Winter Green; these include polychrome hand-painted overglaze and the Japanese technique of *kasuri-mon* (incising the exterior of the vessel before glazing) (Ross 2012). Accession # 104 is a Chinese porcelain rice bowl with wintergreen glaze.

Lister and Lister (1989) note the Double Happiness motif is usually found in California Chinese community sites dating before 1880, while the Bamboo (Three Circles and Dragonfly) motif is found in the early part of the 1860-1900 period. The Four Seasons and Winter Green dishes are usually found in the later part of the 1860-1900 period. However, Lister and Lister (1989:53) caution that Chinese ceramic styles are “notably long-lived” and that some styles, especially the Four Seasons and Winter Green types, may have been exported to America into the mid-twentieth century. Sando and Felton (1993), using the inventory of a nineteenth century Chinese store in Northern California, researched the various prices of ceramics with different patterns. Both Double Happiness and the Bamboo pattern were considered low-priced wares, in contrast with the more high-priced ceramics, such as Four Seasons and Winter Green. Of the inexpensive patterns, Double Happiness wares are found in contexts that pre-date 1870; they are superseded by the Bamboo pattern after that date. Accession #s 13 and 129 are decorated with the Double Happiness motif (see Figure 149).

Accession # 124 is an undecorated porcelain spoon fragment. Spoons were an important Chinese eating utensil (Frierman 1983:176). The Chinese table setting would have consisted of a teacup, spoon, chopsticks, bowl, and saucer to eat soups, stews, noodles, meats, and broth (Anderson 1988; Knee 2012:69; Lister and Lister 1989). Accession # 124 dates to post-1852 (date of the first immigration of Chinese workers). Accession # 20, a porcelain hollowware fragment with an overglaze decoration, also dates to post-1852, as it lacks the necessary characteristics for further dating.

Accession #s 101 and 102 are Chinese brown-glazed stoneware (CBGS) vessel fragments. CBGS is one of the most common types of ceramics found in archaeological contexts with Chinese artifacts. They were utilitarian in function, primarily used for the shipment and storage of food (Yang and Hellmann 2013). Most vessels were produced in Canton, a province in southern China,

and were made using a combination of slab and coil technology. Because the vessels were made by hundreds of potters, there are variations in form; however, standard shapes include wide-mouth, spouted, barrel, and straight-sided jars, liquor bottles, stew pots, and pans (Yang and Hellmann 2013). CBGS vessels have buff-colored paste, an exterior glaze ranging from brown to black, and a thin, light brown interior glaze, although the glaze rarely covers the entire vessel; usually, the heel, base, and footring are unglazed (Choy 2014). CBGS can be difficult to date because similar vessel forms have been manufactured for hundreds of years (Munsey 1970:136; Yang and Hellman 1996:59).

5.2.2.2.2 Japanese Ceramics

Three decoration methods are used on Japanese ceramics: hand-painting, stencil-printing, and transfer-printing. Stencil-printing is when a paper stencil is placed over the vessel, and color decoration is applied. The two stenciling methods are called *fukizumi* and *katagami*. *Fukizumi*, or negative, stenciling is when the stencil is placed on the vessel to block pigment, and color is sprayed around the edges, creating an outline. *Katagami*, or positive, stenciling is when the color is applied to the vessel through holes in the stencil. Stenciling was used during the seventeenth century, abandoned in the eighteenth century, and reinvented in the early 1870s in Hizen province. From there, it spread to Tobe and Mino provinces between 1878 and 1882 and was later adopted in other porcelain centers across Japan (Ross 2012:7). The first Japanese transfer-printed wares were produced by potters in Tajimi in 1888 and were soon copied by other major ceramic centers. By ca. 1920, transfer-printed wares replaced stenciled wares (Ross 2012:8).

Accession #s 12, 21, and 85 (Figure 150) are hand-painted porcelain bowls dating to post-1868 (date of the first immigration of Japanese workers). Accession # 49 is a small porcelain sauce dish, with a relief-molded flower on the interior, also dating to post-1868. Accession # 82 (see Figure 150) is a porcelain hollowware fragment with an underglaze blue *fukizumi* decoration on the interior dating from the 1870s to 1920. Accession # 131 (see Figure 150) is a flatware *kozara* dish with an underglaze blue *katagami* decoration on the interior. The combination of the dish style and the stencil decoration provides a manufacture date range of 1870s to 1912 (Ross 2012:10). Accession # 84 is a rice bowl lid (*futa*) with a mix of transfer-printed and hand-painted lines dating to post-1888 (date of the first Japanese transfer-printed wares). Accession #s 17, 18 (see Figure 150), and 134 are hollowware fragments with a blue transfer-print decoration, also dating to post-1888.

5.2.3 Miscellaneous Artifacts

Accession # 48 (Figure 151) is a bone toothbrush handle fragment. Bone was the most common material for toothbrush handles up to the end of the nineteenth century. Celluloid brushes began to be made as early as 1869 and, along with other synthetic materials, almost completely replaced bone as the handle/head material by the 1940s. Two attributes that provide definitive date ranges are the number of holes/number of rows and the presence of a hole on the handle end. Before ca. 1890, brushes tended to have four or five rows of holes, with about 21 holes per row. From 1890 to 1910, brushes had three or four rows, with an average of 17 holes per row. After 1910, a brush had three or four rows, with an average of ten holes per row (Mattick 1993:182). Toothbrush makers drilled a hole at the end of the handle, starting in 1884, to encourage people to hang up their brushes to dry thoroughly and prevent the growth of bacteria (Mattick 1993:165). Based on these criteria, Acc. # 48 dates to pre-1884.

Figure 150. 1) Acc. # 85, porcelain rice bowl with hand-painted decoration; 2) Acc. # 82, porcelain hollowware body fragment with *fukizumi* decoration; 3) Acc. # 131, porcelain *kozara* dish base to rim fragment with *katagami* decoration; 4) Acc. # 18, porcelain hollowware base to body fragment with transfer-print decoration

Figure 151. Acc. # 48, polished bone toothbrush handle

Accession #s 36, 38 (Figure 152), 39, and 81 are wire nails. Wire nails are the most recently produced type of nail, manufactured in the United States from ca. 1850 to the present. They have round heads and round shafts, with consistently shaped shanks, and exhibit little change over time. Thus, distinguishing early wire nails from modern wire nails is very difficult (IMACS 1992). Wire nails were first imported to Hawai‘i by E.O. Hall and Son in 1894 (Hurst and Allen 1992 in Lebo 1997:112).

Accession # 26 is a polished bone artifact fragment that was likely part of a folding personal hygiene tool. It is incised with the words “MADE IN JAPAN,” which indicates the object was imported to the United States post-1921 (Ross 2012:24).

Accession # 87 is a 15-cm diameter ferrous metal utility pipe fragment. The first iron pipes for government utility use arrived in Hawai‘i in 1850 (Taylor 1922:374).

Accession # 78 is a slate fragment, with one straight edge indicating it was part of a square or rectangular panel. It is painted black on both sides. As slate pencils do not mark it, this is not a slate board. However, it could be an early chalkboard.

Accession # 77 is a carbon battery electrode. The first modern batteries were invented in 1800 by Alessandro Volta (Spude 2002), who produced “wet cell” batteries containing liquid electrolyte and metal electrodes. Based on principles pioneered by Volta, William Cruichshank was the first to mass produce batteries for purchase starting in 1802. In 1836, the first rechargeable battery was invented by John D. Daniell. It produced a more stable current with a system using lead acid. In 1886, the first “dry cell” battery was invented using ammonium chloride mixed with plaster (Spude 2002). This type of battery, often called a zinc-carbon battery, is the modern standard for batteries. Accession # 77 is a carbon electrode from a zinc-carbon “dry cell” battery, manufactured post-1912 (Goodman 1998:36).

Accession # 138 (Figure 153) is a dark red brick fragment with attached mortar. The first brick building in Hawai‘i was the King’s palace built in Lahaina, Maui in 1802. By 1820, “California” or “Victoria” bricks were being imported to Hawai‘i (Greer 1968:16). Local brick-making began on O‘ahu in 1839, and the first structure was built in Honolulu in 1847 (Lebo 1997:106–107). However, bricks were only manufactured for a brief time in Hawai‘i. In the 1860s, bricks started being imported from Japan (Lebo 1999). Accession # 138 is too small to provide datable information.

Accession # 137 (Figure 154) is a coral block, faced on all sides, with no mortar. It appears too small to be part of the outer wall of a structure but may be a paving brick. It measures 12.3 cm long by 11.4 cm wide and 6.6 cm thick. The block was not able to be dated.

Accession # 157 is a dark gray concrete block, faced on all sides, but not ground to a smooth finish. It is 18.6 cm long by 8.3 cm wide, and 5.6 cm thick. Solid concrete blocks were first used for construction in Hawai‘i in 1871 (Schmitt 1995:77). Accession # 158 is a concrete masonry unit (CMU) fragment. The first machine to manufacture the hollow concrete blocks was invented in 1900 (Madehow.com).

5.2.4 Summary

CSH personnel collected 161 artifacts during the AIS. Most are composed of glass (n=89) and ceramics (n=53). Artifacts were collected from fill deposits, including demolition fills and a burnt trash fill (SIHP # -8840 Component 3, Feature 6), and the Stratum IIa/SIHP # -8840 Component 2 habitation layer, mainly from historical trash pit features. In general, the artifact assemblage dates from the mid-nineteenth to mid-twentieth century and consists of domestic items associated with the residential and commercial development of the study area.

The glass artifacts consist primarily of beverage bottles, with more than twice as many mold-blown bottles (1800-1920) as machine-made bottles (post-1908). Many of the mold-blown bottles are early mold types and have applied finishes (1800-1885), although a small number of later two-piece molds with tooled finishes are also present. Most of the bottles for which country of origin could be identified were manufactured in the United States, while the rest are from Scotland, the Netherlands, Japan, and China. Three were identified as having been manufactured for use by Hawaiian companies. Likely manufacture dates of bottles in the current assemblage span the full length of a century from ca. 1850-1950.

The ceramic artifacts are mostly hollowware vessels originating from Euro-American countries, primarily England. Ironstone is the most common ware type, with most dating to the latter half of the nineteenth century. Porcelain artifacts from Japan and China that could be dated from decoration type date primarily to the latter half of the nineteenth century as well. The ceramics from Euro-America date to the late nineteenth to early twentieth century.

The dating of diagnostic artifacts can be used to assess the earliest and latest possible dates for the deposition of fills and structural remnants and the use of cultural layers and features. Artifacts

were collected and analyzed from four pit features associated with the Stratum IIa/SIHP # -8840 Component 2 habitation layer. Three of these features (Features 8, 12, and 14) were documented at the upper boundary of the layer and are interpreted as historical trash pits. The fourth (Feature 17) extended from the lower portion of the layer; its function is indeterminate. As features were documented within different vertical portions of the quite thick layer, Stratum IIa was likely deposited in multiple episodes over a potentially extended period of time. If this were the case, features in the upper portion of the layer would therefore post-date those in the lower portion of the layer. Furthermore, radiocarbon dating (see Section 5.4.3 below) suggests the lower portion of Stratum IIa was in place by 1810. The artifact assemblage supports this timeline, as two diagnostic glass fragments (Acc. #s 74 and 76) collected from Feature 17, at the lower boundary of Stratum IIa, date to 1800-1910, indicating use of the feature during that time period. In contrast, diagnostic artifacts collected from Features 8, 12, and 14, at the upper boundary of the stratum, indicate use of these features post-1910 (Acc. #s 37, 41, and 47), post-1890 (Acc. # 55), and post-1880 (Acc. # 159), respectively.

Furthermore, analysis of artifacts collected from fill deposits overlying the Stratum IIa/SIHP # -8840 Component 2 habitation layer can provide an indication of how long Stratum IIa was exposed and functioned as a surface prior to being in-filled. The results of this analysis indicate Stratum IIa functioned as a surface into the twentieth century, as recently as the mid-1930s. This is based on diagnostic artifacts associated with T-2 Stratum Id (Acc. # 44), T-2B Stratum Ie (Acc. # 26), T-2C Stratum If (Acc. # 161), T-6 Stratum Ie (Acc. # 77), T-10 Stratum Ie (Acc. # 110), and T-12 Stratum Id (Acc. # 126), which date to post-1921, post-1926, 1935, post-1912, 1924-1940, and 1923-1956, respectively.

Artifact analysis also assists in establishing dates of likely deposition for SIHP # -8840 Component 3 infrastructure remnants. For instance, a glass beverage bottle (Acc. # 132) collected from T-1 Stratum Ig, base course associated with SIHP # -8840 Component 3, Feature 1 (oil-rolled crushed coral surface), dates to post-1908, indicating Feature 1 was deposited after that date. Furthermore, the dating of SIHP # -8840 Component 2, Feature 8 (historical trash pit, discussed above), provides a *terminus post quem* of 1910 for SIHP # -8840 Component 3, Feature 2 (hollow tile wall), which directly overlies it.

In addition, artifacts were collected from SIHP # -8840 Component 3, Feature 6, burnt trash fill (T-10 Stratum If). Although none of the collected artifacts were sufficiently diagnostic to be dated to a particular year or even decade, the date ranges for the items fall between the 1840s and 1930s. However, the date range for the deposition of Feature 6 can be narrowed further, since it overlies and therefore post-dates the Stratum IIa/SIHP # -8840 Component 2 habitation layer. Analysis of artifacts from features associated with Stratum IIa and from overlying fill deposits suggests Stratum IIa functioned as a surface until at least 1935 (see discussion above); hence, the Feature 6 burnt trash fill was likely deposited after that date. In addition, a review of historical maps suggests the overlying SIHP # -8840 Component 3, Feature 4 (etched concrete surface), was in place by 1950, indicating Feature 6 pre-dates that time. The Feature 6 artifact assemblage, with its potential range of 1840s to 1930s, is consistent with deposition of the layer sometime between 1935 and 1950.

5.3 Faunal Analysis

5.3.1 Faunal Osseous Remains

CSH personnel collected faunal osseous remains from ten of the 15 test excavations during the current AIS. The identified remains, as shown in Table 21, include pig (*S. scrofa*), cow (*B. taurus*), fish (Osteichthyes), bird (Aves), goat (*C. hircus*), and possibly baleen whale (Mysticeti). These include a Polynesian-introduced species (i.e., pig), historically introduced species (i.e., cow and goat), and possible native/endemic species (fish, birds, and possibly whale). Most of these remains are considered to be food refuse, with many exhibiting evidence of post-Contact butchering methods as indicated by striated cut marks from a saw; these butchered remains are primarily cow and pig. One sample of pig remains also exhibits potential evidence of heat alteration, further supporting its interpreted function as food refuse.

The collected material for which the provenience was known came from fill deposits (Stratum I), usually demolition fill layers, and from Stratum IIa/SIHP # -8840 Component 2, the upper of two habitation layers. Most of the material associated with Stratum IIa/SIHP # -8840 Component 2 was collected from three pit features in T-9 (Features 12–14), interpreted as historical trash pits. These features originate at the upper boundary of the stratum and are therefore interpreted as being more recent than features identified within lower portions of the stratum, which appears to have accumulated over a relatively long period of time and may have functioned as a surface from the pre- or very early post-Contact period into at least the 1920s (see Section 6.2.1 discussion). The identification of faunal osseous material from historically introduced species (goat, cow) and with evidence of post-Contact butchering methods within the features supports this interpretation.

Only in T-12 were faunal osseous remains collected from the general layer of Stratum IIa (i.e., not collected from a feature). Notably, these remains include material tentatively identified as possible baleen whale by Dr. Kenneth Longenecker of the Hawai‘i Institute of Marine Biology, who examined photographs of the material. Whales are divided into two suborders: baleen whales (Mysteceti) and toothed whales (Odontoceti). In place of teeth, baleen whales have baleen, bristly plates composed of keratin, which the whale uses to “filter, sift, sieve or trap” its prey from seawater inside its mouth (Whale and Dolphin Conservation, n.d.). The humpback whale is by far the most common baleen species found in Hawaiian waters, although there have been rare sightings of other species (State of Hawai‘i Division of Aquatic Resources 2019).

Whalers, primarily American vessels, began arriving in Hawai‘i in the early nineteenth century. For Hawaiian ports, especially Lahaina and Honolulu (0.7 km southwest of the current project), the whaling fleet was the crux of the economy at that time, and whale oil was used for heating, lamps, and in industrial machinery (HawaiiHistory.org 2019). Because dried baleen is strong, light, flexible, and hard-wearing, it was useful as construction material. Baleen was used in a variety of commercial enterprises, including the manufacture of fashion items, particularly corsets, collars, and frames for hooped skirts. In addition, it was also used in chimney sweep brushes, umbrella ribs, riding crops, buggy whips, hat brims, and upholstery stuffing (Smithsonian, n.d.; University of Aberdeen Department of Zoology 2002). The discovery of petroleum in 1859 in Pennsylvania signaled the end of the whaling industry (HawaiiHistory.org 2019).

Table 21. Faunal osseous remains collected during the AIS

Provenience	Taxon	Weight (g)	Description
T-1, Str. Ig/SIHP # -8840 Component 3, Fea. 1 Base course	*S. scrofa* (pig)	12.3	Mandible portion with M1, M2
T-2, Str. Id Demolition fill	*S. scrofa* (pig)	27.0	Proximal rib portion, various fragments; possible heat alteration
T-2B, Spoils	*B. taurus* (cow)	177.9	Long bone section, saw-cut
T-2C, Str. If Demolition fill	Medium mammal, inconsistent with human	7.9	Small fragments
T-4, Spoils	Small mammal	4.3	Long bone portion
	B. taurus (cow)	12.7	Rib section, saw-cut
T-6, Str. Ic Demolition fill	Osteichthyes (fish)	0.8	Unknown portion
T-6, Str. Ie, Fill	*Sphyraenidae* sp. (barracuda)	3.8	Dentary
T-9, Str. IIa/SIHP # -8840	Aves (bird)	4.7	Femur, ulna
Component 2, Fea. 12 Historical trash pit	Mammal, inconsistent with human	6.2	Fragments, saw-cut
T-9, Str. IIa/SIHP # -8840 Component 2, Fea. 12 Historical trash pit	Aves (bird)	8.4	Phalanx, carpometacarpus, and distal tibiotarsus, various portions and fragments
	B. taurus (cow)	22.0	Vertebral portion
T-9, Str. IIa/SIHP # -8840 Component 2, Fea. 12, Historic trash pit	*C. hircus* (goat)	5.4	Femur fragment
T-10, Spoils	*B. taurus* (cow)	42.4	Scapula section, saw-cut; other fragment
	Small mammal	1.6	Misc. fragments
T-11, Spoils	Small mammal	1.5	Long bone portion, saw-cut
T-12, Str. IIa/SIHP # -8840 Component 2	Possible Mysticeti (whale)	67.6	Possible baleen
Habitation layer	Osteichthyes (fish)	9.7	Vertebral fragments
	B. taurus (cow)	2.8	Cortical fragment, saw cut

5.3.2 Invertebrate Faunal Remains

Invertebrate faunal remains were collected from a single test excavation (T-9) and are summarized in Table 22. The shells, identified as *Periglypta reticulata*, were collected from SIHP # -8840 Component 2, Feature 12, interpreted as a historical trash pit. This bivalve species is consistent with midden (i.e., food refuse). Based on the completeness of the shells, the consistency of their sizes, and their lack of damage, this is likely historical (i.e., post-Contact) midden. This interpretation is supported by the Feature 12 artifact assemblage, which indicates the feature post-dates 1890.

5.4 Floral Analysis

5.4.1 Pollen Analysis

Ten samples from two test excavations (T-7 and T-9) were submitted to BGP Consulting, LLC, for pollen analysis. The samples target a vertical series of natural alluvium deposits (Stratum II), including interpreted agricultural deposits (SIHP # -8840 Component 1). The samples are summarized in Table 23, and the report by BGP Consulting, LLC (Phillips 2019), is presented in Appendix C. The results of the analysis are discussed below.

It should be noted that no samples were sufficient for standard counts, and pollen is completely absent from four samples. In samples containing pollen, the percentages of degraded grains range from relatively high (19.3%) to very high (39.5%), indicating poor preservation. Hence, the data is likely not an accurate reflection of the original pollen assemblage.

5.4.1.1 Test Excavation 7

Six samples from T-7 were submitted for palynological analysis. The samples were collected from Strata IIa–IIf, naturally deposited alluvium. Strata IIc and IId contain charcoal flecking and oxidized (red) mottling and are interpreted as agricultural deposits (SIHP # -8840 Component 1). The Strata IIa, IIb, and IIf samples contained no pollen and are therefore not discussed further.

Asteraceae and Cheno-Ams dominate the Stratum IIe sample, suggesting a shrubland environment. Grass pollen gradually increases over time (i.e., increases up the column sample), becoming dominant in Stratum IIc. A single large grass grain identified in Stratum IIc may represent rice (*laiki*; *Oryza sativa*) or sugarcane (*kō*; *Saccharum* sp.) cultivation in the vicinity or the collection of *pili* (*Heteropogon contortus*) grass. In addition, a high proportion of fern spores in Stratum IIc might reflect increased input from upslope and/or overbank flooding.

5.4.1.2 Test Excavation 9

Four samples from T-9 were submitted for palynological analysis. The samples were collected from Strata IIb and IId–IIf (naturally deposited alluvium). Strata IId–IIf contain abundant oxidized (red) mottling and are interpreted as agricultural deposits (SIHP # -8840 Component 1). The Stratum IIe sample contained no pollen and is therefore not discussed further.

The T-9 assemblage is more diverse than the T-7 assemblage (discussed above), with a greater number of types identified in all productive samples. No distinct temporal trends are apparent; rather, the assemblage is characterized by less common types, particularly the spurge and madder families. Normally, this data would be interpreted as reflecting local stands of shrubs and herbs.

Table 22. Invertebrate faunal remains collected during the AIS

Provenience	Taxon	Comment
T-9, Str. IIa SIHP # -8840 Component 2, Fea. 12 Historic trash pit	*P. reticulata*	MNI of 25 valves; completeness of shells, consistency of size, and lack of damage indicate this is likely historic (i.e., post-Contact) midden

Table 23. Samples submitted for palynological analysis

Test Excavation	Sample #	Stratum	Depth (cmbs)	SIHP #	Description
7	1	IIa	44–47	–	Natural alluvium
	2	IIb	76–79		
	3	IIc	107–110	SIHP # -8840	Agricultural deposit
	4	IId	148–151	Component 1	
	5	IIe	172–175	–	Natural alluvium
	6	IIf	190–193		
9	7	IIb	111–114		
	8	IId	128–131	SIHP # -8840	Agricultural deposit
	9	IIe	150–154	Component 1	
	10	IIf	170–173		

Large grass grains in Strata IIb and IId provide additional evidence for rice (*laiki*; *O. sativa*) or sugarcane (*kō*; *Saccharum* sp.) cultivation in the vicinity or the collection of *pili* (*H. contortus*) grass, as suggested by the single grain identified in the T-7 Stratum IIc sample (see above). In addition, a single pollen grain from historically introduced *kiawe* (*Prosopis pallida*) was identified in Stratum IIb, and two grains from historically introduced pine (*Pinus* sp.) were identified in Stratum IId.

5.4.1.3 Summary and Interpretation

The most common pollen types identified in the current samples are low-spine Asteraceae (*Ambrosia* type) and Cheno-Am (*‘āweoweo*), spurge family, and grass family. Sedge family pollen, representing wetlands, is present but found in relatively low percentages. Polynesian introductions include coconut (*niu*; *Cocos nucifera*), paper mulberry (*wauke*; *Broussonetia papyrifera*), and possibly ti (kī; *Cordyline fruticosa*). Large grass pollen grains may represent rice (*laiki*; *O. sativa*) or sugarcane (*kō*; *Saccharum* sp.) cultivation in the vicinity or the collection of *pili* (*H. contortus*) grass.

Historically introduced mesquite (*kiawe*; *P. pallida*) and pine (*Pinus* sp.), identified in T-9 Strata IIb and IId, respectively, likely indicate disturbance throughout the sample column. Radiocarbon dating of a fire-related feature associated with Stratum IIa (in T-1, see Section 5.4.3) suggests use of that layer as a living surface by 1810. As *kiawe* was not introduced to the island until 1828, the single grain identified in Stratum IIb is likely intrusive from above. The two *Pinus*

pollen grains identified in Stratum IId are even more incongruous, as pine trees were not introduced to the island until the twentieth century.

Although there is strong evidence suggesting the current study area was once in taro cultivation, no *Colocasia* pollen was identified in the samples. According to Phillips (2019), despite the widespread practice of wetland taro cultivation across O‘ahu, *Colocasia* pollen is rare, even in suspected and known agricultural settings, such as the current study area. Typically propagated from a corm/root cutting or from a shoot, taro rarely blooms or sets seeds naturally (Onwueme 1999 in Phillips 2019). Like other members of the Araceae family, taro produces relatively small quantities of pollen when in bloom; in fact, some varieties have never been known to flower. Furthermore, taro is harvested at a time when the edible corm has its highest nutritional value and is most viable for propagation, which occurs before flowering, further reducing the likelihood of pollen deposition.

The likelihood of finding *Colocasia* pollen was further decreased by the very poor pollen preservation within the samples. Only six of the ten samples contain pollen; within those six, the percentages of degraded grains are very high, while the total pollen concentrations are very low. Taken at face value, the data from T-7 suggests a change over time from shrubland to grassland. In nearby T-9, no such change is evidenced, and the assemblage is more diverse. However, given the proximity of the two excavations, these apparent differences are more likely a product of poor pollen preservation rather than an accurate reflection of past vegetation. Sedge pollen, indicative of a wetland environment such as a *lo‘i*, is unexpectedly scarce—likely also a product of taphonomic factors.

5.4.2 Wood Taxa Identification

Two charcoal samples were submitted to the Wood Identification Laboratory at IARII for taxa identification. Both samples were collected from fire-related features in T-1 Stratum IIa/SIHP # -8840 Component 2, designated as Features 2 and 4. The samples are summarized in Table 24, and the report from IARII (Huebert 2019) is included in Appendix D. The results of the analysis are presented in Table 25 and discussed below.

Most of the examined material was small (< 1 cm), and all fragments except one were wood charcoal; the other was parenchyma charcoal. Most of Sample 1 (SIHP # -8840 Component 2, Feature 2) is *kiawe* (*P. pallida*); the rest is indeterminate hardwood. *Kiawe* is a tree native to Peru, Colombia, and Ecuador, which was likely introduced to Hawai‘i by Father Bachelot in 1828 (Huebert 2019:3).

Sample 2 (SIHP # -8840 Component 2, Feature 4) contains wood from native species including *‘ōhi‘a lehua* (*Metrosideros polymorpha*), *koa* (*Acacia* cf. *koa*), *kōpiko* (*Psychotria* sp.), and possibly *hau* (*Hibiscus* sp.). There are seven native shrub and tree species of *Hibiscus*, including several endemic varieties, as well as at least three naturalized historical (i.e., post-Contact) introductions (Wagner et al. 2005 in Huebert 2019:3). Most species feature showy flowers. *Hibiscus tiliaceus*, or *hau*, occurs commonly in moist areas on most of the main Hawaiian Islands. In addition to ornamental plantings, the bark of *hau* was sometimes used to make *lei*, while the soft wood was used for canoe outriggers, fishnet floats, and in the native fireplow (Abbott 1992 in Huebert 2019:3).

Table 24. Samples from T-1 Stratum IIa/SIHP # -8840 Component 2 submitted for wood identification analysis

Sample #	Depth (cmbs)	Fea. #	Description
1	111	2	Fire-related feature at the upper boundary of the habitation layer
2	128–131	4	Fire-related feature in the lower-middle portion of the habitation layer

Table 25. Results of wood identification analysis

Sample #	WIDL #	Taxon	Plant Part	Count	Weight (g)	Comment
1	1916-1	*P. pallida* (*kiawe*)	Wood charcoal	18	0.4	–
	1916-2	Indeterminate hardwood	Wood charcoal	1	0.01	–
2	1916-3	*M. polymorpha* (*‘ōhi‘a lehua*)	Wood charcoal	2	0.06	–
	1916-4	Indeterminate	Parenchyma charcoal	1	0.01	Thin; superficially resembles nutshell but is not endocarp
	1916-5	*Psychotria* sp. (*kōpiko*)	Wood charcoal	1	0.01	–
	1916-6	*Hibiscus* sp. (*hau* and others)	Wood charcoal	1	0.04	–
	1916-7	*Acacia* cf. *koa* (*koa* and others)	Wood charcoal	5	0.08	–
	1916-8	Indeterminate hardwood	Wood charcoal	4	0.06	–

‘Ōhi‘a lehua (*M. polymorpha*) is an endemic species used for making spears, mallets, idols, posts and rafters for houses, and enclosures around temples (Buck 1957, Malo 1951, and Neal 1965 in Huebert 2019:3). *Kōpiko* (*Psychotria* sp.) comprises 11 endemic species, of which five are known to grow on O‘ahu. The species range from small to up to 20 m tall (Wagner et al. 1990 in Huebert 2019:3). *Kōpiko* was used as firewood and to make *kapa* (barkcloth) logs (Malo 1951 in Huebert 2019:4).

None of these are short-lived materials preferred for radiocarbon dating. However, Huebert (2019:2) indicates the parenchyma is not likely to have much inbuilt age, since soft storage tissues are not long-lived; hence, it is the best option available for radiocarbon dating (see Section 5.4.3 below for results). As some *Psychotria* species are small trees, and *Hibiscus* species are fast growing, Huebert (2019:2) suggests one of these as the next best option.

As mentioned above, Sample 1, collected from SIHP # -8840 Component 2, Feature 2, consists mainly of a post-Contact introduction, *kiawe* (*P. pallida*). As it is believed *kiawe* was introduced to the Islands in 1828, its presence indicates the feature was used after that time. In contrast,

Sample 2, collected from SIHP # -8840 Component 2, Feature 4, consists mainly of native or endemic species, with no positive identification of post-Contact introductions; these results are in agreement with the stratigraphic positions of the features. Although both were identified within T-1 Stratum IIa, Feature 2 originates at the upper boundary of the stratum, while Feature 4 is within the lower-middle portion; hence, Feature 2 post-dates Feature 4. As Feature 2 dates securely to the post-Contact period, Feature 4 may therefore date to the pre- or early post-Contact period—a hypothesis supported by the radiocarbon dating results (see Section 5.4.3 below).

5.4.3 Radiocarbon Dating Analysis

One sample was submitted to Beta Analytic, Inc., for radiocarbon dating analysis. This sample comprises parenchyma charcoal recovered from a charcoal sample (Sample 2; see Section 5.4.2 above) analyzed at IARII's Wood Identification Laboratory. The parenchyma charcoal was selected for radiocarbon analysis because it is not likely to have much inbuilt age, as soft storage tissues are not long-lived. The results of the radiocarbon analysis are presented in Table 26 and discussed below. The report from Beta Analytic is included in Appendix E.

The sample was recovered from SIHP # -8840 Component 2, Feature 4, a fire-related feature identified within the lower-middle portion of T-1 Stratum IIa, interpreted as a habitation layer (SIHP # -8840 Component 2). The radiocarbon analysis yielded two-sigma calibrated date ranges of AD 1728-1810 (53.5% probability), 1646-1690 (26.0%), and 1925-post 1950 (15.9%); however, the most recent date range can likely be discarded. While diagnostic artifacts recovered from overlying fill deposits (see Section 5.2.4) suggest Stratum IIa functioned as a surface into the 1930s, the identification of pit features within different vertical portions of the quite thick stratum indicates the layer was not deposited all at once, but rather over a (potentially extended) period of time. As Feature 4 was identified within the lower portion of IIa, it would therefore date to the earlier part of that time period. Furthermore, the cobble-lined fire pit is consistent with traditional Hawaiian fire-related features. Hence, the radiocarbon analysis, like the wood taxa analysis (discussed above), supports a pre- or early post-Contact date for Feature 4 and suggests use of the Stratum IIa habitation layer by 1810.

Table 26. Results of radiocarbon analysis

Lab #	Beta Lab #	Material Dated	SIHP/Fea. #	Stratum (matrix)	Depth (cmbs)	Activity Rep. by Date	Conventional Age (BP)	C12/13 Ratio	Calibrated Dates (AD; 2-sigma) (% probability)
1	541406	Parenchyma charcoal	SIHP # -8840 Component 2, Fea. 4 (fire-related feature)	IIa (silty clay)	128–131	Fire pit use	200±30	-24.3	1728-1810 (53.5%) 1646-1690 (26.0%) 1925-post 1950 (15.9%)

Section 6 Historic Property Description

One archaeological historic property was newly identified during the Halewai‘olu Senior Residences AIS: SIHP # 50-80-14-8840, subsurface cultural deposits. SIHP # -8840 was identified in all 15 test excavations and comprises 0.52 acre (including interpolated boundaries), encompassing nearly the entire AIS study area. It has three components, which are summarized in Table 27 and depicted on Figure 155 through Figure 157. SIHP # -8840 Components 1–3 span the pre-Contact period through the mid-twentieth century and are discussed in detail in Sections 6.1–6.3 below. The significance assessment of SIHP # -8840 is presented in Section 6.4 below.

Table 27. Summary of SIHP # 50-80-14-8840 components

Component #	Formal Type	Function
1	Agricultural deposits	Agriculture
2	Habitation layers	Habitation; human interment
3	Subsurface infrastructure remnants	Residential; commercial

6.1 SIHP # 50-80-14-8840 Component 1

FORMAL TYPE:	Agricultural deposits
FUNCTION:	Agriculture
AGE:	Pre-Contact
NUMBER OF FEATURES:	0
TEST EXCAVATIONS:	T-2, T-2B, T-3 through T-10, and T-12
DIMENSIONS	0.43 acre
TAX MAP KEY:	[1] 1-7-006:012
LAND JURISDICTION:	City and County of Honolulu
PREVIOUS DOCUMENTATION:	N/A

SIHP # 50-80-14-8840 Component 1 consists of multiple buried agricultural deposits, identified throughout the majority of the AIS study area, within 13 of the 15 test excavations (absent only in T-1 and T-11) (see Figure 35 and Figure 155 through Figure 157). These agricultural deposits are within a vertical series of primarily silty clay loam alluvial deposits, which appear to represent Nu‘uanu Stream overflow or flooding episodes. The agricultural deposits were identified beneath the upper two alluvial deposits (Strata IIa and IIb), which functioned as possibly pre- to post-Contact habitation layers and are designated as SIHP # -8840 Component 2 (see Section 6.2 below). As radiocarbon dating suggests use of Stratum IIa by 1810, with Stratum IIb therefore even earlier, the Component 1 agricultural deposits (Strata IIc–IIg) likely date to the pre-Contact period, with at least three chronological periods of agricultural use indicated (Table 28). Given the location of the AIS study area within the floodplain of Nu‘uanu Stream, these agricultural deposits likely represent *lo‘i kalo*.

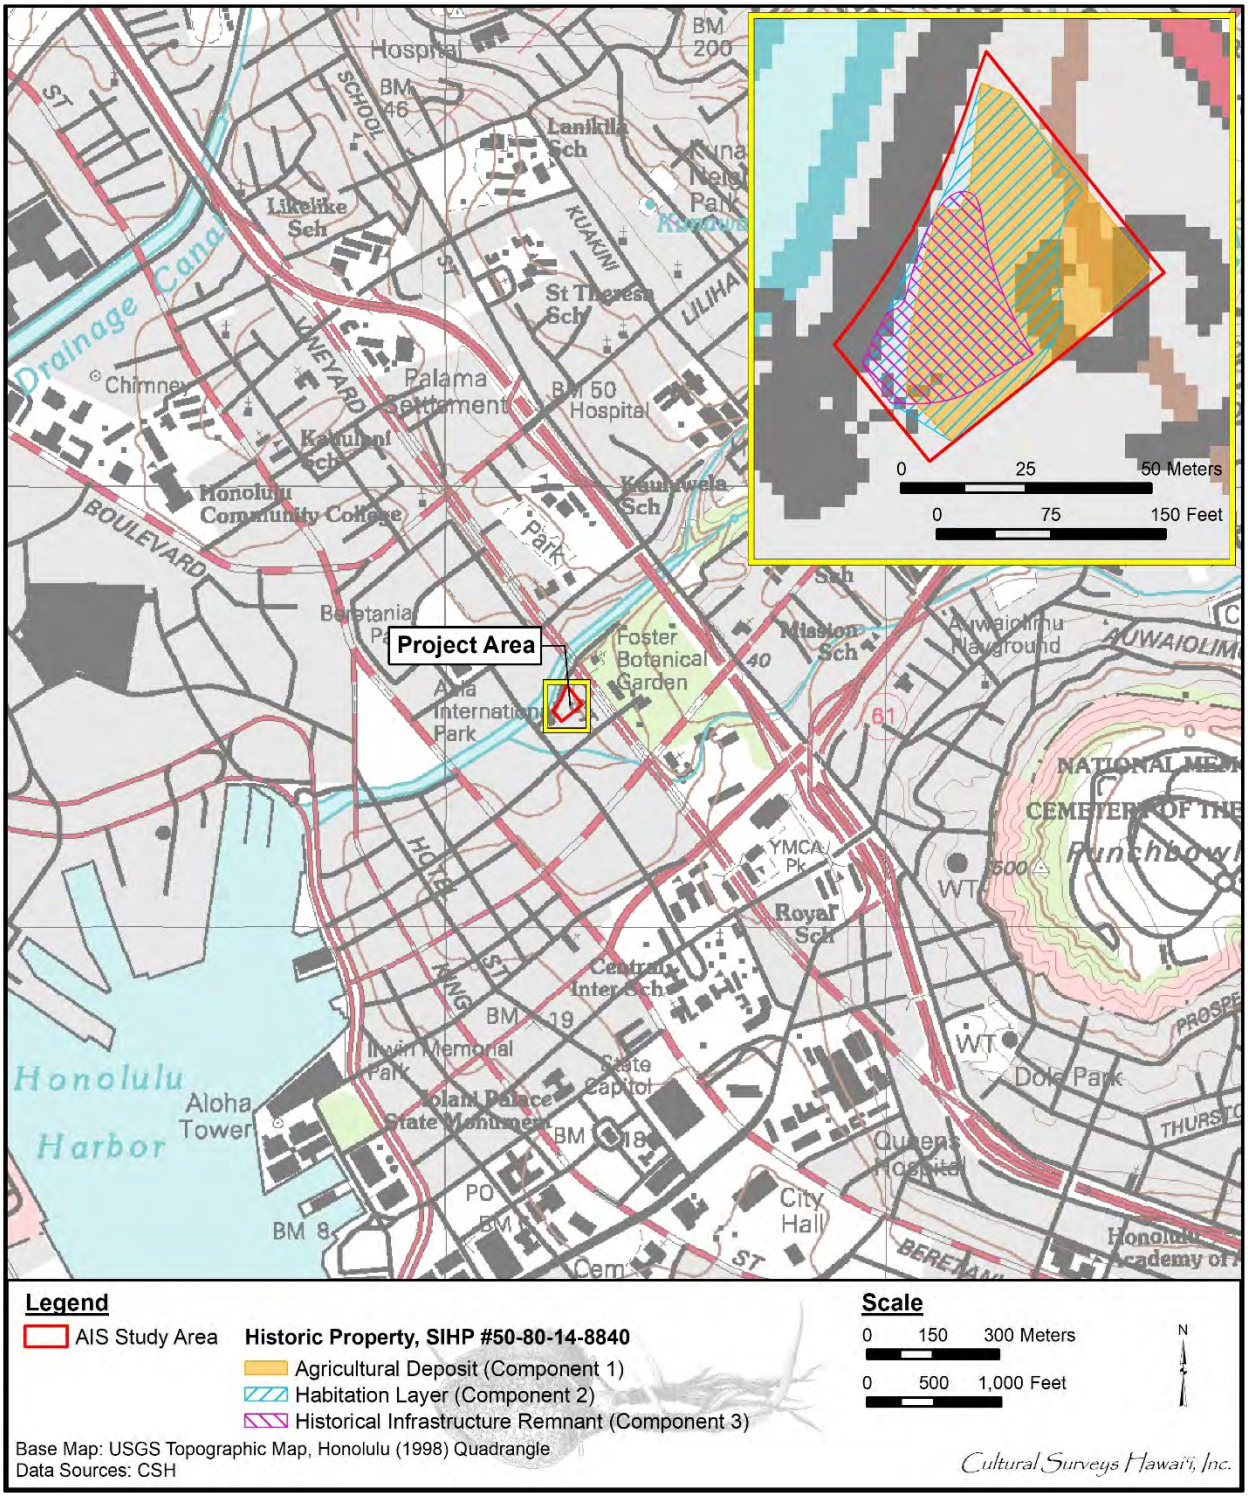

Figure 155. Portion of the 1998 Honolulu USGS 7.5-minute topographic quadrangle, showing the distribution of SIHP # -8840 Components 1–3 within the Halewai‘olu Senior Residences AIS study area

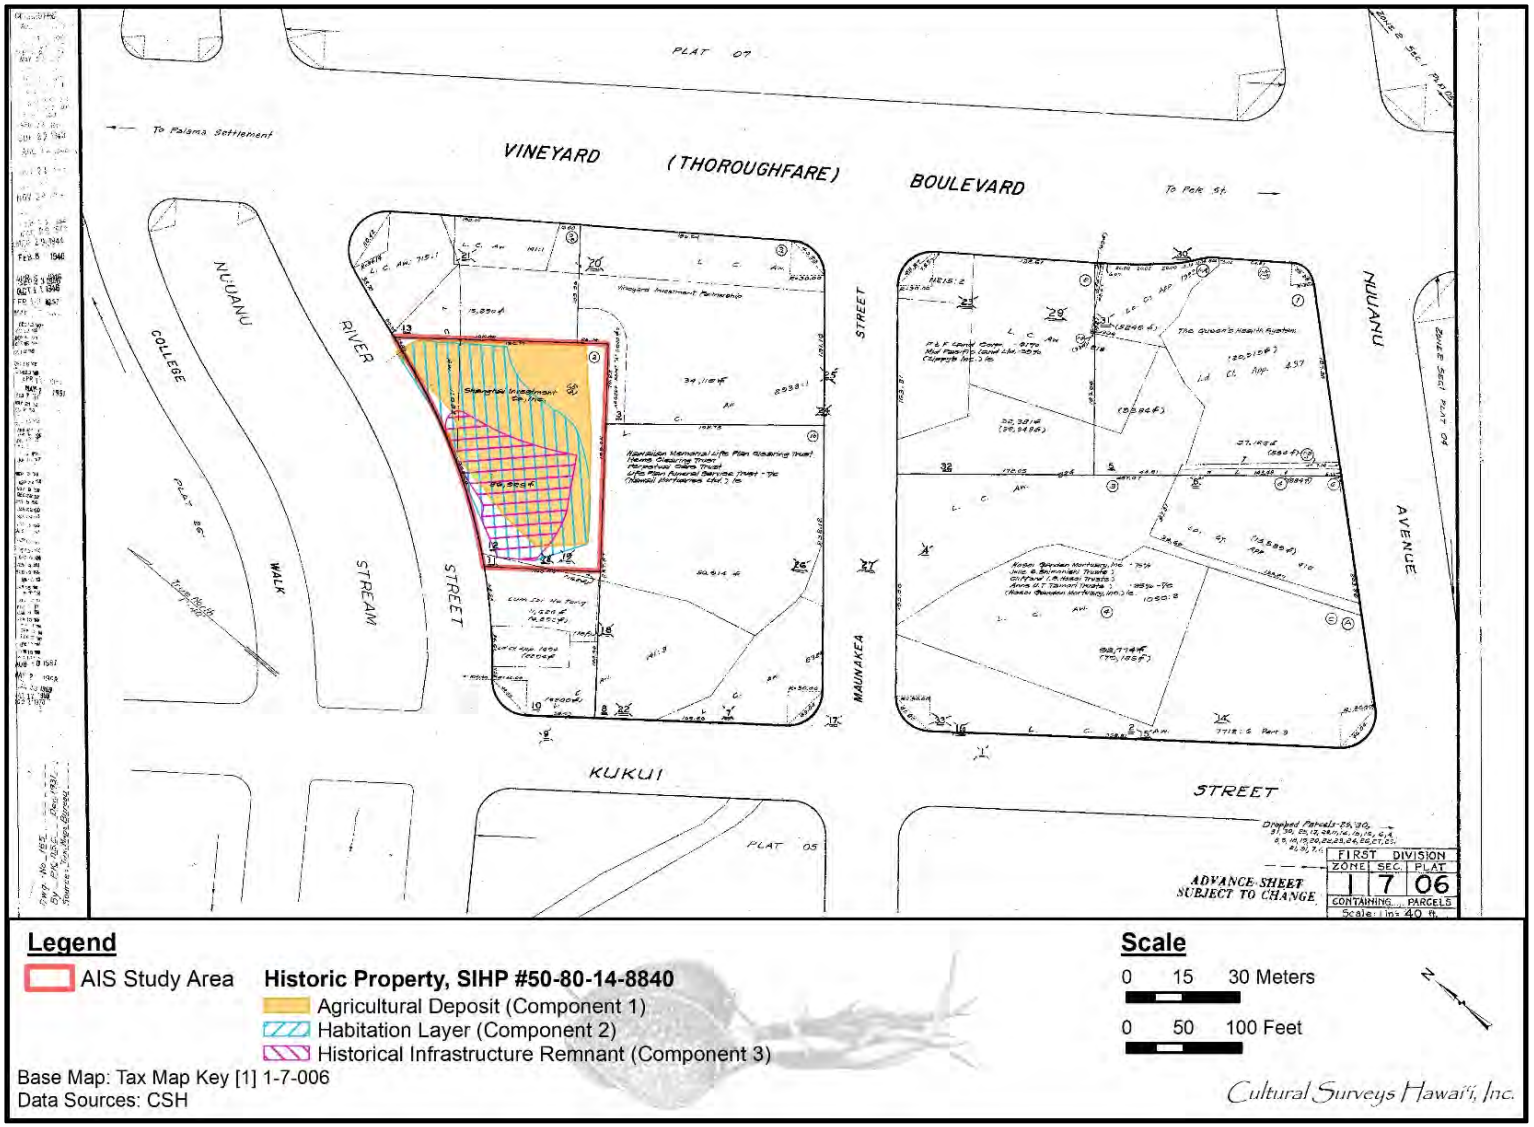

Figure 156. TMK: [1] 1-7-006, showing the distribution of SIHP # -8840 Components 1–3 within the Halewai‘olu Senior Residences AIS study area (Hawai‘i TMK Service 2014)

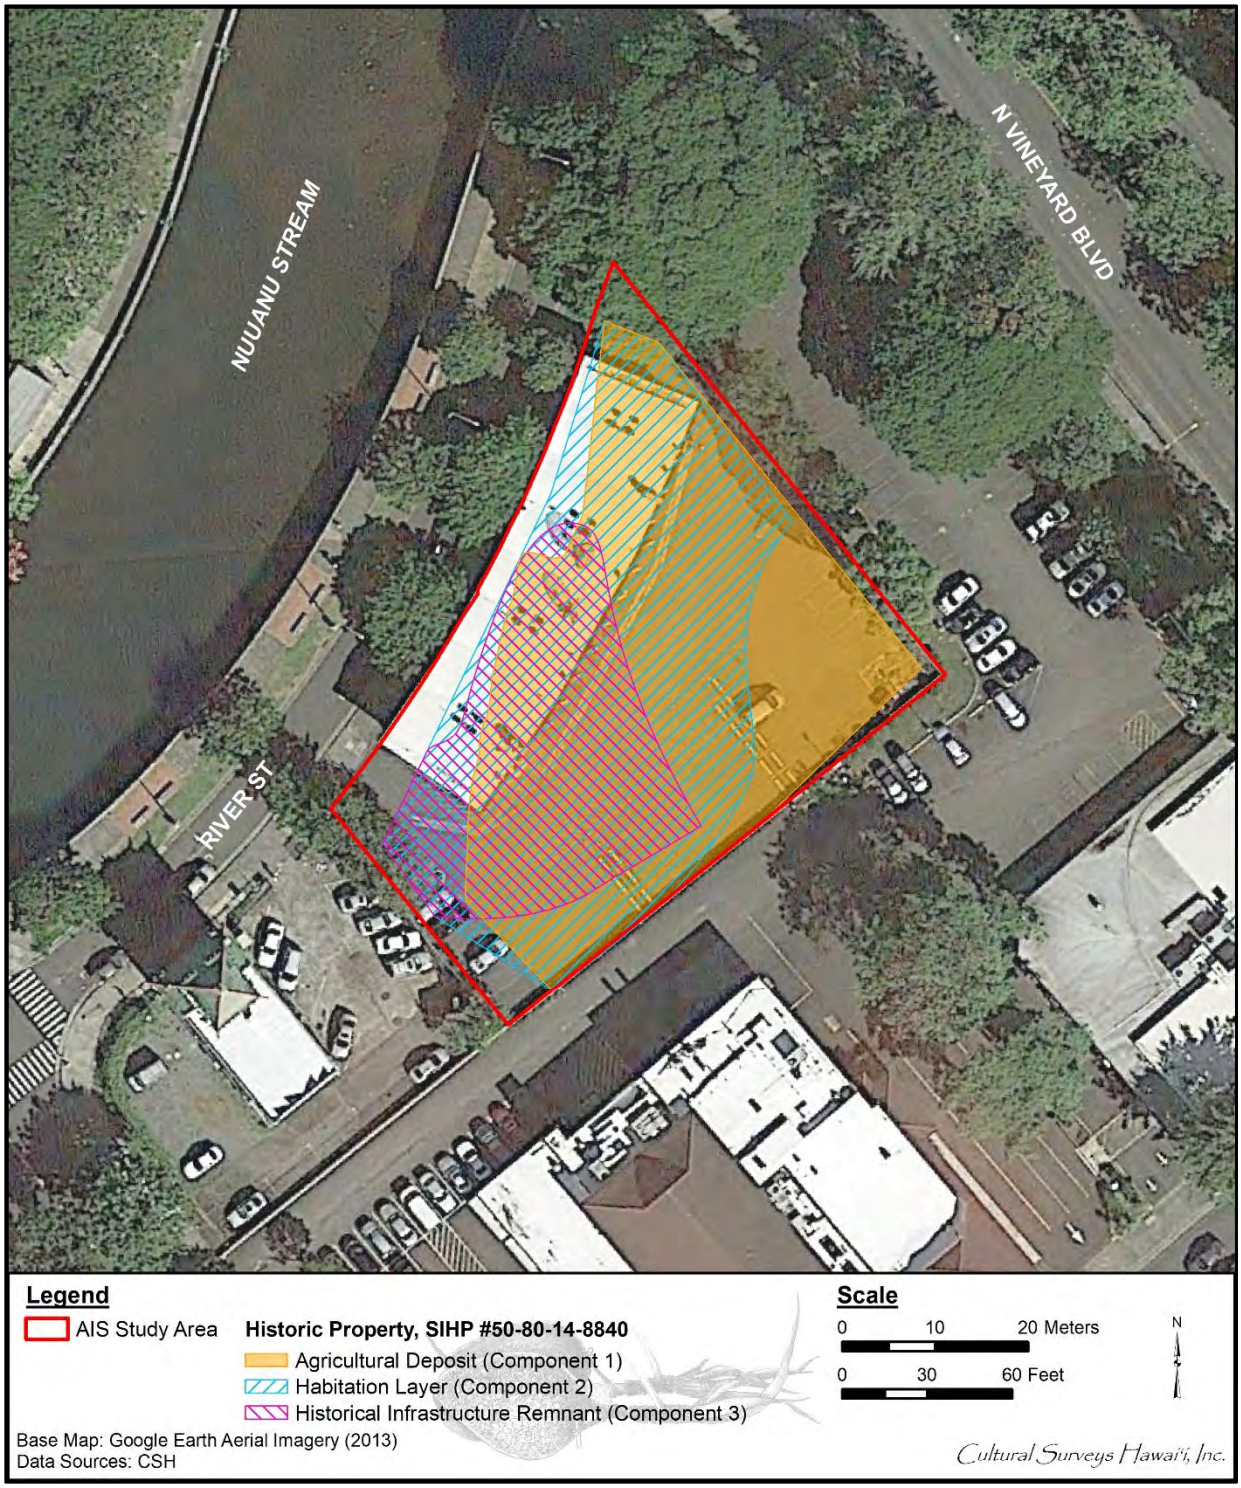

Figure 157. Aerial photograph (Google Earth 2013), showing the distribution of SIHP # -8840 Components 1–3 within the Halewai‘olu Senior Residences AIS study area

Table 28. SIHP # -8840 Component 1 agricultural deposits identified during the AIS

Formal Type	Stratum	Test Excavation
Agricultural deposit	IIc	T-2, T-2B, T-3 through T-8, T-10, and T-12
	IId	T-7, T-8, T-9, T-9B
	IIe	T-4, T-9
	IIf	T-5, T-9
	IIg	T-8
Agricultural berm	IIc	T-9, T-9B

6.1.1 Uppermost Agricultural Deposit

The most recent agricultural deposit (Stratum IIc in T-2, T-2B, T-3 through T-8, and T-10; Stratum IId in T-9 and T-9B) was identified almost ubiquitously across the AIS study area, in 13 of the 15 test excavations. It typically presents as dark brown silty clay loam and contains cinder gravel in some areas (Figure 158 and Figure 159). The deposit is characterized by a dense latticework of oxidized (red) mottling, which is believed to be the result of chemical interactions between taro roots and the surrounding soil. In addition, limonite nodules and/or root casts were identified within bulk samples collected from the uppermost agricultural deposits in T-2B, T-9, and T-12; based on previous archaeological studies (see Section 5.1.1), these are also interpreted as evidence of agricultural use.

This interpretation is further supported in T-9 and T-9B by the presence of small berms (Stratum IIc) adjacent to the uppermost agricultural deposit (Stratum IId) (see Figure 94 and Figure 100). In T-9, the Stratum IIc berm measures approximately 2 m across and 25 cm tall in the southeast sidewall. In the northwest sidewall, it is only 50 cm across, as it appears to be truncated by SIHP # -8840 Component 2, Feature 14 (pit feature). In T-9B, the berm at the *mauka* (northeast) end measures approximately 1.7 m across by 35 cm tall (see Figure 102), while the berm at the *makai* (southwest) end measures approximately 1.5 m across by 30 cm tall, although it is bisected by SIHP # -8840 Component 2, Feature 15 (pit feature). As these berms do not align with the berm identified in T-9, this area may represent the convergence of multiple agricultural plots.

6.1.2 Deeper Agricultural Deposits

Deeper (i.e., older) agricultural deposits were identified within a discrete zone in the central/*mauka* (northeast) portion of the AIS study area (within T-4, T-5, T-7 through T-9B). Directly beneath the youngest agricultural deposit within T-7 through T-9B is a silty clay loam deposit (T-7 and T-8 Stratum IId; T-9 and T-9B Stratum IIe) interpreted as an agricultural layer. This deposit contains a similar latticework of oxidized (red) mottling, although generally less dense than the overlying stratum (Figure 160). The layer is described as brown, dark yellowish brown, or very dark grayish brown and lacks the cinder content of the overlying deposit.

The deepest agricultural deposits were documented within T-4, T-5, T-8, and T-9, just above or at the level of the water table. These deposits (Strata IIe–IIg) range from silty clay loam to sandy clay loam and contain a dense latticework of oxidized (red) mottling similar to the uppermost agricultural deposit (Figure 161).

Figure 158. Close-up of Stratum IIc (youngest SIHP # -8840 Component 1 agricultural deposit) within T-7 northeast wall, showing a dense latticework of oxidized (red) mottling

Figure 159. T-9 Stratum IId, SIHP # -8840 Component 1 agricultural deposit, characterized by oxidized (red) mottling

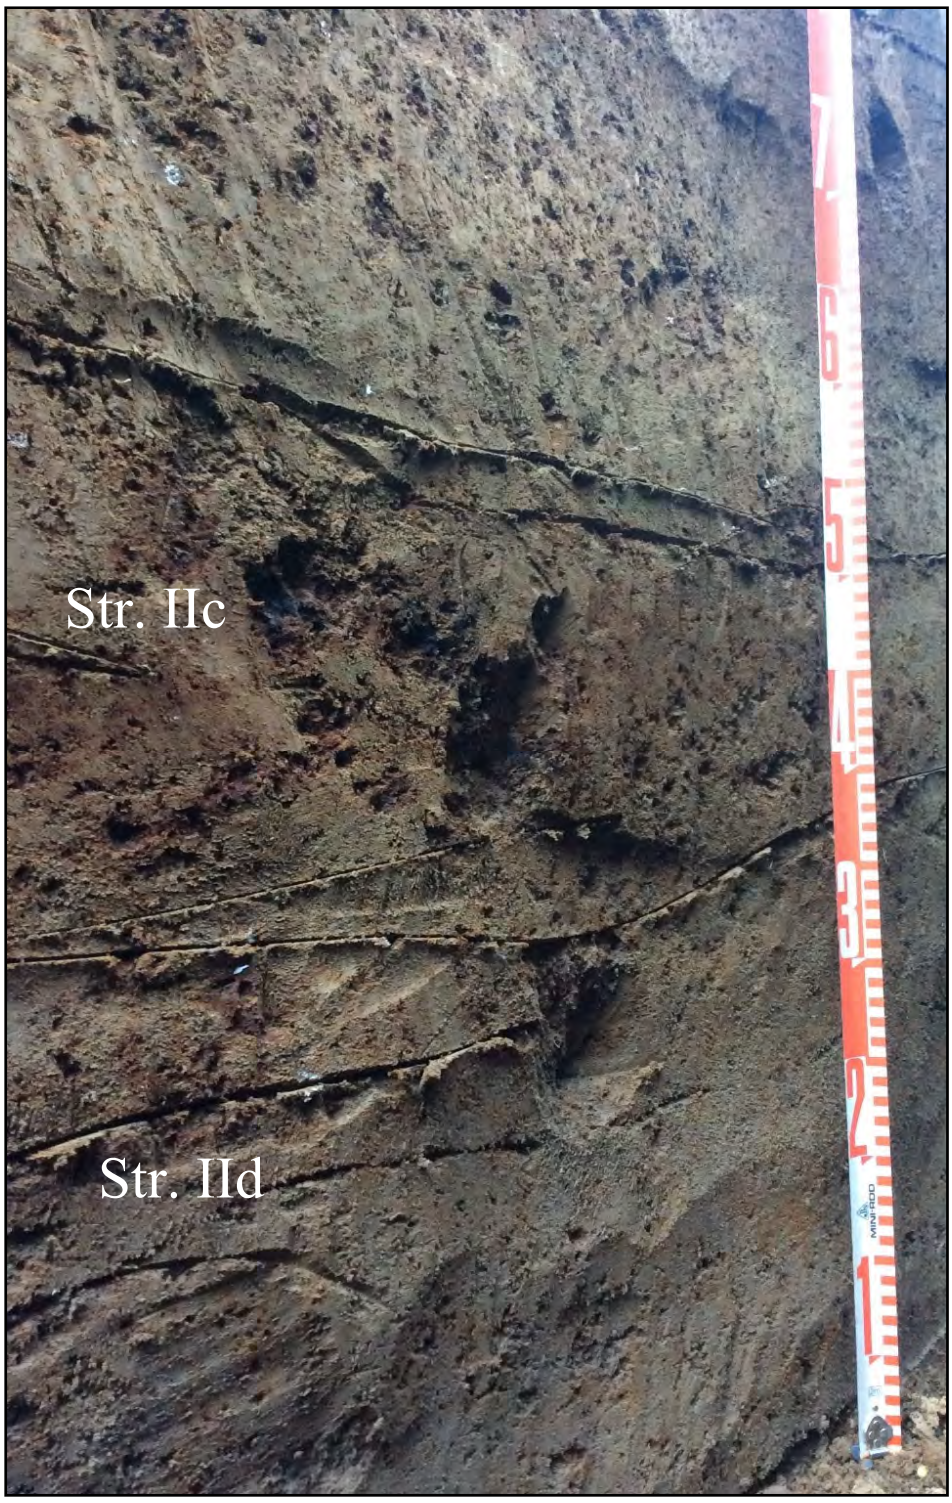

Figure 160. T-7 northeast wall, showing SIHP # -8840 Component 1 agricultural deposits (Strata IIc and IId) characterized by oxidized (red) mottling; the darker areas and voids of Stratum IIc contain cinder gravel

Figure 161. T-9 Stratum IIe, SIHP # -8840 Component 1 agricultural deposit, characterized by oxidized (red) mottling

6.1.3 Pollen Analysis

Abundant bulk samples were collected from the Stratum II alluvium series, including the interpreted SIHP # -8840 Component 1 agricultural deposits. In addition, several column samples were collected; two of these column series (from T-7 and T-9) were submitted for palynological analysis (see Section 5.4.1 for full results).

The most common pollen types identified in the samples are low-spine Asteraceae (*Ambrosia* type) and Cheno-Am (*‘āweoweo*), spurge family, and grass family. Sedge family pollen, representing wetlands (including *lo‘i*), is present but found in relatively low percentages. Polynesian introductions include coconut (*niu*; *Cocos nucifera*), paper mulberry (*wauke*; *Broussonetia papyrifera*), and possibly ti (*kī*; *Cordyline fruticosa*). Large grass pollen grains may represent rice (*laiki*; *O. sativa*) or sugarcane (*kō*; *Saccharum* sp.) cultivation in the vicinity or the collection of *pili* (*H. contortus*) grass.

Historically introduced mesquite (*kiawe*; *P. pallida*) and pine (*Pinus* sp.), identified in T-9 Strata IIb and IId, respectively, likely indicate disturbance throughout the sample column. Radiocarbon dating of a fire-related feature associated with Stratum IIa (in T-1, see Section 5.4.3) indicates use of that layer as a living surface by 1810. As *kiawe* was not introduced to the island until 1828, the single grain identified in Stratum IIb is likely intrusive from above. The two *Pinus* pollen grains identified in Stratum IId are even more incongruous, as pine trees were not introduced to the island until the twentieth century; hence, they are also likely intrusive from above.

Although there is strong evidence suggesting the current study area was once in taro cultivation, no *Colocasia* pollen was identified in the samples. According to Phillips (2019), despite the widespread practice of wetland taro cultivation across O‘ahu, *Colocasia* pollen is rare, even in suspected and known agricultural settings such as the current study area. Typically propagated from a corm/root cutting or from a shoot, taro rarely blooms or sets seeds naturally (Onwueme 1999 in Phillips 2019). Like other members of the Araceae family, taro produces relatively small quantities of pollen when in bloom; in fact, some varieties have never been known to flower. Furthermore, taro is harvested at a time when the edible corm has its highest nutritional value and is most viable for propagation, which occurs before flowering, further reducing the likelihood of pollen deposition.

The likelihood of finding *Colocasia* pollen was further decreased by the very poor pollen preservation within the samples. Only six of the ten samples contain pollen; within those six, the percentages of degraded grains are very high, while the total pollen concentrations are very low. Hence, the data is likely not an accurate reflection of the original pollen assemblage.

6.2 **SIHP # 50-80-14-8840 Component 2**

FORMAL TYPE:	Habitation layers
FUNCTION:	Habitation; human interment
AGE:	Possibly pre- to post-Contact
NUMBER OF FEATURES:	19
TEST EXCAVATIONS:	T-1 through T-5 and T-8 through T-12
DIMENSIONS	0.43 acre
TAX MAP KEY:	[1] 1-7-006:012
LAND JURISDICTION:	City and County of Honolulu
PREVIOUS DOCUMENTATION:	N/A

SIHP # -8840 Component 2 consists of buried habitation layers, which developed within the uppermost natural alluvium deposits alongside Nu‘uanu Stream. Component 2 was documented throughout the majority of the AIS study area (absent only in the eastern corner of the AIS study area; see Figure 155 through Figure 157). Only two test excavations (T-6 and T-7) are not included within the boundaries of SIHP # -8840 Component 2 due to negligible cultural content (i.e., only sparse amounts of charcoal flecking). SIHP # -8840 Component 2 is primarily composed of the uppermost (i.e., youngest) natural alluvial deposit, designated as Stratum IIa. Within two adjacent test excavations (T-2 and T-2B) in the southern portion of the AIS study area, the underlying Stratum IIb alluvial deposit also evidences cultural activity and is therefore designated as part of SIHP # -8840 Component 2. A total of 19 features (17 associated with Stratum IIa and two associated with Stratum IIb) were documented. SIHP # -8840 Component 2 layers and features are summarized in Table 29 and discussed in detail below.

6.2.1 Stratum IIa

Stratum IIa typically presents as a very dark grayish brown silty clay loam deposit, between 25 and 70 cm thick. Cultural use of Stratum IIa is indicated by strong charcoal flecking, historical

Table 29. Summary of SIHP # -8840 Component 2 layers and features identified during the AIS

Stratum	Formal Type	Function	Test Excavation/Fea. #
IIa	Habitation layer	Habitation; human burial	T-1 through T-5, T-8 through T-12
	Pit feature (n=17)	Indeterminate (n=7)	T-2 (Fea. 5), T-2B (Fea. 9), T-2C (Fea. 11), T-9B (Fea. 15), T-10 (Feas. 16, 17), T-11 (Fea. 18)
		Historical trash pit (n=4)	T-2B (Fea. 8), T-9 (Feas. 12–14)
		Fire-related feature (n=4)	T-1 (Feas. 1–4)
		Post hole (n=1)	T-11 (Fea. 19)
		Human burial (n=1)	T-2 (Fea. 6)
IIb	Habitation layer	Habitation	T-2, T-2B
	Stacked basalt cobbles (n=1)	Indeterminate	T-2 (Fea. 7)
	Pit feature (n=1)	Indeterminate	T-2B (Fea. 10)

artifacts within the upper 4–15 cm, and/or the presence of pit features. Within five test excavations (T-3 through T-5, T-8, and T-12), the upper portion of the layer contains charcoal, red brick fragments, bottle glass, ceramic, metal, coral, and/or faunal bone. Associated features were documented within eight test excavations (T-1, T-2, T-2B, T-2C, T-9, T-9B, T-10, and T-11). As features were documented originating in different vertical portions of the stratum, it is likely the Stratum IIa sediment was not deposited all at once but rather through multiple episodes over a period of time, with features in the lower portion of the stratum pre-dating those in the upper portion; this hypothesis is supported by the results of various laboratory analyses (discussed in Section 6.2.3 below).

The Stratum IIa features consist of four fire-related features (Features 1–4), one posthole (Feature 19), four historical trash pits (Features 8, 12–14), a human burial (Feature 6), and seven pits of indeterminate function (Features 5, 9, 11, and 15–18) (see Table 29). The 17 features associated with Stratum IIa are described in detail below. Profiles, plan maps, and photographs are presented in Section 4.3 Subsurface Testing Results and are referenced in the descriptions below.

Feature 1 is a basin-shaped pit feature identified in the southwest wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 39 and Figure 41). It was documented between 77 and 93 cmbs and measures 35 cm across. A thin, heat-altered band of reddened sediment, a fire-affected basalt cobble, and a 6-cm thick layer of charcoal were observed at the base of the pit, which is interpreted as a fire-related feature. A charcoal sample was collected.

Feature 2 is a basin-shaped pit feature identified in the northeast wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 36, Figure 37, and Figure 42). It was documented between 71 and 115 cmbs and measures 1 m across. A thin, heat-altered band of reddened sediment and a 4-cm thick layer of charcoal were observed at the base of the pit, which is interpreted as a fire-related feature. Several small, non-diagnostic bottle glass fragments (not collected) and fire-affected basalt cobbles were also observed within the pit. A charcoal sample was collected.

Feature 3 is a basin-shaped pit feature identified in the southwest wall of T-1, at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 (see Figure 39 and Figure 43). It was documented between 76 and 120 cmbs and measures 1.5 m across. Multiple heat-altered bands of reddened sediment and layers of charcoal ranging from 510 cm thick were observed within the pit, which is interpreted as a fire-related feature. A charcoal sample was collected.

Feature 4 is a pit feature identified in both sidewalls of T-1, within Stratum IIa/SIHP # -8840 Component 2 (see Figure 37 and Figure 44). It was documented between 111 and 127 cmbs and measures 55 cm across; the exposed portion is 85 cm long, spanning the width of the trench. The pit is lined with fire-affected basalt cobbles, and charcoal flecking was observed in the matrix surrounding the cobbles. This is interpreted as a fire-related feature.

Feature 5 is a basin-shaped pit feature identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 within both sidewalls of T-2 (see Figure 47, Figure 48, and Figure 54). It was documented between 60 and 103 cmbs and measures 85 cm across. The exposed portion is 76 cm wide, with the feature spanning the width of the trench. The feature contains red brick, glass, metal, charcoal, FAR, and coral gravel. Its function is indeterminate.

Feature 6 is a small pit feature containing human skeletal remains (see Figure 45, Figure 46, Figure 55 through Figure 57). It was documented between 120 and 127 cmbs within the southwest wall of T-2, near the southeast end of the excavation. It originates at the base of Stratum IIa/SIHP # -8840 Component 2 and terminates in the underlying Stratum IIb/ SIHP # -8840 Component 2. The pit measures 26 cm across and contains the remains of a single fetal individual (at or near birth). Observed skeletal elements comprise the lower limbs; the upper body likely remains in situ within the southwest sidewall (see Figure 56). The remains are in good condition, and the individual is approximately 85% complete.

The majority of the remains were observed in situ (i.e., within the burial pit) and were left in place. Several additional small fragments which had been displaced by cleaning of the sidewall were recovered and reinterred 15 cm northeast of the Feature 6 pit feature, within a small, hand-carved niche. A burial treatment plan (BTP) addressing this human burial site is forthcoming.

Feature 8 is a large pit feature identified at the *mauka* (northeast) end of T-2B in the southeast sidewall (see Figure 58, Figure 59, and Figure 62). It was documented between 70 and 145 cmbs at the upper boundary of Stratum IIa/SIHP # -8840 Component 2. Glass, metal, ceramic, and bone artifacts were collected from this feature, which is interpreted as a historical trash pit. A machine-made glass marble (Acc. # 37) dates to post-1910, indicating use of the feature after that date. Feature 8 truncates and therefore post-dates Feature 9, discussed below.

Feature 9 is a large pit feature identified at the *mauka* (northeast) end of T-2B in the southeast sidewall (see Figure 58, Figure 59, and Figure 62). It was documented between 115 and 191 cmbs, originating in Stratum IIa/SIHP # -8840 Component 2, intrusive through Stratum IIb, and terminating in Stratum IIc. It is truncated by Feature 8 (described above), which it therefore pre-dates. The exposed portion of the feature is approximately 2 m long. No cultural materials were identified within the feature; its function is indeterminate.

Feature 11 is a small pit feature identified in the southeast sidewall of T-2C (see Figure 65 and Figure 66). It was documented between 137 and 152 cmbs, originating in Stratum IIa/SIHP # -8840 Component 2 and terminating in Stratum IIb. It measures 30 cm across. No cultural materials were observed within the feature; its function is indeterminate.

Feature 12 is a large pit feature identified in both sidewalls of T-9, originating at the upper boundary of Stratum IIa/SIHP # -8840 Component 2, intruding through Strata IIb–III and continuing beyond the base of excavation (see Figure 92 through Figure 96). It was documented between 45 and 196 cmbs and measures 65–100 cm across (*mauka-makai*). The exposed portion of the feature is 80 cm wide, spanning the width of the trench. Feature 12 contains abundant bottle glass and ceramics, as well as marine shell midden, faunal bone, charcoal, and FAR. It is interpreted as a historical trash pit. The faunal bone and a grab sample of glass, ceramics, and shell midden were collected. Diagnostic artifacts are mainly of European and Euro-American origin and date from the late nineteenth to possibly early twentieth century. One item, a Dutch glass gin bottle (Acc. #55), dates between 1890 and 1910, placing use of the feature firmly post-1890. The completeness, lack of damage, and consistent size of the collected shells similarly indicate this is historical (i.e., post-Contact) midden.

Feature 13 is a shallow pit feature identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 in the northwest sidewall of T-9 (see Figure 93, Figure 95, and Figure 97). It was documented between 45 and 67 cmbs and measures 1.7 m across. It truncates and therefore post-dates the underlying Feature 14 (see description below). Feature 13 contains metal, glass, ceramic, bird (Aves) and cow (*B. taurus*) bone, and charcoal. The faunal bone was collected.

Feature 14 is a large pit feature identified in the northwest sidewall of T-9, originating at the upper boundary of Stratum IIa/SIHP # -8840 Component 2, intruding through Strata IIa–IIc, and terminating in Stratum IId/SIHP # -8840 Component 1 (see Figure 93, Figure 95, and Figure 97). It was documented between 44 and 137 cmbs and measures 1.8 m across. The feature contains metal, ceramic, faunal bone, charcoal, and FAR. It is interpreted as a historical trash pit. The faunal bone and a grab sample of metal, glass, and ceramics were collected. Diagnostic artifacts are Euro-American dating from the late nineteenth to possibly the early twentieth century. One glass bottle fragment (Acc. # 159) dates between 1880 and 1920, indicating use of the feature post-1880.

Feature 15 is an oblong pit feature identified in the southeast wall of T-9B. It extends from the lower boundary of Stratum IIa/SIHP # -8840 Component 2, intrudes through Strata IIb and IIc, and terminates in Stratum IIe (see Figure 100 and Figure 101). It was documented between 65 and 150 cmbs and measures 35–45 cm across. No cultural materials were identified within the feature; its function is indeterminate.

Feature 16 is a basin-shaped pit feature identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 in the northeast wall of T-10 (see Figure 105 and Figure 108). It was documented between 46 and 99 cmbs, overlying and therefore post-dating Feature 17 (see description below). It measures 65 cm across. No cultural materials were observed within the feature; its function is indeterminate.

Feature 17 is a large pit feature identified in the northeast wall of T-10, below Feature 16 (described above), which it therefore pre-dates (see Figure 105 and Figure 108). It extends from the lower boundary of Stratum IIa/SIHP # -8840 Component 2, intrudes through Strata IIb and IIc, and terminates in Stratum III. It was documented between 60 and 110 cmbs and measures 95 cm across. Several pieces of bottle glass and FAR were identified at the base of the feature. The bottle glass was collected; two diagnostic fragments date to 1800-1910, indicating use of the feature post-1800. The function of this feature is indeterminate.

Feature 18 is a basin-shaped pit feature identified at the upper boundary of Stratum IIa/SIHP # -8840 Component 2 in the west corner of T-11 (see Figure 109, Figure 110, and Figure 112). It was documented between 61 and 105 cmbs within the northwest sidewall and southwest endwall. The exposed portion of the feature is 70 cm long (northwest-southeast) by 60 cm wide (northeast-southwest). The feature contains charcoal. Its function is indeterminate.

Feature 19 is a long, rectangular pit feature identified in the northwest wall of T-11 (see Figure 109, Figure 110, and Figure 113). It was documented between 85 and 156 cmbs, originating in Stratum IIa/SIHP # -8840 Component 2, intrusive through Stratum IIb, and terminating in Stratum III. Based on morphology, this feature is interpreted as a posthole. The darker, organic-stained portion at the center of the feature represents the location of the former post, while the surrounding pit matrix is lighter in color (see Figure 113). A small amount of charcoal was observed near the base of the feature.

6.2.2 Stratum IIb

Stratum IIb consists of a fairly homogenous, dark brown to dark yellowish brown fine silty clay loam. Based on its homogeneity and fine silts, it appears to represent a low energy deposit. Stratum IIb was documented within all AIS test excavations; however, it is only designated as part of SIHP # -8840 Component 2 where it contains evidence of human activity, within T-2 and the adjacent T-2B. Within T-2, Stratum IIb contains three stacked waterworn basalt cobbles of indeterminate function (Feature 7). Within T-2B, it contains an angled pit, also of indeterminate function (Feature 10). These two features are described in detail below. Profiles, plan maps, and photographs are presented in Section 4.3: Subsurface Testing Results and are referenced in the descriptions below.

Feature 7 comprises three stacked basalt cobbles identified within Stratum IIb/SIHP # -8840 Component 2 in the northwest wall of T-2 (see Figure 47, Figure 48, and Figure 54). It was documented between 124 and 160 cmbs and measures 25 cm across. Its function is indeterminate.

Feature 10 is an oblong pit feature identified in the southeast wall of T-2B (see Figure 58, Figure 59, and Figure 63). It was documented at the upper boundary of Stratum IIb/SIHP # -8840 Component 2 between 117 and 171 cmbs and measures 25 cm across. Its function is indeterminate.

6.2.3 Laboratory Analyses

Two charcoal samples, collected from SIHP # -8840 Component 2, Features 2 and 4, were submitted to the Wood Identification Laboratory at IARII for taxa identification (see Section 5.4.2 for full results). Features 2 and 4 are both fire-related features identified in T-1 Stratum IIa. Feature 2 was documented at the upper boundary of the stratum, while Feature 4 was documented in the lower-middle portion of the stratum; hence, Feature 2 post-dates Feature 4.

Most of Sample 1 (Feature 2) was identified as *kiawe* (*P. pallida*), while the rest is indeterminate hardwood. As *kiawe* was likely introduced to Hawai‘i in 1828, Feature 2 therefore post-dates that time and dates securely to the post-Contact period. In contrast, Sample 2 (Feature 4) contains wood from native species including *‘ōhi‘a lehua* (*M. polymorpha*), *koa* (*Acacia* cf. *koa*), *kōpiko* (*Psychotria* sp.), and possibly *hau* (*Hibiscus* sp.); no post-Contact introductions were identified. These results suggest Feature 4 may date to the pre- or early post-Contact period; hence, a subsample recovered from Sample 2 (Feature 4) was submitted to Beta Analytic, Inc., for radiocarbon dating analysis.

The radiocarbon analysis yielded two-sigma calibrated date ranges of AD 1728-1810 (53.5% probability), 1646-1690 (26.0%), and 1925-post 1950 (15.9%). However, the most recent date range (1925-post 1950) can likely be discarded. Although diagnostic artifacts recovered from overlying fill deposits suggest Stratum IIa functioned as a surface into the 1930s (see Section 5.2.4), the identification of pit features within different vertical portions of the quite thick stratum indicates the layer was not deposited all at once but rather over a (potentially extended) period of time. As Feature 4 was identified within the lower portion of Stratum IIa, it would therefore date to the early part of that time period. Hence, the radiocarbon analysis, like the wood taxa analysis (discussed above), supports a pre- or early post-Contact date for the lower portion of Stratum IIa.

The artifact assemblage further supports the timeline suggested by radiocarbon dating and wood taxa identification. Artifacts were collected and analyzed from four pit features associated with the Stratum IIa/SIHP # -8840 Component 2 habitation layer. Two diagnostic glass fragments (Acc. #s 74 and 76) collected from Feature 17, documented at the lower boundary of Stratum IIa, date to 1800-1910, indicating use of the feature during that time period and consistent with an early post-Contact date for that portion of the layer. In contrast, diagnostic artifacts collected from Features 8, 12, and 14, documented at the upper boundary of the stratum, indicate use of these features post-1910 (Acc. #s 37, 41, and 47), post-1890 (Acc. # 55), and post-1880 (Acc. # 159), respectively, reflecting more recent use of that portion of the layer. Although shell midden (*P. reticulata*) was retrieved from Feature 12, it was assessed as likely historical (i.e., post-Contact), rather than traditional Hawaiian, and therefore not in conflict with the interpretation of the feature as a post-1890 historical trash pit.

Stratum IIb underlies and therefore pre-dates Stratum IIa. Based on the radiocarbon dating of the lower portion of Stratum IIa to the pre- or early post-Contact period and the lack of historical materials identified within Stratum IIb and its associated features, Stratum IIb likely dates to the pre- or very early post-Contact period. It is worth noting that this timeline places Stratum IIa during the time of Marín’s Vineyard, which was planted in 1815; however, no evidence of grape cultivation was identified within Stratum IIa. It is possible this portion of Marín’s land was not in active cultivation.

6.3 SIHP # 50-80-14-8840 Component 3

FORMAL TYPE:	Infrastructure remnants
FUNCTION:	Habitation; commercial
AGE:	Post-Contact
NUMBER OF FEATURES:	6
TEST EXCAVATIONS:	T-1, T-2, T-2B, T-4, T-10, and T-11
DIMENSIONS	0.2 acre
TAX MAP KEY:	[1] 1-7-006:012
LAND JURISDICTION:	City and County of Honolulu
PREVIOUS DOCUMENTATION:	N/A

SIHP # -8840 Component 3 consists of historical infrastructure remnants, documented within roughly the *makai* (southwest) half of the AIS study area (see Figure 35 and Figure 162 through

Figure 166). These remnants consist of an oil-rolled crushed coral surface with associated base course (Feature 1; T-1), a hollow tile wall with concrete base (Feature 2; T-2 and T-2B), a concrete footing (Feature 3; T-4), an etched concrete surface (Feature 4; T-10 and T-11), a mortared brick structure (Feature 5; T-10), and a burnt trash fill (Feature 6; T-11). These are summarized in Table 30 and are described in detail in the following subsections. Profiles, plan maps, and photographs are presented in Section 4.3: Subsurface Testing Results and are referenced in the descriptions below.

It should be noted that various demolition layers identified throughout the AIS study area are not included in SIHP # -8840 Component 3. These layers contain concrete, brick, metal, and hollow tile debris, as well as ceramics and bottle glass. They likely represent the remains of previous structures within the AIS study area; however, due to lack of integrity and association, they are not included within SIHP # -8840. Demolition layers were documented within eight test excavations (T-2, T-2B, T-2C, T-3, T-4, T-6, T-10, and T-12).

6.3.1 SIHP # -8840 Component 3, Feature 1, Oil-rolled Crushed Coral Surface with Associated Base Course

An oil-rolled crushed coral surface and associated basalt gravel base course (Strata If and Ig) were identified within T-1, near the southwestern boundary of the AIS study area. They are designated as SIHP # -8840 Component 3, Feature 1. Feature 1 was documented within all four trench walls, although it was absent from the northeastern corner of the excavation (see Figure 36 through Figure 40). Strata If and Ig are each approximately 10 cm thick, and Stratum Ig contains brick, glass, and ceramic fragments, as well as pig (*S. scrofa*) bone. The pig bone and a grab sample of artifacts were collected. Diagnostic artifacts are of primarily Asian origin and date from the mid-nineteenth to twentieth century. One machine-made bottle fragment (Acc. # 132) dates to post-1908, indicating the layer was deposited after that time.

According to an RLS of the project area by Fung Associates (Hibbard and Chiu 2016; see Appendix A), the parking lot was improved in 1966, and aerial photographs (see Figure 25 and Figure 29) indicate the AIS study area was asphalt-paved sometime between 1941 and 1968. Hence, SIHP # -8840 Component 3, Feature 1, likely functioned as a surface for some period of time between 1908 and 1966.

6.3.2 SIHP # -8840 Component 3, Feature 2, Hollow Tile Wall with Concrete Base

A hollow tile wall with concrete base was identified within two adjacent test excavations, T-2 and T-2B, near the southern corner of the AIS study area. It is designated as SIHP # -8840 Component 3, Feature 2. A review of historical maps suggests this wall may have served as a boundary marker between dwellings in the southeastern portion of the AIS study area and tenements in the central portion of the study area. This boundary is indicated with a solid line on the 1906 Dakin map (see Figure 163) and the 1914, 1927, and 1950 Sanborn maps (see Figure 164 through Figure 166). A line in approximately the same location appears on the 1893 Dodge and Wall map (see Figure 162), suggesting the boundary (if not the wall) dates back to at least the nineteenth century, when it appears to have been associated with agricultural and/or house lots of LCA 2938 (see Section 3.1.2.1 discussion). However, it should be noted that although the portion of Feature 2 within T-2 lines up quite well with the boundary on the 1950 Sanborn map (see Figure 166), the portion within T-2B does not line up as well. On the earlier maps, both remnants appear

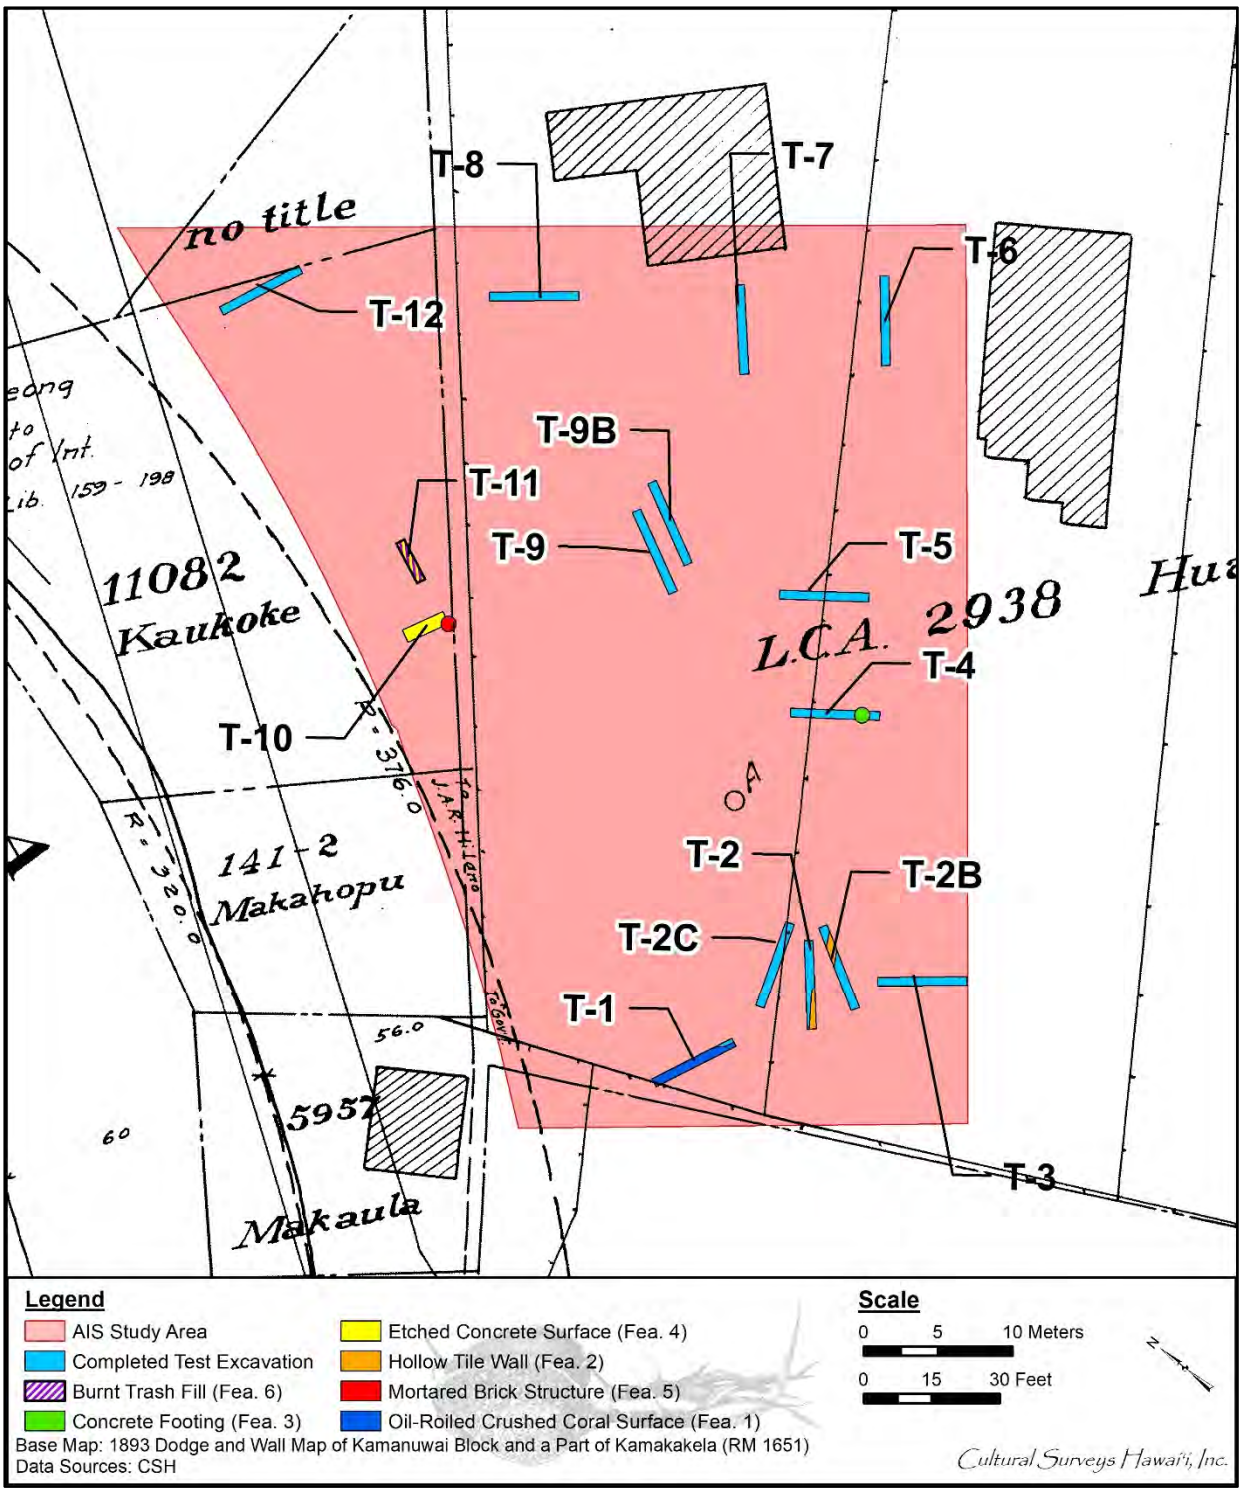

Figure 162. 1893 Dodge and Wall map of Kamanuwai Block and a part of Kamakakela (RM 1651), with overlay of completed test excavations and SIHP # -8840 Component 3, Features 1–6

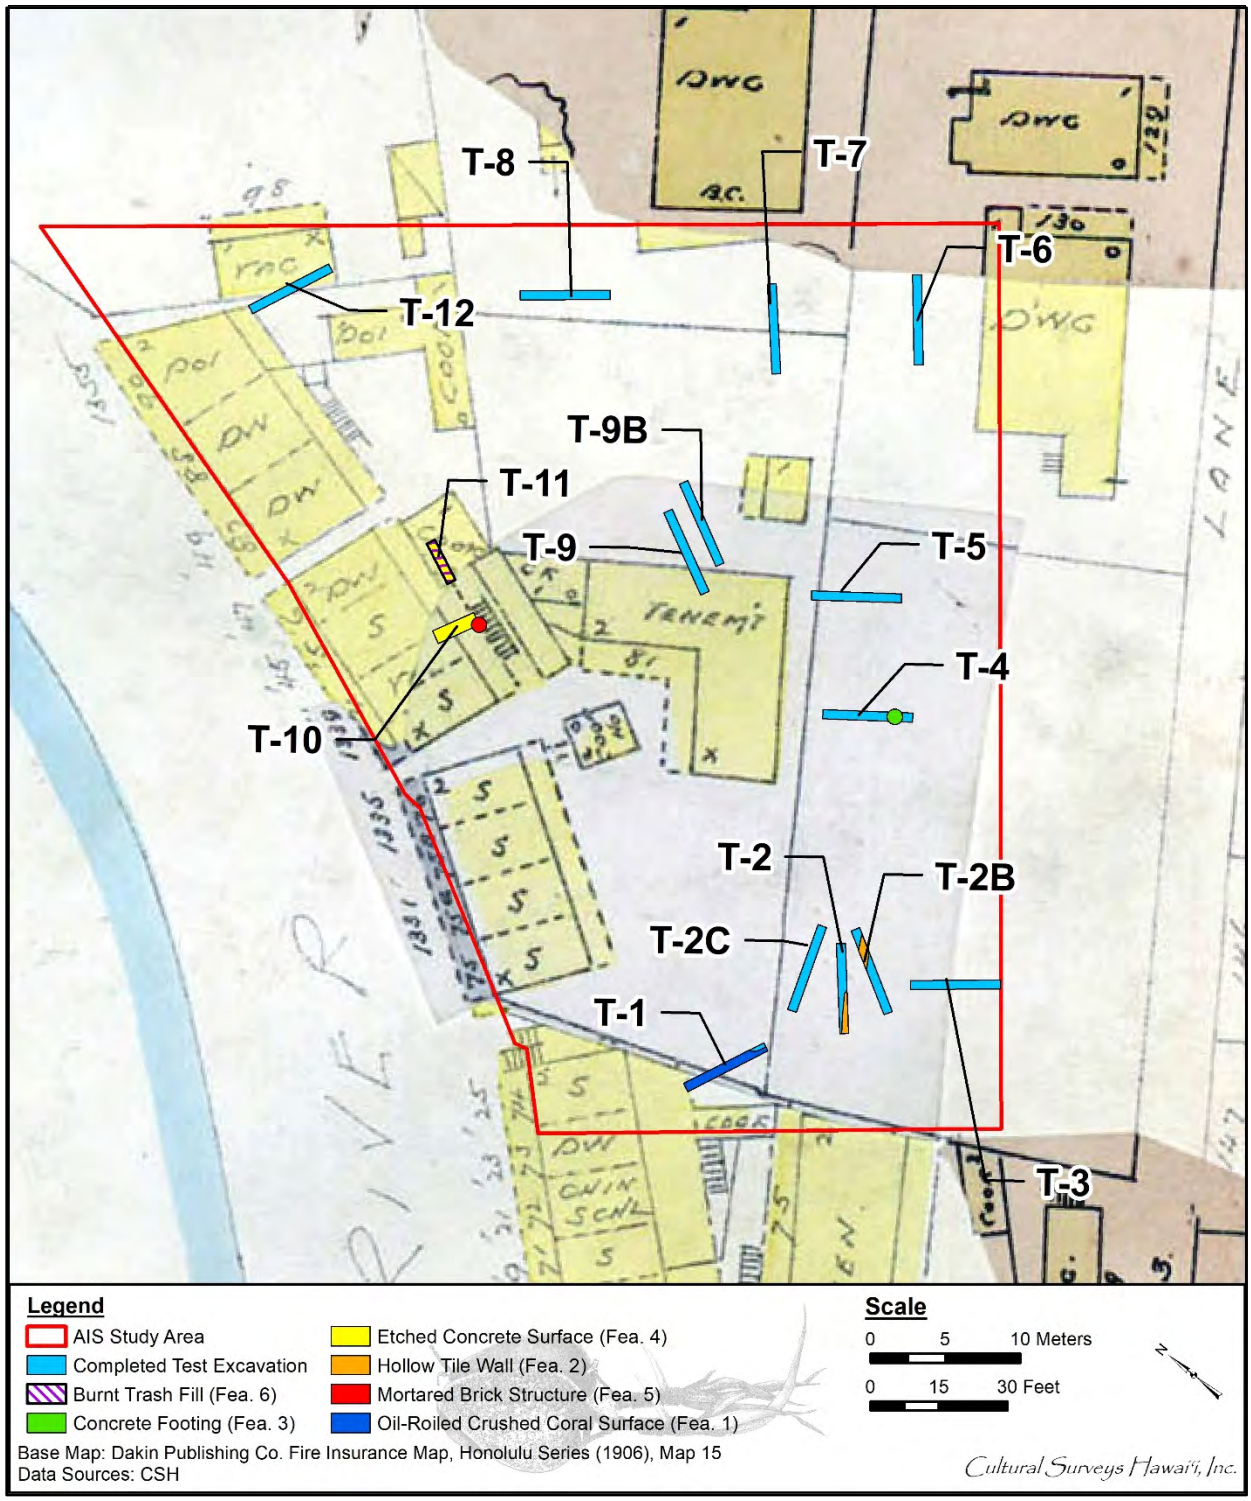

Figure 163. 1906 Dakin Publishing Company fire insurance map, Honolulu series, Map 15, with overlay of completed test excavations and SIHP # -8840 Component 3, Features 1–6

Table 30. SIHP # -8840 Component 3 features identified during the AIS

Fea. #	Formal Type	Test Excavation	Comment
1	Oil-rolled crushed coral surface and associated base course	T-1	Functioned as a surface for some period of time between 1908 and 1966
2	Hollow tile wall with a concrete base	T-2, T-2B	Possible boundary wall between dwellings and tenements (see Figure 166*)
3	Concrete footing	T-4	Possibly concrete portion of the above hollow tile boundary wall
4	Etched concrete surface	T-10, T-11	Unspecified store fronting River St, present by 1950 (see Figure 166*)
5	Mortared brick structure with a concrete foundation	T-10	Likely constructed between 1847 and 1906
6	Burnt trash fill	T-11	Likely deposited between 1935 and 1950

*Sanborn Map Company fire insurance map, Honolulu series (1950), Sheets 110, 112, and 115

to be several meters southeast of the indicated boundary, although the margin of error for these maps is unknown. Hence, the association between Feature 2 and this former boundary cannot be stated definitively.

SIHP # -8840 Component 3, Feature 2, as identified in T-2 and T-2B, is described in detail below.

6.3.2.1 SIHP # -8840 Component 3, Feature 2 within T-2

SIHP # -8840 Component 3, Feature 2, was documented at the *makai* (southwest) end of T-2, extending roughly east-west from the southwest endwall into the southeast sidewall (see Figure 49 through Figure 52). It was documented between 37 and 70 cmbs. The exposed portion is 3.1 m long with a maximum width of 20 cm. The hollow tile portion comprises a single course and is approximately 20 cm thick. The underlying concrete base is 15 cm thick. No associated builder’s pit was observed; rather, it appeared the wall was founded on Stratum IIa (SIHP # -8840 Component 2, habitation layer; see Section 6.2 above) prior to the deposition of the Stratum Id fill.

6.3.2.2 SIHP # -8840 Component 3, Feature 2 within T-2B

Within T-2B, Feature 2 was documented between 22 and 73 cmbs, extending roughly east-west from near the east corner of the trench into the northwest sidewall (see Figure 58 through Figure 61, and Figure 62). The exposed portion is approximately 2.5 m long, with a maximum width of 35 cm. The hollow tile portion is discontinuous, comprising 1–2 courses where it was observed, with a maximum thickness of 35 cm. The underlying concrete base is approximately 18 cm thick. No associated builder’s pit was observed; rather, it appeared the wall was founded on Stratum IIa (SIHP # -8840 Component 2 habitation layer [see Section 6.2]) prior to the deposition of the Strata Ie and If fills.

Within T-2B, Feature 2 directly overlay a pit feature interpreted as a historical trash pit (SIHP # -8840 Component 2, Feature 8). Artifact analysis indicates use of the underlying pit feature no earlier than 1910; hence, Feature 2 was constructed no earlier than 1910.

6.3.3 SIHP # -8840 Component 3, Feature 3, Concrete Footing

A concrete infrastructure remnant identified as a footing was documented near the southeast end of T-4, within the trench floor and extending into both sidewalls. Designated as SIHP # -8840 Component 3, Feature 3, it appeared to be founded upon Stratum IIa (SIHP # -8840 Component 2 habitation layer [see Section 6.2]) and was documented between 43 and 58 cmbs. The exposed portion is 85 cm long by 45 cm wide and 15 cm thick.

This remnant may represent the concrete base of the hollow tile wall identified in T-2 and T-2B (SIHP # -8840 Component 3, Feature 2; see Section 6.3.2 above); it is of approximately the same thickness, width, and orientation (roughly east-west), as well as being at approximately the same depth and stratigraphic position (founded upon Stratum IIa). Furthermore, the presence of hollow tile debris in the surrounding Stratum Ic fill material suggests the upper hollow tile portion was once present but had been demolished. However, as T-4 is approximately 15 m *mauka* (northeast) of T-2 and T-2B, and since the hollow tile portion was not observed in T-4, the association cannot be stated definitively.

6.3.4 SIHP # -8840 Component 3, Feature 4, Etched Concrete Surface

An etched concrete surface was identified within the two interior excavations, T-10 and T-11, and designated as SIHP # -8840 Component 3, Feature 4. A review of historical maps suggests Feature 4 is associated with a former unspecified store fronting River Street, indicated on the 1950 Sanborn map (see Figure 166) as having a “CONC FL” (concrete floor). SIHP # -8840 Component 3, Feature 5, as documented in T-10 and T-11, is described in detail below.

6.3.4.1 T-10

Within T-10, Feature 4 was documented between 28 and 43 cmbs, beneath the concrete floor of the John R. Gilliland Sr. Building and underlying fill deposit (Strata Ia and Ib) (see Figure 103 through Figure 106 and Figure 108). Feature 4 is 10–15 cm thick and extended across the entire excavation (3.05 m long [northwest-southeast] by 0.89 m wide [northeast-southwest]) prior to being removed. It overlies crushed coral fill (Stratum Id) and construction fill (Stratum Ie).

6.3.4.2 T-11

Within T-11, Feature 4, was documented between 18 and 41 cmbs, beneath the current concrete floor of the John R. Gilliland Sr. Building and associated base course layer (Strata Ia and Ib) (see Figure 109 through Figure 111). It is 15–20 cm thick and extended across the entire excavation (2.96 m long [northeast-southwest] by 0.71 m wide [northwest-southeast]) prior to being removed. As in T-10, it overlies construction fill (Stratum Id) and crushed coral fill (Stratum Ie).

6.3.5 SIHP # -8840 Component 3, Feature 5, Mortared Brick Structure with Concrete Foundation

The remnant of a mortared brick structure with a concrete foundation was identified at the southern corner of T-10, between 60 and 110 cmbs (see Figure 104, Figure 105, and Figure 107). It is designated as SIHP # -8840 Component 3, Feature 5. Each brick is 13 cm long by 10 cm wide

and 6 cm tall; no maker’s mark was observed. The concrete base is approximately 10 cm thick. A maximum of seven courses were observed within the exposed portion of the feature (within the southwest sidewall, not depicted in the profile drawing), which comprises two walls at right angles, representing the northern corner of the former building/structure. The exposed portion of the feature is 50 cm long (northeast-southwest) by 45 cm wide (northwest-southeast) and 50 cm tall. It was not possible to extend the excavation in order to expose the feature further due to the presence of an active subsurface electrical line.

SIHP # -8840 Component 3, Feature 5, appeared to be founded on Stratum IIb, natural alluvium, as no builder’s pit was identified within the surrounding Stratum IIa (SIHP # -8840 Component 2, habitation layer), suggesting Feature 5 pre-dates Stratum IIa. However, according to Lebo (1997:106–107), the first brick structure was built in Honolulu in 1847. As radiocarbon dating (see Section 5.4.3) indicates use of Stratum IIa by 1810, it appears Feature 5 post-dates at least the lower (i.e., earlier) portion of Stratum IIa. A review of historical maps dating from 1906 to 1950 (see Figure 163 through Figure 166) revealed no former brick structure or building in this location, suggesting Feature 5 dates to the period between 1847 and 1906. Furthermore, diagnostic artifacts indicate deposition of the overlying Stratum Ie sometime after 1924, which is consistent with a late nineteenth or early twentieth century date for the construction of Feature 5.

6.3.6 SIHP # -8840 Component 3, Feature 6, Burnt Trash Fill

A thin burnt trash layer (Stratum If), approximately 5–10 cm thick, was documented in T-11, between 45 and 56 cmbs (see Figure 109, Figure 110, and Figure 112). Designated as SIHP # -8840 Component 3, Feature 6, it is composed of very dark brown silty clay loam and contains bottle glass, charcoal, and ceramics; a grab sample of glass and ceramics was collected. A saw-cut faunal bone recovered from the backdirt pile may also be associated with the trash layer; however, its provenience is uncertain.

SIHP # -8840 Component 3, Feature 6, underlies and therefore pre-dates the SIHP # -8840 Component 3, Feature 4 etched concrete surface (see Section 6.3.5 above), which was likely in place by 1950. Based on artifact analysis, the underlying Stratum IIa/SIHP # -8840 Component 2 habitation layer was exposed as a surface until at least 1935. Hence, Feature 6 was likely deposited sometime between 1935 and 1950. Although none of the artifacts recovered from Feature 6 were sufficiently diagnostic to be dated to a particular year or even decade, the date ranges for the items, which fall between the 1840s and 1930s, is consistent with deposition between 1935 and 1950.

6.4 SIHP # -8840 Significance Assessment

SIHP # -8840 is assessed as significant under Hawai‘i State historic property significance Criterion d (has yielded information important for research on prehistory or history) and Criterion e (has an important value to the native Hawaiian people or another ethnic group of the state), pursuant to HAR § 13-275-6. Additionally, it is recommended eligible for inclusion on the Hawai‘i and National Registers under Criterion D. This assessment is based on the historic property’s association with the extensive traditional Hawaiian agricultural system and habitation along Nu‘uanu Stream and the urban development of Honolulu. SIHP # -8840 has provided, and can potentially provide additional information on traditional Hawaiian agricultural practices and chronology; on the residential and commercial growth and ethnic distribution of Honolulu Town

from the nineteenth through mid-twentieth centuries; and on late pre-Contact to post-Contact burial practices. SIHP # -8840 retains integrity of location, materials, and design.

Section 7 Consultation

Consultation regarding the Halewai‘olu Senior Residences project has been ongoing since the project’s inception. This section summarizes consultation efforts among the project proponents, the SHPD, consulting parties, and the River Street community.

On 12 April 2017, Liz Char of Halewai‘olu Senior Development, LLC; Alison Chiu and Tonia Moy of Fung Associates, Inc.; and Matt McDermott of CSH met with Dr. Susan Lebo (Archaeology Branch chief), Kimi Matsushima and Stephanie Hacker (O‘ahu archaeologists), and Tanya Gumpac-Maguire (architectural historian) of the SHPD. This meeting initiated HRS §6E-8 consultation with the SHPD. Ms. Char introduced the project and provided a background of the property ownership, agency of record, proposed development, and known consulting parties. At that time, consulting parties consisted of the Chinatown Community Center Association, the Historic Hawai‘i Foundation, and Lum Sai Ho Tong. Because the demolition of the John R. Gilliland Sr. Building would likely result in an adverse effect, the SHPD staff recommended drafting an MOA in parallel with the project consultation and development and suggested additional parties for consultation. Mr. McDermott noted there was no data about subsurface archaeology within the project area, but that archaeological testing would likely yield findings. The SHPD staff recommended consultation with the O‘ahu Island Burial Council (OIBC) and proposed to meet at a later date to discuss a testing strategy for an AIS.

On 8 May 2019, Matt McDermott of CSH gave a presentation at the OIBC meeting to introduce the project, the AIS, and the consultation process. Mr. McDermott discussed the need for federal historic preservation review of the project triggered by federal funding and discussed previous land use within the AIS study area as indicated by background research. Finally, he presented the proposed subsurface testing strategy for the AIS and explained that as a part of the consultation process, letters would be sent to the OIBC, Chinatown community groups, Nu‘uanu Stream groups, architecture groups, and NHOs. Mr. McDermott asked for suggestions for additional parties to be consulted, and Board Member Aulii Mitchell suggested Kehaulani Lum. Board Member Kali Fermantez inquired as to how the effects of the proposed project on the John R. Gilliland Sr. Building would be mitigated, and Mr. McDermott emphasized the need to balance the impacts of building demolition with the good of the community. Board Chair Hina Wong-Kalu stated she looked forward to future consultation meetings and mentioned that she would come forward as a cultural descendant if she were not the Board Chair, as she is a descendant of both Hawaiian and Chinese in that area. Aulii Mitchell then offered that he is a descendant of the Tong Yees. Finally, Hina Wong-Kalu expressed concern regarding the crematorium at the Hosoi Garden Mortuary (one block Diamond Head [southeast] of the current project) and suggested including the Mortuary in the consultation process.

On 10 June 2019, invitations to the 25 June public meeting (see discussion below) were sent via email or U.S. mail to the SHPD and consulting parties; this letter formally initiated Section 106 consultation with the SHPD. Letters were sent to the following individuals/organizations:

On 25 June 2019, a public informational meeting was held at the Blaisdell Center. Sandra Pfund (City and County of Honolulu DLM) introduced the project and described the purpose of the meeting. Sharon Har (Halewai‘olu Senior Development) provided a project overview. Alison Chiu and Bethany Zedalis (Fung Associates) provided an architectural background. Matt McDermott of CSH summarized the historical and archaeological background. This was followed by questions from the audience. In attendance were Liana Benn, Wesley Fong, and Roland Louie of the Chinatown Community Center Association; Jay Morford and Ennilee Anulao of Hawaiian Memorial Life Plan; Kiersten Faulkner of the Historic Hawai‘i Foundation; Honorary Mayor of Chinatown Joseph Young; Pamela Liu of the Honolulu Police Department; members of the Caceres ‘Ohana (cultural descendants); Joette Yago and Janet Meinke-Lau of the City and County of Honolulu Department of Planning and Permitting; Karl Rhoads of the Hawai‘i State Senate (District 13); Councilmember Carol Fukunaga and Kim Ribellia from her office; Cheryl Tanaka and Randall Goto of the City and County of Honolulu Department of Budget and Fiscal Services; Christy MacPherson of Faith Action; City and County of Honolulu Managing Director Roy Amemiya; Kehaulani and Howard Lum of Lum Sai Ho Tong; and Donna and Daron Makaiwi of the Marin ‘Ohana. Questions included inquiries about possible project effects on the Mun Lun School; whether the planned multi-purpose room will be used as a community center; whether the project footprint could change as a result of the AIS findings; whether the Native American Grave Protection and Repatriation Act (NAGPRA) applies to the project; and the possible effects of mortuary smoke on the new building and its residents.

On 9 July 2019, a Section 106 consultation meeting was attended by Alison Chiu and Bethany Zedalis of Fung Associates; Tanya Gumpac-Maguire of the SHPD (Architecture Branch); Sharon Har and Questor Lau of Halewai‘olu Senior Development, LLC; Keith Kurahashi of R.M. Towill; Sandra Pfund from the City and County of Honolulu DLM; and Matt McDermott of CSH. Sharon Har provided an overview of the project and comments from consulting parties, including a request to incorporate historical documentation of the presence of *ali‘i* in the area and the Battle of Nu‘uanu, how smoke from the crematorium might affect the project, questions surrounding possible NAGPRA triggers, the name of the multi-purpose room, the impacts of construction and mitigation concerns, and whether the results of the AIS could alter the footprint of the senior residences. Mr. McDermott provided an update of the ongoing AIS, including the burial find of 8 July 2019 (SIHP # -8840 Component 2, Feature 6). Ms. Chiu and Ms. Zedalis proposed the area

of potential effect (APE) for the project to consist of an archaeological APE and an additional architectural APE. Ms. Gumpac-Maguire concurred with the two APEs.

On 22 July 2019, Ena Sroat and Matt McDermott of CSH met with Susan Lebo of the SHPD (Archaeology Branch) to discuss the results of the AIS testing up to that point and additional testing based on the identification of an in situ burial (SIHP # -8840 Component 2, Feature 6) in T-2. Based on this discussion, it was agreed that the AIS testing strategy would be increased by three test excavations—two in the vicinity of T-2 and one in the vicinity of T-9, where a potential agricultural berm had been identified.

On 14 August 2019, Matt McDermott of CSH presented the results of the current AIS investigation at the OIBC meeting. Mr. McDermott discussed the burial find of 8 July 2019 (SIHP # -8840 Component 2, Feature 6) and how excavation of two additional trenches—one on either side of the initial trench—failed to identify any additional remains. He explained that the forthcoming burial treatment plan (BTP) will be part of the MOA and that NAGPRA does not apply as the project does not involve tribal or federal land; this is confirmed by Kamana‘o Mills (large landowner). Board Member Aulii Mitchell inquired as to whether testing would be conducted to determine the burial date, and Mr. McDermott explained that the remains were found in a sediment layer that is not pre-Contact; hence, the burial is likely historic. He stated that Board Member Mana Caceres had been involved in the early stages of consultation regarding the burial find, and that Mr. Caceres would be applying as a cultural descendant of the remains.

On 19 September 2019, a second public informational meeting was held at the Blaisdell Center. Sandra Pfund of the City and County of Honolulu DLM explained the purpose of the meeting was to provide the community with an update regarding the AIS and CIA studies and how they relate to the project’s historic preservation review process. Sharon Har (Halewai‘olu Senior Development) provided a project overview. Bethany Zedalis (Fung Associates) provided an architectural background. Matt McDermott of CSH presented the preliminary results of the project’s AIS and proposed mitigation commitments, including burial treatment. There were no questions from the audience members, who included Sharon Pang of Care Companions & Consulting; cultural descendants Mana Caceres, Logan Keola, and Gerry Lam; Jay Morford of Hawaiian Memorial Life Plan; Cheryl Tanaka and Randall Goto of the City and County of Honolulu Department of Budget and Fiscal Services; Howard Lum of Lum Sai Ho Tong; Anni Peterson of Better Tomorrows; Allen Stack and Wesley Fong of the Chinatown Community Center Association; Karl Rhoads of the Hawai‘i State Senate (District 13); and Kiersten Faulkner of the Historic Hawai‘i Foundation. Also in attendance were Tonia Moy of Fung Associates; Ben Edger and Questor Lau of Halewai‘olu Senior Development, LLC; and Chantel Spencer and Kamuela Ka‘apana of CSH.

On 6, 8, and 9 October 2019, the following notice was published in the *Honolulu Star-Advertiser*:

> NOTICE TO INTERESTED PARTIES IS HEREBY GIVEN that human skeletal remains were identified by Cultural Surveys Hawai’i, Inc. during the course of an archaeological inventory survey related to the Halewai’olu Senior Residences, Honolulu Ahupua’a, Honolulu (Kona) District, O’ahu, TMK: [1] 1-7-060:120 [sic].
>
> Following the procedures of Hawai’i Revised Statutes (HRS) Section 6E-43, and Hawai’i Administrative Rules (HAR) Chapter 13-300, these remains are considered

previously identified. Based on the context of the finds, they are over 50 years old and most likely Native Hawaiian.

Background research indicates that this burial was located in the ‘ili of Kalawahine, within the boundaries of a Land Commission Award (LCA) to Huanu for Lahilani, daughter of Francisco Manini (Francisco Marin). On an 1871 Lyons map this particular award is identified as LCA 3:189; on an 1893 Dodge and Wall map it is identified as LCA 2938. Nearby LCAs include an award to Kaukoke (identified variously as LCA 2:1025 ‘Apana 3 and LCA 11082), an award to Makahopu (LCA 141-2), and an award to Keikenui no Makahopu (LCA 141-3).

The project proponent is the City and County of Honolulu—contact the Department of Land Management, ATTN: Director, 558 S. King Street, Honolulu, Hawai’i 96813 [Tel: (808) 768-4277].

The project proponent has proposed preservation in place for these remains; however, the decision to preserve in place or relocate these previously identified human remains shall be made by the O’ahu Island Burial Council in consultation with the State Historic Preservation Division (SHPD) and any recognized lineal and/or cultural descendants, per the requirements of HAR Section 13-300-33. Appropriate treatment shall occur in accordance with HAR Section 13-300-38.

All persons having any knowledge of the identity or history of these human remains are requested to immediately contact Ms. Regina Hilo, SHPD Burial Site Specialist, at 601 Kamokila Boulevard, Room 555, Kapolei, Hawai’i 96707 [Tel: (808) 692-8015, Fax: (808) 692-8020, Email: Regina.Hilo@hawaii.gov].

All interested parties shall respond within thirty (30) days of this notice and file descendancy claim forms and/or provide information to the SHPD adequately demonstrating lineal descent from these designated burials or cultural descent from ancestors buried in the same ahupua’a or district.

At the 9 October 2019 OIBC meeting, Brandy Caceres and ‘Ohana were recognized as cultural descendants of the *‘iwi kupuna* (human remains) identified on 8 July 2019 (SIHP # -8840 Component 2, Feature 6).

On 19 November 2019, a Section 106 Consultation meeting regarding the project’s MOA was attended by Susan Lebo (Archaeology Branch) and Tanya Gumpac-McGuire (Architecture Branch [via phone]) of the SHPD; Randy Chiu of the City and County DLM; Howard and Kehaulani Lum of Lum Sai Ho Ton; Liana Benn of the Chinatown Community Center Association; cultural descendants Mana and Kalehua Caceres; Daron Makaiwi of the Marin ‘Ohana; Sharon Har, Questor Lau, and Benjamin Edger of Halewai‘olu Senior Development, LLC; Matt McDermott of CSH; Tonia Moy and Alison Chiu of Fung Associates; Jay Morford of Hawaiian Memorial Life Plan; Mel Kalahiki of Borthwick Mortuary; Kiersten Faulkner of the Historic Hawai‘i Foundation; and Sylvia Young of the HawaiiUSA Federal Credit Union. Ms. Har explained that the purpose of the meeting was to discuss mitigation. Mr. McDermott explained that the MOA is being developed to alleviate the adverse effect of the project’s construction on the John R. Gilliland Sr. Building and the archaeological historic property identified during the AIS. SHPD staff proposed that mitigation should focus on benefitting the community. Ms. Faulkner suggested this could be

achieved through a display, a video, an oral history, a traveling exhibit, or by putting funds into an adjacent building. She further emphasized that the MOA needs to be enforceable, with a timeline and specific stipulations as to who does what and to what standard. Discussion also included the proposed activity center within the senior residence, and that it will not just be for residents but also for the community at large.

On 21 November 2019, Matt McDermott and Ena Sroat of CSH met with Susan Lebo, Samantha Cragen, and Andrew McCallister of SHPD's Archaeology Branch. Discussion topics included the outstanding SIHP numbers for the historic property identified during the AIS and possible mitigation measures.

Section 8 Summary and Interpretation

At the request of Halewai‘olu Senior Development, LLC, CSH has prepared this AIS report for the Halewai‘olu Senior Residences project, Honolulu Ahupua‘a, Honolulu (Kona) District, O‘ahu, TMK: [1] 1-7-006:012. The Halewai‘olu Senior Residences project is at 1331–1347 River Street, between Vineyard Boulevard and North Kukui Street. The John R. Gilliland Sr. Building and its surrounding parking lot are planned for demolition, to be replaced by proposed affordable senior housing.

The current project is within the portion of downtown Honolulu surrounding the mouth of Nu‘uanu Stream, known to Hawaiians as “Kou.” Kou had a long tradition as a royal center, where the *ali‘i* would meet and entertain. It also possessed shoreward fishponds and irrigated fields, and nearby Honolulu Harbor was brimming with marine resources. The land surrounding Nu‘uanu Stream was particularly densely populated, with a concentration of *lo‘i* and *‘auwai*. Historical maps show the AIS study area as within that dense cluster of *lo‘i*.

By the 1830s, Western commercial and missionary interests had supplanted the Native Hawaiian traditions that once shaped the environment, and Western and urban ideals propelled Honolulu’s growth. The Organic Acts of 1845 and 1846 initiated the process of the Māhele, the division of Hawaiian lands, which introduced private property into Hawaiian society. Historical maps indicate the majority of the AIS study area was within LCA 2938 to Huanu, for the heirs of Lahilahi (Gilliland ‘Ohana). Huanu was the grandson of Francisco de Paula Marín, whose land within the current study area was known as “The Vineyard.” Marín had planted his vineyard with grape cuttings sourced from California in 1815.

A review of twentieth century historical maps and aerial photographs indicates modern development within the study area by 1906. At that time, a tenement was at the center of the study area, while several dwellings and stores were along the northwestern boundary. By 1950, additional dwellings were present in the eastern and southeastern portions of the study area, and a parking area for automobiles was in the southern corner. The John R. Gilliland Sr. Building was constructed within the study area in 1958. In 2016, Fung Associates assessed this two-story commercial building as eligible inclusion on the National Register under Criterion C, as a very good example of a small retail/office building constructed in Hawai‘i in a modern style in the 1950s.

Based on background research, it was anticipated that the current AIS could identify buried agricultural deposits and features associated with taro and/or grape cultivation; pre- and/or post-Contact habitation layer(s) with associated features, potentially including human remains; landscape features or structural remnants associated with LCA boundaries; and nineteenth and twentieth century structural remnants with associated artifacts and/or historical trash pits. As the AIS study area consists of a two-story commercial building (the John R. Gilliland Sr. Building) and associated asphalt parking lot, no surface archaeological historic properties were anticipated.

Fifteen test excavations (T-1 through T-12, including T-2B, T-2C, and T-9B) were completed. In general, the observed stratigraphy consists of the modern land surface, fill deposits, and infrastructure remnants (Stratum I); a vertical series of natural alluvium (Stratum II); and a buried streambed, likely associated with a former braid of Nu‘uanu Stream (Stratum III). In addition, one

archaeological historic property was identified: SIHP # -8840, subsurface cultural deposits, documented in all 15 test excavations.

SIHP # -8840 is a newly identified historic property with three components spanning the pre-Contact period through the mid-twentieth century. Component 1 consists of agricultural deposits, likely representing pre-Contact taro farming along the banks of Nu‘uanu Stream; these comprise the deeper alluvial deposits (Strata IIc–IIg) and reflect at least three periods of agriculture. Associated berm structures (Stratum IId) were identified in two adjacent test excavations (T-9 and T-9B), indicating that area may represent the intersection of two or more agricultural plots.

Component 2 consists of habitation layers with associated pit features, including a human burial site (Feature 6). This component comprises the upper alluvial deposits (Strata IIa and IIb), which likely functioned as living surfaces from the late pre-Contact period at least into the 1930s. The uppermost alluvial deposit, Stratum IIa, is a thick layer with pit features documented throughout its vertical extent. This layer likely accumulated over an extended period of time and, based on radiocarbon dating, functioned as a surface by 1810. Hence, Stratum IIa was likely contemporaneous with Marín’s Vineyard, although no evidence for grape cultivation was identified within the layer. It is possible this portion of the Vineyard was not actively cultivated.

Component 3 consists of historical infrastructure remnants, including an oil-rolled crushed coral surface, a hollow tile wall remnant, a concrete footing, an etched concrete surface, a mortared brick structural remnant, and burnt trash fill. Based on stratigraphic context and analysis of associated artifacts, all of these remnants date to the twentieth century, except possibly for the brick structural remnant (Feature 5), which may date to the nineteenth century (post-1847, the date of the first brick structure in Honolulu).

SIHP # -8840 is assessed as significant under Hawai‘i State historic property significance Criterion d (has yielded information important for research on prehistory or history) and Criterion e (has an important value to the native Hawaiian people or another ethnic group of the state), pursuant to HAR §13-275-6. Additionally, it is recommended eligible for inclusion on the Hawai‘i and National Registers under Criterion D. This assessment is based on the historic property’s association with the extensive traditional Hawaiian agricultural system and habitation along Nu‘uanu Stream and the urban development of Honolulu. SIHP # -8840 has provided, and can potentially provide additional information on traditional Hawaiian agricultural practices and chronology; on the residential and commercial growth and ethnic distribution of Honolulu Town from the nineteenth through mid-twentieth centuries; and on late pre-Contact to post-Contact burial practices. SIHP # -8840 retains integrity of location, materials, and design.

Section 9 Significance Assessment

Once a historic property is identified, then an assessment of significance shall occur pursuant to HAR §13-275-6. To be significant, a historic property shall possess integrity of location, design, setting, materials, workmanship, feeling, and/or association and meet one or more of the following significance criteria:

a. be associated with events that have made an important contribution to the broad patterns of our history;
b. be associated with the lives of persons significant in our past;
c. embody the distinctive characteristics of a type, period, or method of construction; represent the work of a master, or possess high artistic value;
d. have yielded, or is likely to yield, information important for research on prehistory or history; or
e. have an important value to the native Hawaiian people or to another ethnic group of the state due to associations with cultural practices once carried out, or still carried out, at the property or due to associations being important to the group's history and cultural identity.

Table 31 presents the significance assessment and mitigation commitments for the historic property identified during the Halewai‘olu Senior Residences AIS, SIHP # -8840 (subsurface cultural deposits). This significance assessment is included in this AISR for the review and concurrence of the SHPD. In addition, historic property integrity, which is the ability of a property to convey its significance, was assessed based on the guidance provided in National Register Bulletin #15, "How to Apply the National Register Criteria for Evaluation" (NPS 1997) and "Assessing Site Significance: A Guide for Archaeologists and Historians" (Hardesty and Little 2000). The seven aspects of integrity and their descriptions are as follows:

- *Location* is the place where the historic property was constructed or the place where the historic event occurred
- *Design* is the combination of elements that create the form, plan, space, structure, and style of the property
- *Setting* is the physical environment of a historic property
- *Materials* are the physical elements that were combined or deposited during a particular period of time and in a particular pattern or configuration to form a historic property
- *Workmanship* is the physical evidence of the crafts of a particular culture or people during any given period in history or prehistory
- *Feeling* is a property's expression of the aesthetic or historic sense of a particular period of time
- *Association* is the direct link between an important historic event or person and a historic property (NPS 1997; Hardesty and Little 2000)

Table 31. Archaeological historic property integrity, significance, and mitigation commitments

SIHP # 50-80-14-	AIS Test Excavations	Formal Type/Name	Function	Age	Integrity							Hawai‘i State Significance Criteria	National Register Eligibility Criteria	Mitigation Commitments
					Location	Design	Setting	Materials	Workmanship	Feeling	Association	HAR §13-275-6	36 CFR 60.4	
8840	T-1 through T-12	Subsurface cultural deposits	Agriculture, habitation, human interment, commercial and residential infrastructure	Pre-Contact to mid-twentieth century	Y	Y	N	Y	N	N	N	d and e	D	Archaeological monitoring; burial treatment (BTP forthcoming)

SIHP # -8840, subsurface cultural deposits, has three components, designated as Components 1–3. Component 1 comprises agricultural deposits. Component 2 comprises habitation layers with associated pit features, including a human burial. Component 3 comprises historical infrastructure remnants. SIHP # -8840 is assessed as significant under Hawai‘i State historic property significance Criterion d (has yielded information important for research on prehistory or history) and Criterion e (has an important value to the native Hawaiian people or another ethnic group of the state), pursuant to Hawai‘i Administrative Rules (HAR) §13-275-6. Additionally, it is recommended eligible for inclusion on the Hawai‘i and National Registers under Criterion D. This assessment is based on the historic property’s association with the extensive traditional Hawaiian agricultural system and habitation along Nu‘uanu Stream and the urban development of Honolulu. SIHP # -8840 has provided, and can potentially provide additional information on traditional Hawaiian agricultural practices and chronology; on the residential and commercial growth and ethnic distribution of Honolulu Town from the nineteenth through mid-twentieth centuries; and on late pre-Contact to post-Contact burial practices. SIHP # -8840 retains integrity of location, materials, and design.

Section 10 Project Effect and Mitigation Commitments

The following project effect and mitigation commitment discussions are intended to facilitate project planning and to support the proposed project's required historic preservation consultation. It is also intended to provide specific mitigation commitments for the Halewai‘olu Senior Residences project.

10.1 Project Effect

Under Hawai‘i State historic preservation review legislation, one of two project effect determinations must be established: 1) "No historic properties affected," the project will have no effect on significant historic properties; or 2) "Effect, with proposed mitigation commitments," the project will affect one or more significant historic properties, and the effects will potentially be harmful. However, the agreed upon mitigation commitments involving one or more forms of mitigation will reasonably and acceptably mitigate any harmful effects (HAR §13-275-7).

One significant archaeological historic property (SIHP # -8840) was documented during the Halewai‘olu Senior Residences AIS, and the proposed project has the potential to affect this historic property. Based on the AIS investigation, the project effect determination per HAR §13-275-7 is "effect, with agreed upon mitigation commitments." In addition, under Section 106 of the NHPA, the proposed project will have an "adverse effect" on the identified archaeological historic property, SIHP # -8840. The mitigation commitments outlined below will reduce the project's potential adverse effect on SIHP # -8840, subsurface cultural deposits.

10.2 Mitigation Commitments

Under Hawai‘i State historic preservation review legislation, if a project will have an "effect" (impact) on significant historic properties, then a mitigation commitment proposing the form of mitigation to be undertaken for each significant historic property shall be submitted for SHPD review and acceptance. Mitigation may occur in the following five forms: A) Preservation, B) Architectural Recordation, C) Archaeological Data Recovery (which includes archaeological monitoring), D) Historical Data Recovery, and E) Ethnographic Documentation (HAR §13-275-8).

This AIS indicates the Halewai‘olu Senior Residences AIS study area contains one archaeological historic property: SIHP # -8840, subsurface cultural deposits. SIHP # -8840 was identified in all 15 test excavations. Under Section 106 of the NHPA, the proposed project will have an "adverse effect" on this archaeological historic property. In addition, due to the inherent limitations of any sampling strategy, it is possible additional historic properties may be identified during construction activities.

Based on the AIS results, the agreed upon mitigation commitments consist of a burial treatment plan (BTP) addressing the previously identified human burial site (SIHP # -8840 Component 2, Feature 6) and data recovery in the form of archaeological monitoring for SIHP # -8840 Components 1–3 (see Table 31). Mitigation measures will be detailed in the MOA currently being prepared pursuant to 36 CFR Part 800.6.

VI. Narrative Description

Include within the description of resource features any changes to the resource that have been made over time.

A. Describe exterior features:

This two-story modern style building is distinguished by a canopy between the first and second stories that runs the length of the façade and has a folded plate roof with a drip edge. The façade is further enriched by the roof, which is a series of front-facing, segmental-arched, barrel vaults with overhanging eaves on both the front and rear elevations of the structure. The reinforced concrete building is eight bays wide, with all the bays being of similar width except the northeast-most bay, which is narrower. The barrel vaults define the bays with one covering each bay. On the second story each bay features a picture window, flanked on either side by a pair of jalousie windows. A window air-conditioning unit is set in the lower half of one jalousie window in each bay. At ground level, each bay contained a store front, but the three southeast bays have been modified to address the consolidation of the interior spaces to develop a larger restaurant area. The original store fronts have a hinged door to the north with an adjoining display window to the south. The windows have been modified over time. The kick plate below the windows is simply the flat wall, which is composed of concrete masonry units (CMU) blocks. The narrower, north bay has a set of three jalousie windows on the second story and on the first a tri-fold door, opening the store space to the sidewalk. The three south bays each have six panels. The six north-most panels are solid, while in the middle bay each panel contains a fixed, plate glass window in its upper portion. The south-most bay has a north of center, recessed doorway with a fixed plate glass window to the entry's south. A box neon sign is suspended from the canopy above the entry and reads, "Uptown Café." A second box neon sign is similarly suspended from the canopy in the third bay from the north and this one reads, "Hanagasa Inn."

The rear, southeast side of the building on the ground level has a single door entry in each bay at its south side. The second story is handled the same as the façade's second story. A 3'-6" concrete sidewalk runs the length of the rear elevation and is defined by a 3" curb on its parking lot edge. The parking lot is elevated above the sidewalk and is flush with the top of the curb. Air conditioning/ventilation duct work, conduits, and electrical equipment protrude from the face of the rear elevation.

At either end of the building a double stair, each stair having eighteen steps, leads up to the second floor. The steps are concrete, and a flat roof extends 3'-9" from the sides of the end barrel vaults to protect the stairs from the elements. The space under the stairways has been enclosed with T-111 in recent years, to provide storage areas. The storage spaces are accessed by a centered, hinged, T-111 door. The stairways retain their wrought iron railings with their stylized post and rail pattern. A hinged, metal, security screen door is at the head of the stair.

B. Describe distinguishing interior features:

The screen doors at the head of the stairs provide access to a double-loaded, central hallway. The hall is approximately 4'-0" wide and curves to follow the line of the street. The ceiling in the hallway follows the vaulting of the roof and is approximately 20'-6" high at its apex. The concrete floor has been covered by modern tiles. There are eight doors on each side of the hall, which lead into office spaces. Nine of the doors are original and feature four horizontal-paned windows. At the bottom of some of the doors is a gravity flap letter plate. None of the original doors retain their original knobs. Each office has a picture window flanked on either side by a pair of jalousie windows, except the narrower, northern-most offices which only have a set of three jalousie windows. In a corner of each office is a half bath, which is entered via a single panel door. None of these doors have their original knobs. The offices have 9'-4" high dropped ceilings and originally had connecting doors in the plastered partition walls to allow access to the other office spaces. A number of these openings have been sealed up, but some original single panel doors still remain, again minus their original knobs.

On the ground floor only two spaces are occupied: the Uptown Café and Hanagasa Inn. The former occupies the three southern-most bays of the building. It has an L-shaped dining area with a bar niche at the north end of the dining room. It was remodeled around 2000. The Hanagasa Inn occupies the second and third bays from the north. It was remodeled in the 1990s. Chikara Mochi occupied the space south of Hanagasa Inn. It still retains obscure, wire fire glass jalousie windows in its front and rear walls, a material which is rarely found today.

C. Describe the landscape and setting (include adjacent sites/resources):

This commercial building sits on a flat, 26,925 square foot lot, and fronts on River Street with vacant lots to either side. Three Royal Poincianna trees (*Delonix regia*) line the sidewalk in front of the building. A blacktop-paved parking lot occupies the rear of the property behind the building. The rear parking lot was improved and enclosed in 1966 by a CMU retaining wall.

VII. Statement of Significance

The Gilliland Building was constructed in 1958, following designs prepared by Kenneth Sato. It is architecturally significant as a very good example of a small retail/office building constructed in Hawaii in a modern style in the 1950s. It is typical of its period in its design, materials, workmanship, and construction methods. It is also important as a very good example of the architectural work of Kenneth Sato.

The façade of the building is distinguished by its folded plate canopy and segmental arched barrel vaulted roof. Folded plate technology originated in Germany in 1925 when it was utilized to cover a coal bunker. The idea spread to Russia and its earliest known use in the United States was in a 44'-0" x 77'-0" San Francisco warehouse in 1935. Other warehouses in California utilized this new type of roof, but as late as 1949, it was still not well known in the United States. An assembly of flat plates, or slabs, inclined in different directions and joined along their longitudinal edges, the folded plate structural system is capable of carrying loads without the need for additional supporting beams along mutual edges. Typically made of cast *in situ* or precast reinforced concrete, these roofs require less material, are cheaper to construct, are simpler to manufacture than other shells and are economical over long spans that need to be free of internal columns. Following World War II the distinctive, eye catching appeal of the form slipped nicely into the mid-century modern architectural vocabulary, celebrating the new age, the wonders of technology and its accompanying affluence. The only other use of a folded plate canopy utilized on a commercial building in Honolulu's downtown area is at 1165 Bethel Street.

The segmental ached, barrel-vaulted, concrete roof also enunciated the advances in concrete technology as applied to the building trade. The designer of the building, Kenneth Sato, also utilized this form at the Waimalu Shopping Center in both the roof and first-story canopy.

As such the building stands as an excellent example of the dramatic and eye-catching mid-century modern movement in Hawaii. The building's folded plate canopy, combined with its concrete barrel vaulted roof, make it a distinctive architectural statement, celebrating the plastic qualities of concrete and the variety of forms it could assume. There are no other comparable buildings in the city.

Kenneth Sato (1908-2006) was born in Kahuku, on Oahu, graduated from McKinley High School, and received a degree in civil engineering from the University of Hawaii in 1930. He owned the Kewalo Steel Company, and designed a number of churches, apartments, and low rise commercial buildings, and worked on a number of public schools and bridges for the Territory of Hawaii. Other works include the Waiola Congregational Church in Lahaina, the Miyamoto Buildings at 1331 Nuuanu Avenue, and the Door of Faith Church on Young Street in Honolulu.

VIII. Survey Analysis

Please provide your observations about the survey; including constraints and opportunities for future research and/or survey in connection to this site.

The survey was straight-forward and encountered no problems. Two of the ground floor commercial spaces were boarded up and could not be accessed. It would be of value to learn more about the designer of the building, Kenneth Sato, and at some point an inventory should be compiled on folded plate roofs in Honolulu.

Appendix C Pollen Analysis

Pollen Analysis

Bruce G. Phillips
BGP Consulting LLC

In advance of development at the Halewai‘olu Senior Residences, Honolulu *ahupua‘a*, Honolulu District, Island of O‘ahu, Cultural Surveys Hawai‘i (CSH) identified multiple buried agricultural deposits, designated CSH 1. Also identified were habitation layers, designated CSH 2. Trench 7 was excavated in the area consisting primarily of agricultural deposits (CSH 1); six sediment samples were collected from Trench 7. Trench 9 was excavated an area where both habitation and agricultural layers were found (CSH 2); four sediment samples were collected. Subsequently, the ten sediment samples were submitted to BGP Consulting for pollen analysis, with the goal of identifying past cultural activities in the area and characterizing vegetation communities at the time of deposition.

The project area is situated on former floodplain of and immediately adjacent to Nu‘uanu Stream. Elevation is approximately 10 feet above mean sea level. Annual rainfall averages 24 to 31 inches (Giambelluca et al. 1986). Soils in the project area are mapped as Ewa silty clay loam, deep, well drained soils that formed in alluvium on alluvial fans and river terraces (Soil Survey Staff 2019). *Mauka* of the project area are soils classified as Kaena clay, deep, poorly drained soils that formed in alluvium and colluvium, primarily found on alluvial fans. Prior to urban development and channelization of Nu‘uanu Stream in the early 20th century, the area served for many centuries as irrigated *lo‘i kalo* (taro wetland fields).

Before Polynesian agriculture transformed coastal lowlands, natural vegetation along the coastline would have primarily been characterized as Coastal Dry communities, having elevations less than 50 feet and rainfall less 47 inches per year (Gagne and Cuddihy 1990). Local edaphic conditions determine the makeup of various herblands, grasslands, shrublands, forests, and mixed communities. In turn, these communities can be further differentiated based on dominant species, such as *‘aki ‘aki* Grassland dominated by *Sporobolus virginicus*. Many areas once covered with extensive grasslands are now dominated by alien species, such as *kiawe* (*Prosopis pallida*) forests.

Coastal Wet communities occur on all of the main islands. Native examples, however, were much disturbed by the early Hawaiians, as nutrient-rich floodplains, marshes, and lowland riparian areas were turned into fishponds and irrigated farmlands (*lo‘i*) for the cultivation of *kalo* (taro; *Colocasia esculenta*). Much of these same farmlands were subsequently turned into rice fields. Common natural constituents would have included members of the sedge family (Cyperaceae) and grass family (Poaceae).

Methods

Sediment samples were sent to the Palynology Laboratory, Texas A&M University, College Station, for pollen extractions (fern-type spores are herein included under “pollen”). Sample bag contents were thoroughly mixed and 10-gram subsamples were taken. Approximately 19,666

grains of *Lycopodium* were added to estimate pollen concentration. Samples were then treated with 10 percent hydrochloric acid to reduce carbonates, followed by a swirl-and-decant step (Mehringer 1967):136–137) to reduce the heavier matrix fraction (greater than 180 µm). Silicates were reduced by a hydrofluoric acid treatment of approximately 20 hours. Heavy liquid flotation in zinc bromide (with a specific gravity of 1.9) was followed by acetolysis to further reduce organics. The remaining residues were washed with water and alcohol, stained with saffranin, and suspended in glycerol.

At BGP Consulting facilities, extracts were mounted and examined at a viewing power of 400X on an Olympus BHTU compound microscope. Typically, standard counts of 100- to 200-pollen grains are conducted. In the current project, however, total pollen concentrations were insufficient for standard counts. In this case, entire slides were scanned and all grains were counted. Identifications were aided by BGP Consulting reference material and by keys (Selling 1946, 1947; Moore et al. 1991). Each fossil pollen grain was identified to the generic level when possible. If a grain could not be differentiated from similar genera, it was identified to the family level. Pollen grains that were broken, corroded, or degraded beyond recognition were assigned to the "degraded" category. Percentages of types were calculated for each sample. Pollen concentrations were calculated with the following formula:

$$\text{Concentration (grains/gram)} = \frac{\text{pollen grains counted}}{\text{tracers counted}} \times \frac{\text{tracer concentration}}{\text{sample weight}}$$

Results

No samples were sufficient for standard counts and pollen was entirely absent from four samples. Twenty-five types of pollen and spores are identified (Table 1). The assemblage is diverse, primarily reflecting relatively dry shrub-covered terrain; forested land upslope is indicated by fern spores. In samples containing pollen, the percentages of degraded grains range from relatively high (19.3) to very high (39.5), indicating poor preservation within the sample set (Tables 2 and 3). Therefore, the data likely are not an accurate reflection of the original pollen assemblage. That is, they probably do not convey a realistic scenario of the former floral landscape.

The most common types are low-spine Asteraceae (*Ambrosia* type), Cheno-Am (*aweoweo*), spurge family, and grass family, all in variable percentages. Sedge family pollen, representing wetlands, is present, but found in relatively low percentages. Polynesian introductions include *niu* (coconut), *wauke* (paper mulberry), and possibly *ti*. Historic introductions are pine and *kiawe* (mesquite). Large grass pollen grains could represent *laiki* (rice) and/or *ko* (sugarcane) farming in the area, or the collection of *pili* grass (*Heteropogon contortus*). In practice, *laiki*, *ko*, and *pili* grass pollen grains have common traits under light microscopy and cannot be distinguished (Moore et al. 1990); SEM is required.

Considerations

Despite the widespread practice of *lo'i kalo* cultivation across O'ahu, *Colocasia* pollen is rare in suspected and even known agricultural settings, such as the current project area. Typically propagated from a corm/root cutting or from a shoot, *kalo* rarely blooms or sets seed naturally (Onwueme 1999). Like other members of the Araceae (arum family), *kalo* produces relatively small quantities of pollen when in bloom. Some varieties have never been known to flower. *Kalo* is harvested at a time when the edible corm has its highest nutritional content and is most viable for propagation. This occurs before flowering, further reducing the possibility of pollen deposition.

Degraded pollen assemblages are not uncommon in archaeological contexts (Hall 1981, 1985; Holloway 1981). Unfortunately, there currently are no standards and guideline by which analysts record and report degraded pollen grains (Bryant and Hall 1993), often making comparisons difficult. Many factors cause pollen deterioration, and the process is not well understood. Mechanical factors can cause grains to be crushed or torn apart, whereas chemical agents can affect their structural integrity. Chief among chemical agents is the cycle of wetting and drying (Holloway 1989). It is possible that pollen in sediments at or near the water table have suffered deterioration due to fluctuations in groundwater level, caused by climatic (e.g., rainfall) and/or oceanic (e.g., sea levels) factors, or possibly even tides. Also affecting the number and distribution of pollen types is the amount of sporopollenin in grains of different plants. Sporopollenin is a highly resistant organic compound that allows pollen to be preserved in sediments and other settings. Because Cheno-Ams and Asteraceae have large amounts of the compound and hence preserve well, they are often over-represented in the pollen record. Soil chemistry can also cause pollen to degrade. For example, ancient soils in the American Southwest are highly basic, causing deterioration. This likely is not the case in young A and C horizons along the O'ahu coast. Mechanical processes include degradation during fluvial transport and repeated trampling in high-traffic areas. Although technically not a process of degradation, mechanical sorting can affect the amount of pollen in sediment samples. That is, during fluvial transport, pollen acts like clastic particles, moving and settling according to water velocity; the largest grains are deposited in coarse silt and fine sand, while smaller grains settle in fine silt and clay. As most samples come from clay layers, mechanical sorting likely is not responsible for the differences in pollen concentrations. Although Stratum IIc is somewhat gravelly and potentially affected by sorting, the layer in Trench 7 has the highest pollen concentration in the assemblage (296 grains per gram), albeit extremely low. Although soil pH may not have caused pollen deterioration, some other chemical factor might be to blame, such as reduction/oxidation reactions. A likely cause is repeated cycles of wetting and drying near the water table, though this may not be the only cause.

Discussion

Within Trench 7, no data is available for Strata IIa and IIb, the habitation layers (CSH 2). Representing CSH 1, Stratum IIc contains a single large grass grain, potentially reflecting nearby *laiki* or *ko* farming. The grain might also be intrusive. In the lower portion of the sample column (Stratum IIe), Asteraceae and Cheno-Ams dominate, suggesting a shrubland environment. Grass pollen gradually increases over time, becoming dominant in Stratum IIc. If taken at face value,

the data suggest a shift from shrubland to grassland. A high portion of fern spores in Stratum IIc might reflect increased input from upslope, and more overbank flooding.

The Trench 9 assemblage is more diverse than Trench 7, having greater numbers of types in every productive sample. No distinct temporal trends are apparent. Rather, the assemblage is characterized by a relative abundance of less common types, particularly the spurge and madder families. A spike of *Helianthus*-type pollen in Stratum IId also is unusual. Under normal circumstances, these data would be interpreted as reflecting local stands of herbs and shrubs. Preservation, however, must be taken into account. Higher percentages of large grass grains in Strata IIb and IIc than in Trench 7 are stronger evidence for *laiki* or *ko* farming. *Kiawe* pollen in Stratum IIb and pine pollen in Stratum IId indicate disturbance throughout the sample column.

Although preservation must be considered, there are some distinct differences between the Trench 7 and Trench 9 assemblages. As mentioned above, the Trench 9 assemblage is more diverse, suggesting a richer flora. Trench 7 is dominated by grass and shrub pollen versus the abundance of rather unusual types in Trench 9, further suggesting contrasting vegetation. Given the proximity of the trenches, these differences are more likely the result of taphonomic factors than actual variation on the former landscape.

In recent investigations of suspected *lo‘i kalo* fields in Waikiki (e.g., Phillips 2019), the common element of pollen assemblages was high proportions of sedge family pollen, often in excess of 60 percent. While *kalo* pollen was extremely rare or absent, the abundance of sedge pollen reflected the wetland environment in which the staple was cultivated. In some cases, relatively high percentages of large grass grains indicated samples were from *laiki* fields. In the current project, sedge pollen is found low percentages or absent, suggesting sample columns in neither trench represented wetland environments.

Regarding pollen preservation, although degradation such as that found in the current assemblage is uncommon, it is not unprecedented. As part of the Transit Corridor Project (Phillips 2016), a highly degraded assemblage was obtained from a site in Waikele *ahupua‘a*: only five of ten samples contained pollen. The norm, however, are pollen-rich assemblages with concentrations in excess of 5,000 grains per gram in nearly every sample (e.g., Phillips 2018).

In summary, six of ten samples contain pollen. Within the six, the percentages of degraded grains are very high and total pollen concentrations extremely low, both indicating very poor preservation. The pollen data should be viewed in this light. Polynesian introductions include *niu, wauke,* and possibly *ti*, all found in scarce quantities. Large grass pollen grains might reflect *laiki* and/or *ko* farming in historic times. If taken at face value, pollen data from the Trench 7 sequence suggest a change over time from shrublands to grasslands. No such landscape change transformation is seen in Trench 9. Rather, a diverse assemblage and a relative abundance of otherwise unusual types reflects a rich local flora. Given the proximity of the trenches, the differences likely are due to poor pollen preservation rather than actual conditions of former vegetation. Sedge pollen is scarce and no distinct indication of a former *lo‘i* is present.

RE: Analysis of charcoal samples from Halewaiolu Senior Housing Project, Honolulu, HONOLULU 87 [WIDL1916]

Greetings Ena,

The report for analysis of your charcoal samples from the Halewaiolu Senior Housing Project, Honolulu (HONOLULU 87) is attached. Don't hesitate to contact me if you would like to discuss the results. Digital microscope photographs of some of your specimens have been archived at IARII. Should you wish to view the images or use them in a report, please let me know.

Best regards,

Jennifer Huebert
(808) 946-2548, Ext. 107
jhuebert@iarii.org

* * * * * * * * *

METHODS

The freshly fractured transverse, tangential, and radial facets of selected charcoal fragments were examined with an epi-illuminated microscope at magnifications of 50–500X. Taxonomic identifications were made by comparing observed anatomical characteristics with those of woods in the IARII reference collection. Vouchers associated with this collection have been verified and archived at the Department of Botany, University of Hawai‘i at Mānoa. Other published references, including books, journal articles, technical documents, and wood atlases, were also consulted. Material that was not examined was returned to its original packaging and marked as residual.

RESULTS

WIDL No.	Taxon	Plant Part & State of Preservation	Count	Weight (g)	Comment
Sample 1, Fe.2, Test Unit 1, 111 cmbs, IIIa					
1916-1	*Prosopis pallida* (*kiawe*)	Wood charcoal	18	0.4	
1916-2	Indeterminate hardwood	Wood charcoal	1	0.01	
Sample 2, Fe.4, Test Unit 1, 128-131 cmbs, IIIa					
1916-3	*Metrosideros polymorpha* (*‘ōhi‘a lehua*)	Wood charcoal	2	0.06	
1916-4	Indeterminate	Parenchyma charcoal	1	0.01	Thin; superficially resembles nutshell but is not endocarp
1916-5	*Psychotria* sp. (*kōpiko*)	Wood charcoal	1	0.01	
1916-6	*Hibiscus* sp. (*hau* and others)	Wood charcoal	1	0.04	
1916-7	*Acacia* cf. *koa* (*koa* and others)	Wood charcoal	5	0.08	
1916-8	Indeterminate hardwood	Wood charcoal	4	0.06	

The two submitted samples were moist and were dried before analysis. Many fragments became quite brittle and/or crumbly; this can occur naturally when charcoal is subject to wetting and drying while in the ground, or when it is dried too quickly after recovery from a moist matrix. Most of the examined material was small, well under 1 cm, and all fragments but one were wood charcoal.

Most of Sample 1 is *kiawe*. The unidentified residual fragments are all extremely small; they all appear to more *kiawe* charcoal. Sample 2 contained a variety of wood from native taxa, including *‘ōhi‘a lehua*, *koa*, possibly *hau*, *kopiko*, and a fragment of some type of thin parenchymous (storage) tissue.

None are the short-lived materials preferred for radiocarbon dating. The parenchyma (1916-4) is not likely to have much inbuilt age, however, as soft storage tissues such as these are not long-lived. Some *Psychotria* (1916-5) are smaller trees (but see below), and *Hibiscus* are fast-growing, so either might be the next best choice to date. *Koa* and *‘ōhi‘a lehua* trees can be very long-lived. Several papers regarding the selection of charcoal for radiocarbon dating can be provided upon request (Allen and Huebert 2014, Athens and Rieth 2013). Consider choosing one fragment of material for radiocarbon dating, when possibly, to eliminate the chance of dating more than one event (Ashmore 1999; also see Higham and Petchey 2000:Table 4).

A brief systematic review is given below; for more information on Hawaiian plants, suggested references are the Manual of the Flowering Plants of Hawai‘i (Wagner et al. 1999; also available online at http://botany.si.edu/pacificislandbiodiversity/hawaiianflora/query2.cfm) and the Bishop Museum’s Hawaiian Ethnobotany Online Database (http://data.bishopmuseum.org/ethnobotanydb).

TAXA REVIEW

LEGUMINOSAE / FABACEAE (Pea family)

Acacia koa A. Gray (*Koa*)

One of the largest endemic trees in Hawai‘i, *koa* may attain 35 m in height at higher elevations (Wagner et al. 1990:641-642) and not branch until 12 m or more above the ground (Rock 1913:175). This straight trunk was especially useful for canoes as well as paddles, and surfboards (Malo 1951:126, 223). *Koa* trees which are also found at lower elevations in the dry regions, have a distribution range of 60 to 2,060 m on all of the main Hawaiian Islands except Ni‘ihau and Kaho‘olawe (Wagner et al. 1990:641).

Prosopis pallida (Humb. & Bonpl. ex Willd.) Kunth (*Kiawe*, mesquite)

This tree, native to Peru, Colombia and Ecuador, is believed to have been introduced into Hawai‘i by Father Bachelot who grew a tree from a single seed in 1828. Today the 8-20 m tall trees may dominate low elevation, dry, and disturbed sites and can be found in vegetation from behind the beaches up into degraded dry forests, ranging in elevation from sea level to 610 m on all of the main Hawaiian Islands (Wagner et al. 1990:693).

MALVACEAE (Mallow family)

Hibiscus sp. (*Hau, hau hele, koki‘o,* and others)

In the Hawaiian Islands, there are 7 native shrub and tree species of *Hibiscus*, several of which include endemic varieties, and at least 3 naturalized historic introductions (Wagner et al. 2005-onwards). *H. tiliaceus*, or *hau*, occurs commonly in moist areas from sea level to over 1,000 m in elevation on most of the main islands (Wagner et al. 1990:888). Most species feature showy flowers. In addition to ornamental plantings, the bark of *hau* was sometimes used to make *lei*, there are herbal remedies made from different parts of the various species, and the soft wood was used for many purposes including canoe outriggers, fishnet floats, and in the native fireplow by rubbing a harder wood against it (Abbott 1992).

MYRTACEAE (Myrtle family)

Metrosideros polymorpha Gaud. (*‘Ōhi‘a lehua*)

This endemic species ranges in habit from prostrate shrubs to tall trees and in distribution from sea level to 2200 m elevation in many ecological situations on all of the main Hawaiian Islands (Wagner et al. 1990:967). The hard wood was once used for making spears and mallets, idols, posts and rafters for houses, and enclosures around temples (Buck 1957:87; Malo 1951:20; Neal 1965:638).

RUBIACEAE (Coffee family)

Psychotria sp. (*Kōpiko*)

The 11 endemic species of *Psychotria* in the Hawaiian Islands are found in mesic to wet forests. Five species are known on O‘ahu; these species range from small trees to trees up to 20 m tall (Wagner et

al. 1990:1160-1170). *Kōpiko* was previously used as firewood, and also to make kapa logs (Malo 1951:21).

RE: Radiocarbon Dating Results

Dear Ms. Farley,

Enclosed is the radiocarbon dating result for one sample recently sent to us. As usual, specifics of the analysis are listed on the report with the result and calibration data is provided where applicable. The Conventional Radiocarbon Age has been corrected for total fractionation effects and where applicable, calibration was performed using 2013 calibration databases (cited on the graph pages).

The web directory containing the table of results and PDF download also contains pictures, a cvs spreadsheet download option and a quality assurance report containing expected vs. measured values for 3-5 working standards analyzed simultaneously with your samples.

The reported result is accredited to ISO/IEC 17025:2005 Testing Accreditation PJLA #59423 standards and all pretreatments and chemistry were performed here in our laboratories and counted in our own accelerators here in Miami. Since Beta is not a teaching laboratory, only graduates trained to strict protocols of the ISO/IEC 17025:2005 Testing Accreditation PJLA #59423 program participated in the analysis.
